    1.8.3.6 Sparse ...................................................... 84
    1.8.3.7 Reshaping ................................................... 85
    1.8.3.8 Numeric ..................................................... 85
1.9.1 New features

1.9.1.1 aggregate API for DataFrame/Series
1.9.1.2 dtype keyword for data IO
1.9.1.3 .to_datetime() has gained an origin parameter
1.9.1.4 Groupby Enhancements
1.9.1.5 Better support for compressed URLs in read_csv
1.9.1.6 Pickle file I/O now supports compression
1.9.1.7 UInt64 Support Improved
1.9.1.8 GroupBy on Categoricals
1.9.1.9 Table Schema Output
1.9.1.10 SciPy sparse matrix from/to SparseDataFrame
1.9.1.11 Excel output for styled DataFrames
1.9.1.12 IntervalIndex
1.9.1.13 Other Enhancements

1.9.2 Backwards incompatible API changes

1.9.2.1 Possible incompatibility for HDF5 formats created with pandas < 0.13.0
1.9.2.2 Map on Index types now return other Index types
1.9.2.3 Accessing datetime fields of Index now return Index
1.9.2.4 pd.unique will now be consistent with extension types
1.9.2.5 S3 File Handling
1.9.2.6 Partial String Indexing Changes
1.9.2.7 Concat of different float dtypes will not automatically upcast
1.9.2.8 Pandas Google BigQuery support has moved
1.9.2.9 Memory Usage for Index is more Accurate
1.9.2.10 DataFrame.sort_index changes
1.9.2.11 Groupby Describe Formatting
1.9.2.12 Window Binary Corr/Cov operations return a MultiIndex DataFrame
1.9.2.13 HDFStore where string comparison
1.9.2.14 Index.intersection and inner join now preserve the order of the left Index
1.9.2.15 Pivot Table always returns a DataFrame
1.9.2.16 Other API Changes

1.9.3 Reorganization of the library: Privacy Changes

1.9.3.1 Modules Privacy Has Changed
1.9.3.2 pandas.errors
1.9.3.3 pandas.testing
1.9.3.4 pandas.plotting
1.9.3.5 Other Development Changes

1.9.4 Deprecations

1.9.4.1 Deprecate .ix
1.9.4.2 Deprecate Panel
1.9.4.3 Deprecate groupby.agg() with a dictionary when renaming
1.9.4.4 Deprecate .plotting
1.9.4.5 Other Deprecations

1.9.5 Removal of prior version deprecations/changes

1.9.6 Performance Improvements

1.9.7 Bug Fixes

1.9.7.1 Conversion
1.9.7.2 Indexing
1.9.7.3 I/O
1.9.7.4 Plotting
1.9.7.5 Groupby/Resample/Rolling
1.12 v0.19.2 (December 24, 2016) .......... 126
  1.12.1 New features .......................... 132
  1.12.2 API changes .......................... 145
    1.12.2.1 Series.tolist() will now return Python types . 145
    1.12.2.2 Series operators for different indexes . 146
    1.12.2.3 Series type promotion on assignment . 149
    1.12.2.4 .to_datetime() changes ............... 150
    1.12.2.5 Merging changes ........................ 150
    1.12.2.6 .describe() changes ................... 151
    1.12.2.7 Period changes ........................ 150
    1.12.2.8 Index +/- no longer used for set operations . 154
    1.12.2.9 Index.difference and .symmetric_difference changes . 155
    1.12.2.10 Index.unique consistently returns Index . 156
    1.12.2.11 MultiIndex constructors, groupby and set_index preserve categorical dtypes . 156
    1.12.2.12 read_csv will progressively enumerate chunks . 158
    1.12.2.13 Sparse Changes ........................ 158
    1.12.2.14 Indexer dtypes changes ............... 161
    1.12.2.15 Other API Changes .................... 162
  1.12.3 Deprecations .......................... 163
  1.12.4 Removal of prior version deprecations/changes ...... 163
  1.12.5 Performance Improvements .................. 164
  1.12.6 Bug Fixes ............................ 165
1.13 v0.18.1 (May 3, 2016) .................. 170
  1.13.1 New features .......................... 171
    1.13.1.1 Custom Business Hour ..................... 171
    1.13.1.2 .groupby(...) syntax with window and resample operations .... 172
    1.13.1.3 Method chaining improvements ............. 174
    1.13.1.4 Partial string indexing on DateTimeIndex when part of a MultiIndex . 176
    1.13.1.5 Assembling Datetimes ..................... 177
    1.13.1.6 Other Enhancements .................... 178
1.13.2 Sparse changes .......................................................... 179
1.13.3 API changes ............................................................. 180
  1.13.3.1 groupby(..).nth() changes ..................................... 180
  1.13.3.2 numpy function compatibility ................................ 182
  1.13.3.3 Using .apply on groupby resampling ....................... 182
  1.13.3.4 Changes in read_csv exceptions ............................. 183
  1.13.3.5 to_datetime error changes ................................. 184
  1.13.3.6 Other API changes ........................................... 185
  1.13.3.7 Deprecations ................................................ 185
1.13.4 Performance Improvements ....................................... 185
1.13.5 Bug Fixes ............................................................ 186
1.14 v0.18.0 (March 13, 2016) ............................................. 188
  1.14.1 New features ...................................................... 190
    1.14.1.1 Window functions are now methods ....................... 190
    1.14.1.2 Changes to rename ....................................... 192
    1.14.1.3 Range Index ............................................. 192
    1.14.1.4 Changes to str.extract ................................. 193
    1.14.1.5 Addition of str.extractall ............................. 194
    1.14.1.6 Changes to str.cat ..................................... 195
    1.14.1.7 Datetimelike rounding .................................. 195
    1.14.1.8 Formatting of Integers in FloatIndex ................... 197
    1.14.1.9 Changes to dtype assignment behaviors ................. 198
    1.14.1.10 to_xarray ............................................. 199
    1.14.1.11 Latex Representation .................................. 200
    1.14.1.12 pd.read_sas() changes ................................ 200
    1.14.1.13 Other enhancements .................................. 200
  1.14.2 Backwards incompatible API changes .......................... 201
    1.14.2.1 NaT and Timedelta operations ........................... 201
    1.14.2.2 Changes to msgpack ..................................... 202
    1.14.2.3 Signature change for .rank ............................. 203
    1.14.2.4 Bug in QuarterBegin with n=0 .......................... 204
    1.14.2.5 Resample API ........................................... 204

### 1.25 v0.13.1 (February 3, 2014)

* Output Formatting Enhancements
* Prior Version Deprecations/Changes

### 1.24 v0.14.0 (May 31, 2014)

* API changes
* Display Changes
* Text Parsing API Changes
* Groupby API Changes
* SQL
* MultiIndexing Using Slicers
* Plotting
* Prior Version Deprecations/Changes
* Deprecations
* Known Issues
* Enhancements
* Performance
* Experimental
* Bug Fixes

### 1.23 v0.14.1 (July 11, 2014)

* API changes
* Enhancements
* Performance
* Bug Fixes

### 1.22 v0.15.0 (October 18, 2014)

* API changes
* Enhancements
* Bug Fixes

### 1.21 v0.15.1 (November 9, 2014)

* API changes
* Enhancements
* Bug Fixes

### 1.20 v0.14.1 (July 11, 2014)

* API changes
* Performance
* Bug Fixes

### 1.20 v0.14.0 (May 31, 2014)

* API changes
* Enhancements
* Bug Fixes

### 1.20 v0.13.1 (February 3, 2014)

* API changes
* Enhancements
* Performance
* Bug Fixes

# Enhancing Performance

## Cython (Writing C extensions for pandas)

### 25.1 Cython (Writing C extensions for pandas)

- **25.1.1** Pure python
- **25.1.2** Plain Cython
- **25.1.3** Adding type
- **25.1.4** Using ndarray
- **25.1.5** More advanced techniques

## Using Numba

### 25.2 Using Numba

- **25.2.1** Jit
- **25.2.2** Vectorize
- **25.2.3** Caveats

### 25.3 Expression Evaluation via eval()

- **25.3.1** Supported Syntax
- **25.3.2** eval() Examples
- **25.3.3** The DataFrame.eval method
- **25.3.4** Local Variables
- **25.3.5** pandas.eval() Parsers
- **25.3.6** pandas.eval() Backends
- **25.3.7** pandas.eval() Performance
- **25.3.8** Technical Minutia Regarding Expression Evaluation

## Sparse data structures

### 26 Sparse data structures

- **26.1** SparseArray
- **26.2** SparseIndex objects
- **26.3** Sparse Dtypes
- **26.4** Sparse Calculation

Bibliography .................................................. 2565

Python Module Index ......................................... 2567
pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis / manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, Series (1-dimensional) and DataFrame (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, DataFrame provides everything that R’s data.frame provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of missing data (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be inserted and deleted from DataFrame and higher dimensional objects
- Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible group by functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it easy to convert ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based slicing, fancy indexing, and subsetting of large data sets
- Intuitive merging and joining data sets
- Flexible reshaping and pivoting of data sets
- Hierarchical labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from flat files (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast HDF5 format
- Time series-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.
Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- **pandas is fast.** Many of the low-level algorithmic bits have been extensively tweaked in Cython code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

- **pandas is a dependency of statsmodels,** making it an important part of the statistical computing ecosystem in Python.

- **pandas has been used extensively in production in financial applications.**

---

**Note:** This documentation assumes general familiarity with NumPy. If you haven’t used NumPy much or at all, do invest some time in learning about NumPy first.

See the package overview for more detail about what’s in the library.
WHAT'S NEW

These are new features and improvements of note in each release.

1.1 v0.23.2

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

Note:  Pandas 0.23.2 is first pandas release that’s compatible with Python 3.7 (GH20552)

What's new in v0.23.2

- Logical Reductions over Entire DataFrame
  - DataFrame.all() and DataFrame.any() now accept axis=None to reduce over all axes to a scalar (GH19976)

```python
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
In [2]: df.all(axis=None)
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to DataFrame.all. With NumPy 1.15 and pandas 0.23.1 or earlier, numpy.all() will no longer reduce over every axis:

```python
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A  False
B  False
dtype: bool
```
With pandas 0.23.2, that will correctly return False, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
Out[3]: False
```

### 1.1.2 Fixed Regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly (GH21471)
- Re-allowed duplicate level names of a MultiIndex. Accessing a level that has a duplicate name by name still raises an error (GH19029).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values (GH21441)
- Fixed printing of DataFrames with hierarchical columns with long names (GH21180)
- Fixed regression in `reindex()` and `groupby()` with a MultiIndex or multiple keys that contains categorical datetime-like values (GH21390).
- Fixed regression in unary negative operations with object dtype (GH21380)
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency (GH21262)
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited (GH21104)

### 1.1.3 Build Changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()` (GH19320)

### 1.1.4 Bug Fixes

#### Conversion

- Bug in constructing `Index` with an iterator or generator (GH21470)
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present (GH21426)

#### Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key (GH21448)
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a MultiIndex with `nlevels == 1` (GH21149)
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes (GH21494)
- Bug in `DataFrame.duplicated()` with a large number of columns causing a ‘maximum recursion depth exceeded’ (GH21524).

#### I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0`, `low_memory=True`, and `index_col` was not `None` (GH21414)
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns (GH21536)
Categorical

- Bug in rendering Series with Categorical dtype in rare conditions under Python 2.7 (GH21002)

Timezones

- Bug in Timestamp and DatetimeIndex where passing a Timestamp localized after a DST transition would return a datetime before the DST transition (GH20854)
- Bug in comparing DataFrame's with tz-aware :class:`DatetimeIndex` columns with a DST transition that raised a KeyError (GH19970)

Timedelta

- Bug in Timedelta where non-zero timedeltas shorter than 1 microsecond were considered False (GH21484)

1.2 v0.23.1

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

What's new in v0.23.1

- Fixed Regressions
- Performance Improvements
- Bug Fixes

1.2.1 Fixed Regressions

Comparing Series with datetime.date

We've reverted a 0.23.0 change to comparing a Series holding datetimes and a datetime.date object (GH21152). In pandas 0.22 and earlier, comparing a Series holding datetimes and datetime.date objects would coerce the datetime.date to a datetime before comparing. This was inconsistent with Python, NumPy, and DatetimeIndex, which never consider a datetime and datetime.date equal.

In 0.23.0, we unified operations between DatetimeIndex and Series, and in the process changed comparisons between a Series of datetimes and datetime.date without warning.

We've temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here's the behavior in 0.22.0, 0.23.0, 0.23.1:

```python
# 0.22.0... Silently coerce the datetime.date
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0  True
1  False
dtype: bool

# 0.23.0... Do not coerce the datetime.date
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0  False
1  False
```

(continues on next page)
dtype: bool

# 0.23.1... Coerce the datetime.date with a warning
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
Currently, the 'datetime.date' is coerced to a datetime. In the future pandas will not coerce, and the values not compare equal to the 'datetime.date'. To retain the current behavior, convert the 'datetime.date' to a datetime with 'pd.Timestamp'.
   #!/bin/python3
   0  True
   1  False
dtype: bool

In addition, ordering comparisons will raise a TypeError in the future.

Other Fixes

- Reverted the ability of to_sql() to perform multivalue inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the DatetimeIndex.date and DatetimeIndex.time attributes in case of timezone-aware data: DatetimeIndex.time returned a tz-aware time instead of tz-naive (GH21267) and DatetimeIndex.date returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in pandas.io.json.json_normalize() when called with None values in nested levels in JSON, and to not drop keys with value as None (GH21158, GH21356).
- Bug in to_csv() causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with -OO optimization (GH21071)
- Bug in Categorical.fillna() incorrectly raising a TypeError when value the individual categories are iterable and value is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing NA values like None to strings when passing dtype=str (GH21083)
- Regression in pivot_table() where an ordered Categorical with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

1.2.2 Performance Improvements

- Improved performance of CategoricalIndex.is_monotonic_increasing(), CategoricalIndex.is_monotonic_decreasing() and CategoricalIndex.is_monotonic() (GH21025)
- Improved performance of CategoricalIndex.is_unique() (GH21107)

1.2.3 Bug Fixes

Groupby/Resample/Rolling

- Bug in DataFrame.agg() where applying multiple aggregation functions to a DataFrame with duplicated column names would cause a stack overflow (GH21063)
• Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations' use of a non-stable sort (GH21207)

• Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying method='dense' and pct=True

• Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)

Data-type specific

• Bug in `Series.str.replace()` where the method throws `TypeError` on Python 3.5.2 (GH21078)

• Bug in `Timedelta`: where passing a float with a unit would prematurely round the float precision (GH14156)

• Bug in `pandas.testing.assert_index_equal()` which raised `AssertionError` incorrectly, when comparing two `CategoricalIndex` objects with param `check_categorical=False` (GH19776)

Sparse

• Bug in `SparseArray.shape` which previously only returned the shape `SparseArray.sp_values` (GH21126)

Indexing

• Bug in `Series.reset_index()` where appropriate error was not raised with an invalid level name (GH20925)

• Bug in `interval_range()` when start/periods or end/periods are specified with float start or end (GH21161)

• Bug in `MultiIndex.set_names()` where error raised for a `MultiIndex` with nlevels == 1 (GH21149)

• Bug in `IntervalIndex` constructors where creating an `IntervalIndex` from categorical data was not fully supported (GH21243, GH21253)

• Bug in `MultiIndex.sort_index()` which was not guaranteed to sort correctly with level=1; this was also causing data misalignment in particular `DataFrame.stack()` operations (GH20994, GH20945, GH21052)

Plotting

• New keywords (sharex, sharey) to turn on/off sharing of x/y-axis by subplots generated with pandas.DataFrame().groupby().boxplot() (GH20968)

I/O

• Bug in IO methods specifying `compression='zip'` which produced uncompressed zip archives (GH17778, GH21144)

• Bug in `DataFrame.to_stata()` which prevented exporting DataFrames to buffers and most file-like objects (GH21041)

• Bug in `read_stata()` and `StataReader` which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)

• Bug in IO JSON `read_json()` reading empty JSON schema with `orient='table'` back to `DataFrame` caused an error (GH21287)

Reshaping
• Bug in `concat()` where error was raised in concatenating `Series` with numpy scalar and tuple names (GH21015)
• Bug in `concat()` warning message providing the wrong guidance for future behavior (GH21101)

Other
• Tab completion on `Index` in IPython no longer outputs deprecation warnings (GH21125)
• Bug preventing pandas being used on Windows without C++ redistributable installed (GH21106)

1.3 v0.23.0 (May 15, 2018)

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:
• Round-trippable JSON format with ‘table’ orient.
• Instantiation from dicts respects order for Python 3.6+.
• Dependent column arguments for `assign`.
• Merging / sorting on a combination of columns and index levels.
• Extending Pandas with custom types.
• Excluding unobserved categories from `groupby`.
• Changes to make output shape of `DataFrame.apply` consistent.

Check the API Changes and deprecations before updating.

Warning: Starting January 1, 2019, pandas feature releases will support Python 3 only. See Plan for dropping Python 2.7 for more.

What’s new in v0.23.0

• New features
  – JSON read/write round-trippable with `orient='table'`
  – `.assign()` accepts dependent arguments
  – Merging on a combination of columns and index levels
  – Sorting by a combination of columns and index levels
  – Extending Pandas with Custom Types (Experimental)
  – New `observed` keyword for excluding unobserved categories in `groupby`
  – `Rolling/Expanding.apply()` accepts `raw=False` to pass a `Series` to the function
  – `DataFrame.interpolate` has gained the `limit_area` kwarg
  – `get_dummies` now supports `dtype` argument
  – `Timedelta mod method`
pandas: powerful Python data analysis toolkit, Release 0.23.2

- `Series.rank()` handles inf values when NaN are present
- `Series.str.cat` has gained the `join` kwarg
- `DataFrame.astype` performs column-wise conversion to `Categorical`
- Other Enhancements

- **Backwards incompatible API changes**
  - Dependencies have increased minimum versions
  - Instantiation from dicts preserves dict insertion order for python 3.6+
  - Deprecate Panel
  - `pandas.core.common` removals
  - Changes to make output of `DataFrame.apply` consistent
  - Concatenation will no longer sort
  - Build Changes
  - `Index Division By Zero Fills Correctly`
  - Extraction of matching patterns from strings
  - Default value for the `ordered` parameter of `CategoricalDtype`
  - Better pretty-printing of DataFrames in a terminal
  - Datetimelike API Changes
  - Other API Changes

- **Deprecations**
- **Removal of prior version deprecations/changes**
- **Performance Improvements**
- **Documentation Changes**
- **Bug Fixes**
  - Categorical
  - Datetimelike
  - `Timedelta`
  - `Timezones`
  - `Offsets`
  - `Numeric`
  - `Strings`
  - `Indexing`
  - `MultiIndex`
  - `I/O`
  - `Plotting`
  - `Groupby/Resample/Rolling`

1.3. v0.23.0 (May 15, 2018)
1.3.1 New features

1.3.1.1 JSON read/write round-trippable with `orient='table'`

A DataFrame can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see GH18912 and GH9146). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.

```
In [1]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
                       'bar': ['a', 'b', 'c', 'd'],
                       'baz': pd.date_range('2018-01-01', freq='d', periods=4),
                       'qux': pd.Categorical(['a', 'b', 'c', 'c'])}, index=pd.Index(range(4), name='idx'))

In [2]: df
Out[2]:
       foo  bar    baz        qux
    idx
0  1    a  2018-01-01 a
1  2    b  2018-01-02 b
2  3    c  2018-01-03 c
3  4    d  2018-01-04 c

In [3]: df.dtypes
   →
       foo       int64
bar       object
baz  datetime64[ns]
qux      category
dtype: object

In [4]: df.to_json('test.json', orient='table')

In [5]: new_df = pd.read_json('test.json', orient='table')

In [6]: new_df
Out[6]:
       foo  bar    baz        qux
    idx
0  1    a  2018-01-01 a
1  2    b  2018-01-02 b
2  3    c  2018-01-03 c
3  4    d  2018-01-04 c

In [7]: new_df.dtypes
   →
       foo       int64
```
Please note that the string index is not supported with the round trip format, as it is used by default in write_json to indicate a missing index name.

```python
In [8]: df.index.name = 'index'
In [9]: df.to_json('test.json', orient='table')
In [10]: new_df = pd.read_json('test.json', orient='table')
In [11]: new_df
Out[11]:
   foo  bar   baz  qux
0    1    a 2018-01-01  a
1    2    b 2018-01-02  b
2    3    c 2018-01-03  c
3    4    d 2018-01-04  c
```

### 1.3.1.2 .assign() accepts dependent arguments

The DataFrame.assign() now accepts dependent keyword arguments for python version later than 3.6 (see also PEP 468). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the documentation here (GH14207)

```python
In [13]: df = pd.DataFrame({'A': [1, 2, 3]})
In [14]: df
Out[14]:
   A
0  1
1  2
2  3
In [15]: df.assign(B=df.A, C=lambda x:x['A']+ x['B'])
   A  B  C
0  1  1  2
1  2  2  4
2  3  3  6
```
Warning: This may subtly change the behavior of your code when you’re using .assign() to update an existing column. Previously, callables referring to other variables being updated would get the “old” values.

Previous Behavior:

```
In [2]: df = pd.DataFrame({"A": [1, 2, 3]})
In [3]: df.assign(A=lambda df: df.A + 1, C=lambda df: df.A * -1)
```

```
Out[3]:
   A  C
0  2 -1
1  3 -2
2  4 -3
```

New Behavior:

```
In [16]: df.assign(A=df.A+1, C=lambda df: df.A* -1)
Out[16]:
   A    C
0  2   -2
1  3   -3
2  4   -4
```

1.3.1.3 Merging on a combination of columns and index levels

Strings passed to DataFrame.merge() as the on, left_on, and right_on parameters may now refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes. See the Merge on columns and levels documentation section. (GH14355)

```
In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')
In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                          'B': ['B0', 'B1', 'B2', 'B3'],
                          'key2': ['K0', 'K1', 'K0', 'K1']},
                          index=left_index)
In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')
In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                          'D': ['D0', 'D1', 'D2', 'D3'],
                          'key2': ['K0', 'K0', 'K0', 'K1']},
                          index=right_index)
In [21]: left.merge(right, on=['key1', 'key2'])
```

```
Out[21]:
   A  B   key2  C  D
key1
K0  A0  B0  K0  C0  D0
K1  A2  B2  K0  C1  D1
K2  A3  B3  K1  C3  D3
```
1.3.1.4 Sorting by a combination of columns and index levels

Strings passed to DataFrame.sort_values() as the by parameter may now refer to either column names or index level names. This enables sorting DataFrame instances by a combination of index levels and columns without resetting indexes. See the Sorting by Indexes and Values documentation section. (GH14353)

```
# Build MultiIndex
In [22]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                                            ('b', 2), ('b', 1), ('b', 1)])

In [23]: idx.names = ['first', 'second']

# Build DataFrame
In [24]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1),
                                  index=idx})

In [25]: df_multi
Out [25]:
       A
    first second
     a 1  6
     2 5
     2 4
     b 2  3
     1 2
     1 1

# Sort by 'second' (index) and 'A' (column)
In [26]: df_multi.sort_values(by=['second', 'A'])
```

1.3.1.5 Extending Pandas with Custom Types (Experimental)

Pandas now supports storing array-like objects that aren’t necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy’s types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we’ll use cyberpandas, which provides an IPArray type for storing ip addresses.

```
In [1]: from cyberpandas import IPArray

In [2]: values = IPArray([
    ...:    0,
    ...:    3232235777,
    ...:    42540766452641154071740215577757643572
    ...])
```
IPArray isn’t a normal 1-D NumPy array, but because it’s a pandas ~pandas.api.extension.ExtensionArray, it can be stored properly inside pandas’ containers.

```python
In [3]: ser = pd.Series(values)
In [4]: ser
Out[4]:
       0  0.0.0.0
        1  192.168.1.1
        2  2001:db8:85a3::8a2e:370:7334
dtype: ip
```

Notice that the dtype is `ip`. The missing value semantics of the underlying array are respected:

```python
In [5]: ser.isna()
Out[5]:
       0   True
       1  False
       2  False
dtype: bool
```

For more, see the extension types documentation. If you build an extension array, publicize it on our ecosystem page.

### 1.3.1.6 New observed keyword for excluding unobserved categories in groupby

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```python
In [27]: cat1 = pd.Categorical(
               ["a", "a", "b", "b"],
               categories=["a", "b", "z"], ordered=True)
In [28]: cat2 = pd.Categorical(
               ["c", "d", "c", "d"],
               categories=["c", "d", "y"], ordered=True)
In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})
In [30]: df['C'] = ['foo', 'bar'] * 2
In [31]: df
Out[31]:
       A    B  values  C
    0  a   c    1  foo
    1  a   d    2  bar
    2  b   c    3  foo
    3  b   d    4  bar
```

To show all values, the previous behavior:
In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()

Out[32]:

<table>
<thead>
<tr>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>A B C</td>
</tr>
<tr>
<td>a c bar NaN</td>
</tr>
<tr>
<td>foo 1.0</td>
</tr>
<tr>
<td>d bar 1.0</td>
</tr>
<tr>
<td>foo NaN</td>
</tr>
<tr>
<td>y bar NaN</td>
</tr>
<tr>
<td>foo NaN</td>
</tr>
<tr>
<td>b c bar NaN</td>
</tr>
</tbody>
</table>
| ... ...
| y foo NaN |
| z c bar NaN |
| foo NaN |
| d bar NaN |
| foo NaN |
| y bar NaN |
| foo NaN |

[18 rows x 1 columns]

To show only observed values:

In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()

Out[33]:

<table>
<thead>
<tr>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>A B C</td>
</tr>
<tr>
<td>a c foo 1</td>
</tr>
<tr>
<td>d bar 1</td>
</tr>
<tr>
<td>b c foo 1</td>
</tr>
<tr>
<td>d bar 1</td>
</tr>
</tbody>
</table>

For pivoting operations, this behavior is already controlled by the dropna keyword:

In [34]: cat1 = pd.Categorical(['a', 'a', 'b', 'b'], categories=['a', 'b', 'z'], ordered=True)

In [35]: cat2 = pd.Categorical(['c', 'd', 'c', 'd'], categories=['c', 'd', 'y'], ordered=True)

In [36]: df = DataFrame({'A': cat1, 'B': cat2, 'values': [1, 2, 3, 4]})

In [37]: df

Out[37]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>c 1</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
<td>d 2</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>c 3</td>
</tr>
<tr>
<td>3</td>
<td>b</td>
<td>d 4</td>
</tr>
</tbody>
</table>

In [38]: pd.pivot_table(df, values='values', index=['A', 'B'], dropna=True)

Out[38]:

(continues on next page)
values
A  B
a  1
d  2
b  3
d  4

In [39]: pd.pivot_table(df, values='values', index=['A', 'B'],
....:   dropna=False)

Out[39]:

   values
  A  B
a  1  0.0
   d  2.0
   y  NaN
b  3  0.0
   d  4.0
   y  NaN
z  4  0.0
   y  NaN

1.3.1.7 Rolling/Expanding.apply() accepts raw=False to pass a Series to the function

Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() have gained a `raw=None` parameter. This is similar to DataFrame.apply(). This parameter, if True allows one to send a np.ndarray to the applied function. If False a Series will be passed. The default is None, which preserves backward compatibility, so this will default to True, sending an np.ndarray. In a future version the default will be changed to False, sending a Series. (GH5071, GH20584)

In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)

In [41]: s
Out[41]:
   0  1  2  3  4
Index: 0 1 2 3 4
dtype: int64

Pass a Series:

In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
Out[42]:
   0  1  2  3  4
Index: 0 1 2 3 4
   0  0  1  2  3  4
dtype: float64
Mimic the original behavior of passing a ndarray:

```python
In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
Out[43]:
    1    0.0
    2    1.0
    3    2.0
    4    3.0
    5    4.0
 dtype: float64
```

### 1.3.1.8 DataFrame.interpolate has gained the `limit_area` kwarg

`DataFrame.interpolate()` has gained a `limit_area` parameter to allow further control of which NaNs are replaced. Use `limit_area='inside'` to fill only NaNs surrounded by valid values or use `limit_area='outside'` to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the full documentation here.

```python
In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
In [45]: ser
Out[45]:
0      NaN
1      NaN
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7      NaN
8      NaN
dtype: float64
```

Fill one consecutive inside value in both directions

```python
In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[46]:
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64
```

Fill all consecutive outside values backward

```python
In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[47]:
0     5.0
1     5.0
2     5.0
```

(continues on next page)
Fill all consecutive outside values in both directions

```
In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[48]:
0  5.0
1  5.0
2  5.0
3  NaN
4  NaN
5  NaN
6  13.0
7  13.0
8  13.0
dtype: float64
```

1.3.1.9 get_dummies now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains uint8. (GH18330)

```
In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
In [50]: pd.get_dummies(df, columns=['c']).dtypes
Out[50]:
a  int64
b  int64
c_5  uint8
c_6  uint8
dtype: object
In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
```

1.3.1.10 Timedelta mod method

The `mod (%)` and `divmod` operations are now defined on `Timedelta` objects when operating with either timedelta-like or with numeric arguments. See the documentation here. (GH19365)

```
In [52]: td = pd.Timedelta(hours=37)
```

(continues on next page)
In [53]: td % pd.Timedelta(minutes=45)
Out[53]: Timedelta('0 days 00:15:00')

1.3.1.11 .rank() handles inf values when NaN are present

In previous versions, .rank() would assign inf elements NaN as their ranks. Now ranks are calculated properly. (GH6945)

In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])
In [55]: s
Out[55]:
0   -inf
1    0
2    1
3   NaN
4    inf
Name: 0, dtype: float64

Previous Behavior:

In [11]: s.rank()
Out[11]:
0   1.0
1   2.0
2   3.0
3   NaN
4   NaN
Name: 0, dtype: float64

Current Behavior:

In [56]: s.rank()
Out[56]:
0   1.0
1   2.0
2   3.0
3   NaN
4   4.0
Name: 0, dtype: float64

Furthermore, previously if you rank inf or -inf values together with NaN values, the calculation won’t distinguish NaN from infinity when using ‘top’ or ‘bottom’ argument.

In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])
In [58]: s
Out[58]:
0   NaN
1   NaN
2   -inf
3   -inf
Name: 0, dtype: float64

Previous Behavior:
In [15]: s.rank(na_option='top')
Out[15]:
0   2.5
1   2.5
2   2.5
3   2.5
dtype: float64

Current Behavior:

In [59]: s.rank(na_option='top')
Out[59]:
0   1.5
1   1.5
2   3.5
3   3.5
dtype: float64

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations (GH15630)
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending='False'` failed to return correct ranks for infinity if NaN were present (GH19538)
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and NaN were present (GH20561)

1.3.1.12 Series.str.cat has gained the join kwarg

Previously, `Series.str.cat()` did not – in contrast to most of pandas – align `Series` on their index before concatenation (see GH18657). The method has now gained a keyword `join` to control the manner of alignment, see examples below and here.

In v.0.23 `join` will default to None (meaning no alignment), but this default will change to 'left' in a future version of pandas.

In [60]: s = pd.Series(['a', 'b', 'c', 'd'])
In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])
In [62]: s.str.cat(t)
Out[62]:
0   ab
1   bd
2   ce
3   dc
dtype: object

In [63]: s.str.cat(t, join='left', na_rep='-')
Out[63]:
0   a-
1   bb
2   cc
3   dd
dtype: object
Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see GH20842).

### 1.3.1.13 DataFrame.astype performs column-wise conversion to Categorical

`DataFrame.astype()` can now perform column-wise conversion to Categorical by supplying the string 'category' or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the [Object Creation](#) section of the documentation for more details and examples. (GH12860, GH18099)

Supplying the string 'category' performs column-wise conversion, with only labels appearing in a given column set as categories:

```python
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [65]: df = df.astype('category')
In [66]: df['A'].dtype
Out[66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)
In [67]: df['B'].dtype
Out[67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```python
In [68]: from pandas.api.types import CategoricalDtype
In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
In [71]: df = df.astype(cdt)
In [72]: df['A'].dtype
Out[72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [73]: df['B'].dtype
Out[73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

### 1.3.1.14 Other Enhancements

- Unary + now permitted for `Series` and `DataFrame` as numeric operator (GH16073)
- Better support for `to_excel()` output with the `xlsxwriter` engine. (GH16149)
- `pandas.tseries.frequencies.to_offset()` now accepts leading ‘+’ signs e.g. ‘+1h’. (GH18171)
- `MultiIndex.unique()` now supports the `level` argument, to get unique values from a specific index level (GH17896)
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output (GH14194)
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output (GH14194)
\begin{itemize}
\item Improved wording of \texttt{ValueError} raised in \texttt{to_datetime()} when \texttt{unit=} is passed with a non-convertible value (GH14350)
\item \texttt{Series.fillna()} now accepts a Series or a dict as a value for a categorical dtype (GH17033)
\item \texttt{pandas.read_clipboard()} updated to use qtpy, falling back to PyQt5 and then PyQt4, adding compatibility with Python3 and multiple python-qt bindings (GH17722)
\item Improved wording of \texttt{ValueError} raised in \texttt{read_csv()} when the \texttt{usecols} argument cannot match all columns. (GH17301)
\item \texttt{DataFrame.corrwith()} now silently drops non-numeric columns when passed a Series. Before, an exception was raised (GH18570).
\item \texttt{IntervalIndex} now supports time zone aware \texttt{Interval} objects (GH18537, GH18538)
\item \texttt{Series()} / \texttt{DataFrame()} tab completion also returns identifiers in the first level of a \texttt{MultiIndex()}. (GH16326)
\item \texttt{read_excel()} has gained the \texttt{nrows} parameter (GH16645)
\item \texttt{DataFrame.append()} can now in more cases preserve the type of the calling dataframe’s columns (e.g. if both are \texttt{CategoricalIndex}) (GH18359)
\item \texttt{DataFrame.to_json()} and \texttt{Series.to_json()} now accept an index argument which allows the user to exclude the index from the JSON output (GH17394)
\item \texttt{IntervalIndex.to_tuples()} has gained the \texttt{na_tuple} parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
\item \texttt{Categorical.rename_categories}, \texttt{CategoricalIndex.rename_categories} and \texttt{Series.cat.rename_categories} can now take a callable as their argument (GH18862)
\item \texttt{Interval} and \texttt{IntervalIndex} have gained a \texttt{length} attribute (GH18789)
\item \texttt{Resampler} objects now have a functioning \texttt{pipe} method. Previously, calls to \texttt{pipe} were diverted to the mean method (GH17905).
\item \texttt{is_scalar()} now returns \texttt{True} for \texttt{DateOffset} objects (GH18943).
\item \texttt{DataFrame.pivot()} now accepts a list for the \texttt{values=} kwarg (GH17160).
\item Added \texttt{pandas.api.extensions.register_dataframe_accessor()}, \texttt{pandas.api.extensions.register_series_accessor()}, and \texttt{pandas.api.extensions.register_index_accessor()}, accessor for libraries downstream of pandas to register custom accessors like \texttt{.cat} on pandas objects. See \texttt{Registering Custom Accessors} for more (GH14781).
\item \texttt{IntervalIndex.astype} now supports conversions between subtypes when passed an \texttt{IntervalDtype} (GH19197)
\item \texttt{IntervalIndex} and its associated constructor methods (\texttt{from_arrays}, \texttt{from_breaks}, \texttt{from_tuples}) have gained a \texttt{dtype} parameter (GH19262)
\item Added \texttt{pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()} and \texttt{pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()} (GH17015)
\item For subclassed \texttt{DataFrames}, \texttt{DataFrame.apply()} will now preserve the \texttt{Series} subclass (if defined) when passing the data to the applied function (GH19822)
\item \texttt{DataFrame.from_dict()} now accepts a \texttt{columns} argument that can be used to specify the column names when \texttt{orient='index'} is used (GH18529)
\item Added option \texttt{display.html.use_mathjax} so MathJax can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)
\end{itemize}
- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is `None` (GH19632)

- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)

- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)

- `DataFrame.to_sql()` now performs a multivalue insert if the underlying connection supports `itk` rather than inserting row by row. SQLAlchemy dialects supporting multivalue inserts include: `mysql`, `postgresql`, `sqlite` and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)

- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (True by default) (GH20027)

- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)

- `quantile()` and `quantile()` now accept the `interpolation` keyword, `linear` by default (GH20497)

- `zip` compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()`. (GH17778)

- `WeekOfMonth` constructor now supports `n=0` (GH20517).

- `DataFrame` and `Series` now support matrix multiplication (`@`) operator (GH10259) for Python>3.5

- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)

- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings with lengths up to 2,000,000 characters (GH16450)

- `to_hdf()` and `read_hdf()` now accept an `errors` keyword argument to control encoding error handling (GH20835)

- `cut()` has gained the `duplicates='raise'`|'drop' option to control whether to raise on duplicated edges (GH20947)

- `date_range()`, `timedelta_range()`, and `interval_range()` now return a linearly spaced index if `start`, `stop`, and `periods` are specified, but `freq` is not. (GH20808, GH20983, GH20976)

### 1.3.2 Backwards incompatible API changes

#### 1.3.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15184). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Issue</th>
</tr>
</thead>
<tbody>
<tr>
<td>python-dateutil</td>
<td>2.5.0</td>
<td>X</td>
<td>GH15184</td>
</tr>
<tr>
<td>openpyxl</td>
<td>2.4.0</td>
<td></td>
<td>GH15184</td>
</tr>
<tr>
<td>beautifulsoup4</td>
<td>4.2.1</td>
<td></td>
<td>GH20082</td>
</tr>
<tr>
<td>setuptools</td>
<td>24.2.0</td>
<td></td>
<td>GH20698</td>
</tr>
</tbody>
</table>
1.3.2.2 Instantiation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see PEP 468. Pandas will use the dict’s insertion order, when creating a Series or DataFrame from a dict and you’re using Python version 3.6 or higher. (GH19884)

Previous Behavior (and current behavior if on Python < 3.6):

```python
```

Expenses -1500
Income 2000
Net result 300
Taxes -200
dtype: int64

Note the Series above is ordered alphabetically by the index values.

New Behavior (for Python >= 3.6):

```python
In [74]: pd.Series({'Income': 2000, 'Expenses': -1500, 'Taxes': -200, 'Net result': 300})
```

```output
Out[74]:
Income 2000
Expenses -1500
Taxes -200
Net result 300
dtype: int64
```

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (Series, DataFrame, SparseSeries and SparseDataFrame).

If you wish to retain the old behavior while using Python >= 3.6, you can use .sort_index():

```python
In [75]: pd.Series({'Income': 2000, 'Expenses': -1500, 'Taxes': -200, 'Net result': 300}).sort_index()
```

```output
Out[75]:
Expenses -1500
Income 2000
Net result 300
Taxes -200
dtype: int64
```

1.3.2.3 Deprecate Panel

Panel was deprecated in the 0.20.x release, showing as a DeprecationWarning. Using Panel will now show a FutureWarning. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the to_frame() or with the xarray package. Pandas provides a to_xarray() method to automate this conversion. For more details see Deprecate Panel documentation. (GH13563, GH18324).
In [76]: p = tm.makePanel()

In [77]: p
Out[77]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame

In [78]: p.to_frame()
Out[78]:
<table>
<thead>
<tr>
<th></th>
<th>ItemA</th>
<th>ItemB</th>
<th>ItemC</th>
</tr>
</thead>
<tbody>
<tr>
<td>major</td>
<td>minor</td>
<td></td>

</tbody>
</table>

Convert to an xarray DataArray

In [79]: p.to_xarray()
Out[79]:
xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)
array([[-1.474071, 0.781836, 2.353925, -0.858447],  # 2000-01-03
        [-0.064034, -1.071357, 0.583787, 0.758527],
        [-1.282782, 0.441153, 0.221471, 1.729689]],
       [[-0.964980, 1.846883, -1.717693, 0.901805],
        [-0.845696, -1.328865, 0.888782, 1.171216],
        [-1.340896, 1.682706, 0.228444, 0.520264]],
       [[-1.197071, -0.858447, 0.384316, 0.476720],
        [-1.066969, 0.306996, 1.574159, 0.473424],
        [-0.303421, -0.028665, 1.588931, -0.242861]])
Coordinates:
* items (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'

1.3.2.4 pandas.core.common removals

The following error & warning messages are removed from pandas.core.common (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
• `UnsortedIndexError`
• `AbstractMethodError`

These are available from import from `pandas.errors` (since 0.19.0).

### 1.3.2.5 Changes to make output of `DataFrame.apply` consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. tuple or list is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```python
In [80]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1, columns=['A', 'B', 'C'])

In [81]: df
Out[81]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3

Previous Behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.

```python
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

New Behavior: When the applied function returns a list-like, this will now _always_ return a Series.

```python
In [82]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[82]:
   0  1  2  3
   1  1  2  3
   2  1  2  3
```

(continues on next page)
To have expanded columns, you can use `result_type='expand'`

```
In [84]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
```

```
   A   B   C
0  1   2   3
1  1   2   3
2  1   2   3
3  1   2   3
4  1   2   3
5  1   2   3
```

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use `result_type='broadcast'`. The shape must match the original columns.

```
In [85]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
```

```
   A   B   C
0  1   2   3
1  1   2   3
2  1   2   3
3  1   2   3
4  1   2   3
5  1   2   3
```

Returning a `Series` allows one to control the exact return structure and column names:

```
In [86]: df.apply(lambda x: Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
```

```
   D   E   F
0  1   2   3
1  1   2   3
2  1   2   3
3  1   2   3
4  1   2   3
5  1   2   3
```
1.3.2.6 Concatenation will no longer sort

In a future version of pandas `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```python
In [87]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [88]: df2 = pd.DataFrame({"a": [4, 5]})
In [89]: pd.concat([df1, df2])
Out[89]:
   a   b
0  1  1.0
1  2  2.0
0  4  NaN
1  5  NaN
```

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```python
In [90]: pd.concat([df1, df2], sort=True)
Out[90]:
   a   b
0  1  1.0
1  2  2.0
0  4  NaN
1  5  NaN
```

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

1.3.2.7 Build Changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

1.3.2.8 Index Division By Zero Fills Correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous Behavior:

```python
In [6]: index = pd.Int64Index([-1, 0, 1])
In [7]: index / 0
Out[7]: Int64Index([0, 0, 0], dtype='int64')
```

# Previous behavior yielded different results depending on the type of zero in the divisor

(continues on next page)
1.3.2.9 Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a `Series` if a single group was being extracted (a `DataFrame` if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a `DataFrame`, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. (GH11386)

Previous Behavior:

```python
In [1]: s = pd.Series(['number 10', '12 eggs'])
In [2]: extracted = s.str.extract('.*\d.*')
In [3]: extracted
Out [3]:
         0    1
0   10   12

In [4]: type(extracted)
Out [4]:
```
```
New Behavior:

```python
In [97]: s = pd.Series(['number 10', '12 eggs'])
In [98]: extracted = s.str.extract('.*(\d\d).*')
In [99]: extracted
Out[99]:
    0 10
   1 12

In [100]: type(extracted)
Out[100]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```python
In [101]: s = pd.Series(['number 10', '12 eggs'])
In [102]: extracted = s.str.extract('.*(\d\d).*', expand=False)
In [103]: extracted
Out[103]:
    0 10
   1 12
dtype: object

In [104]: type(extracted)
Out[104]: pandas.core.series.Series
```

### 1.3.2.10 Default value for the `ordered` parameter of CategoricalDtype

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of categories without impacting `ordered`. Behavior should remain consistent for downstream objects, such as `Categorical` (GH18790)

In previous versions, the default value for the `ordered` parameter was `False`. This could potentially lead to the `ordered` parameter unintentionally being changed from `True` to `False` when users attempt to update categories if `ordered` is not explicitly specified, as it would silently default to `False`. The new behavior for `ordered=None` is to retain the existing value of `ordered`.

New Behavior:

```python
In [105]: from pandas.api.types import CategoricalDtype

In [106]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))
In [107]: cat
Out[107]:
    [a, b, c, a, b, a]
Categories (3, object): [c < b < a]

In [108]: cdt = CategoricalDtype(categories=list('cbad'))

In [109]: cat.astype(cdt)
Out[109]:
    [a, b, c, a, b, a]
Categories (3, object): [c < b < a]
```

(continues on next page)
Notice in the example above that the converted Categorical has retained ordered=True. Had the default value for ordered remained as False, the converted Categorical would have become unordered, despite ordered=False never being explicitly specified. To change the value of ordered, explicitly pass it to the new dtype, e.g. `CategoricalDtype(categories=list('cbad'), ordered=False)`.

Note that the unintentional conversion of ordered discussed above did not arise in previous versions due to separate bugs that prevented astype from doing any type of category to category conversion (GH10696, GH18593). These bugs have been fixed in this release, and motivated changing the default value of ordered.

### 1.3.2.11 Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) (GH17023). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:
Note that if you don’t like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

### 1.3.2.12 Datetimelike API Changes

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)
- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)
- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)
- `DatetimeIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)
- Addition and subtraction of `NaN` from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)
- `NaT` division with `datetime.timedelta` will now return `NaN` instead of raising (GH17876)
- Operations between a `Series` with `dtype='datetime64[ns]'` and a `PeriodIndex` will correctly raise `TypeError` (GH18850)
- Subtraction of `Series` with timezone-aware `dtype='datetime64[ns]'` with mis-matched timezones will raise `TypeError` instead of `ValueError` (GH18817)
- `Timestamp` will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- `Timestamp` will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- `Series.first` and `DataFrame.first` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- `Series.last` and `DataFrame.last` will now raise a `TypeError` rather than `NotImplementedError` when index is not a `DatetimeIndex` (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)
- For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise `NullFrequencyError` instead of `TypeError` (GH19895)
- `Timestamp` constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

### 1.3.2.13 Other API Changes

- `Series.astype()` and `Index.astype()` with an incompatible dtype will now raise a `TypeError` rather than a `ValueError` (GH18231)
- Series construction with an object dtyped tz-aware datetime and `dtype=object` specified, will now return an object dtyped `Series`, previously this would infer the datetime dtype (GH18231)
- A `Series` of `dtype=category` constructed from an empty `dict` will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed (GH18515)
- All NaN levels in a MultiIndex are now assigned `float` rather than `object` dtype, promoting consistency with `Index` (GH17929).
- Levels names of a MultiIndex (when not None) are now required to be unique: trying to create a MultiIndex with repeated names will raise a `ValueError` (GH18872)
- Both construction and renaming of `Index/MultiIndex` with non-hashable name/`names` will now raise `TypeError` (GH20527)
Index.map() can now accept Series and dictionary input objects (GH12756, GH18482, GH18509).

DataFrame.unstack() will now default to filling with np.nan for object columns. (GH12815)

IntervalIndex constructor will raise if the closed parameter conflicts with how the input data is inferred to be closed (GH18421)

Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (NaN, NaT, etc.) regardless of the type passed in (GH18295)

When created with duplicate labels, MultiIndex now raises a ValueError. (GH17464)

Series.fillna() now raises a TypeError instead of a ValueError when passed a list, tuple or DataFrame as a value (GH18293)

pandas.DataFrame.merge() no longer casts a float column to object when merging on int and float columns (GH16572)

pandas.merge() now raises a ValueError when trying to merge on incompatible data types (GH9780)

The default NA value for UInt64Index has changed from 0 to NaN, which impacts methods that mask with NA, such as UInt64Index.where() (GH18398)

Refactored setup.py to use find_packages instead of explicitly listing out all subpackages (GH18535)

Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

wide_to_long() previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible (GH17627)

In read_excel(), the comment argument is now exposed as a named parameter (GH18735)

Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

The options html.border and mode.use_inf_as_null were deprecated in prior versions, these will now show FutureWarning rather than a DeprecationWarning (GH19003)

IntervalIndex and IntervalDtype no longer support categorical, object, and string subtypes (GH19016)

IntervalDtype now returns True when compared against 'interval' regardless of subtype, and IntervalDtype.name now returns 'interval' regardless of subtype (GH18980)

KeyError now raises instead of ValueError in drop(), drop(), drop(), drop() when dropping a non-existent element in an axis with duplicates (GH19186)

Series.to_csv() now accepts a compression argument that works in the same way as the compression argument in DataFrame.to_csv() (GH18958)

Set operations (union, difference...) on IntervalIndex with incompatible index types will now raise a TypeError rather than a ValueError (GH19329)

DateOffset objects render more simply, e.g. <DateOffset: days=1> instead of <DateOffset: kwds={'days': 1}> (GH19403)

Categorical.fillna now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of Series.fillna() (GH19682)

pd.to_datetime('today') now returns a datetime, consistent with pd.Timestamp('today'); previously pd.to_datetime('today') returned a .normalized() datetime (GH19935)

Series.str.replace() now takes an optional regex keyword which, when set to False, uses literal string replacement rather than regex replacement (GH16808)

DatetimeIndex.strftime() and PeriodIndex.strftime() now return an Index instead of a numpy array to be consistent with similar accessors (GH20127)
• Constructing a Series from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).

  DataFrame.to_dict() with orient='index' no longer casts int columns to float for a DataFrame with only int and float columns (GH18580)

• A user-defined-function that is passed to Series.rolling().aggregate(), DataFrame.rolling().aggregate(), or its expanding cousins, will now always be passed a Series, rather than a np.array; .apply() only has the raw keyword, see here. This is consistent with the signatures of .aggregate() across pandas (GH20584)

• Rolling and Expanding types raise NotImplementedError upon iteration (GH11704).

1.3.3 Deprecations

• Series.from_array and SparseSeries.from_array are deprecated. Use the normal constructor Series(..) and SparseSeries(..) instead (GH18213).

• DataFrame.as_matrix is deprecated. Use DataFrame.values instead (GH18458).

• Series.asobject, DatetimeIndex.asobject, PeriodIndex.asobject and TimeDeltaIndex.asobject have been deprecated. Use .astype(object) instead (GH18572)

• Grouping by a tuple of keys now emits a FutureWarning and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314)

• Series.valid is deprecated. Use Series.dropna() instead (GH18800).

• read_excel() has deprecated the skip_footer parameter. Use skipfooter instead (GH18836)

• ExcelFile.parse() has deprecated sheetname in favor of sheet_name for consistency with read_excel() (GH20920).

• The is_copy attribute is deprecated and will be removed in a future version (GH18801).

• IntervalIndex.from_intervals is deprecated in favor of the IntervalIndex constructor (GH19263)

• DataFrame.from_items is deprecated. Use DataFrame.from_dict() instead, or DataFrame.from_dict(OrderedDict()) if you wish to preserve the key order (GH17320, GH17312)

• Indexing a MultiIndex or a FloatIndex with a list containing some missing keys will now show a FutureWarning, which is consistent with other types of indexes (GH17758).

• The broadcast parameter of .apply() is deprecated in favor of result_type='broadcast' (GH18577)

• The reduce parameter of .apply() is deprecated in favor of result_type='reduce' (GH18577)

• The order parameter of factorize() is deprecated and will be removed in a future release (GH19727)

• Timestamp.weekday_name, DatetimeIndex.weekday_name, and Series.dt.weekday_name are deprecated in favor of Timestamp.day_name(), DatetimeIndex.day_name(), and Series.dt.day_name() (GH12806)

• pandas.tseries.plotting.tsplot is deprecated. Use Series.plot() instead (GH18627)

• Index.summary() is deprecated and will be removed in a future version (GH18217)

• NDFrame.get_ftype_counts() is deprecated and will be removed in a future version (GH18243)
• The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).

• `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()` and `DataFrame.expanding().apply()` have deprecated passing an `np.array` by default. One will need to pass the new `raw` parameter to be explicit about what is passed (GH20584).

• The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).

• `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716).

• Floor division between an integer ndarray and a `Timedelta` is deprecated. Divide by `Timedelta.value` instead (GH19761).

• Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678).

• `Index.get_duplicates()` is deprecated and will be removed in a future version (GH20239).

• The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).

• Passing multiple axes to the `axis` parameter in `DataFrame.dropna()` has been deprecated and will be removed in a future version (GH20987).

### 1.3.4 Removal of prior version deprecations/changes

• Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074).

• The `levels` and `labels` attributes of a `MultiIndex` can no longer be set directly (GH4039).

• `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370).

• `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in Datetime-likes instead (GH18370).

• `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459).

• The `SparseList` class has been removed (GH14007).

• The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735).

• `Categorical.from_array` has been removed (GH13854).

• The `freq` and `how` parameters have been removed from the `rolling/expandng/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, resample before calling the methods. (GH18601 & GH18668).

• `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113).

• `read_csv()` has dropped the `skip_footer` parameter (GH13386).

• `read_csv()` has dropped the `as_recarray` parameter (GH13373).

• `read_csv()` has dropped the `buffer_lines` parameter (GH13360).
• **read_csv()** has dropped the compact_ints and use_unsigned parameters (GH13323)

• The Timestamp class has dropped the offset attribute in favor of freq (GH13593)

• The Series, Categorical, and Index classes have dropped the reshape method (GH13012)

• pandas.tseries.frequencies.get_standard_freq has been removed in favor of pandas.tseries.frequencies.to_offset(freq).rule_code (GH13874)

• The freqstr keyword has been removed from pandas.tseries.frequencies.to_offset in favor of freq (GH13874)

• The Panel4D and PanelND classes have been removed (GH13776)

• The Panel class has dropped the to_long and toLong methods (GH19077)

• The options display.line_with and display.height are removed in favor of display.width and display.max_rows respectively (GH4391, GH19107)

• The labels attribute of the Categorical class has been removed in favor of Categorical.codes (GH7768)

• The flavor parameter have been removed from func:to_sql method (GH13611)

• The modules pandas.tools.hashing and pandas.util.hashing have been removed (GH16223)

• The top-level functions pd.rolling_*, pd.expanding_* and pd.ewm* have been removed (Deprecated since v0.18). Instead, use the DataFrame/Series methods rolling, expanding and ewm (GH18723)

• Imports from pandas.core.common for functions such as is_datetime64_dtype are now removed. These are located in pandas.api.types (GH13634, GH19769)

• The infer_dst keyword in Series.tz_localize(), DatetimeIndex.tz_localize() and DatetimeIndex have been removed. infer_dst=True is equivalent to ambiguous='infer', and infer_dst=False to ambiguous='raise' (GH7963).

• When .resample() was changed from an eager to a lazy operation, like .groupby() in v0.18.0, we put in place compatibility (with a FutureWarning), so operations would continue to work. This is now fully removed, so a Resampler will no longer forward compat operations (GH20554)

• Remove long deprecated axis=None parameter from .replace() (GH20271)

### 1.3.5 Performance Improvements

• Indexers on Series or DataFrame no longer create a reference cycle (GH17956)

• Added a keyword argument, cache, to to_datetime() that improved the performance of converting duplicate datetime arguments (GH11665)

• DateOffset arithmetic performance is improved (GH18218)

• Converting a Series of Timedelta objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)

• Improved performance of .map() with a Series/dict input (GH15081)

• The overridden Timedelta properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)

• Series construction will reduce the number of copies made of the input data in certain cases (GH17449)

• Improved performance of Series.dt.date() and DatetimeIndex.date() (GH18058)

• Improved performance of Series.dt.time() and DatetimeIndex.time() (GH18461)
• Improved performance of `IntervalIndex.symmetric_difference()` (GH18475)
• Improved performance of `DatetimeIndex` and `Series` arithmetic operations with Business-Month and Business-Quarter frequencies (GH18489)
• `Series() / DataFrame()` tab completion limits to 100 values, for better performance. (GH18587)
• Improved performance of `DataFrame.median()` with `axis=1` when bottleneck is not installed (GH16468)
• Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones (GH18519)
• Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)
• Improved performance of `Index.get_loc()` for non-unique indexes (GH19478)
• Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations (GH17917)
• Improved performance of `pandas.core.groupby.GroupBy.rank()` (GH15779)
• Improved performance of variable `.rolling()` on `.min()` and `.max()` (GH19521)
• Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
• Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
• Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
• Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
• Improved performance of `getattr(Series, attr)` when the Series has certain index types. This manifested in slow printing of large Series with a `DatetimeIndex` (GH19764)
• Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)
• Improved performance of `pandas.core.arrays.Categorical.from_codes()` (GH18501)

### 1.3.6 Documentation Changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the `API` docstrings have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this GitHub search should give you an idea of how many docstrings were improved.

Special thanks to Marc Garcia for organizing the sprint. For more information, read the NumFOCUS blogpost recapping the sprint.

• Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
• Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
• Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)
1.3.7 Bug Fixes

1.3.7.1 Categorical

**Warning:** A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order (GH16603)
- Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with Categorical data (GH19096).
- Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order (GH19551)
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when `target` was an unordered `Categorical` that had the same categories as `self` but in a different order (GH19551)
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index (GH18630)
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated (GH10696, GH18593)
- Bug in `Series.str.split()` with `expand=True` incorrectly raising an `IndexError` on empty strings (GH20002).
- Bug in `Index` constructor with `dtype=CategoricalDtype(...)` where categories and ordered are not maintained (GH19032)
- Bug in `Series` constructor with scalar and `dtype=CategoricalDtype(...)` where categories and ordered are not maintained (GH19565)
- Bug in `Categorical.__iter__` not converting to Python types (GH19909)
- Bug in `pandas.factorize()` returning the unique codes for the uniques. This now returns a `Categorical` with the same dtype as the input (GH19721)
- Bug in `pandas.factorize()` including an item for missing values in the uniques return value (GH19721)
- Bug in `Series.take()` with categorical data interpreting `-1` in `indices` as missing value markers, rather than the last element of the Series (GH20664)

1.3.7.2 Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results (GH7996)
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results (GH19012)
• Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised (np.array, pd.Index) or broadcast incorrectly (pd.Series) (GH18849)

• Bug in `Series.__add__()` adding Series with dtype `timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information (GH13905)

• Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` (GH17983)

• Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` (GH15183)

• Bug in `Series.floor-division` where operating on a scalar `timedelta` raises an exception (GH18846)

• Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., 23:59:59.999999999) (GH19030)

• Bug in `astype()` to non-ns timedelta units would hold the incorrect dtype (GH19176, GH19223, GH12425)

• Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` (GH19158)

• Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` (GH17717)

• Bug in `pct_change()` using periods and freq returned different length outputs (GH7292)

• Bug in comparison of `DatetimeIndex` against None or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of all-False and all-True, respectively (GH19301)

• Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` (GH19382)

• Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly (GH19206)

• Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` (GH19612)

• Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. (GH19744)

• Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` (GH19847)

• Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the freq attribute was not fully supported (GH20678)

1.3.7.3 Timedelta

• Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` (GH19819)

• Bug in `Series` with dtype='timedelta64[ns]' where addition or subtraction of `TimedeltaIndex` had results cast to dtype='int64' (GH17250)

• Bug in `Series` with dtype='timedelta64[ns]' where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)

• Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)

• Bug where dividing a scalar timedelta-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)
• Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` (GH19042)

• Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` (GH19738)

• Bug in `Timedelta.__floordiv__(), Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)

• Bug in `Period.asfreq()` where periods near datetime(1, 1, 1) could be converted incorrectly (GH19643, GH19834)

• Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds() == 30.000000000000004` (GH19458)

• Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)

• Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match (GH19333)

• Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` (GH20393)

1.3.7.4 Timezones

• Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose dtype is tz-aware instead of object (GH16406)

• Bug in comparison of timezone-aware `DatetimeIndex` against `NaT` incorrectly raising `TypeError` (GH19276)

• Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive (GH18951)

• Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)

• Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype (GH174151)

• `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)

• Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with dtype='timedelta64[ns]' was incorrect (GH17558)

• Bug in `DatetimeIndex.insert()` where inserting `NaT` into a time-zone-aware index incorrectly raised (GH16357)

• Bug in `DataFrame` constructor, where tz-aware Datetimeindex and a given column name will result in an empty `DataFrame` (GH19157)

• Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)

• Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)

• Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)

• Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)
• Bug in `Dataframe.count()` that raised a `ValueError`, if `Dataframe.dropna()` was called for a single column with timezone-aware values. (GH13407)

### 1.3.7.5 Offsets

• Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)

• Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` (GH19142)

• Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)

• Bug in `FY5253` where datetime addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)

• Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)

### 1.3.7.6 Numeric

• Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)

• Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)

• Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)

• Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)

• Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or other has length zero (GH19522)

• Multiplication and division of numeric-dtyped `Index` objects with timedelta-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)

• Bug where NaN was returned instead of 0 by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)

### 1.3.7.7 Strings

• Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

### 1.3.7.8 Indexing

• Bug in `Index` construction from list of mixed type tuples (GH18505)

• Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)

• Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)
• Bug in indexing a datetimelike Index that raised ValueError instead of IndexError (GH18386).
• Index.to_series() now accepts index and name kwargs (GH18699)
• DatetimeIndex.to_series() now accepts index and name kwargs (GH18699)
• Bug in indexing non-scalar value from Series having non-unique Index will return value flattened (GH17610)
• Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
• Fixed inconsistency in .ix between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
• Bug in __setitem__ when indexing a DataFrame with a 2-d boolean ndarray (GH18582)
• Bug in str.extractall when there were no matches empty Index was returned instead of appropriate MultiIndex (GH19034)
• Bug in IntervalIndex where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
• Bug in IntervalIndex.symmetric_difference() where the symmetric difference with a non-IntervalIndex did not raise (GH18475)
• Bug in IntervalIndex where set operations that returned an empty IntervalIndex had the wrong dtype (GH19101)
• Bug in DataFrame.drop_duplicates() where no KeyError is raised when passing in columns that don’t exist on the DataFrame (GH19726)
• Bug in Index subclasses constructors that ignore unexpected keyword arguments (GH19348)
• Bug in Index.difference() when taking difference of an Index with itself (GH20040)
• Bug in DataFrame.first_valid_index() and DataFrame.last_valid_index() in presence of entire rows of NaNs in the middle of values (GH20499).
• Bug in IntervalIndex where some indexing operations were not supported for overlapping or non-monotonic uint64 data (GH20636)
• Bug in Series.is_unique where extraneous output in stderr is shown if Series contains objects with __ne__ defined (GH20661)
• Bug in .loc assignment with a single-element list-like incorrectly assigns as a list (GH19474)
• Bug in partial string indexing on a Series/DataFrame with a monotonic decreasing DatetimeIndex (GH19362)
• Bug in performing in-place operations on a DataFrame with a duplicate Index (GH17105)
• Bug in IntervalIndex.get_loc() and IntervalIndex.get_indexer() when used with an IntervalIndex containing a single interval (GH17284, GH20921)
• Bug in .loc with a uint64 indexer (GH20722)

1.3.7.9 MultiIndex

• Bug in MultiIndex.__contains__() where non-tuple keys would return True even if they had been dropped (GH19027)
• Bug in MultiIndex.set_labels() which would cause casting (and potentially clipping) of the new labels if the level argument is not 0 or a list like [0, 1, ...] (GH19057)
• Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values (GH17924)
• Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)
• Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)
• Bug in `MultiIndex.remove_unused_levels()` which would fill nan values (GH18417)
• Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)
• Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int (GH18818, GH15994)
• Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)
• Bug in `MultiIndex.get_loc()` which would fail to locate keys containing NaN (GH18485)
• Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes (GH18520)
• Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

1.3.7.10 I/O

• `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser (GH17975)
• `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag (GH8496)
• Bug in `read_msgpack()` with a non existent file is passed in Python 2 (GH15296)
• Bug in `read_csv()` where a `MultiIndex` with duplicate columns was not being mangled appropriately (GH18062)
• Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
• Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures (GH20785)
• Bug in `read_sas()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` (GH18184)
• Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
• Bug in `DataFrame.to_latex()` where a NaN in a MultiIndex would cause an `IndexError` or incorrect output (GH14249)
• Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an `AttributeError` (GH19981)
• Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)
• Bug in `DataFrame.to_latex()` where a MultiIndex with an empty string as its name would result in incorrect output (GH18669)
• Bug in `DataFrame.to_parquet()` where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)
• Bug in `read_json()` where large numeric values were causing an `OverflowError` (GH18842)
• Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 (GH19134)
• Interval now supported in DataFrame.to_excel() for all Excel file types (GH19242)
• Timedelta now supported in DataFrame.to_excel() for all Excel file types (GH19242, GH9155, GH19900)
• Bug in pandas.io.stata.StataReader.value_labels() raising an AttributeError when called on very old files. Now returns an empty dict (GH19417)
• Bug in read_pickle() when unpickling objects with TimedeltaIndex or Float64Index created with pandas prior to version 0.20 (GH19939)
• Bug in usecols parameter in read_csv() where error is not raised correctly when passing a string. (GH20529)
• Bug in HDFStore.keys() when reading a file with a softlink causes exception (GH20523)
• Bug in HDFStore.select_column() where a key which is not a valid store raised an AttributeError instead of a KeyError (GH17912)

1.3.7.11 Plotting

• Better error message when attempting to plot but matplotlib is not installed (GH19810).
• DataFrame.plot() now raises a ValueError when the x or y argument is improperly formed (GH18671)
• Bug in DataFrame.plot() when x and y arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056)
• Fixing error message when using datetime.time() and fractional seconds (GH18478).
• Series.plot.kde() has exposed the args ind and bw_method in the docstring (GH18461). The argument ind may now also be an integer (number of sample points).
• DataFrame.plot() now supports multiple columns to the y argument (GH19699)

1.3.7.12 Groupby/Resample/Rolling

• Bug when grouping by a single column and aggregating with a class like list or tuple (GH18079)
• Fixed regression in DataFrame.groupby() which would not emit an error when called with a tuple key not in the index (GH18798)
• Bug in DataFrame.resample() which silently ignored unsupported (or mistyped) options for label, closed and convention (GH19303)
• Bug in DataFrame.groupby() where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)
• Bug in DataFrame.groupby() where aggregation by first/last/min/max was causing timestamps to lose precision (GH19526)
• Bug in DataFrame.transform() where particular aggregation functions were being incorrectly cast to match the dtype(s) of the grouped data (GH19200)
• Bug in DataFrame.groupby() passing the on= kwarg, and subsequently using .apply() (GH17813)
• Bug in DataFrame.resample().aggregate not raising a KeyError when aggregating a non-existent column (GH16766, GH19566)
• Bug in `DataFrameGroupBy.cumsum()` and `DataFrameGroupBy.cumprod()` when `skipna` was passed (GH19806)

• Bug in `DataFrame.resample()` that dropped timezone information (GH13238)

• Bug in `DataFrame.groupby()` where transformations using `np.all` and `np.any` were raising a `ValueError` (GH20653)

• Bug in `DataFrame.resample()` where `ffill`, `bfill`, `pad`, `backfill`, `fillna`, `interpolate`, and `asfreq` were ignoring `loffset`. (GH20744)

• Bug in `DataFrame.groupby()` when applying a function that has mixed data types and the user supplied function can fail on the grouping column (GH20949)

• Bug in `DataFrameGroupBy.rolling().apply()` where operations performed against the associated `DataFrameGroupBy` object could impact the inclusion of the grouped item(s) in the result (GH14013)

1.3.7.13 Sparse

• Bug in which creating a `SparseDataFrame` from a dense `Series` or an unsupported type raised an uncontrolled exception (GH19374)

• Bug in `SparseDataFrame.to_csv` causing exception (GH19384)

• Bug in `SparseSeries.memory_usage` which caused segfault by accessing non sparse elements (GH19368)

• Bug in constructing a `SparseArray`: if `data` is a scalar and `index` is defined it will coerce to `float64` regardless of scalar’s dtype. (GH19163)

1.3.7.14 Reshaping

• Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would `KeyError` (GH20777)

• Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)

• Bug in `DataFrame.unstack()` which casts int to float if `columns` is a `MultiIndex` with unused levels (GH17845)

• Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level (GH18562)

• Fixed construction of a `Series` from a `dict` containing `NaN` as key (GH18480)

• Fixed construction of a `DataFrame` from a `dict` containing `NaN` as key (GH18455)

• Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)

• Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed index (GH18600)

• Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)

• Bug in `Series.rank()` where `Series` containing `NaT` modifies the `Series` inplace (GH18521)

• Bug in `cut()` which fails when using readonly arrays (GH18773)

• Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)
• Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an Exception (GH19038)

• Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)

• Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)

• Bug in `concat()` when concatting sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)

• Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)

• Bug in `DataFrame.join()` which does an `outer` instead of a `left` join when being called with multiple DataFrames and some have non-unique indices (GH19624)

• `Series.rename()` now accepts `axis` as a kwarg (GH18589)

• Bug in `rename()` where an Index of same-length tuples was converted to a MultiIndex (GH19497)

• Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the Index’s name attribute (GH19582)

• Bug in `qcut()` where datetime and timedelta data with NaT present raised a `ValueError` (GH19768)

• Bug in `DataFrame.iterrows()`, which would infer strings not compliant to ISO8601 to datetimes (GH19671)

• Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)

• Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)

• Bug in `cut()` and `qcut()` where timezone information was dropped (GH19872)

• Bug in `Series` constructor with a `dtype=str`, previously raised in some cases (GH19853)

• Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior (GH20848)

• Bug in `isna()`, which cannot handle ambiguous typed lists (GH20675)

• Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-NaT dataframes (GH12396)

• Bug in `concat()` which raises an error when concatenating empty TZ-aware series (GH18447)

1.3.7.15 Other

• Improved error message when attempting to use a Python keyword as an identifier in a `numexpr` backed query (GH18221)

• Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existant option key in some cases (GH19789)

• Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for Series or DataFrames with differing unicode data (GH20503)
1.4 v0.22.0 (December 29, 2017)

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

1.4.1 Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-NA sums and products. The summary is that

- The sum of an empty or all-NA Series is now 0
- The product of an empty or all-NA Series is now 1
- We’ve added a min_count parameter to .sum() and .prod() controlling the minimum number of valid values for the result to be valid. If fewer than min_count non-NA values are present, the result is NA. The default is 0. To return NaN, the 0.21 behavior, use min_count=1.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-NA series depending on whether or not bottleneck was installed. See *Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN*. At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we’ve partially reverted those changes.

1.4.1.1 Arithmetic Operations

The default sum for empty or all-NA Series is now 0.

**pandas 0.21.x**

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

**pandas 0.22.0**

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()  
\n\n\n\n\n\nOut[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy’s `np.nansum` on empty and all-NA arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-NA series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1)  # skipna=True by default
Out[4]: nan
```
The `min_count` parameter refers to the minimum number of *non-null* values required for a non-NA sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

### 1.4.1.2 Grouping by a Categorical

Grouping by a `Categorical` and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

*pandas 0.21.x*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a  3.0
   b  NaN
dtype: float64
```

*pandas 0.22*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a  3
   b  0
dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
Out[10]:
   a  3.0
   b  NaN
dtype: float64
```

### 1.4.1.3 Resample

The sum and product of all-NA bins has changed from NaN to 0 for sum and 1 for product.

*pandas 0.21.x*
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
                  index=pd.date_range('2017', periods=4))
In [11]: s
Out[11]:
2017-01-01 1.0
2017-01-02 1.0
2017-01-03 NaN
2017-01-04 NaN
Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01 2.0
2017-01-03 NaN
Freq: 2D, dtype: float64

To restore the 0.21 behavior of returning NaN, use min_count>=1.

In [13]: s.resample('2d').sum(min_count=1)
Out[13]:
2017-01-01 2.0
2017-01-03 NaN
dtype: float64

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

pandas 0.21.x

In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])
In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out[15]:
2017-01-01 00:00:00 1.0
2017-01-01 12:00:00 NaN
2017-01-02 00:00:00 2.0
Freq: 12H, dtype: float64

pandas 0.22.0

In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])
In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
Out[15]:
2017-01-01 00:00:00 1
(continues on next page)
Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```python
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
Out[16]:
2017-01-01 00:00:00 1.0
2017-01-01 12:00:00 NaN
2017-01-02 00:00:00 2.0
Freq: 12H, dtype: float64
```

### 1.4.1.4 Rolling and Expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-NA values were in the window. Now it returns 0.

**pandas 0.21.1**

```python
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0 NaN
1 NaN
dtype: float64
```

**pandas 0.22.0**

```python
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0 0.0
1 0.0
dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

### 1.4.2 Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With setuptools, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With conda, use

```
requirements:
  run:
    - pandas !=0.21.0,!=0.21.1
```

1.4. v0.22.0 (December 29, 2017)
Note that the inconsistency in the return value for all-NA series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

1.5 v0.21.1 (December 12, 2017)

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See here.
- Improvements to the Parquet IO functions introduced in 0.21.0. See here.

What’s new in v0.21.1

- Restore Matplotlib datetime Converter Registration
- New features
  - Improvements to the Parquet IO functionality
  - Other Enhancements
- Deprecations
- Performance Improvements
- Bug Fixes
  - Conversion
  - Indexing
  - I/O
  - Plotting
  - Groupby/Resample/Rolling
  - Reshaping
  - Numeric
  - Categorical
  - String

1.5.1 Restore Matplotlib datetime Converter Registration

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with datetime or Period values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of import pandas.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular matplotlib.pyplot plotting methods, so we’re temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.
We’ve added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas’ formatters and restore any converters we overwrote when registering them (GH18301).

We’re working with the matplotlib developers to make this easier. We’re trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn’t have the side effect of overwriting any custom converters you’ve already set). In the future we hope to have most of the date-time formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We’ll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

1.5.2 New features

1.5.2.1 Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

1.5.2.2 Other Enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

1.5.3 Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

1.5.4 Performance Improvements

- Improved performance of plotting large series/dataframes (GH18236).

1.5.5 Bug Fixes

1.5.5.1 Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when NaT is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from DatetimeIndex could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default `closed` (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising `TypeError` (GH18372)
- Bug in `DateTimeIndex` and `date_range()` where mismatching tz-aware start and end timezones would not raise an err if `end.tzinfo` is None (GH18431)
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 (GH18159).
1.5.5.2 Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype Series (GH17965)
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute (GH18165)
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` (GH18334)
- Bug in `Index.putmask` when an invalid mask passed (GH18368)
- Bug in masked assignment of a `timedelta64[ns]` dtype Series, incorrectly coerced to float (GH18493)

1.5.5.3 I/O

- Bug in class: `pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file (GH18071)
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` (GH5239)
- Bug in `read_csv()` when reading numeric category fields with high cardinality (GH18186)
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for `header` (GH5539)
- Bug in parsing integer datetime-like columns with specified format in `read_sql` (GH17855).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype (GH18390)
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in `pandas.io.json.json_normalize()` to avoid modification of `meta` (GH18610)
- Bug in `to_latex()` where repeated multi-index values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in `HDFStore` (GH18413)
- Bug in `DataFrame.to_latex()` with longtable=True where a latex multicolumn always spanned over three columns (GH17959)

1.5.5.4 Plotting

- Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 (GH18439)

1.5.5.5 Groupby/Resample/Rolling

- Bug in `DataFrame.resample(...) .apply(...)` when there is a callable that returns different columns (GH15169)
- Bug in `DataFrame.resample(...) when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
- Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
- Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)
1.5.5.6 Reshaping

- Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key (GH18068)
- Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
- Bug in `DataFrame.filter(...)` when unicode is passed as a condition in Python 2 (GH13101)
- Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set (GH17776)

1.5.5.7 Numeric

- Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue (GH18044)

1.5.5.8 Categorical

- Bug in `DataFrame.astype()` where casting to 'category' on an empty `DataFrame` causes a segmentation fault (GH18004)
- Error messages in the testing module have been improved when items have different `CategoricalDtype` (GH18069)
- `CategoricalIndex` can now correctly take a `pd.api.types.CategoricalDtype` as its dtype (GH18116)
- Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN (GH18051)
- Bug in `DataFrame.groupby(axis=1)` with a `CategoricalIndex` (GH18432)

1.5.5.9 String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None (GH18450)

1.6 v0.21.0 (October 27, 2017)

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with Apache Parquet, including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see here.
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see here.
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether `bottleneck` is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see here.
- Compatibility fixes for pypy, see here.
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see here.
pandas: powerful Python data analysis toolkit, Release 0.23.2

- Addition of the new methods `DataFrame.infer_objects` (see here) and `GroupBy.pipe` (see here).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a KeyError in a future version, see here.

Check the API Changes and deprecations before updating.

What’s new in v0.21.0

- **New features**
  - Integration with Apache Parquet file format
  - `infer_objects` type conversion
  - Improved warnings when attempting to create columns
  - `drop` now also accepts index/columns keywords
  - `rename`, `reindex` now also accept axis keyword
  - `CategoricalDtype` for specifying categoricals
  - `GroupBy` objects now have a `pipe` method
  - `Categorical.rename_categories` accepts a dict-like
  - **Other Enhancements**
- **Backwards incompatible API changes**
  - Dependencies have increased minimum versions
  - Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN
  - Indexing with a list with missing labels is Deprecated
  - NA naming Changes
  - Iteration of Series/Index will now return Python scalars
  - Indexing with a Boolean Index
  - `PeriodIndex` resampling
  - Improved error handling during item assignment in `pd.eval`
  - Dtype Conversions
  - `MultiIndex` Constructor with a Single Level
  - UTC Localization with Series
  - Consistency of Range Functions
  - No Automatic Matplotlib Converters
  - **Other API Changes**
- **Deprecations**
  - `Series.select` and `DataFrame.select`
  - `Series.argmax` and `Series.argmin`
- **Removal of prior version deprecations/changes**
- **Performance Improvements**
1.6.1 New features

1.6.1.1 Integration with Apache Parquet file format

Integration with Apache Parquet, including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see [here](GH15838, GH17438).

Apache Parquet provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the `pyarrow` or `fastparquet` library. For more details, see the [IO docs on Parquet](103).

1.6.1.2 `infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation [here](201) for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```python
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
                       'B': np.array([1, 2, 3], dtype='object'),
                       'C': ['1', '2', '3']})

In [2]: df.dtypes
Out[2]:
A    int64
B    object
C    object
```
Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()
In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')
In [6]: df.dtypes
Out[6]:
    A  int64
    B  int64
    C  int64
dtype: object
```

1.6.1.3 Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on `DataFrame` instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the `DataFrame`:

```
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In[2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In[3]: df
Out[3]:
    one
  0   1.0
  1   2.0
  2   3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See `Attribute Access`.

1.6.1.4 `drop` now also accepts index/columns keywords

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the `axis`. This is similar to the behavior of `reindex` (GH12392).

For example:
In [7]: df = pd.DataFrame(np.arange(8).reshape(2,4),
    ...:                     columns=['A', 'B', 'C', 'D'])
    ...

In [8]: df
Out[8]:
   A  B  C  D
0  0  1  2  3
1  4  5  6  7

In [9]: df.drop(['B', 'C'], axis=1)
Out[9]:
   A  D
0  0  3
1  4  7

# the following is now equivalent
In [10]: df.drop(columns=['B', 'C'])
Out[10]:
   A  D
0  0  3
1  4  7

1.6.1.5 rename, reindex now also accept axis keyword

The DataFrame.rename() and DataFrame.reindex() methods have gained the axis keyword to specify the axis to target with the operation (GH12392).

Here's rename:

In [11]: df = pd.DataFrame({"A": [1, 2, 3], "B": [4, 5, 6]})

In [12]: df.rename(str.lower, axis='columns')
Out[12]:
   a  b
0  1  4
1  2  5
2  3  6

In [13]: df.rename(id, axis='index')
   A  B
4458898752 1  4
4458898784 2  5
4458898816 3  6

And reindex:

In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
Out[14]:
   A  B  C
0  1  4 NaN
1  2  5 NaN
2  3  6 NaN

(continues on next page)
In [15]: df.reindex([0, 1, 3], axis='index')

Out[15]:
A  B
0 1.0 4.0
1 2.0 5.0
3 NaN NaN

The “index, columns” style continues to work as before.

In [16]: df.rename(index=id, columns=str.lower)

Out[16]:
a  b
4458898752 1 4
4458898784 2 5
4458898816 3 6

In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])

Out[17]:
A  B  C
0 1.0 4.0 NaN
1 2.0 5.0 NaN
3 NaN NaN NaN

We highly encourage using named arguments to avoid confusion when using either style.

### 1.6.1.6 CategoricalDtype for specifying categoricals

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the categories and ordered attributes. A `CategoricalDtype` can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a `Categorical` (GH14711, GH15078, GH16015, GH17643):

In [18]: from pandas.api.types import CategoricalDtype
In [19]: s = pd.Series(['a', 'b', 'c', 'a']) # strings
In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [21]: s.astype(dtype)

Out[21]:
0 a
1 b
2 c
3 a
dtype: category
Categories (4, object): [a < b < c < d]

One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

In [22]: data = 'A,B
   ...: a,1
   ...: b,2
   ...: c,3'
In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories

Out[23]: Index(['1', '2', '3'], dtype='object')
Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

```python
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}
In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
Out[25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex`, or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string 'category'. We’ll take this moment to remind users that the preferred way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`.

See the `CategoricalDtype docs` for more.

### 1.6.1.7 GroupBy objects now have a pipe method

GroupBy objects now have a `pipe` method, similar to the one on DataFrame and Series, that allow for functions that take a GroupBy to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a DataFrame with columns for stores, products, revenue and sold quantity. We’d like to do a groupwise calculation of `prices` (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```python
In [26]: import numpy as np
In [27]: n = 1000
In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
                     'Product': np.random.choice(['Product_1', 'Product_2', 'Product_3'], n),
                     'Revenue': (np.random.random(n)*50+10).round(2),
                     'Quantity': np.random.randint(1, 10, size=n)})
In [29]: df.head(2)
```

```
Store  Product  Revenue  Quantity
0  Store_1  Product_3   54.28       3
1  Store_2  Product_2   30.91       1
```

Now, to find prices per store/product, we can simply do:

```python
In [30]: (df.groupby(['Store', 'Product'])
            .pipe(lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
            .unstack().round(2))
```

```
Product    Product_1   Product_2   Product_3
Store
```

(continues on next page)
See the documentation for more.

### 1.6.1.8 Categorical.rename_categories accepts a dict-like

`rename_categories()` now accepts a dict-like argument for `new_categories`. The previous categories are looked up in the dictionary’s keys and replaced if found. The behavior of missing and extra keys is the same as in `DataFrame.rename()`.

```python
In [31]: c = pd.Categorical(['a', 'a', 'b'])

In [32]: c.rename_categories({'a': 'eh', 'b': 'bee'})
Out[32]:
[eh, eh, bee]
Categories (2, object): [eh, bee]
```

**Warning:** To assist with upgrading pandas, `rename_categories` treats `Series` as list-like. Typically, `Series` are considered to be dict-like (e.g. in `.rename`, `.map`). In a future version of pandas `rename_categories` will change to treat them as dict-like. Follow the warning message’s recommendations for writing future-proof code.

```python
In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
```

```
FutureWarning: Treating Series 'new_categories' as a list-like and using the values. In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()'  
For list-like, use 'new_categories.values'.
```

```
Out[33]:
[0, 0, 1]
Categories (2, int64): [0, 1]
```

### 1.6.1.9 Other Enhancements

**New functions or methods**

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

**New keywords**

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)
• Series.to_pickle() and DataFrame.to_pickle() have gained a protocol parameter (GH16252). By default, this parameter is set to HIGHEST_PROTOCOL.
• read_feather() has gained the nthreads parameter for multi-threaded operations (GH16359).
• DataFrame.clip() and Series.clip() have gained an inplace argument. (GH15388)
• crosstab() has gained a margins_name parameter to define the name of the row/column that will contain the totals when margins=True. (GH15972)
• read_json() now accepts a chunksize parameter that can be used when lines=True. If chunksize is passed, read_json now returns an iterator which reads in chunksize lines with each iteration. (GH17048)
• read_json() and to_json() now accept a compression argument which allows them to transparently handle compressed files. (GH17798)

Various enhancements

• Improved the import time of pandas by about 2.25x. (GH16764)
• Support for PEP 519 – Adding a file system path protocol on most readers (e.g. read_csv()) and writers (e.g. DataFrame.to_csv()) (GH13823).
• Added a __fspath__ method to pd.HDFStore, pd.ExcelFile, and pd.ExcelWriter to work properly with the file system path protocol (GH13823).
• The validate argument for merge() now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type MergeError will be raised. For more, see here (GH16270)
• Added support for PEP 518 (pyproject.toml) to the build system (GH16745)
• RangeIndex.append() now returns a RangeIndex object when possible (GH16212)
• Series.rename_axis() and DataFrame.rename_axis() with inplace=True now return None while renaming the axis inplace. (GH15704)
• api.types.infer_dtype() now infers decimals. (GH15690)
• DataFrame.select_dtypes() now accepts scalar values for include/exclude as well as list-like. (GH16855)
• date_range() now accepts ‘YS’ in addition to ‘AS’ as an alias for start of year. (GH9313)
• date_range() now accepts ‘Y’ in addition to ‘A’ as an alias for end of year. (GH9313)
• DataFrame.add_prefix() and DataFrame.add_suffix() now accept strings containing the ‘%’ character. (GH17151)
• Read/write methods that infer compression (read_csv(), read_table(), read_pickle(), and to_pickle()) can now infer from path-like objects, such as pathlib.Path. (GH17206)
• read_sas() now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
• DataFrame.items() and Series.items() are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
• pandas.io.formats.style.Styler.where() has been implemented as a convenience for pandas.io.formats.style.Styler.applymap(). (GH17474)
• MultiIndex.is_monotonic_decreasing() has been implemented. Previously returned False in all cases. (GH16554)
pandas: powerful Python data analysis toolkit, Release 0.23.2

- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of **kwargs for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex(),DataFrame.reindex(),Index.get_indexer()` now support list-like argument for tolerance. (GH17367)

1.6.2 Backwards incompatible API changes

1.6.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numpy</td>
<td>1.9.0</td>
<td>X</td>
</tr>
<tr>
<td>Matplotlib</td>
<td>1.4.3</td>
<td></td>
</tr>
<tr>
<td>Scipy</td>
<td>0.14.0</td>
<td></td>
</tr>
<tr>
<td>Bottleneck</td>
<td>1.0.0</td>
<td></td>
</tr>
</tbody>
</table>

Additionally, support has been dropped for Python 3.4 (GH15251).

1.6.2.2 Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN

**Note:** The changes described here have been partially reverted. See the v0.22.0 Whatsnew for more.

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the docs.

```
In [33]: s = Series([np.nan])
```

Previously WITHOUT `bottleneck` installed:
```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH `bottleneck`:
```
In [2]: s.sum()
Out[2]: 0.0
```

New Behavior, without regard to the bottleneck installation:
```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a bottleneck installation:
but for consistency with the all-NaN case, this was changed to return NaN as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

### 1.6.2.3 Indexing with a list with missing labels is Deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a `FutureWarning`. In the future this will raise a `KeyError` (GH15747). This warning will trigger on a `DataFrame` or a `Series` for using `.loc[]` or `[[ ]]` when passing a list-of-labels with at least 1 missing label. See the deprecation docs.

```
In [36]: s = pd.Series([1, 2, 3])
In [37]: s
Out[37]:
0 1
1 2
2 3
dtype: int64
```

**Previous Behavior**

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

**Current Behavior**

```
In [4]: s.loc[[1, 2, 3]]
```

Passing list-likes to `.loc` or `[]` with any missing label will raise `KeyError` in the future, you can use `.reindex()` as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-˓
listlike

```
Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64
```

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`

```
In [38]: s.reindex([1, 2, 3])
Out[38]:
1 2.0
2 3.0
```

(continues on next page)
Selection with all keys found is unchanged.

```
In [39]: s.loc[[1, 2]]
Out[39]:
1  2
2  3
dtype: int64
```

### 1.6.2.4 NA naming Changes

In order to promote more consistency among the pandas API, we have added additional top-level functions `isna()` and `notna()` that are aliases for `isnull()` and `notnull()`. The naming scheme is now more consistent with methods like `.dropna()` and `.fillna()`. Furthermore in all cases where `.isnull()` and `.notnull()` methods are defined, these have additional methods named `.isna()` and `.notna()`, these are included for classes Categorical, Index, Series, and DataFrame. (GH15001).

The configuration option `pd.options.mode.use_inf_as_null` is deprecated, and `pd.options.mode.use_inf_as_na` is added as a replacement.

### 1.6.2.5 Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a Series with dtype `int` or `float`, you would receive a numpy scalar, e.g. a `np.int64`, rather than a Python `int`. Issue (GH10904) corrected this for `Series.tolist()` and `list(Series)`. This change makes all iteration methods consistent, in particular, for `__iter__()` and `.map()`. Note that this only affects int/float dtypes. (GH13236, GH13258, GH14216).

```
In [40]: s = pd.Series([1, 2, 3])
In [41]: s
Out[41]:
0  1
1  2
2  3
dtype: int64

Previously:

```
In [2]: type(list(s)[0])
Out[2]: numpy.int64
```

New Behaviour:

```
In [42]: type(list(s)[0])
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a':[1], 'b':['b']}
In [44]: df = pd.DataFrame(d)
```
Previously:

```
In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64
```

New Behaviour:

```
In [45]: type(df.to_dict()['a'][0])
Out[45]: int
```

### 1.6.2.6 Indexing with a Boolean Index

Previously when passing a boolean Index to `.loc`, if the index of the Series/DataFrame had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. (GH17738)

Previous Behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])
In [47]: s
Out[47]:
False 1
True 2
False 3
dtype: int64
In [59]: s.loc[pd.Index([True, False, True])]
Out[59]:
True 2
False 1
False 3
True 2
dtype: int64
```

Current Behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False 1
False 3
dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously Behavior:

```
In [49]: s = pd.Series([1,2,3], index=['a', 'b', 'c'])
In [50]: s
Out[50]:
a 1
b 2
c 3
dtype: int64
```
```python
s.loc[pd.Index([True, False, True])]
```

```
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current Behavior

```python
s.loc[pd.Index([True, False, True])]
```

```
Out[51]:
a  1
c  3
dtype: int64
```

1.6.2.7 PeriodIndex resampling

In previous versions of pandas, resampling a Series/DataFrame indexed by a PeriodIndex returned a DatetimeIndex in some cases (GH12884). Resampling to a multiplied frequency now returns a PeriodIndex (GH15944). As a minor enhancement, resampling a PeriodIndex can now handle NaT values (GH13224)

Previous Behavior:

```python
pi = pd.period_range('2017-01', periods=12, freq='M')
s = pd.Series(np.arange(12), index=pi)
resampled = s.resample('2Q').mean()
resampled
```

```
2017-03-31  1.0
2017-09-30  5.5
2018-03-31 10.0
Freq: 2Q-DEC, dtype: float64
```

```python
resampled.index
```

```
DatetimeIndex(["2017-03-31", "2017-09-30", "2018-03-31"], dtype='datetime64[ns]', freq='2Q-DEC')
```

New Behavior:

```python
pi = pd.period_range('2017-01', periods=12, freq='M')
s = pd.Series(np.arange(12), index=pi)
resampled = s.resample('2Q').mean()
resampled
```

```
2017Q1  2.5
2017Q3  8.5
Freq: 2Q-DEC, dtype: float64
```

```python
resampled.index
```

```
PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]', freq='2Q-DEC')
```

Upsampling and calling .ohlc() previously returned a Series, basically identical to calling .asfreq(). OHLC upsampling now returns a DataFrame with columns open, high, low and close (GH13083). This is consistent with downsampling and DatetimeIndex behavior.
Previous Behavior:

```python
In [1]: pi = pd.PeriodIndex(start='2000-01-01', freq='D', periods=10)

In [2]: s = pd.Series(np.arange(10), index=pi)

In [3]: s.resample('H').ohlc()
Out[3]:
2000-01-01 00:00 0.0
...
2000-01-10 23:00 NaN
Freq: H, Length: 240, dtype: float64

In [4]: s.resample('M').ohlc()
Out[4]:
   open  high  low  close
2000-01  0 9 0 9
```

New Behavior:

```python
In [57]: pi = pd.PeriodIndex(start='2000-01-01', freq='D', periods=10)

In [58]: s = pd.Series(np.arange(10), index=pi)

In [59]: s.resample('H').ohlc()
Out[59]:
   open  high  low  close
2000-01-01 00:00 0.0 0.0 0.0 0.0
2000-01-01 01:00 NaN NaN NaN NaN
2000-01-01 02:00 NaN NaN NaN NaN
2000-01-01 03:00 NaN NaN NaN NaN
2000-01-01 04:00 NaN NaN NaN NaN
2000-01-01 05:00 NaN NaN NaN NaN
2000-01-01 06:00 NaN NaN NaN NaN
...
2000-01-10 17:00 NaN NaN NaN NaN
2000-01-10 18:00 NaN NaN NaN NaN
2000-01-10 19:00 NaN NaN NaN NaN
2000-01-10 20:00 NaN NaN NaN NaN
2000-01-10 21:00 NaN NaN NaN NaN
2000-01-10 22:00 NaN NaN NaN NaN
2000-01-10 23:00 NaN NaN NaN NaN
[240 rows x 4 columns]

In [60]: s.resample('M').ohlc()
```

1.6.2.8 Improved error handling during item assignment in `pd.eval`

`eval()` will now raise a `ValueError` when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression (GH16732)
Previously, if you attempted the following expression, you would get a not very helpful error message:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...: IndexError: only integers, slices (':'), ellipsis ('...'), numpy.newaxis ('None')
and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don’t support string-item indexing. With this change, the error message is now this:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...: ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...: ValueError: Cannot operate inplace if there is no assignment
```

### 1.6.2.9 Dtype Conversions

Previously assignments, `.where()` and `.fillna()` with a `bool` assignment, would coerce to same the type (e.g. `int` / `float`), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. (GH16821).

```
In [62]: s = Series([1, 2, 3])
In [5]: s[1] = True
```

```
In [6]: s
Out[6]:
0   1
1   1
2   3
dtype: int64
```

New Behavior

```
In [63]: s[1] = True
In [64]: s
Out[64]:
0   1
1   True
2   3
dtype: object
```
Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

```
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])

In [1]: s[1] = 1

In [2]: s
Out[2]:
0  2011-01-01 00:00:00.000000000
1  1970-01-01 00:00:00.000000001
dtype: datetime64[ns]
```

These now coerce to object dtype.

```
In [66]: s[1] = 1

In [67]: s
Out[67]:
0  2011-01-01 00:00:00
1  1
dtype: object
```

- Inconsistent behavior in .where() with datetimelikes which would raise rather than coerce to object (GH16402)
- Bug in assignment against int64 data with np.ndarray with float64 dtype may keep int64 dtype (GH14001)

### 1.6.2.10 MultiIndex Constructor with a Single Level

The MultiIndex constructors no longer squeezes a MultiIndex with all length-one levels down to a regular Index. This affects all the MultiIndex constructors. (GH17178)

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a MultiIndex is always returned from all of the MultiIndex constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[68]: MultiIndex(levels=['a', 'b'],
labels=[[0, 1]])
```

### 1.6.2.11 UTC Localization with Series

Previously, `to_datetime()` did not localize datetime Series data when utc=True was passed. Now, `to_datetime()` will correctly localize Series with a datetime64[ns, UTC] dtype to be consistent with how list-like and Index data are handled. (GH6415).

Previous Behavior

```
1.6. v0.21.0 (October 27, 2017) 71
```
In [69]: s = Series(["20130101 00:00:00"] * 3)

In [12]: pd.to_datetime(s, utc=True)
Out[12]:
0  2013-01-01
1  2013-01-01
2  2013-01-01
dtype: datetime64[ns]

New Behavior

In [70]: pd.to_datetime(s, utc=True)
Out[70]:
0  2013-01-01 00:00:00+00:00
1  2013-01-01 00:00:00+00:00
2  2013-01-01 00:00:00+00:00
dtype: datetime64[ns, UTC]

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

1.6.2.12 Consistency of Range Functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()` (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

Previous Behavior:

In [2]: pd.interval_range(start=0, end=4, periods=6)
Out[2]:
IntervalIndex([(0, 1], (1, 2], (2, 3]],
closed='right',
dtype='interval[int64]')

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
Out[3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'],
dtype='period[Q-DEC]', freq='Q-DEC')

New Behavior:

In [2]: pd.interval_range(start=0, end=4, periods=6)
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be
->specified

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be
->specified
Additionally, the endpoint parameter \texttt{end} was not included in the intervals produced by \texttt{interval_range}. However, all other range functions include \texttt{end} in their output. To promote consistency among the range functions, \texttt{interval_range} will now include \texttt{end} as the right endpoint of the final interval, except if \texttt{freq} is specified in a way which skips \texttt{end}.

\textbf{Previous Behavior:}

\begin{verbatim}
In [4]: pd.interval_range(start=0, end=4)
Out[4]:
IntervalIndex([[(0, 1], (1, 2], (2, 3)]]
closed='right',
dtype='interval[int64]')
\end{verbatim}

\textbf{New Behavior:}

\begin{verbatim}
In [71]: pd.interval_range(start=0, end=4)
Out[71]:
IntervalIndex([[(0, 1], (1, 2], (2, 3], (3, 4)]]
closed='right',
dtype='interval[int64]')
\end{verbatim}

\subsection*{1.6.2.13 No Automatic Matplotlib Converters}

Pandas no longer registers our \texttt{date}, \texttt{time}, \texttt{datetime}, \texttt{datetime64}, and \texttt{Period} converters with matplotlib when pandas is imported. Matplotlib plot methods (\texttt{plt.plot}, \texttt{ax.plot}, . . . ), will not nicely format the x-axis for \texttt{DatetimeIndex} or \texttt{PeriodIndex} values. You must explicitly register these methods:

Pandas built-in Series.plot and DataFrame.plot will register these converters on first-use (GH17710).

\textbf{Note: } This change has been temporarily reverted in pandas 0.21.1, for more details see \texttt{here}.

\subsection*{1.6.2.14 Other API Changes}

- The Categorical constructor no longer accepts a scalar for the \texttt{categories} keyword. (GH16022)
- Accessing a non-existent attribute on a closed \texttt{HDFStore} will now raise an AttributeError rather than a ClosedFileError (GH16301)
- \texttt{read_csv()} now issues a UserWarning if the \texttt{names} parameter contains duplicates (GH17095)
- \texttt{read_csv()} now treats \texttt{'null'} and \texttt{'n/a'} strings as missing values by default (GH16471, GH16078)
- pandas.HDFStore's string representation is now faster and less detailed. For the previous behavior, use pandas.HDFStore.info(). (GH16503).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if \texttt{complib} is missing and \texttt{complevel} > 0 zlib is used (GH15943)
- \texttt{Index.get_indexer_non_unique()} now returns a ndarray indexer rather than an Index; this is consistent with \texttt{Index.get_indexer()} (GH16819)
- Removed the \texttt{@slow} decorator from pandas.util.testing, which caused issues for some downstream packages’ test suites. Use \texttt{@pytest.mark.slow} instead, which achieves the same thing (GH16850)
- Moved definition of MergeError to the pandas.errors module.
• The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` (GH14636).

• `Series.argmin()` and `Series.argmax()` will now raise a `TypeError` when used with object dtypes, instead of a `ValueError` (GH13595).

• `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the ordinal or freq attributes (GH17116).

• `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842).

• `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774).

• Renamed non-functional `index` to `index_col` in `read_stata()` to improve API consistency (GH16342).

• Bug in `DataFrame.drop()` caused boolean labels `False` and `True` to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877).

• Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

### 1.6.3 Deprecations

• `DataFrame.from_csv()` and `Series.from_csv()` have been deprecated in favor of `read_csv()` (GH4191).

• `read_excel()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `.to_excel()` (GH10559).

• `read_excel()` has deprecated `parse_cols` in favor of `usecols` for consistency with `read_csv()` (GH4988).

• `read_csv()` has deprecated the `tupleize_cols` argument. Column tuples will always be converted to a MultiIndex (GH17060).

• `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. Multi-index columns will be always written as rows in the CSV file (GH17060).

• The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948).

• `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).

• `SeriesGroupBy.nth()` has deprecated `True` in favor of `'all'` for its `dropna` (GH11038).

• `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302).

• `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747).

• `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the documentation for more details (GH17596).

• passing `categories` or `ordered` kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636).

• `.get_value` and `.set_value` on `Series`, `DataFrame`, `Panel`, `SparseSeries`, and `SparseDataFrame` are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269).
• Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295)

• `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968)

• Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column `labels` is now deprecated in favor of using `.rename.rename_axis` may still be used to alter the name of the index or columns (GH17833).

• `reindex_axis()` has been deprecated in favor of `reindex()`. See here for more (GH17833).

1.6.3.1 Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```python
In [72]: df = DataFrame({
'A': [1, 2, 3],
}, index=['foo', 'bar', 'baz'])

In [3]: df.select(lambda x: x in ['bar', 'baz'])
```

```
FutureWarning: select is deprecated and will be removed in a future release. You can use .loc[crit] as a replacement
```

```python
Out[3]:
   A
bar 2
baz 3
```

```python
In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
```

```
Out[73]:
   A
bar 2
baz 3
```

1.6.3.2 Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the `label` of the maximum or minimum, rather than the `position`.

We’ve deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

1.6.4 Removal of prior version deprecations/changes

• `read_excel()` has dropped the `has_index_names` parameter (GH10967)

• The `pd.options.display.height` configuration has been dropped (GH3663)

• The `pd.options.display.line_width` configuration has been dropped (GH2881)

• The `pd.options.display.mpl_style` configuration has been dropped (GH12190)
• Index has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)
• Categorical has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
• `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)
• The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
• pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

1.6.5 Performance Improvements

• Improved performance of instantiating `SparseDataFrame` (GH16773)
• `Series.dt` no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
• Improved performance of `set_categories()` by not materializing the values (GH17508)
• `Timestamp.microsecond` no longer re-computes on attribute access (GH17331)
• Improved performance of the `CategoricalIndex` for data that is already categorical dtype (GH17513)
• Improved performance of `RangeIndex.min()` and `RangeIndex.max()` by using `RangeIndex` properties to perform the computations (GH17607)

1.6.6 Documentation Changes

• Several `NaT` method docstrings (e.g. `NaT.ctime()`) were incorrect (GH17327)
• The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

1.6.7 Bug Fixes

1.6.7.1 Conversion

• Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
• Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
• Fixed the return type of `IntervalIndex.is_non_overlapping_monotonic` to be a Python `bool` for consistency with similar attributes/methods. Previously returned a numpy.bool_. (GH17237)
• Bug in `IntervalIndex.is_non_overlapping_monotonic` when intervals are closed on both sides and overlap at a point (GH16560)
• Bug in `Series.fillna()` returns frame when `inplace=True` and `value` is dict (GH16156)
• Bug in `Timestamp.weekday_name` returning a UTC-based weekday name when localized to a timezone (GH17354)
• Bug in `Timestamp.replace` when replacing `tzinfo` around DST changes (GH15683)
• Bug in `Timedelta` construction and arithmetic that would not propagate the `Overflow` exception (GH17367)
• Bug in `astype()` converting to object dtype when passed extension type classes (`DatetimeTZDtype`, `CategoricalDtype`) rather than instances. Now a `TypeError` is raised when a class is passed (GH17780).

• Bug in `to_numeric()` in which elements were not always being coerced to numeric when `errors='coerce'` (GH17007, GH17125)

• Bug in `DataFrame` and `Series` constructors where `range` objects are converted to `int32` dtype on Windows instead of `int64` (GH16804)

1.6.7.2 Indexing

• When called with a null slice (e.g. `df.iloc[:],`), the `.iloc` and `.loc` indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).

• When called on an unsorted `MultiIndex`, the `.loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels (GH16734).

• Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` (GH16896).

• Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs (GH16909).

• Fix `MultiIndex.sort_index()` ordering when `ascending` argument is a list, but not all levels are specified, or are in a different order (GH16934).

• Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised (GH16957)

• Bug in reindexing on an empty `CategoricalIndex` (GH16770)

• Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` (GH16889)

• Avoids `IndexError` when passing an `Index` or `Series` to `.iloc` with older `numpy` (GH17193)

• Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)

• Bug in `.iloc` when used with inplace addition or assignment and an int indexer on a `MultiIndex` causing the wrong indexes to be read from and written to (GH17148)

• Bug in `.isin()` in which checking membership in empty `Series` objects raised an error (GH16991)

• Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)

• Bug in intersection of `RangeIndex` with negative step (GH17296)

• Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)

• Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)

• Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)

• Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

1.6.7.3 I/O

• Bug in `read_hdf()` when reading a timezone aware index from fixed format HDFStore (GH17618)

• Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)

• Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
• Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)

• Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).

• Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a MemoryError (GH16798).

• Bug in `read_csv()` when called with a single-element list `header` would return a DataFrame of all NaN values (GH7757)

• Bug in `DataFrame.to_csv()` defaulting to ‘ascii’ encoding in Python 3, instead of ‘utf-8’ (GH17097)

• Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)

• Bug in `read_stata()` where the index was not set (GH16342)

• Bug in `read_html()` where import check fails when run in multiple threads (GH16928)

• Bug in `read_csv()` where automatic delimiter detection caused a TypeError to be thrown when a bad line was encountered rather than the correct error message (GH13374)

• Bug in `DataFrame.to_html()` with `notebook=True` where DataFrames with named indices or non-MultiIndex indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)

• Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)

• Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring VLArray (GH17021)

• Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

1.6.7.4 Plotting

• Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)

• Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)

• Line plots no longer assume monotonic x data when calculating xlims, they show the entire lines now even for unsorted x data. (GH11310, GH11471)

• With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)

• Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed color (GH16822)

• Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

1.6.7.5 Groupby/Resample/Rolling

• Bug in `DataFrame.resample(...).size()` where an empty `DataFrame` did not return a Series (GH14962)

• Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)

• Bug in `.rolling(...).quantile()` which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)
pandas: powerful Python data analysis toolkit, Release 0.23.2

- Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)
- Bug in `Series.resample(...) .apply()` where an empty `Series` modified the source index and did not return the name of a `Series` (GH14313)
- Bug in `rolling(...).apply(...)` with a `DataFrame` with a `DatetimeIndex`, a window of a `timedelta`-convertible and `min_periods >= 1` (GH15305)
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis (GH16859)
- Bug in `groupby.nunique()` with `TimeGrouper` which cannot handle `NaT` correctly (GH17575)
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts (GH17537)
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name (GH17383)
- Bug in `TimeGrouper` differs when passes as a list and as a scalar (GH17530)

1.6.7.6 Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data (GH16905)
- Bug in `SparseDataFrame.fillna()` not filling all NaNs when frame was instantiated from SciPy sparse matrix (GH16112)
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` (GH16614, GH15045)
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array dtype is `object` (GH17574)
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented (GH17570)

1.6.7.7 Reshaping

- Joining/Merging with a non unique `PeriodIndex` raised a `TypeError` (GH16871)
- Bug in `crosstab()` where non-aligned series of integers were casted to float (GH17005)
- Bug in merging with categorical dtypes with datetimelikes incorrectly raised a `TypeError` (GH16900)
- Bug when using `isin()` on a large object series and large comparison array (GH16012)
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again (GH17013)
- Fixes dtype of result with integer dtype input, from `pivot_table()` when called with `margins=True` (GH17013)
- Bug in `crosstab()` where passing two `Series` with the same name raised a `KeyError` (GH13279)
- `Series.argmin()`, `Series.argmax()`, and their counterparts on `DataFrame` and groupby objects work correctly with floating point data that contains infinite values (GH13595).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` (GH13595)
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements (GH17344)
• Fixes regression when sorting by multiple columns on a `datetime64` dtype `Series` with NaT values (GH16836)
• Bug in `pivot_table()` where the result’s columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
• Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a ValueError (GH17836)
• Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
• Bug in the alignment of `range` objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

1.6.7.8 Numeric
• Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
• `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

1.6.7.9 Categorical
• Bug in `Series.isin()` when called with a categorical (GH16639)
• Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
• Bug in categorical operations with `Series.cat` not preserving the original Series’ name (GH17509)
• Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
• Bug in constructing a `Categorical/CategoricalDtype` when the specified categories are of categorical type (GH17884).

1.6.7.10 PyPy
• Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
• Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
• Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

1.6.7.11 Other
• Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
• Bug in `eval()` where the `inplace` parameter was being incorrectly handled (GH16732)
1.7 v0.20.3 (July 7, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

What’s new in v0.20.3

- **Bug Fixes**
  - Conversion
  - Indexing
  - I/O
  - Plotting
  - Reshaping
  - Categorical

1.7.1 Bug Fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame (GH16789, GH16825)
- Fixed a pytest marker failing downstream packages’ tests suites (GH16680)

1.7.1.1 Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index (GH16608)
- Bug in Series construction when passing a Series with dtype='category' (GH16524).
- Bug in DataFrame.astype() when passing a Series as the dtype kwarg. (GH16717).

1.7.1.2 Indexing

- Bug in Float64Index causing an empty array instead of None to be returned from .get(np.nan) on a Series whose index did not contain any NaNs (GH8569)
- Bug in MultiIndex.isin causing an error when passing an empty iterable (GH16777)
- Fixed a bug in a slicing DataFrame/Series that have a TimedeltaIndex (GH16637)

1.7.1.3 I/O

- Bug in read_csv() in which files weren’t opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail (GH16039, GH16559, GH16675)
- Bug in read_hdf() in which reading a Series saved to an HDF file in ‘fixed’ format fails when an explicit mode=’r’ argument is supplied (GH16583)
• Bug in DataFrame.to_latex() where bold_rows was wrongly specified to be True by default, whereas in reality row labels remained non-bold whatever parameter provided. (GH16707)
• Fixed an issue with DataFrame.style() where generated element ids were not unique (GH16780)
• Fixed loading a DataFrame with a PeriodIndex, from a format='fixed' HDFStore, in Python 3, that was written in Python 2 (GH16781)

1.7.1.4 Plotting
• Fixed regression that prevented RGB and RGBA tuples from being used as color arguments (GH16233)
• Fixed an issue with DataFrame.plot.scatter() that incorrectly raised a KeyError when categorical data is used for plotting (GH16199)

1.7.1.5 Reshaping
• PeriodIndex/TimedeltaIndex.join was missing the sort= kwarg (GH16541)
• Bug in joining on a MultiIndex with a category dtype for a level (GH16627).
• Bug in merge() when merging/joining with multiple categorical columns (GH16767)

1.7.1.6 Categorical
• Bug in DataFrame.sort_values not respecting the kind parameter with categorical data (GH16793)

1.8 v0.20.2 (June 4, 2017)
This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What’s new in v0.20.2
• Enhancements
• Performance Improvements
• Bug Fixes
  – Conversion
  – Indexing
  – I/O
  – Plotting
  – Groupby/Resample.Rolling
  – Sparse
  – Reshaping
  – Numeric
  – Categorical
1.8.1 Enhancements

- Series provides a `to_latex` method (GH16180)
- A new groupby method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see here.

1.8.2 Performance Improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)
- Improved performance of groupby with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)

1.8.3 Bug Fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using `pathlib.Path` or `py.path.local` objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal MultiIndex’s, results in a `TypeError` (GH13490)
- Bug in `DataFrame.update()` with `overwrite=False` and `NaN` values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative `ValueError` rather than `UnboundLocalError`. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when labels are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on Categoricals (GH16409)

1.8.3.1 Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting `DataFrame` to `Series` with comparison ops (GH16378, GH16306)
1.8.3.2 Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
- Bug in `MultiIndex.remove_unused_levels()` that would not return a `MultiIndex` equal to the original. (GH16556)

1.8.3.3 I/O

- Bug in `read_csv()` when `comment` is passed in a space delimited text file (GH16472)
- Bug in `read_csv()` not raising an exception with nonexistent columns in `usecols` when it had the correct length (GH14671)
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
- Bug that raised `IndexError` when HTML-rendering an empty `DataFrame` (GH15953)
- Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
- Bug where `DataFrame.to_html()` ignored the `index_names` parameter (GH16493)
- Bug where `pd.read_hdf()` returns numpy strings for index names (GH13492)
- Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected (GH16209)

1.8.3.4 Plotting

- Bug in `DataFrame.plot` with a single column and a list-like color (GH3486)
- Bug in `plot` where `NaT` in `DatetimeIndex` results in `Timestamp.min` (GH12405)
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots (GH11959)

1.8.3.5 Groupby/Resample/Rolling

- Bug in creating a time-based rolling window on an empty `DataFrame` (GH15819)
- Bug in `rolling.cov()` with offset window (GH16058)
- Bug in `.resample()` and `.groupby()` when aggregating on integers (GH16361)

1.8.3.6 Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` (GH16179)
1.8.3.7 Reshaping

• Bug in `DataFrame.stack` with unsorted levels in `MultiIndex` columns (GH16323)
• Bug in `pd.wide_to_long()` where no error was raised when `i` was not a unique identifier (GH16382)
• Bug in `Series.isin( )` with a list of tuples (GH16394)
• Bug in construction of a `DataFrame` with mixed dtypes including an all-NaT column. (GH16395)
• Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes (GH16405)

1.8.3.8 Numeric

• Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed (GH16282)

1.8.3.9 Categorical

• Fixed comparison operations considering the order of the categories when both categoricals are unordered (GH16014)

1.8.3.10 Other

• Bug in `DataFrame.drop()` with an empty-list with non-unique indices (GH16270)

1.9 v0.20.1 (May 5, 2017)

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• New `.agg()` API for Series/DataFrame similar to the groupby-rolling-resample API’s, see here
• Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see here.
• The `.ix` indexer has been deprecated, see here
• `Panel` has been deprecated, see here
• Addition of an IntervalIndex and Interval scalar type, see here
• Improved user API when grouping by index levels in `.groupby()`, see here
• Improved support for `UInt64` dtypes, see here
• A new orient for JSON serialization, `orient='table'`, that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see here
• Experimental support for exporting styled DataFrames (DataFrame.style) to Excel, see here
• Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see here
• Support for S3 handling now uses s3fs, see here
Google BigQuery support now uses the pandas-gbq library, see here.

**Warning:** Pandas has changed the internal structure and layout of the codebase. This can affect imports that are not from the top-level pandas.* namespace, please see the changes here.

Check the API Changes and deprecations before updating.

**Note:** This is a combined release for 0.20.0 and and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas’ utils routines. (GH16250)

**What’s new in v0.20.0**

- **New features**
  - `agg` API for DataFrame/Series
  - `dtype` keyword for data IO
  - `.to_datetime()` has gained an origin parameter
  - Groupby Enhancements
  - Better support for compressed URLs in `read_csv`
  - Pickle file I/O now supports compression
  - UInt64 Support Improved
  - GroupBy on Categoricals
  - Table Schema Output
  - SciPy sparse matrix from/to SparseDataFrame
  - Excel output for styled DataFrames
  - `IntvallIndex`
  - Other Enhancements

- **Backwards incompatible API changes**
  - Possible incompatibility for HDF5 formats created with pandas < 0.13.0
  - Map on Index types now return other Index types
  - Accessing datetime fields of Index now return Index
  - `pd.unique` will now be consistent with extension types
  - `S3 File Handling`
  - Partial String Indexing Changes
  - Concat of different float dtypes will not automatically upcast
  - Pandas Google BigQuery support has moved
  - Memory Usage for Index is more Accurate
  - `DataFrame.sort_index` changes
1.9.1 New features

1.9.1.1 agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and
transform(). The full documentation is here (GH1623).

Here is a sample

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
    ...:                        index=pd.date_range('1/1/2000', periods=10))

In [2]: df.iloc[3:7] = np.nan

In [3]: df
Out[3]:
   A          B          C
2000-01-01  1.682600  0.413582  1.689516
2000-01-02 -2.099110 -1.180182  1.595661
2000-01-03 -0.419048  0.522165 -1.208946
2000-01-04    NaN        NaN        NaN
2000-01-05    NaN        NaN        NaN
2000-01-06    NaN        NaN        NaN
2000-01-07    NaN        NaN        NaN
2000-01-08  0.955435 -0.133009  2.011466
2000-01-09  0.578780  0.897126 -0.980013
2000-01-10 -0.045748  0.361601 -0.208039
```

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to .apply.

```python
In [4]: df.agg('sum')
Out[4]:
   A    0.652908
   B    0.881282
   C    2.899645
dtype: float64
```

Multiple aggregations with a list of functions.

```python
In [5]: df.agg(['sum', 'min'])
Out[5]:
    A          B          C
   sum  0.652908  0.881282  2.899645
   min -2.099110 -1.180182 -1.208946
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will be NaN:

```python
In [6]: df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
Out[6]:
   A          B
max    NaN  0.897126
min -2.099110 -1.180182
sum  0.652908    NaN
```

The API also supports a .transform() function for broadcasting results.

```python
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out[7]:
```

(continues on next page)
When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how `groupby` `.agg()` works. (GH15015)

```python
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
                      'B': [1., 2., 3.],
                      'C': ['foo', 'bar', 'baz'],
                      'D': pd.date_range('20130101', periods=3)})

In [9]: df.dtypes
Out[9]:
A     int64
B     float64
C     object
D  datetime64[ns]
dtype: object

In [10]: df.agg(['min', 'sum'])
Out[10]:
  A   B     C     D
min 1  1.0   bar   2013-01-01
sum 6  6.0  foobar baz  NaT
```

### 1.9.1.2 `dtype` keyword for data IO

The `python` engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns (GH14295). See the `io docs` for more information.

```python
In [11]: data = "a b\n1 \n2\n3 4"

In [12]: pd.read_fwf(StringIO(data)).dtypes
Out[12]:
a    int64
b    int64
dtype: object

In [13]: pd.read_fwf(StringIO(data), dtype={'a':'float64', 'b':'object'}).dtypes
     a: float64
     b: object
dtype: object
```

1.9. v0.20.1 (May 5, 2017)
1.9.1.3 `.to_datetime()` has gained an origin parameter

to_datetime() has gained a new parameter, origin, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific unit specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

```
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

The default is set at origin='unix', which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

```
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```

1.9.1.4 Groupby Enhancements

Strings passed to DataFrame.groupby() as the by parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
                ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
                    'B': np.arange(8)},
                    index=index)
In [19]: df
Out [19]:
    A  B
first second
   bar one  1  0
         two  1  1
   baz one  1  2
         two  1  3
   foo one  2  4
         two  2  5
   qux one  3  6
         two  3  7
In [20]: df.groupby(['second', 'A']).sum()
   →
    B
second A
   one  1  2
        2  4
        3  6
```

(continues on next page)
1.9.1.5 Better support for compressed URLs in read_csv

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in read_csv() or read_table() now supports additional compression methods: xz, bz2, and zip (GH14570). Previously, only gzip compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for bz2 compression in the python 2 C-engine improved (GH14874).

```python
In [21]: url = 'https://github.com/{repo}/raw/{branch}/{path}'.format(
    repo = 'pandas-dev/pandas',
    branch = 'master',
    path = 'pandas/tests/io/parser/data/salaries.csv.bz2',
)

In [22]: df = pd.read_table(url, compression='infer')  # default, infer compression
In [23]: df = pd.read_table(url, compression='bz2')   # explicitly specify compression
In [24]: df.head(2)
Out[24]:
          S       X       E       M
0   13876  1.0000  1.0000  1.0000
1   11608  1.0000  3.0000  0.0000
```

1.9.1.6 Pickle file I/O now supports compression

read_pickle(), DataFrame.to_pickle() and Series.to_pickle() can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See the docs here.

```python
In [25]: df = pd.DataFrame({
    'A': np.random.randn(1000),
    'B': 'foo',
    'C': pd.date_range('20130101', periods=1000, freq='s')})

In [26]: df.to_pickle("data.pkl.compress", compression="gzip")
In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
In [28]: rt.head()
Out[28]:
       A         B          C
0  1.578227  foo 2013-01-01 00:00:00
1 -0.230575  foo 2013-01-01 00:00:01
2  0.695530  foo 2013-01-01 00:00:02
3 -0.466001  foo 2013-01-01 00:00:03
4 -0.154972  foo 2013-01-01 00:00:04
```
The default is to infer the compression type from the extension (compression='infer'):

```python
In [29]: df.to_pickle("data.pkl.gz")

In [30]: rt = pd.read_pickle("data.pkl.gz")

In [31]: rt.head()
Out[31]:
   A       B       C
0  1.578227 foo 2013-01-01 00:00:00
1 -0.230575 foo 2013-01-01 00:00:01
2  0.695530 foo 2013-01-01 00:00:02
3 -0.466001 foo 2013-01-01 00:00:03
4 -0.154972 foo 2013-01-01 00:00:04

In [32]: df["A"].to_pickle("s1.pkl.bz2")

In [33]: rt = pd.read_pickle("s1.pkl.bz2")

In [34]: rt.head()
Out[34]:
   0   1.578227
   1  -0.230575
   2   0.695530
   3  -0.466001
   4  -0.154972

Name: A, dtype: float64
```

### 1.9.1.7 UInt64 Support Improved

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created (GH14937)

```python
In [35]: idx = pd.UInt64Index([1, 2, 3])

In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c'], index=idx})

In [37]: df.index
Out[37]: UInt64Index([1, 2, 3], dtype='uint64')
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers (GH4471, GH14982)
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow (GH14721)
- Bug in `DataFrame` construction in which unsigned 64-bit integer elements were being converted to objects (GH14881)
- Bug in `pd.read_csv()` in which unsigned 64-bit integer elements were being improperly converted to the wrong data types (GH14983)
- Bug in `pd.unique()` in which unsigned 64-bit integers were causing overflow (GH14915)
- Bug in `pd.value_counts()` in which unsigned 64-bit integers were being erroneously truncated in the output (GH14934)
1.9.1.8 GroupBy on Categoricals

In previous versions, `.groupby(..., sort=False)` would fail with a `ValueError` when grouping on a categorical series with some categories not appearing in the data. (GH13179)

```python
In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]
In [39]: df = pd.DataFrame(
    ...:     {'A': np.random.randint(100),
    ...:      'B': np.random.randint(100),
    ...:      'C': np.random.randint(100),
    ...:      'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
    ...:                                     categories=chromosomes,
    ...:                                     ordered=True))
In [40]: df
Out[40]:
   A  B  C  chromosomes
  0  80 36  94          12
  1  80 36  94           X
  2  80 36  94           19
  3  80 36  94           22
  4  80 36  94           17
  5  80 36  94            6
  6  80 36  94           13
...
93  80 36  94           21
94  80 36  94           20
95  80 36  94           11
96  80 36  94           16
97  80 36  94           21
98  80 36  94           18
99  80 36  94            8
[100 rows x 4 columns]
```

Previous Behavior:

```python
In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
---------------------------------------------------------------------------
ValueError: items in new_categories are not the same as in old categories
```

New Behavior:

```python
In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:
   A  B  C  chromosomes
  2 320 144  376
  3 400 180  470
  4 240 108  282
  5 240 108  282
  6 400 180  470
  7 400 180  470
  8 480 216  564
...
19 400 180  470
(continues on next page)
1.9.1.9 Table Schema Output

The new orient 'table' for `DataFrame.to_json()` will generate a Table Schema compatible string representation of the data.

```python
In [42]: df = pd.DataFrame(
       ...:     {'A': [1, 2, 3],
       ...:     'B': ['a', 'b', 'c'],
       ...:     'C': pd.date_range('2016-01-01', freq='d', periods=3),
       ...:     }, index=pd.Index(range(3), name='idx'))

In [43]: df
Out[43]:
       A  B             C
      idx
0   1   a 2016-01-01
1   2   b 2016-01-02
2   3   c 2016-01-03

In [44]: df.to_json(orient='table')

"schema": {
    "fields": [
        {
            "name": "idx",
            "type": "integer"
        },
        {
            "name": "A",
            "type": "integer"
        },
        {
            "name": "B",
            "type": "string"
        },
        {
            "name": "C",
            "type": "datetime"
        }
    ],
    "primaryKey": ["idx"],
    "pandas_version": "0.20.0",
    "data": [
        {
            "idx": 0,
            "A": 1,
            "B": "a",
            "C": "2016-01-01T00:00:00.000Z"
        },
        {
            "idx": 1,
            "A": 2,
            "B": "b",
            "C": "2016-01-02T00:00:00.000Z"
        },
        {
            "idx": 2,
            "A": 3,
            "B": "c",
            "C": "2016-01-03T00:00:00.000Z"
        }
    ]
)
```

See [IO: Table Schema for more information.](#)

Additionally, the repr for DataFrame and Series can now publish this JSON Table schema representation of the Series or DataFrame if you are using IPython (or another frontend like nteract using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and nteract more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

1.9.1.10 SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the [documentation](#) for more information. (GH4343)

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed.
In [45]: from scipy.sparse import csr_matrix

In [46]: arr = np.random.random(size=(1000, 5))

In [47]: arr[arr < .9] = 0

In [48]: sp_arr = csr_matrix(arr)

In [49]: sp_arr

Out[49]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
with 521 stored elements in Compressed Sparse Row format>

In [50]: sdf = pd.SparseDataFrame(sp_arr)

In [51]: sdf

Out[51]:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>

</tbody>
</table>

[1000 rows x 5 columns]

To convert a SparseDataFrame back to sparse SciPy matrix in COO format, you can use:

In [52]: sdf.to_coo()

Out[52]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
with 521 stored elements in COOrdinate format>

1.9.1.11 Excel output for styled DataFrames

Experimental support has been added to export DataFrame.style formats to Excel using the openpyxl engine. (GH15530)

For example, after running the following, styled.xlsx renders as below:

In [53]: np.random.seed(24)

In [54]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})

In [55]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
....:                columns=list('BCDE'))],
(continues on next page)
In [56]: df.iloc[0, 2] = np.nan

In [57]: df

Out[57]:

     A    B       C      D       E
0  1.0  1.329212 NaN -0.316280 -0.990810
1  2.0 -1.070816 -1.438713  0.564417  0.295722
2  3.0 -1.626404  0.219565  0.678805  1.889273
3  4.0  0.961538  0.104011 -0.481165  0.850229
4  5.0  1.453425  1.057737  0.165562  0.515018
5  6.0 -1.336936  0.562861  1.392855 -0.063328
6  7.0  0.121668  1.207603 -0.002040  1.627796
7  8.0  0.354493  1.037528 -0.385684  0.519818
8  9.0  1.686583 -1.325963  1.428984 -2.089354
9 10.0 -0.129820  0.631523 -0.586538  0.290720

In [58]: styled = df.style.

In [59]: styled.to_excel('styled.xlsx', engine='openpyxl')

See the Style documentation for more detail.

1.9.1.12 IntervalIndex

pandas has gained an IntervalIndex with its own dtype, interval as well as the Interval scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in cut() and qcut(). The IntervalIndex allows some unique indexing, see the docs. (GH7640, GH8625)
Warning: These indexing behaviors of the IntervalIndex are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:

The returned categories were strings, representing Intervals

In [1]: c = pd.cut(range(4), bins=2)

In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]]

In [3]: c.categories
Out[3]: Index(['(-0.003, 1.5]', '(1.5, 3]'], dtype='object')

New behavior:

In [60]: c = pd.cut(range(4), bins=2)

In [61]: c
Out[61]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [62]: c.categories

IntervalIndex([(-0.003, 1.5], (1.5, 3.0]
   closed='right',
   dtype='interval[float64]')

Furthermore, this allows one to bin other data with these same bins, with NaN representing a missing value similar to other dtypes.

In [63]: pd.cut([0, 3, 1, 1], bins=c.categories)
Out[63]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

An IntervalIndex can also be used in Series and DataFrame as the index.

In [64]: df = pd.DataFrame({'A': range(4),
....:            'B': pd.cut([0, 3, 1, 1], bins=c.categories)}
....: ).set_index('B')

In [65]: df
Out[65]:
   A
   B
(-0.003, 1.5]  0
(1.5, 3.0]  1
(-0.003, 1.5]  2
(-0.003, 1.5]  3
Selecting via a specific interval:

```
In [66]: df.loc[pd.Interval(1.5, 3.0)]
Out[66]:
   A
Name: (1.5, 3.0], dtype: int64
```

Selecting via a scalar value that is contained in the intervals.

```
In [67]: df.loc[0]
Out[67]:

   A
  B
(-0.003, 1.5]  0
(-0.003, 1.5]  2
(-0.003, 1.5]  3
```

### 1.9.1.13 Other Enhancements

- DataFrame.rolling() now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the documentation (GH13965).

- Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see here.

- Series.str.replace() now accepts a callable, as replacement, which is passed to `re.sub` (GH15055).

- Series.str.replace() now accepts a compiled regular expression as a pattern (GH15446).

- Series.sort_index accepts parameters `kind` and `na_position` (GH13589, GH14444).

- DataFrame and DataFrame.groupby() have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).

- DataFrame has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).

- `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930).

- Multiple offset aliases with decimal points are now supported (e.g. 0.5min is parsed as 30s) (GH8419).

- `.isnull()` and `.notnull()` have been added to Index object to make them more consistent with the Series API (GH15300).

- New UnsortedIndexError (subclass of KeyError) raised when indexing/slicing into an unsorted MultiIndex (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See here.

- MultiIndex has gained a `.to_frame()` method to convert to a DataFrame (GH12397).

- `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798).

- `pd.qcut` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH7751).

- Series provides a `to_excel` method to output Excel files (GH8825).

- The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154).

- The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882).

- The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755).
**pandas: powerful Python data analysis toolkit, Release 0.23.2**

- `DataFrame.plot` now prints a title above each subplot if `subplots=True` and `title` is a list of strings (GH14753)
- `DataFrame.plot` can pass the matplotlib 2.0 default color cycle as a single string as color parameter, see here. (GH15516)
- `Series.interpolate()` now supports timedelta as an index type with `method='time'` (GH6424)
- Addition of a level keyword to `DataFrame/Series.rename` to rename labels in the specified level of a MultiIndex (GH4160).
- `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a MultiIndex (GH16164)
- `Timedelta.isoformat` method added for formatting Timedeltas as an ISO 8601 duration. See the `Timedelta docs` (GH15136)
- `.select_dtypes()` now allows the string `datetimetz` to generically select datetimes with tz (GH14910)
- The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements
- `pd.merge_asof()` gained the option `direction='backward' | 'forward' | 'nearest'` (GH14887)
- `Series/DataFrame.asfreq()` have gained a `fill_value` parameter, to fill missing values (GH3715).
- `Series/DataFrame.resample.asfreq` have gained a `fill_value` parameter, to fill missing values during resampling (GH3715).
- `pandas.util.hash_pandas_object()` has gained the ability to hash a MultiIndex (GH15224)
- `Series/DataFrame.squeeze()` have gained the `axis` parameter. (GH15339)
- `DataFrame.to_excel()` has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel (GH15160)
- `pd.read_html()` will parse multiple header rows, creating a MutliIndex header. (GH13434).
- HTML table output skips `colspan` or `rowspan` attribute if equal to 1. (GH15403)
- `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the example notebook (GH15649)
- `Styler.render()` now accepts `**kwargs` to allow user-defined variables in the template (GH15649)
- Compatibility with Jupyter notebook 5.0; MultiIndex column labels are left-aligned and MultiIndex row-labels are top-aligned (GH15379)
- `TimedeltaIndex` now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711)
- `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the `categorical union docs` for more information.
- `DataFrame.to_latex()` and `DataFrame.to_string()` now allow optional header aliases. (GH15536)
- Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates (GH14326)
- Added `.empty` property to subclasses of Index. (GH15270)
- Enabled floor division for `Timedelta` and `TimedeltaIndex` (GH15828)
- `pandas.io.json.json_normalize()` gained the option `errors='ignore' | 'raise';` the default is `errors='raise'` which is backward compatible. (GH14583)
• pandas.io.json.json_normalize() with an empty list will return an empty DataFrame (GH15534)

• pandas.io.json.json_normalize() has gained a sep option that accepts str to separate joined fields; the default is ‘.’, which is backward compatible. (GH14883)

• MultiIndex.remove_unused_levels() has been added to facilitate removing unused levels. (GH15694)

• pd.read_csv() will now raise a ParserError error whenever any parsing error occurs (GH15913, GH15925)

• pd.read_csv() now supports the error_bad_lines and warn_bad_lines arguments for the Python parser (GH15925)

• The display.show_dimensions option can now also be used to specify whether the length of a Series should be shown in its repr (GH7117).

• parallel_coordinates() has gained a sort_labels keyword argument that sorts class labels and the colors assigned to them (GH15908)

• Options added to allow one to turn on/off using bottleneck and numexpr, see here (GH16157)

• DataFrame.style.bar() now accepts two more options to further customize the bar chart. Bar alignment is set with align='left'|'mid'|'zero', the default is “left”, which is backward compatible; You can now pass a list of color=[color_negative, color_positive]. (GH14757)

1.9.2 Backwards incompatible API changes

1.9.2.1 Possible incompatibility for HDF5 formats created with pandas < 0.13.0

pd.TimeSeries was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of pd.Series. (GH15098).

This may cause HDF5 files that were created in prior versions to become unreadable if pd.TimeSeries was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```
In [2]: s = pd.TimeSeries([1,2,3], index=pd.date_range('20130101', periods=3))

In [3]: s
Out[3]:
2013-01-01  1
2013-01-02  2
2013-01-03  3
Freq: D, dtype: int64

In [4]: type(s)
Out[4]: pandas.core.series.TimeSeries

In [5]: s = pd.Series(s)

In [6]: s
Out[6]:
2013-01-01  1
2013-01-02  2
2013-01-03  3
Freq: D, dtype: int64
```

(continues on next page)
In [7]: type(s)
Out[7]: pandas.core.series.Series

1.9.2.2 Map on Index types now return other Index types

map on an Index now returns an Index, not a numpy array (GH12766)

In [68]: idx = Index([1, 2])
In [69]: idx
Out[69]: Int64Index([1, 2], dtype='int64')
In [70]: mi = MultiIndex.from_tuples([(1, 2), (2, 4)])
In [71]: mi
Out[71]: MultiIndex(levels=[[1, 2], [2, 4]], labels=[[0, 1], [0, 1]])

Previous Behavior:

In [5]: idx.map(lambda x: x * 2)
Out[5]: array([2, 4])
In [6]: idx.map(lambda x: (x, x * 2))
Out[6]: array([(1, 2), (2, 4)], dtype=object)
In [7]: mi.map(lambda x: x)
Out[7]: array([(1, 2), (2, 4)], dtype=object)
In [8]: mi.map(lambda x: x[0])
Out[8]: array([1, 2])

New Behavior:

In [72]: idx.map(lambda x: x * 2)
Out[72]: Int64Index([2, 4], dtype='int64')
In [73]: idx.map(lambda x: (x, x * 2))
MultiIndex(levels=[[1, 2], [2, 4]], labels=[[0, 1], [0, 1]])
In [74]: mi.map(lambda x: x)
MultiIndex(levels=[[1, 2], [2, 4]], labels=[[0, 1], [0, 1]])
In [75]: mi.map(lambda x: x[0])
Int64Index([1, 2], dtype='int64')

map on a Series with datetime64 values may return int64 dtypes rather than int32
In [76]: s = Series(date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H').tz_localize('Asia/Tokyo'))

In [77]: s
Out[77]:
0  2011-01-02 00:00:00+09:00
1  2011-01-02 01:00:00+09:00
2  2011-01-02 02:00:00+09:00

dtype: datetime64[ns, Asia/Tokyo]

Previous Behavior:

In [9]: s.map(lambda x: x.hour)
Out[9]:
0  0
1  1
2  2
dtype: int32

New Behavior:

In [78]: s.map(lambda x: x.hour)
Out[78]:
0  0
1  1
2  2
dtype: int64

1.9.2.3 Accessing datetime fields of Index now return Index

The datetime-related attributes (see here for an overview) of DatetimeIndex, PeriodIndex and TimedeltaIndex previously returned numpy arrays. They will now return a new Index object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [2]: idx.hour
Out[2]: array([ 0, 10, 20, 6, 16], dtype=int32)

New Behavior:

In [79]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [80]: idx.hour
Out[80]: Int64Index([0, 10, 20, 6, 16], dtype='int64')

This has the advantage that specific Index methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, Index objects are not mutable. To get the original ndarray, you can always convert explicitly using np.asarray(idx.hour).

1.9.2.4 pd.unique will now be consistent with extension types

In prior versions, using Series.unique() and pandas.unique() on Categorical and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)
Datetime tz-aware

Previous behaviour:

```
# Series
In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                   pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
               dtype=object)

In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                           pd.Timestamp('20160101', tz='US/Eastern')]))
Out[6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

# Index
In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                     dtype='datetime64[ns, US/Eastern]', freq=None)

In [8]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                         pd.Timestamp('20160101', tz='US/Eastern')]))
Out[8]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                     dtype='datetime64[ns, US/Eastern]', freq=None)
```

New Behavior:

```
# Series, returns an array of Timestamp tz-aware
In [81]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                   ...:  pd.Timestamp('20160101', tz='US/Eastern')]).unique()
   ...:  Out[81]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
                    dtype=object)

In [82]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                         ...:  pd.Timestamp('20160101', tz='US/Eastern')]))
   ...:  Out[82]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
                    dtype=object)

# Index, returns a DatetimeIndex
In [83]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                ...:  pd.Timestamp('20160101', tz='US/Eastern')]).unique()
   ...:  Out[83]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                           dtype='datetime64[ns, US/Eastern]',
                           freq=None)

In [84]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                         ...:  pd.Timestamp('20160101', tz='US/Eastern')]))
   ...:  Out[84]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                           dtype='datetime64[ns, US/Eastern]',
                           freq=None)
```

Categoricals

Previous behaviour:
### 1.9.2.5 S3 File Handling

pandas now uses `s3fs` for handling S3 connections. This shouldn’t break any code. However, since `s3fs` is not a required dependency, you will need to install it separately, like `boto` in prior versions of pandas. (GH11915).

### 1.9.2.6 Partial String Indexing Changes

`DatetimeIndex Partial String Indexing` now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See `Slice vs. Exact Match` for details.
### 1.9.2.7 Concat of different float dtypes will not automatically upcast

Previously, `concat` of multiple objects with different `float` dtypes would automatically upcast results to a dtype of `float64`. Now the smallest acceptable dtype will be used (GH13247)

```python
In [88]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))
In [89]: df1.dtypes
Out[89]:
0  float32
   dtype: object
In [90]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))
In [91]: df2.dtypes
Out[91]:
0  float32
   dtype: object

Previous Behavior:

```python
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0  float64
   dtype: object
```

New Behavior:

```python
In [92]: pd.concat([df1, df2]).dtypes
Out[92]:
0  float32
   dtype: object
```

### 1.9.2.8 Pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package `pandas-gbq`. You can `conda` install `pandas-gbq` -c conda-forge or `pip` install `pandas-gbq` to get it. The functionality of `read_gbq()` and `DataFrame.to_gbq()` remain the same with the currently released version of `pandas-gbq=0.1.4`. Documentation is now hosted here (GH15347)

### 1.9.2.9 Memory Usage for Index is more Accurate

In previous versions, showing `.memory_usage()` on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for `Index` and `MultiIndex` and less-so for other index types. (GH15237)

Previous Behavior:

```python
In [8]: index = Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
Out[10]: 0
```

(continues on next page)
In [11]: index.memory_usage(deep=True)
Out[11]: 180

New Behavior:

In [8]: index = Index(['foo', 'bar', 'baz'])
In [9]: index.memory_usage(deep=True)
Out[9]: 180
In [10]: index.get_loc('foo')
Out[10]: 0
In [11]: index.memory_usage(deep=True)
Out[11]: 260

1.9.2.10 DataFrame.sort_index changes

In certain cases, calling .sort_index() on a MultiIndexed DataFrame would return the same DataFrame without seeming to sort. This would happen with a lexsorted, but non-monotonic levels. (GH15622, GH15687, GH14015, GH13431, GH15797)

This is unchanged from prior versions, but shown for illustration purposes:

In [93]: df = DataFrame(np.arange(6), columns=['value'], index=MultiIndex.from_product([list('BA'), range(3)])

In [94]: df
Out[94]:
   value
  B 0  0
   1  1
   2  2
  A 0  3
   1  4
   2  5

In [95]: df.index.is_lexsorted()
Out[95]: False
In [96]: df.index.is_monotonic
Out[96]: False

Sorting works as expected

In [97]: df.sort_index()
Out[97]:
   value
  A  0  3
   1  4
   2  5
  B  0  0
   1  1
   2  2
However, this example, which has a non-monotonic 2nd level, doesn’t behave as desired.

```
In [100]: df = pd.DataFrame(
       .....:    {'value': [1, 2, 3, 4]},
       .....:    index=pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
       .....:                        labels=[[0, 0, 1, 1], [0, 1, 0, 1]]))

In [101]: df
Out[101]:
     value
  a  bb  1
  a  aa  2
  b  bb  3
  b  aa  4
```

Previous Behavior:

```
In [11]: df.sort_index()
Out[11]:
     value
  a  bb  1
  a  aa  2
  b  bb  3
  b  aa  4
In [14]: df.sort_index().index.is_lexsorted()
Out[14]: True
In [15]: df.sort_index().index.is_monotonic
Out[15]: False
```

New Behavior:

```
In [102]: df.sort_index()
Out[102]:
     value
  a  aa  2
  b  bb  1
  b  aa  4
  a  bb  3
In [103]: df.sort_index().index.is_lexsorted()
Out[103]: True
In [104]: df.sort_index().index.is_monotonic
Out[104]: True
```
1.9.2.11 Groupby Describe Formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous Behavior:

```python
In [1]: df = pd.DataFrame({
    'A': [1, 1, 2, 2],
    'B': [1, 2, 3, 4]
})

In [2]: df.groupby('A').describe()
Out[2]:
         B
   A   count  mean   std  min  25%  50%  75%  max
1     2.0  1.50  0.71  1.0  1.25  1.5  1.75  2.0
2     2.0  3.50  0.71  3.0  3.25  3.5  3.75  4.0
```

New Behavior:

```python
In [105]: df = pd.DataFrame({
    'A': [1, 1, 2, 2],
    'B': [1, 2, 3, 4]
})

In [106]: df.groupby('A').describe()
Out[106]:
       B
   count  mean  std  min  25%  50%  75%  max
A  1  2.0  1.50  0.71  1.0  1.25  1.5  1.75  2.0
  2  2.0  3.50  0.71  3.0  3.25  3.5  3.75  4.0
```

1.9.2.12 Window Binary Corr/Cov operations return a MultiIndex DataFrame

A binary window operation, like `.corr()` or `.cov()`, when operating on a `.rolling()`, `.expanding()`, or `.ewm()` object, will now return a 2-level MultiIndexed DataFrame rather than a `Panel`, as `Panel` is now deprecated, see `here`. These are equivalent in function, but a MultiIndexed DataFrame enjoys more support in pandas. See the section on Windowed Binary Operations for more information. (GH15677)

```
In [108]: np.random.seed(1234)

In [109]: df = pd.DataFrame(np.random.rand(100, 2),
     ...:                  columns=pd.Index(['A', 'B'], name='bar'),
     ...:                  index=pd.date_range('20160101',
     ...:                  periods=100, freq='D', name='foo'))

In [110]: df.tail()
Out[110]:
bar   A    B
foo
2016-04-05  0.640880  0.126205
2016-04-06  0.171465  0.737086
2016-04-07  0.127029  0.369650
2016-04-08  0.604334  0.103104
2016-04-09  0.802374  0.945553
```

Previous Behavior:

```
In [2]: df.rolling(12).corr()
Out[2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 100 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: 2016-01-01 00:00:00 to 2016-04-09 00:00:00
Major_axis axis: A to B
Minor_axis axis: A to B
```

New Behavior:

```
In [111]: res = df.rolling(12).corr()

In [112]: res.tail()
Out[112]:
bar   A    B
foo   bar
2016-04-07  B  -0.132090  1.000000
2016-04-08  A  1.000000  -0.145775
     B  -0.145775  1.000000
2016-04-09  A  1.000000   0.119645
     B   0.119645  1.000000
```

Retrieving a correlation matrix for a cross-section

```
In [113]: df.rolling(12).corr().loc['2016-04-07']
Out[113]:
bar   A    B
foo   bar
2016-04-07  A  1.000000  -0.13209
     B  -0.132090  1.000000
```
1.9.2.13 HDFStore where string comparison

In previous versions most types could be compared to string column in a HDFStore usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a TypeError (GH15492).

```python
In [114]: df = pd.DataFrame({
   ...:     'unparsed_date': ['2014-01-01', '2014-01-01']
   ...: })
In [115]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)
In [116]: df.dtypes
Out[116]:
unparsed_date  object
dtype: object
```

Previous Behavior:
```
In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
   (unparsed_date > 1970-01-01 00:00:00)
^ SyntaxError: invalid token
```

New Behavior:
```
In [18]: ts = pd.Timestamp('2014-01-01')
In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
```

1.9.2.14 Index.intersection and inner join now preserve the order of the left Index

Index.intersection() now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, DataFrame.join() and merge(), and the .align method.

- Index.intersection

```python
In [117]: left = pd.Index([2, 1, 0])
In [118]: left
Out[118]: Int64Index([2, 1, 0], dtype='int64')
In [119]: right = pd.Index([1, 2, 3])
In [120]: right
Out[120]: Int64Index([1, 2, 3], dtype='int64')
```

Previous Behavior:
```
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New Behavior:
```
In [121]: left.intersection(right)
Out[121]: Int64Index([2, 1], dtype='int64')
```
• DataFrame.join and pd.merge

```
In [122]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])
In [123]: left
Out[123]:
   a
2  20
1  10
0  0
```

```
In [124]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])
In [125]: right
Out[125]:
   b
1  100
2  200
3  300
```

Previous Behavior:

```
In [4]: left.join(right, how='inner')
Out[4]:
   a  b
1  10 100
2  20 200
```

New Behavior:

```
In [126]: left.join(right, how='inner')
Out[126]:
   a  b
2  20 200
1  10 100
```

1.9.2.15 Pivot Table always returns a DataFrame

The documentation for `pivot_table()` states that a DataFrame is always returned. Here a bug is fixed that allowed this to return a Series under certain circumstance. (GH4386)

```
In [127]: df = DataFrame({'col1': [3, 4, 5],
.....:       'col2': ['C', 'D', 'E'],
.....:       'col3': [1, 3, 9]})
In [128]: df
Out[128]:
   col1 col2 col3
0    3    C   1
1    4    D   3
2    5    E   9
```

Previous Behavior:
In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
   col3  col2
1   C    3
3   D    4
9   E    5
Name: col1, dtype: int64

New Behavior:

In [129]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[129]:
   col1
   col3  col2
1   C    3
3   D    4
9   E    5

1.9.2.16 Other API Changes

- numexpr version is now required to be >= 2.4.6 and it will not be used at all if this requisite is not fulfilled (GH15213).
- CParserError has been renamed to ParserError in pd.read_csv() and will be removed in the future (GH12665)
- SparseArray.cumsum() and SparseSeries.cumsum() will now always return SparseArray and SparseSeries respectively (GH12855)
- DataFrame.applymap() with an empty DataFrame will return a copy of the empty DataFrame instead of a Series (GH8222)
- Series.map() now respects default values of dictionary subclasses with a __missing__ method, such as collections.Counter (GH15999)
- .loc has compat with .ix for accepting iterators, and NamedTuples (GH15120)
- interpolate() and fillna() will raise a ValueError if the limit keyword argument is not greater than 0. (GH9217)
- pd.read_csv() will now issue a ParserWarning whenever there are conflicting values provided by the dialect parameter and the user (GH14898)
- pd.read_csv() will now raise a ValueError for the C engine if the quote character is larger than than one byte (GH15192)
- inplace arguments now require a boolean value, else a ValueError is thrown (GH14189)
- pandas.api.types.is_datetime64_ns_dtype will now report True on a tz-aware dtype, similar to pandas.api.types.is_datetime64_any_dtype
- DataFrame.asof() will return a null filled Series instead the scalar NaN if a match is not found (GH15118)
- Specific support for copy.copy() and copy.deepcopy() functions on NDFrame objects (GH15444)
- Series.sort_values() accepts a one element list of bool for consistency with the behavior of DataFrame.sort_values() (GH15604)
- .merge() and .join() on category dtype columns will now preserve the category dtype when possible (GH10409)
• SparseDataFrame.default_fill_value will be 0, previously was nan in the return from pd.get_dummies(..., sparse=True) (GH15594)

• The default behaviour of Series.str.match has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the Series.str.extract method (GH5224). As a consequence, the as_indexer keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.

• NaT will now correctly report False for datetimelike boolean operations such as is_month_start (GH15781)

• NaT will now correctly return np.nan for Timedelta and Period accessors such as days and quarter (GH15782)

• NaT will now returns NaT for tz_localize and tz_convert methods (GH15830)

• DataFrame and Panel constructors with invalid input will now raise ValueError rather than PandasError, if called with scalar inputs and not axes (GH15541)

• DataFrame and Panel constructors with invalid input will now raise ValueError rather than pandas.core.common.PandasError, if called with scalar inputs and not axes; The exception PandasError is removed as well. (GH15541)

• The exception pandas.core.common.AmbiguousIndexError is removed as it is not referenced (GH15541)

1.9.3 Reorganization of the library: Privacy Changes

1.9.3.1 Modules Privacy Has Changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the pandas.core, pandas.compat, and pandas.util top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference theses modules. (GH12588)

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: pandas.errors, pandas.plotting and pandas.testing (more details below). Together with pandas.api.types and certain functions in the pandas.io and pandas.tseries submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from pandas.api.types, formerly from pandas.types.concat (GH15998)
- The type import pandas.tslib.NaTType is deprecated and can be replaced by using `type(pandas.NaT)` (GH16146)
- The public functions in pandas.tools.hashing deprecated from that locations, but are now importable from pandas.util (GH16223)
- The modules in pandas.util: decorators, print_versions, doctools, validators, depr_module are now private. Only the functions exposed in pandas.util itself are public (GH16223)

#### 1.9.3.2 pandas.errors

We are adding a standard public module for all pandas exceptions & warnings pandas.errors. (GH14800). Previously these exceptions & warnings could be imported from pandas.core.common or pandas.io.common. These exceptions and warnings will be removed from the *.common locations in a future release. (GH15541)

The following are now part of this API:

```python
['DtypeWarning',
'EmptyDataError',
'OutOfBoundsDatetime',
'ParserError',
'
(continues on next page)
```
1.9.3.3 pandas.testing

We are adding a standard module that exposes the public testing functions in pandas.testing (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- testing.assert_frame_equal()
- testing.assert_series_equal()
- testing.assert_index_equal()

1.9.3.4 pandas.plotting

A new public pandas.plotting module has been added that holds plotting functionality that was previously in either pandas.tools.plotting or in the top-level namespace. See the deprecations sections for more details.

1.9.3.5 Other Development Changes

- Building pandas for development now requires cython >= 0.23 (GH14831)
- Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
- Switched the test framework to use pytest (GH13097)
- Reorganization of tests directory layout (GH14854, GH15707).

1.9.4 Deprecations

1.9.4.1 Deprecate .ix

The .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers. .ix offers a lot of magic on the inference of what the user wants to do. To wit, .ix can decide to index positionally OR via labels, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is here. (GH14218)

The recommended methods of indexing are:

- .loc if you want to label index
- .iloc if you want to positionally index.

Using .ix will now show a DeprecationWarning with a link to some examples of how to convert code here.

```python
In [130]: df = pd.DataFrame({'A': [1, 2, 3],
                   'B': [4, 5, 6]},
                   index=list('abc'))
```

(continues on next page)
Previous Behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

In [3]: df.ix[[0, 2], 'A']
Out[3]:
a 1
Name: A, dtype: int64

Using .loc. Here we will select the appropriate indexes from the index, then use label indexing.

In [132]: df.loc[df.index[[0, 2]], 'A']
Out[132]:
a 1
Name: A, dtype: int64

Using .iloc. Here we will get the location of the ‘A’ column, then use positional indexing to select things.

In [133]: df.iloc[[0, 2], df.columns.get_loc('A')]
Out[133]:
a 1
Name: A, dtype: int64

1.9.4.2 Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the to_frame() or with the xarray package. Pandas provides a to_xarray() method to automate this conversion. For more details see Deprecate Panel documentation. (GH13563).

In [134]: p = tm.makePanel()

In [135]: p
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame

In [136]: p.to_frame()
Out[136]:
                 ItemA  ItemB         ItemC
major minor
2000-01-03 A  0.628776 -1.409432  0.209395
Convert to an xarray DataArray

In [137]: p.to_xarray()
Out[137]:
xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)
array([[ 0.628776, 0.988138, -0.938153, -0.223019],
[ 0.186494, -0.072608, -1.239072, 2.123692],
[ 0.952478, -0.550603, 0.139683, 0.122273]],
[[ -1.409432, -1.347533, 1.272395, -0.591863],
[ 1.422986, 0.363565, -1.449567, -0.414505],

[-1.473116, -0.431550, 0.288377, -0.619993]]]
Coordinates:
* items (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'

1.9.4.3 Deprecate groupby.agg() with a dictionary when renaming

The .groupby(..).agg(..), .rolling(..).agg(..), and .resample(..).agg(..) syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, .agg(..) can also accept a dict that allows `renaming` of the result columns. This is a complicated and confusing syntax, as well as not consistent between Series and DataFrame. We are deprecating this `renaming` functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled Series. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped DataFrame, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled DataFrame in a similar manner.

This is an illustrative example:

In [138]: df = pd.DataFrame({
'B': range(5),
'C': range(5)})
Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is not deprecated).

```python
In [140]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[140]:
            B  C
   A
1  3  0
2  7  3
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```python
In [6]: df.groupby('A').B.agg({'foo': 'count'})
FutureWarning: using a dict on a Series for aggregation is deprecated and will be removed in a future version
Out[6]:
        foo
   A
1  3
2  2
```

You can accomplish the same operation, more idiomatically by:

```python
In [141]: df.groupby('A').B.agg({'count'}).rename(columns={'count': 'foo'})
Out[141]:
       foo
   A
1  3
2  2
```

Here’s an example of the second deprecation, passing a dict-of-dict to a grouped `DataFrame`:

```python
In [23]: (df.groupby('A')
   .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
FutureWarning: using a dict with renaming is deprecated and will be removed in a future version
Out[23]:
      B  C
   foo
   A
1  3  0
2  7  3
```
You can accomplish nearly the same by:

```python
In [142]: (df.groupby('A')
    ....:   .agg({'B': 'sum', 'C': 'min'})
    ....:   .rename(columns={'B': 'foo', 'C': 'bar'})
    ....:   )
Out[142]:
  foo  bar
  A
  1   3  0
  2   7  3
```

### 1.9.4.4 Deprecate `.plotting`

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` (GH12548).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```python
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```python
pd.plotting.scatter_matrix(df)
```

### 1.9.4.5 Other Deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected (GH14647)
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter (GH14647)
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` (GH12662)
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter (GH15524)
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` (GH12662)
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` (GH12662)
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the key parameter in favor of `value` (GH12662)
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` (GH14878)
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` (GH15099)
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports (GH15358)
• Series/DataFrame/Panel.consolidate() been deprecated as a public method. (GH15483)
• The as_indexer keyword of Series.str.match() has been deprecated (ignored keyword) (GH15257).
• The following top-level pandas functions have been deprecated and will be removed in a future version (GH13790, GH15940)
  - pd.pnow(), replaced by Period.now()
  - pd.Term, is removed, as it is not applicable to user code. Instead use in-line string expressions in the where clause when searching in HDFStore
  - pd.Expr, is removed, as it is not applicable to user code.
  - pd.match(), is removed.
  - pd.groupby(), replaced by using the .groupby() method directly on a Series/DataFrame
  - pd.get_store(), replaced by a direct call to pd.HDFStore(...)
• is_any_int_dtype, is_floating_dtype, and is_sequence are deprecated from pandas.api.types (GH16042)

1.9.5 Removal of prior version deprecations/changes

• The pandas.rpy module is removed. Similar functionality can be accessed through the rpy2 project. See the R interfacing docs for more details.
• The pandas.io.ga module with a google-analytics interface is removed (GH11308). Similar functionality can be found in the Google2Pandas package.
• pd.to_datetime and pd.to_timedelta have dropped the coerce parameter in favor of errors (GH13602)
• pandas.stats.fama_macbeth, pandas.stats.ols, pandas.stats.plm and pandas.stats.var, as well as the top-level pandas.fama_macbeth and pandas.ols routines are removed. Similar functionality can be found in the statsmodels package. (GH11898)
• The TimeSeries and SparseTimeSeries classes, aliases of Series and SparseSeries, are removed (GH10890, GH15098).
• Series.is_time_series is dropped in favor of Series.index.is_all_dates (GH15098)
• The deprecated irow, icol, iget and iget_value methods are removed in favor of iloc and iat as explained here (GH10711).
• The deprecated DataFrame.iterkv() has been removed in favor of DataFrame.iteritems() (GH10711)
• The Categorical constructor has dropped the name parameter (GH10632)
• Categorical has dropped support for NaN categories (GH10748)
• The take_last parameter has been dropped from duplicated(), drop_duplicates(), nlargest(), and nsmallest() methods (GH10236, GH10792, GH10920)
• Series, Index, and DataFrame have dropped the sort and order methods (GH10726)
• Where clauses in pytables are only accepted as strings and expressions types and not other data-types (GH12027)
• DataFrame has dropped the combineAdd and combineMult methods in favor of add and mul respectively (GH10735)
1.9.6 Performance Improvements

- Improved performance of `pd.wide_to_long()` (GH14779)
- Improved performance of `pd.factorize()` by releasing the GIL with object dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular DatetimeIndex (or with `compat_x=True`) (GH15073).
- Improved performance of `groupby().cummin()` and `groupby().cummax()` (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a MultiIndex (GH15245)
- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)
- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of merge/join on category columns (GH10409)
- Improved performance of `drop_duplicates()` on bool columns (GH12963)
- Improve performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group DataFrame (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)
- Improved performance in `pd.read_csv()` on some platforms with buffered reads (GH16039)

1.9.7 Bug Fixes

1.9.7.1 Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` (GH15240)
- Bug in `Timestamp.replace` with compat for passing long integers (GH15030)
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided (GH13303, GH15777)
- Bug in `Timestamp` incorrectly localizing timezones during construction (GH11481, GH15777)
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error (GH14816)
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` (GH14946)
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations (GH15126)
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for Series and DataFrames (GH14265)
- Bug in `DataFrame(..).apply(to_numeric)` when values are of type decimal.Decimal. (GH14827)
• Bug in `describe()` when passing a numpy array which does not contain the median to the `percentiles` keyword argument (GH14908)
• Cleaned up `PeriodIndex` constructor, including raising on floats more consistently (GH13277)
• Bug in using `__deepcopy__` on empty NDFrame objects (GH15370)
• Bug in `.replace()` may result in incorrect dtypes. (GH12747, GH15765)
• Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts (GH15289)
• Bug in `Series.replace` which replaced a numeric by string (GH15743)
• Bug in `Index` construction with NaN elements and integer dtype specified (GH15187)
• Bug in `Series` construction with a datetimetz (GH14928)
• Bug in `Series.dt.round()` inconsistent behaviour on NaT's with different arguments (GH14940)
• Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided (GH15125)
• Incorrect dtyped `Series` was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty `DataFrame` (GH15077)
• Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. (GH14956)
• Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when fillna value was of type dict (GH15277)
• Bug in `.asfreq()`, where frequency was not set for empty `Series` (GH14320)
• Bug in `DataFrame` construction with nulls and datetimes in a list-like (GH15869)
• Bug in `DataFrame.fillna()` with tz-aware datetimes (GH15855)
• Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when None was passed in (GH15941)
• Bug in the return type of `pd.unique` on a `Categorical`, which was returning an ndarray and not a `Categorical` (GH15903)
• Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), (GH15949)
• Bug in indexing with partial string indexing with a len-1 `DataFrame` (GH16071)
• Bug in `Series` construction where passing invalid dtype didn’t raise an error. (GH15520)

1.9.7.2 Indexing

• Bug in `Index` power operations with reversed operands (GH14973)
• Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type int64 and contains NaT (GH14922)
• Bug in `DataFrame.reindex()` in which method was ignored when passing columns (GH14992)
• Bug in `DataFrame.loc` with indexing a MultiIndex with a Series indexer (GH14730, GH15424)
• Bug in `DataFrame.loc` with indexing a MultiIndex with a numpy array (GH15434)
• Bug in `Series.asof` which raised if the series contained all np.nan (GH15713)
• Bug in `.at` when selecting from a tz-aware column (GH15822)
• Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected (GH15414)
• Bug in `Series.where()` where TZ-aware data was converted to float representation (GH15701)
• Bug in `.loc` that would not return the correct dtype for scalar access for a DataFrame (GH11617)
• Bug in output formatting of a `MultiIndex` when names are integers (GH12223, GH15262)
• Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used (GH14522)
• Bug in `Series.iloc` where a `Categorical` object for list-like indexes input was returned, where a `Series` was expected. (GH14580)
• Bug in `DataFrame.isin` comparing datetimelike to empty frame (GH15473)
• Bug in `.reset_index()` when an all NaN level of a `MultiIndex` would fail (GH6322)
• Bug in `.reset_index()` when raising error for index name already present in `MultiIndex` columns (GH16120)
• Bug in creating a `MultiIndex` with tuples and not passing a list of names; this will now raise `ValueError` (GH15110)
• Bug in the HTML display with with a `MultiIndex` and truncation (GH14882)
• Bug in the display of `.info()` where a qualifier (+) would always be displayed with a `MultiIndex` that contains only non-strings (GH15245)
• Bug in `pd.concat()` where the names of `MultiIndex` of resulting `DataFrame` are not handled correctly when `None` is presented in the names of `MultiIndex` of input `DataFrame` (GH15787)
• Bug in `DataFrame.sort_index()` and `Series.sort_index()` where `na_position` doesn’t work with a `MultiIndex` (GH14784, GH16604)
• Bug in in `pd.concat()` when combining objects with a `CategoricalIndex` (GH16111)
• Bug in indexing with a scalar and a `CategoricalIndex` (GH16123)

1.9.7.3 I/O

• Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted (GH14941, GH15005)
• Bug in `pd.read_fwf()` where the skiprows parameter was not being respected during column width inference (GH11256)
• Bug in `pd.read_csv()` in which the dialect parameter was not being verified before processing (GH14898)
• Bug in `pd.read_csv()` in which missing data was being improperly handled with usecols (GH6710)
• Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash (GH14125)
• Bug in `pd.read_csv()` for the C engine where usecols were being indexed incorrectly with parse_dates (GH14792)
• Bug in `pd.read_csv()` with parse_dates when multiline headers are specified (GH15376)
• Bug in `pd.read_csv()` with float_precision='round_trip' which caused a segfault when a text entry is parsed (GH15140)
• Bug in `pd.read_csv()` when an index was specified and no values were specified as null values (GH15835)
• Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash (GH15337)
• Bug in `pd.read_csv()` in which invalid values for `nrows` and `chunksize` were allowed (GH15767)
• Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred (GH15910)
• Bug in `pd.read_csv()` in which the `skipfooter` parameter was not being properly validated (GH15925)
• Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written (GH15982)
• Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. (GH15143)
• Bug in `.to_json()` where `lines=True` and contents (keys or values) contain escaped characters (GH15096)
• Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode (GH15344)
• Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where frac is odd and diff is exactly 0.5 (GH15716, GH15864)
• Bug in `pd.read_json()` for Python 2 where `lines=True` and contents contain non-ascii unicode characters (GH15132)
• Bug in `pd.read_msgpack()` in which `Series` categoricals were being improperly processed (GH14901)
• Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` (GH15487)
• Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` (GH15487)
• Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone (GH13937)
• Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
• Bug in `.to_sql()` when writing a `DataFrame` with numeric index names (GH15404).
• Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` (GH14998)
• Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column (GH15492)
• Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales (GH13856)
• Bug in `StataReader` and `StataWriter` which allows invalid encodings (GH15723)
• Bug in the `Series` `repr` not showing the length when the output was truncated (GH15962).

1.9.7.4 Plotting

• Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) (GH9351)
• Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes (GH15108)
• Bug in the date and time converters pandas registers with `matplotlib` not handling multiple dimensions (GH16026)
• Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both (GH14855)
1.9.7.5 Groupby/Resample/Rolling

- Bug in `.groupby(..).resample()` when passed the on= kwarg. (GH15021)
- Properly set `__name__` and `__qualname__` for Groupby.* functions (GH14620)
- Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
- Bug in `.groupby(...).rolling(...)` when on is specified and using a `DatetimeIndex` (GH15130, GH13966)
- Bug in `Groupby` operations with `timedelta64` when passing numeric_only=False (GH5724)
- Bug in `groupby.apply()` coercing object dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
- Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)
- Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
- Bug in `groupby()`.nunique() with a datetimelike-grouper where bins counts were incorrect (GH13453)
- Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
- Bug in `groupby.agg()` incorrectly localizing timezone on `datetime` (GH15426, GH10668, GH13046)
- Bug in `.rolling/expanded()` functions where count() was not counting np.Inf, nor handling object dtypes (GH12541)
- Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument (GH15440)
- Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range [0, 1] (GH15463)
- Bug in `DataFrame.resample().median()` if duplicate column names are present (GH14233)

1.9.7.6 Sparse

- Bug in `SparseSeries.reindex` on single level with list of length 1 (GH15447)
- Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series (GH15488)
- Bug in `SparseDataFrame` construction with lists not coercing to dtype (GH15682)
- Bug in sparse array indexing in which indices were not being validated (GH15863)

1.9.7.7 Reshaping

- Bug in `pd.merge_asof()` where left_index or right_index caused a failure when multiple by was specified (GH15676)
- Bug in `pd.merge_asof()` where left_index/right_index together caused a failure when tolerance was specified (GH15135)
- Bug in `DataFrame.pivot_table()` where dropna=True would not drop all-NaN columns when the columns was a category dtype (GH15193)
- Bug in `pd.melt()` where passing a tuple value for value_vars caused a TypeError (GH15348)
pandas: powerful Python data analysis toolkit, Release 0.23.2

- Bug in pd.pivot_table() where no error was raised when values argument was not in the columns (GH14938)
- Bug in pd.concat() in which concatenating with an empty dataframe with join='inner' was being improperly handled (GH15328)
- Bug with sort=True in DataFrame.join and pd.merge when joining on indexes (GH15582)
- Bug in DataFrame.nsmallest and DataFrame.nlargest where identical values resulted in duplicated rows (GH15297)
- Bug in pandas.pivot_table() incorrectly raising UnicodeError when passing unicode input for margins keyword (GH13292)

1.9.7.8 Numeric

- Bug in .rank() which incorrectly ranks ordered categories (GH15420)
- Bug in .corr() and .cov() where the column and index were the same object (GH14617)
- Bug in .mode() where mode was not returned if was only a single value (GH15714)
- Bug in pd.cut() with a single bin on an all 0s array (GH15428)
- Bug in pd.qcut() with a single quantile and an array with identical values (GH15431)
- Bug in pandas.tools.utils.cartesian_product() with large input can cause overflow on windows (GH15265)
- Bug in .eval() which caused multiline evals to fail with local variables not on the first line (GH15342)

1.9.7.9 Other

- Compat with SciPy 0.19.0 for testing on .interpolate() (GH15662)
- Compat for 32-bit platforms for .qcut/cut; bins will now be int64 dtype (GH14866)
- Bug in interactions with Qt when a QtApplication already exists (GH14372)
- Avoid use of np.finfo() during import pandas removed to mitigate deadlock on Python GIL misuse (GH14641)

1.10 v0.19.2 (December 24, 2016)

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Compatibility with Python 3.6
- Added a Pandas Cheat Sheet. (GH13202)

What’s new in v0.19.2

- Enhancements
- Performance Improvements
• **Bug Fixes**

### 1.10.1 Enhancements

The `pd.merge_asof()`, added in 0.19.0, gained some improvements:

- `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments (GH14253)
- `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance (GH13936)

### 1.10.2 Performance Improvements

- Performance regression with `PeriodIndex` (GH14822)
- Performance regression in indexing with `getitem` (GH14930)
- Improved performance of `.replace()` (GH12745)
- Improved performance Series creation with a datetime index and dictionary data (GH14894)

### 1.10.3 Bug Fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for Timestamp pickles (GH14689)
- Compat with `dateutil==2.6.0`; segfault reported in the testing suite (GH14621)
- Allow `nanoseconds` in `Timestamp.replace` as a kwarg (GH14621)
- Bug in `pd.read_csv` in which aliasing was being done for `na_values` when passed in as a dictionary (GH14203)
- Bug in `pd.read_csv` in which column indices for a dict-like `na_values` were not being respected (GH14203)
- Bug in `pd.read_csv` where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in `pd.read_sas` and `pandas.io.sas.SAS7BDATReader` that caused problems when reading a SAS file incrementally.
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when `skipfooter` was not being respected by Python’s CSV library (GH13879)
- Bug in `.fillna()` in which timezone aware datetime64 values were incorrectly rounded (GH14872)
- Bug in `.groupby(..., sort=True)` of a non-lexsorted MultiIndex when grouping with multiple levels (GH14776)
- Bug in `pd.cut` with negative values and a single bin (GH14652)
• Bug in `pd.to_numeric` where a 0 was not unsigned on a `downcast='unsigned'` argument (GH14401)
• Bug in plotting regular and irregular timeseries using shared axes (sharex=True or ax.twinx()) (GH13341, GH14322).
• Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
• Bug in resampling a `DateTimeIndex` in local TZ, covering a DST change, which would raise `AmbiguousTimeError` (GH14682)
• Bug in `hdfstore` when writing a `MultiIndex` when using `data_columns=True` (GH14435)
• Bug in `hdfstore.append()` when writing a series and passing a `min_itemsize` argument containing a value for the index (GH11412)
• Bug in writing to a `hdfstore` in table format with a `min_itemsize` value for the index and without asking to append (GH10381)
• Bug in `Series.groupby.nunique()` raising an `IndexError` for an empty `Series` (GH12553)
• Bug in `DataFrame.nlargest` and `DataFrame.nsmallest` when the index had duplicate values (GH13412)
• Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
• Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
• Bug in `.to_clipboard()` and Excel compat (GH12529)
• Bug in `DataFrame.combine_first()` for integer columns (GH14687).
• Bug in `pd.read_csv()` in which the `dtype` parameter was not being respected for empty data (GH14712)
• Bug in `pd.read_csv()` in which the `nrows` parameter was not being respected for large input when using the C engine for parsing (GH7626)
• Bug in `pd.merge_asof()` could not handle timezone-aware `DateTimeIndex` when a tolerance was specified (GH14844)
• Explicit check in `to_stata` and `StataWriter` for out-of-range values when writing doubles (GH14618)
• Bug in `.plot(kind='kde')` which did not drop missing values to generate the KDE Plot, instead generating an empty plot. (GH14821)
• Bug in `unstack()` if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to object (GH11847)

11 1.11 v0.19.1 (November 3, 2016)

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What’s new in v0.19.1

• *Performance Improvements*
• *Bug Fixes*
1.11.1 Performance Improvements

- Fixed performance regression in factorization of `Period` data (GH14338)
- Fixed performance regression in `Series.asof(wheret)` when `where` is a scalar (GH14461)
- Improved performance in `DataFrame.asof(where)` when `where` is a scalar (GH14461)
- Improved performance in `.to_json()` when `lines=True` (GH14408)
- Improved performance in certain types of `loc` indexing with a MultiIndex (GH14551).

1.11.2 Bug Fixes

- Source installs from PyPI will now again work without cython installed, as in previous versions (GH14204)
- Compat with Cython 0.25 for building (GH14496)
- Fixed regression where user-provided file handles were closed in `read_csv(c engine)` (GH14418).
- Fixed regression in `DataFrame.quantile` when missing values were present in some columns (GH14357).
- Fixed regression in `Index.difference` where the `freq` of a `DatetimeIndex` was incorrectly set (GH14323)
- Added back `pandas.core.common.array_equivalent` with a deprecation warning (GH14555).
- Bug in `pd.read_csv` for the C engine in which quotation marks were improperly parsed in skipped rows (GH14459)
- Bug in `pd.read_csv` for Python 2.x in which Unicode quote characters were no longer being respected (GH14477)
- Fixed regression in `Index.append` when categorical indices were appended (GH14545).
- Fixed regression in `pd.DataFrame` where constructor fails when given dict with None value (GH14381)
- Fixed regression in `DatetimeIndex._maybe_cast_slice_bound` when index is empty (GH14354).
- Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
- Bug in `TimedeltaIndex` addition with a Datetime-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
- Bug in string indexing against data with object Index may raise `AttributeError` (GH14424)
- Correctly raise `ValueError` on empty input to `pd.eval()` and `df.query()` (GH13139)
- Bug in `RangeIndex.intersection` when result is a empty set (GH14364).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
- Bug in `Series.__getitem__` which allowed mutating read-only arrays (GH14359).
- Bug in `DataFrame.insert` where multiple calls with duplicate columns can fail (GH14291)
- `pd.merge()` will raise `ValueError` with non-boolean parameters in passed boolean type arguments (GH14434)
- Bug in `Timestamp` where dates very near the minimum (1677-09) could underflow on creation (GH14415)
- Bug in `pd.concat` where names of the keys were not propagated to the resulting MultiIndex (GH14252)
- Bug in `pd.concat` where axis cannot take string parameters 'rows' or 'columns' (GH14369)
• Bug in `pd.concat` with dataframes heterogeneous in length and tuple keys (GH14438)
• Bug in `MultiIndex.set_levels` where illegal level values were still set after raising an error (GH13754)
• Bug in `DataFrame.to_json` where `lines=True` and a value contained a `)` character (GH14391)
• Bug in `df.groupby` causing an `AttributeError` when grouping a single index frame by a column and the index level (GH14327)
• Bug in `df.groupby` where `TypeError` raised when `pd.Grouper(key=...)` is passed in a list (GH14334)
• Bug in `pd.pivot_table` may raise `TypeError` or `ValueError` when `index` or `columns` is not scalar and `values` is not specified (GH14380)

1.12 v0.19.0 (October 2, 2016)

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:
• `merge_asof()` for asof-style time-series joining, see here
• `.rolling()` is now time-series aware, see here
• `read_csv()` now supports parsing `Categorical` data, see here
• A function `union_categorical()` has been added for combining categoricals, see here
• `PeriodIndex` now has its own `period` dtype, and changed to be more consistent with other `Index` classes. See here
• Sparse data structures gained enhanced support of `int` and `bool` dtypes, see here
• Comparison operations with `Series` no longer ignores the index, see here for an overview of the API changes.
• Introduction of a pandas development API for utility functions, see here.
• Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the `xarray` package.
• Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

Warning: pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see here.

What’s new in v0.19.0

• New features
  – `merge_asof` for asof-style time-series joining
  – `.rolling()` is now time-series aware
  – `read_csv` has improved support for duplicate column names
  – `read_csv` supports parsing `Categorical` directly
Categorical Concatenation

- Semi-Month Offsets
- New Index methods
- Google BigQuery Enhancements
- Fine-grained numpy errstate
- `get_dummies` now returns integer dtypes
- Downcast values to smallest possible dtype in `to_numeric`
- `pandas` development API
- Other enhancements

**API changes**

- `Series.tolist()` will now return Python types
- `Series` operators for different indexes
  * Arithmetic operators
  * Comparison operators
  * Logical operators
  * Flexible comparison methods
- `Series` type promotion on assignment
- `.to_datetime()` changes
- Merging changes
- `.describe()` changes
- `Period` changes
  * `PeriodIndex` now has period dtype
  * `Period('NaT')` now returns `pd.NaT`
  * `PeriodIndex.values` now returns array of `Period` object
- `Index` +/ - no longer used for set operations
- `Index.difference` and `.symmetric_difference` changes
- `Index.unique` consistently returns `Index`
- `MultiIndex` constructors, groupby and `set_index` preserve categorical dtypes
- `read_csv` will progressively enumerate chunks

**Sparse Changes**

- `int64` and `bool` support enhancements
- Operators now preserve dtypes
- Other sparse fixes
- `Indexer` dtype changes
- Other API Changes
1.12.1 New features

1.12.1.1 merge_asof for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series (GH1870, GH13695, GH13709, GH13902). Full documentation is here.

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```python
In [1]: left = pd.DataFrame({'a': [1, 5, 10],
                     'left_val': ['a', 'b', 'c']})
In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
                       'right_val': [1, 2, 3, 6, 7]})
In [3]: left
Out[3]:
   a    left_val
0  1      a
1  5      b
2 10     c

In [4]: right
Out[4]:
   a    right_val
0  1       1
1  2       2
2  3       3
3  6       6
4  7       7
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```python
In [5]: pd.merge_asof(left, right, on='a')
Out[5]:
   a    left_val    right_val
0  1      a         1
1  5      b         3
2 10     c         7
```

We can also match rows ONLY with prior data, and not an exact match.

```python
In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
Out[6]:
   a    left_val    right_val
```

(continues on next page)
In a typical time-series example, we have trades and quotes and we want to asof-join them. This also illustrates using the by parameter to group data before merging.

```python
In [7]: trades = pd.DataFrame({
   ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
   ...:                               '20160525 13:30:00.038',
   ...:                               '20160525 13:30:00.048',
   ...:                               '20160525 13:30:00.048',
   ...:                               '20160525 13:30:00.048'],
   ...:     'ticker': ['MSFT', 'MSFT', 'GOOG', 'GOOG', 'AAPL'],
   ...:     'price': [51.95, 51.95, 720.77, 720.92, 98.00],
   ...:     'quantity': [75, 155, 100, 100, 100],
   ...:     columns=['time', 'ticker', 'price', 'quantity'])
   ...

In [8]: quotes = pd.DataFrame({
   ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
   ...:                               '20160525 13:30:00.023',
   ...:                               '20160525 13:30:00.030',
   ...:                               '20160525 13:30:00.041',
   ...:                               '20160525 13:30:00.049',
   ...:                               '20160525 13:30:00.049',
   ...:                               '20160525 13:30:00.072',
   ...:                               '20160525 13:30:00.075'],
   ...:     'ticker': ['GOOG', 'MSFT', 'MSFT', 'MSFT', 'GOOG', 'AAPL', 'GOOG',
   ...:                'MSFT'],
   ...:     'bid': [720.50, 51.95, 51.97, 51.99, 720.50, 97.99, 720.50, 52.01],
   ...:     'ask': [720.93, 51.96, 51.98, 52.00, 720.93, 98.01, 720.88, 52.03],
   ...:     columns=['time', 'ticker', 'bid', 'ask'])
   ...
```

```
In [9]: trades
Out[9]:
          time  ticker  price  quantity
0 2016-05-25 13:30:00.023  MSFT   51.95       75
1 2016-05-25 13:30:00.038  MSFT   51.95      155
2 2016-05-25 13:30:00.048  GOOG  720.77      100
3 2016-05-25 13:30:00.048  GOOG  720.92      100
4 2016-05-25 13:30:00.048   AAPL   98.00      100

In [10]: quotes
   \---------------------------------------------------------------------------
         time  ticker  bid  ask
0 2016-05-25 13:30:00.023  GOOG  720.50  720.93
1 2016-05-25 13:30:00.023  MSFT   51.95   51.96
```

(continues on next page)
An asof merge joins on the `on`, typically a datetimelike field, which is ordered, and in this case we are using a grouper in the `by` field. This is like a left-outer join, except that forward filling happens automatically taking the most recent non-NaN value.

```python
In [11]: pd.merge_asof(trades, quotes,
                           ....:
                           on='time',
                           ....:
                           by='ticker')
                           ....:
Out[11]:
```

```plaintext
time ticker price quantity bid ask
0 2016-05-25 13:30:00.023 MSFT 51.95 75 51.95 51.96
1 2016-05-25 13:30:00.038 MSFT 51.95 155 51.97 51.98
2 2016-05-25 13:30:00.048 GOOG 720.77 100 720.50 720.93
3 2016-05-25 13:30:00.048 GOOG 720.92 100 720.50 720.93
4 2016-05-25 13:30:00.048 AAPL 98.00 100 NaN NaN
```

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (`trades` in this case), with the fields of the `quotes` merged.

### 1.12.1.2 `rolling()` is now time-series aware

`rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the `window` argument (GH13327, GH12995). See the full documentation [here](#).

```python
In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                           index=pd.date_range('20130101 09:00:00', periods=5, freq='s'))
                           ....:
In [13]: dft
Out[13]:
```

```plaintext
B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 2.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 4.0
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```python
In [14]: dft.rolling(2).sum()
Out[14]:
```

```plaintext
B
2013-01-01 09:00:00 NaN
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN
```
Specifying an offset allows a more intuitive specification of the rolling frequency.

```python
In [16]: dft.rolling('2s').sum()
Out[16]:
    B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```python
In [17]: dft = DataFrame({'B': [0, 1, 2, np.nan, 4]},
                   index = pd.Index([pd.Timestamp('20130101 09:00:00'),
                                      pd.Timestamp('20130101 09:00:01'),
                                      pd.Timestamp('20130101 09:00:02'),
                                      pd.Timestamp('20130101 09:00:03'),
                                      pd.Timestamp('20130101 09:00:05')],
                                      name='foo'))

In [18]: dft
Out[18]:
    B
foo 2013-01-01 09:00:00 0.0
     2013-01-01 09:00:02 1.0
     2013-01-01 09:00:03 2.0
     2013-01-01 09:00:05 NaN
     2013-01-01 09:00:06 4.0

In [19]: dft.rolling(2).sum()
```

Using the time-specification generates variable windows for this sparse data.
Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```
In [21]: dft = dft.reset_index()

In [22]: dft
Out[22]:
   foo  B
0  2013-01-01 09:00:00  0.0
1  2013-01-01 09:00:02  1.0
2  2013-01-01 09:00:03  2.0
3  2013-01-01 09:00:05  NaN
4  2013-01-01 09:00:06  4.0
```

```
In [23]: dft.rolling('2s', on='foo').sum()
```

```
0  2013-01-01 09:00:00  0.0
1  2013-01-01 09:00:02  1.0
2  2013-01-01 09:00:03  3.0
3  2013-01-01 09:00:05  NaN
4  2013-01-01 09:00:06  4.0
```

### 1.12.1.3 `read_csv` has improved support for duplicate column names

Duplicate column names are now supported in `read_csv()` whether they are in the file or passed in as the `names` parameter (GH7160, GH9424)

```
In [24]: data = '0,1,2
       :3,4,5'

In [25]: names = ['a', 'b', 'a']
```

Previous behavior:

```
In [2]: pd.read_csv(StringIO(data), names=names)
Out[2]:
   a  b  a
0  2  1  2
1  5  4  5
```

The first `a` column contained the same data as the second `a` column, when it should have contained the values `[0, 3]`.

New behavior:
1.12.1.4 `read_csv` supports parsing Categorical directly

The `read_csv()` function now supports parsing a Categorical column when specified as a dtype (GH10153). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to Categorical after parsing. See the io docs here.

```
In [27]: data = 'col1,col2,col3
    : a,b,1
    : a,b,2
    : c,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
    col1  col2  col3
0    a     b     1
1    a     b     2
2    c     d     3

In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
    col1  col2  col3
    object object  int64

dtype: object

In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[30]:
    col1  col2  col3
    category category category

dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification

```
In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[31]:
    col1  col2  col3
    category object  int64

dtype: object
```

Note: The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```
In [32]: df = pd.read_csv(StringIO(data), dtype='category')

In [33]: df.dtypes
Out[33]:
    col1  col2  col3
    category object  int64
```

(continues on next page)
In [34]: df['col3']
Out[34]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [36]: df['col3']
Out[36]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]

1.12.1.5 Categorical Concatenation

- A function `union_categoricals()` has been added for combining categoricals, see [Unioning Categoricals](GH13361, GH13763, GH13846, GH14173)

```python
In [37]: from pandas.api.types import union_categoricals

In [38]: a = pd.Categorical(['b', 'c'])

In [39]: b = pd.Categorical(['a', 'b'])

In [40]: union_categoricals([a, b])
Out[40]:
[b, c, a]
Categories (3, object): [b, c, a]
```

- `concat` and `append` now can concat category dtypes with different categories as `object` dtype (GH13524)

```python
In [41]: s1 = pd.Series(['a', 'b'], dtype='category')

In [42]: s2 = pd.Series(['b', 'c'], dtype='category')

Previous behavior:

```
In [1]: pd.concat([s1, s2])
ValueError: incompatible categories in categorical concat
```

New behavior:

```python
In [43]: pd.concat([s1, s2])
Out[43]:
```
1.12.1.6 Semi-Month Offsets

Pandas has gained new frequency offsets, SemiMonthEnd (‘SM’) and SemiMonthBegin (‘SMS’). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

```python
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin

SemiMonthEnd:

In [45]: Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')

In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)
```

SemiMonthBegin:

```python
In [47]: Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')

In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```python
In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'],
                       dtype='datetime64[ns]', freq='SMS-16')

In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
```

1.12.1.7 New Index methods

The following methods and options are added to Index, to be more consistent with the Series and DataFrame API.

Index now supports the .where() function for same shape indexing (GH13170)

```python
In [51]: idx = pd.Index(['a', 'b', 'c'])

In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')
```
Index now supports `.dropna()` to exclude missing values (GH6194)

```python
In [53]: idx = pd.Index([1, 2, np.nan, 4])
In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For `MultiIndex`, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.

```python
In [55]: midx = pd.MultiIndex.from_arrays([ [1, 2, np.nan, 4],
                                          [1, 2, np.nan, np.nan]])
In [56]: midx
Out[56]: MultiIndex(levels=[1, 2, 4], labels=[[0, 1, -1, 2], [0, 1, -1, -1]])
In [57]: midx.dropna()
Out[57]: MultiIndex(levels=[1, 2, 4], labels=[[0, 1, 2], [0, 1, -1]])
In [58]: midx.dropna(how='all')
Out[58]: MultiIndex(levels=[1, 2, 4], labels=[[0, 1, 2], [0, 1, -1]])
```

Index now supports `.str.extractall()` which returns a DataFrame, see the docs here (GH10008, GH13156)

```python
In [59]: idx = pd.Index(["a1a2", "b1", "c1"])
In [60]: idx.str.extractall("[ab](?P<digit>[0-9])")
Out[60]:
digit  match
0   0   1
1   2   2
1   0   1
```

`Index.astype()` now accepts an optional boolean argument `copy`, which allows optional copying if the requirements on dtype are satisfied (GH13209)

### 1.12.1.8 Google BigQuery Enhancements

- The `read_gbq()` method has gained the `dialect` argument to allow users to specify whether to use BigQuery’s legacy SQL or BigQuery’s standard SQL. See the docs for more details (GH13615).
- The `to_gbq()` method now allows the DataFrame column order to differ from the destination table schema (GH11359).
1.12.1.9 Fine-grained numpy errstate

Previous versions of pandas would permanently silence numpy’s ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaNs. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the numpy.errstate context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas codebase. (GH13109, GH13145)

After upgrading pandas, you may see new RuntimeWarnings being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use numpy.errstate around the source of the RuntimeWarning to control how these conditions are handled.

1.12.1.10 get_dummies now returns integer dtypes

The pd.get_dummies function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

**Previous behavior:**

```
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[1]:
a float64
b float64
c float64
dtype: object
```

**New behavior:**

```
In [61]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[61]:
a uint8
b uint8
c uint8
dtype: object
```

1.12.1.11 Downcast values to smallest possible dtype in to_numeric

pd.to_numeric() now accepts a downcast parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```
In [62]: s = ['1', 2, 3]

In [63]: pd.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)

In [64]: pd.to_numeric(s, downcast='integer')
```

```
Out[64]: array([1, 2, 3], dtype=int8)
```
1.12.1.12 pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, pandas.api to hold public API's. We are starting by exposing type introspection functions in pandas.api.types. More sub-packages and officially sanctioned API's will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```python
In [65]: import pprint
In [66]: from pandas.api import types
In [67]: funcs = [ f for f in dir(types) if not f.startswith('_') ]
In [68]: pprint.pprint(funcs)
['CategoricalDtype',
 'DatetimeTZDtype',
 'IntervalDtype',
 'PeriodDtype',
 'infer_dtypes',
 'is_any_int_dtypes',
 'is_array_like',
 'is_bool',
 'is_bool_dtype',
 'is_categorical',
 'is_categorical_dtype',
 'is_complex',
 'is_complex_dtype',
 'is_datetime64_any_dtype',
 'is_datetime64_dtypes',
 'is_datetime64_ns_dtype',
 'is_datetime64tz_dtype',
 'is_datetimetz',
 'is_dict_like',
 'is_dtype_equal',
 'is_extension_type',
 'is_float',
 'is_dtype',
 'is_floating_dtype',
 'is_file_like',
 'is_hashable',
 'is_int64_dtype',
 'is_integer',
 'is_integer_dtype',
 'is_interval',
 'is_interval_dtype',
 'is_iterator',
 'is_list_like',
 'is_named_tuple',
 'is_number',
 'is_numeric_dtype',
 'is_object_dtype',
 'is_period',
 'is_period_dtype',
 'is_re',
 'is_re_compilable',
 'is_scalar',
```
1.12.1.13 Other enhancements

- **Timestamp** can now accept positional and keyword parameters similar to `datetime.datetime()` (GH10758, GH11630)

```python
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')

In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
    \n\nOut[70]: Timestamp('2012-01-01 08:30:00')
```

- The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or `MultiIndex` level (GH13500)

```python
In [71]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
                    ....:       'a': np.arange(5),
                    ....:       index=pd.MultiIndex.from_arrays([
                    ....:           [1,2,3,4,5],
                    ....:           pd.date_range('2015-01-01', freq='W', periods=5)],
                    ....:       names=['v','d']})

In [72]: df
Out[72]:
    date  a
    v  d
    1 2015-01-04 2015-01-04 0
    2 2015-01-11 2015-01-11 1
    3 2015-01-18 2015-01-18 2
    4 2015-01-25 2015-01-25 3
    5 2015-02-01 2015-02-01 4

In [73]: df.resample('M', on='date').sum()
```

---

Note: Calling these functions from the internal module `pandas.core.common` will now show a `DeprecationWarning` (GH13990)
In [74]: df.resample('M', level='d').sum()

2015-01-31  6
2015-02-28  4

• The `get_credentials()` method of `GbqConnector` can now first try to fetch the application default credentials. See the docs for more details (GH13577).

• The `tz_localize()` method of `DatetimeIndex` and `Timestamp` has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to `NaT`. The default behavior remains to raising a `NonExistentTimeError` (GH13057).

• `.to_hdf/read_hdf()` now accept path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path (GH11773).

• The `pd.read_csv()` with `engine='python'` has gained support for the `decimal` (GH12933), `na_filter` (GH13321) and the `memory_map` option (GH13381).

• Consistent with the Python API, `pd.read_csv()` will now interpret `+inf` as positive infinity (GH13274).

• The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options (GH13461).

• `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when `dtype` is categorical (GH13209).

• `DataFrame` has gained the `asof()` method to return the last non-NaN values according to the selected subset (GH13358).

• The `DataFrame` constructor will now respect key ordering if a list of `OrderedDict` objects are passed in (GH13304).

• `pd.read_html()` has gained support for the `decimal` option (GH12907).

• `Series` has gained the properties `.is_monotonic`, `.is_monotonic_increasing`, `.is_monotonic_decreasing`, similar to `Index` (GH13336).

• `DataFrame.to_sql()` now allows a single value as the SQL type for all columns (GH11886).

• `Series.append` now supports the `ignore_index` option (GH13677).

• `.to_stata()` and `StataWriter` can now write variable labels to Stata dta files using a dictionary to make column names to labels (GH13535, GH13536).

• `.to_stata()` and `StataWriter` will automatically convert `datetime64[ns]` columns to Stata format `%tc`, rather than raising a `ValueError` (GH12259).

• `read_stata()` and `StataReader` raise with a more explicit error message when reading Stata files with repeated value labels when `convert_categoricals=True` (GH13923).

• `DataFrame.style` will now render sparsified MultiIndexes (GH11655).

• `DataFrame.style` will now show column level names (e.g. `DataFrame.columns.names`) (GH13775).

• `DataFrame` has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` (GH10806).
In 

```python
df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
                 index=['row1', 'row2'])
```

```python
In [76]: df
Out[76]:
   A  B  C
row1 2  3  4
row2 7  5  8
```

```python
In [77]: df.sort_values(by='row2', axis=1)
Out[77]:
   B  A  C
row1 3  2  4
row2 5  7  8
```

• Added documentation to I/O regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)
• `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the html.border option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter’s CSS includes a border-width attribute, the visual effect is the same. (GH11563).
• Raise `ImportError` in the sql functions when `sqlalchemy` is not installed and a connection string is used (GH1920).
• Compatibility with matplotlib 2.0. Older versions of pandas should also work with matplotlib 2.0 (GH13333)
• Timestamp, Period, DatetimeIndex, PeriodIndex and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. (GH13727)
• `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. (GH12086)
• The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see `Line delimited json` (GH9180)
• `read_excel()` now supports the true_values and false_values keyword arguments (GH13347)
• `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-MultiIndex grouper. (GH13907)
• Non-convertible dates in an excel date column will be returned without conversion and the column will be object dtype, rather than raising an exception (GH10001).
• `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)
• `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)
• Series and Index now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).

### 1.12.2 API changes

#### 1.12.2.1 Series.tolist() will now return Python types

`Series.tolist()` will now return Python types in the output, mimicking NumPy `.tolist()` behavior (GH10904)
1.12.2.2 Series operators for different indexes

Following Series operators have been changed to make all operators consistent, including DataFrame (GH1134, GH4581, GH13538)

- Series comparison operators now raise ValueError when index are different.
- Series logical operators align both index of left and right hand side.

**Warning:** Until 0.18.1, comparing Series with the same length, would succeed even if the .index are different (the result ignores .index). As of 0.19.0, this will raises ValueError to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like .eq.

As a result, Series and DataFrame operators behave as below:

### Arithmetic operators

Arithmetic operators align both index (no changes).

```python
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))
In [82]: s1 + s2
Out[82]:
   A  3.0
   B  4.0
   C   NaN
   D   NaN
dtype: float64
```

```python
In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))
In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))
In [85]: df1 + df2
Out[85]:
   0  0
   A  3.0
```
Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

**Previous Behavior (Series):**

Series compared values ignoring the `.index` as long as both had the same length:

```
In [1]: s1 == s2
Out[1]:
A   False
B    True
C   False
dtype: bool
```

**New behavior (Series):**

```
In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects
```

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```
In [86]: s1.values == s2.values
Out[86]: array([False, True, False], dtype=bool)
```

If you want to compare `Series` aligning its `.index`, see flexible comparison methods section below:

```
In [87]: s1.eq(s2)
Out[87]:
A   False
B    True
C   False
D   False
dtype: bool
```

**Current Behavior (DataFrame, no change):**

```
In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects
```

Logical operators

Logical operators align both `.index` of left and right hand side.

**Previous behavior (Series), only left hand side index was kept:**
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A   True
B   False
C   False
dtype: bool

New behavior (Series):

In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [90]: s1 & s2
Out[90]:
A   True
B   False
C   False
dtype: bool

Note: Series logical operators fill a NaN result with False.

Note: To achieve the same result as previous versions (compare values based on only left hand side index), you can use reindex_like:

In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A   True
B   False
C   False
dtype: bool

Current Behavior (DataFrame, no change):

In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
In [94]: df1 & df2
Out[94]:
   0
A   True
B   False
C  NaN
D  NaN
Flexible comparison methods

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both `index`. Use these operators if you want to compare two Series which has the different `index`.

```
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])
In [97]: s1.eq(s2)
Out[97]:
a   False
b   True
c   False
d   False
dtype: bool

In [98]: s1.ge(s2)
Out[98]:
a   False
b   True
c   True
d   False
dtype: bool
```

Previously, this worked the same as comparison operators (see above).

1.12.2.3 Series type promotion on assignment

A Series will now correctly promote its dtype for assignment with incompat values to the current dtype (GH13234)

```
In [99]: s = pd.Series()

Previous behavior:

In [2]: s['a'] = pd.Timestamp("2016-01-01")
In [3]: s['b'] = 3.0
TypeError: invalid type promotion

New behavior:

In [100]: s['a'] = pd.Timestamp("2016-01-01")
In [101]: s['b'] = 3.0
In [102]: s
Out[102]:
a  2016-01-01 00:00:00
b    3
dtype: object
```

1.12. v0.19.0 (October 2, 2016)
1.12.2.4 .to_datetime() changes

Previously if .to_datetime() encountered mixed integers/floats and strings, but no datetimes with errors='coerce' it would convert all to NaT.

**Previous behavior:**

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

**Current behavior:**

This will now convert integers/floats with the default unit of ns.

```
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype='datetime64[ns]', freq=None)
```

Bug fixes related to .to_datetime():

- Bug in pd.to_datetime() when passing integers or floats, and no unit and errors='coerce' (GH13180).
- Bug in pd.to_datetime() when passing invalid datatypes (e.g. bool); will now respect the errors keyword (GH13176)
- Bug in pd.to_datetime() which overflowed on int8, and int16 dtypes (GH13451)
- Bug in pd.to_datetime() raise AttributeError with NaN and the other string is not valid when errors='ignore' (GH12424)
- Bug in pd.to_datetime() did not cast floats correctly when unit was specified, resulting in truncated datetime (GH13834)

1.12.2.5 Merging changes

Merging will now preserve the dtype of the join keys (GH8596)

```
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})
In [106]: df1
Out[106]:
   key  v1
0   1  10

In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
In [108]: df2
Out[108]:
   key  v1
0   1  20
1   2  30
```

**Previous behavior:**

```
In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
   key  v1
0   1.0 10.0
```

(continues on next page)
New behavior:

We are able to preserve the join keys

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

### 1.12.2.6 .describe() changes

Percentile identifiers in the index of a .describe() output will now be rounded to the least precision that keeps them distinct (GH13104)

Previous behavior:

The percentiles were rounded to at most one decimal place, which could raise ValueError for a data frame if the percentiles were duplicated.
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[3]:
    count   5.000000
    mean    2.000000
    std   1.581139
    min   0.000000
    0.0%   0.000400
    0.1%   0.002000
    0.1%   0.004000
    50%    2.000000
    99.9%   3.996000
    100.0%  3.998000
    100.0%  3.999600
    max    4.000000
    dtype: float64

In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
ValueError: cannot reindex from a duplicate axis

New behavior:

In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[115]:
    count   5.000000
    mean    2.000000
    std   1.581139
    min   0.000000
    0.0%   0.000400
    0.05%   0.002000
    0.1%   0.004000
    50%    2.000000
    99.9%   3.996000
    99.95%  3.998000
    99.99%  3.999600
    max    4.000000
    dtype: float64

In [116]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])

Furthermore:
• Passing duplicated percentiles will now raise a `ValueError`.
• Bug in `.describe()` on a DataFrame with a mixed-dtype column index, which would previously raise a `TypeError` (GH13288)

### 1.12.2.7 Period changes

**PeriodIndex now has period dtype**

PeriodIndex now has its own period dtype. The period dtype is a pandas extension dtype like `category` or the `timezone aware dtype` (datetime64[ns, tz])(GH13941). As a consequence of this change, PeriodIndex no longer has an integer dtype:

**Previous behavior:**

```
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')
In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True
In [4]: pi.dtype
Out[4]: dtype('int64')
```

**New behavior:**

```
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')
In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False
In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True
In [121]: pi.dtype
Out[121]: period[D]
In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype
```

**Period('NaT') now returns pd.NaT**

Previously, `Period` has its own `Period('NaT')` representation different from `pd.NaT`. Now `Period('NaT')` has been changed to return `pd.NaT` (GH12759, GH13582)

**Previous behavior:**
New behavior:

These result in `pd.NaT` without providing `freq` option.

Previous behavior:

To be compatible with `Period` addition and subtraction, `pd.NaT` now supports addition and subtraction with `int`. Previously it raised `ValueError`.

New behavior:

`PeriodIndex.values` now returns array of `Period` object

`.values` is changed to return an array of `Period` objects, rather than an array of integers (GH13988).

Previous behavior:

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
array([492, 493])
```

New behavior:

```
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [128]: pi.values
Out[128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

1.12.2.8 Index + / – no longer used for set operations

Addition and subtraction of the base Index type and of DatetimeIndex (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific `.union()` and `.difference()` methods), and is now disabled. When possible, + and – are now used for element-wise operations, for example for concatenating strings or subtracting datetimes (GH8227, GH14127).

Previous behavior:
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .
union()
Out[1]: Index(['a', 'b', 'c'], dtype='object')

New behavior: the same operation will now perform element-wise addition:

In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out[129]: Index(['aa', 'bc'], dtype='object')

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

Previous behavior:

In [1]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
FutureWarning: using '-' to provide set differences with datetimelike Indexes is deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)

New behavior:

In [131]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
Out[131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)

1.12.2.9 Index.difference and .symmetric_difference changes

Index.difference and Index.symmetric_difference will now, more consistently, treat NaN values as any other values. (GH13514)

In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
In [133]: idx2 = pd.Index([0, 1, np.nan])

Previous behavior:

In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')
In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')

New behavior:

In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')
In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')

(continues on next page)
1.12.2.10 Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

**Previous behavior:**

```
In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])
```

```
In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo').unique()
Out[2]: DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00', '2011-01-03 00:00:00+09:00'], dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

**New behavior:**

```
In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')
```

```
In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo').unique()
Out[137]: DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00', '2011-01-03 00:00:00+09:00'], dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

1.12.2.11 MultiIndex constructors, groupby and set_index preserve categorical dtypes

MultiIndex.from_arrays and MultiIndex.from_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))
```

```
In [139]: lvll1 = ['foo', 'bar']
```

```
In [140]: midx = pd.MultiIndex.from_arrays([cat, lvll1])
```

```
In [141]: midx
Out[141]: MultiIndex(levels=[['b', 'a', 'c'], ['bar', 'foo']], labels=[[1, 0], [1, 0]], dtype='object')
```

**Previous behavior:**

```
In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')
```

```
In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')
```
New behavior: the single level is now a CategoricalIndex:

```python
In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False, dtype='category')

In [143]: midx.get_level_values(0)
CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False, dtype='category')
```

An analogous change has been made to MultiIndex.from_product. As a consequence, groupby and set_index also preserve categorical dtypes in indexes

```python
In [144]: df = pd.DataFrame({
                   'A': [0, 1],
                   'B': [10, 11],
                   'C': cat})
In [145]: df_grouped = df.groupby(by=['A', 'C']).first()
In [146]: df_set_idx = df.set_index(['A', 'C'])
```

Previous behavior:

```python
In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [12]: df_grouped.reset_index().dtypes
Out[12]:
   A     int64
  C    object
   B  float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
   A     int64
  C    object
   B     int64
dtype: object
```

New behavior:

```python
In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False, name='C', dtype='category')
In [148]: df_grouped.reset_index().dtypes
   →
   A     int64
  C    category
   B  float64
dtype: object
In [149]: df_set_idx.index.levels[1]
   →
CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False, name='C', dtype='category')
```

(continues on next page)

1.12.2.12 read_csv will progressively enumerate chunks

When read_csv() is called with chunksize=n and without specifying an index, each chunk used to have an independently generated index from 0 to n-1. They are now given instead a progressive index, starting from 0 for the first chunk, from n for the second, and so on, so that, when concatenated, they are identical to the result of calling read_csv() without the chunksize= argument (GH12185).

Previous behavior:

```
In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
    A  B
   --- ---
  0  0  1
  1  2  3
  0  4  5
  1  6  7
```

New behavior:

```
In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[152]:
    A  B
   --- ---
  0  0  1
  1  2  3
  2  4  5
  3  6  7
```

1.12.2.13 Sparse Changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

### int64 and bool support enhancements

Sparse data structures now gained enhanced support of int64 and bool dtype (GH667, GH13849).

Previously, sparse data were float64 dtype by default, even if all inputs were of int or bool dtype. You had to specify dtype explicitly to create sparse data with int64 dtype. Also, fill_value had to be specified explicitly because the default was np.nan which doesn’t appear in int64 or bool data.
In [1]: pd.SparseArray([1, 2, 0, 0])  
Out[1]:  
[1.0, 2.0, 0.0, 0.0]  
Fill: nan  
IntIndex  
Indices: array([0, 1, 2, 3], dtype=int32)  

# specifying int64 dtype, but all values are stored in sp_values because  
# fill_value default is np.nan  
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)  
Out[2]:  
[1, 2, 0, 0]  
Fill: nan  
IntIndex  
Indices: array([0, 1, 2, 3], dtype=int32)  

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)  
Out[3]:  
[1, 2, 0, 0]  
Fill: 0  
IntIndex  
Indices: array([0, 1], dtype=int32)  

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate fill_value defaults (0 for int64 dtype, False for bool dtype).

In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)  
Out[153]:  
[1, 2, 0, 0]  
Fill: 0  
IntIndex  
Indices: array([0, 1], dtype=int32)  

In [154]: pd.SparseArray([True, False, False, False])  
Out[154]:  
[True, False, False, False]  
Fill: False  
IntIndex  
Indices: array([0], dtype=int32)  

See the docs for more details.

Operators now preserve dtypes

- Sparse data structure now can preserve dtype after arithmetic ops (GH13848)

In [155]: s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)  
In [156]: s.dtype  
Out[156]:  
dtype('int64')  
In [157]: s + 1  
Out[157]:  
0 1  
1 3  
(continues on next page)
Sparse data structure now support `astype` to convert internal `dtype` (GH13900)

```python
In [158]: s = pd.SparseSeries([1., 0., 2., 0.], fill_value=0)
In [159]: s
Out[159]:
0  1.0
1  0.0
2  2.0
3  0.0
dtype: float64
```

```python
In [160]: s.astype(np.int64)
```

`astype` fails if data contains values which cannot be converted to specified `dtype`. Note that the limitation is applied to `fill_value` which default is `np.nan`.

```python
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.
\astype{int64})
Out[7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

Other sparse fixes

- Subclassed `SparseDataFrame` and `SparseSeries` now preserve class types when slicing or transposing. (GH13787)
- `SparseArray` with `bool` `dtype` now supports logical (bool) operators (GH14000)
- Bug in `SparseSeries` with `MultiIndex`[] indexing may raise `IndexError` (GH13144)
- Bug in `SparseSeries` with `MultiIndex`[] indexing result may have normal `Index` (GH13144)
- Bug in `SparseDataFrame` in which `axis=None` did not default to `axis=0` (GH13048)
- Bug in `SparseSeries` and `SparseDataFrame` creation with object `dtype` may raise `TypeError` (GH11633)
• Bug in SparseDataFrame doesn’t respect passed SparseArray or SparseSeries ‘s dtype and fill_value (GH13866)
• Bug in SparseArray and SparseSeries don’t apply ufunc to fill_value (GH13853)
• Bug in SparseSeries.abs incorrectly keeps negative fill_value (GH13853)
• Bug in single row slicing on multi-type SparseDataFrame s, types were previously forced to float (GH13917)
• Bug in SparseSeries slicing changes integer dtype to float (GH8292)
• Bug in SparseDataFrame comparison ops may raise TypeError (GH13001)
• Bug in SparseDataFrame.isnull raises ValueError (GH8276)
• Bug in SparseSeries representation with bool dtype may raise IndexError (GH13110)
• Bug in SparseSeries and SparseDataFrame of bool or int64 dtype may display its values like float64 dtype (GH13110)
• Bug in sparse indexing using SparseArray with bool dtype may return incorrect result (GH13985)
• Bug in SparseArray created from SparseSeries may lose dtype (GH13999)
• Bug in SparseSeries comparison with dense returns normal Series rather than SparseSeries (GH13999)

1.12.2.14 Indexer dtype changes

Note: This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as Index.get_indexer that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like numpy.take. Previously, a platform int was defined as np.int_ which corresponds to a C integer, but the correct type, and what is being used now, is np.intp, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, np.int_ is 32 bits, and np.intp is 64 bits. Changing this behavior improves performance for many operations on that platform.

Previous behavior:

```python
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

New behavior:

```python
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```
1.12.2.15 Other API Changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to stdout (GH14101).
- `Series.unique()` with `datetime` and `timezone` now returns return array of `Timestamp with timezone` (GH135665).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).
- `.filter()` enforces mutual exclusion of the keyword arguments (GH12399).
- `eval`’s upcasting rules for `float32` types have been updated to be more consistent with NumPy’s rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` (GH12388).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on groupby or resample objects (GH12811).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior (GH13299).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` (GH13161)
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a DataFrame with identical columns and index labels (GH13222).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains NaN values (GH13149)
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` (GH13209)
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` (GH10364, GH13917)
- `.groupby.groups` will now return a dictionary of `Index objects`, rather than a dictionary of `np.ndarray` or `lists` (GH14293)
1.12.3 Deprecations

- Series.reshape and Categorical.reshape have been deprecated and will be removed in a subsequent release (GH12882, GH12882)
- PeriodIndex.to_datetime has been deprecated in favor of PeriodIndex.to_timestamp (GH8254)
- Timestamp.to_datetime has been deprecated in favor of Timestamp.to_pydatetime (GH8254)
- Index.to_datetime and DatetimeIndex.to_datetime have been deprecated in favor of pd.to_datetime (GH8254)
- pandas.core.datetools module has been deprecated and will be removed in a subsequent release (GH14094)
- SparseList has been deprecated and will be removed in a future version (GH13784)
- DataFrame.to_html() and DataFrame.to_latex() have dropped the colSpace parameter in favor of col_space (GH13857)
- DataFrame.to_sql() has deprecated the flavor parameter, as it is superfluous when SQLAlchemy is not installed (GH13611)
- Deprecated read_csv keywords:
  - compact_ints and use_unsigned have been deprecated and will be removed in a future version (GH13320)
  - buffer_lines has been deprecated and will be removed in a future version (GH13360)
  - as_recarray has been deprecated and will be removed in a future version (GH13373)
  - skip_footer has been deprecated in favor of skipfooter and will be removed in a future version (GH13349)
- top-level pd.ordered_merge() has been renamed to pd.merge_ordered() and the original name will be removed in a future version (GH13358)
- Timestamp.offset property (and named arg in the constructor), has been deprecated in favor of freq (GH12160)
- pd.tseries.util.pivot_annual is deprecated. Use pivot_table as alternative, an example is here (GH736)
- pd.tseries.util.isleapyear has been deprecated and will be removed in a subsequent release. Datetime-likes now have a .is_leap_year property (GH13727)
- Panel4D and PanelND constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the xarray package. Pandas provides a to_xarray() method to automate this conversion (GH13564).
- pandas.tseries.frequencies.get_standard_freq is deprecated. Use pandas.tseries.frequencies.to_offset(freq).rule_code instead (GH13874)
- pandas.tseries.frequencies.to_offset’s freqstr keyword is deprecated in favor of freq (GH13874)
- Categorical.from_array has been deprecated and will be removed in a future version (GH13854)

1.12.4 Removal of prior version deprecations/changes

- The SparsePanel class has been removed (GH13778)
• The pd.sandbox module has been removed in favor of the external library pandas-qt (GH13670)
• The pandas.io.data and pandas.io.wb modules are removed in favor of the pandas-datareader package (GH13724).
• The pandas.tools.rplot module has been removed in favor of the seaborn package (GH13855)
• DataFrame.to_csv() has dropped the engine parameter, as was deprecated in 0.17.1 (GH11274, GH13419)
• DataFrame.to_dict() has dropped the outtype parameter in favor of orient (GH13627, GH8486)
• pd.Categorical has dropped setting of the ordered attribute directly in favor of the set_ordered method (GH13671)
• pd.Categorical has dropped the levels attribute in favor of categories (GH8376)
• DataFrame.to_sql() has dropped the mysql option for the flavor parameter (GH13611)
• Panel.shift() has dropped the lags parameter in favor of periods (GH14041)
• pd.Index has dropped the diff method in favor of difference (GH13669)
• pd.DataFrame has dropped the to_wide method in favor of to_panel (GH14039)
• Series.to_csv has dropped the nanRep parameter in favor of na_rep (GH13804)
• Series.xs, DataFrame.xs, Panel.xs, Panel.major_xs, and Panel.minor_xs have dropped the copy parameter (GH13781)
• str.split has dropped the return_type parameter in favor of expand (GH13701)
• Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) (GH13590, GH13868). Now legacy time rules raises ValueError. For the list of currently supported offsets, see here.
• The default value for the return_type parameter for DataFrame.plot.box and DataFrame.boxplot changed from None to "axes". These methods will now return a matplotlib axes by default instead of a dictionary of artists. See here (GH6581).
• The tquery and uquery functions in the pandas.io.sql module are removed (GH5950).

1.12.5 Performance Improvements

• Improved performance of sparse IntIndex.intersect (GH13082)
• Improved performance of sparse arithmetic with BlockIndex when the number of blocks are large, though recommended to use IntIndex in such cases (GH13082)
• Improved performance of DataFrame.quantile() as it now operates per-block (GH11623)
• Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 (GH13166, GH13334)
• Improved performance of DataFrameGroupBy.transform (GH12737)
• Improved performance of Index and Series.duplicated (GH10235)
• Improved performance of Index.difference (GH12044)
• Improved performance of RangeIndex.is_monotonic_increasing and is_monotonic_decreasing (GH13749)
• Improved performance of datetime string parsing in DatetimeIndex (GH13692)
• Improved performance of hashing Period (GH12817)
• Improved performance of `factorize` of datetime with timezone (GH13750)
• Improved performance of by lazily creating indexing hashtables on larger Indexes (GH14266)
• Improved performance of `groupby.groups` (GH14293)
• Unnecessary materializing of a MultiIndex when introspecting for memory usage (GH14308)

1.12.6 Bug Fixes

• Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
• Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1` (GH13994)
• Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
• Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception (GH13213)
• Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` (GH11858)
• Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
• Bug in `DataFrame` assignment with an object-dtyped Index where the resultant column is mutable to the original object. (GH13522)
• Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)
• Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range (GH8287)
• Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid `ordered` parameter was passed in (GH13522)
• Bug in `Series` construction from a tuple of integers on windows not returning default dtype (int64) (GH13646)
• Bug in `TimedeltaIndex` addition with a Datetime-like object where addition overflow was not being caught (GH14068)
• Bug in `.groupby(..).resample(..)` when the same object is called multiple times (GH13174)
• Bug in `.to_records()` when index name is a unicode string (GH13172)
• Bug in calling `.memory_usage()` on object which doesn’t implement (GH12924)
• Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the Series with the quantile (GH13098, GH13146)
• Bug in `SeriesGroupBy.transform` with datetime values and missing groups (GH13191)
• Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations (GH13844)
• Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones (GH14190)
• Bug in `Series.str.extractall()` with str index raises `ValueError` (GH13156)
• Bug in `Series.str.extractall()` with single group and quantifier (GH13382)
• Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` (GH13078)
• Bug in `Index` and `Series` created with NaN and NaT mixed data may not have `datetime64` dtype (GH13324)
• Bug in Index and Series may ignore np.datetime64('nat') and np.timedelta64('nat') to infer dtype (GH13324)
• Bug in PeriodIndex and Period subtraction raises AttributeError (GH13071)
• Bug in PeriodIndex construction returning a float64 index in some circumstances (GH13067)
• Bug in .resample(...) with a PeriodIndex not changing its freq appropriately when empty (GH13067)
• Bug in .resample(...) with a PeriodIndex not retaining its type or name with an empty DataFrame appropriately when empty (GH13212)
• Bug in groupby(...).apply(...) when the passed function returns scalar values per group (GH13468).
• Bug in groupby(...).resample(...) where passing some keywords would raise an exception (GH13235)
• Bug in .tz_convert on a tz-aware DateTimeIndex that relied on index being sorted for correct results (GH13066)
• Bug in .tz_localize with dateutil.tz.tzlocal may return incorrect result (GH13583)
• Bug in DatetimeTZDtype dtype with dateutil.tz.tzlocal cannot be regarded as valid dtype (GH13583)
• Bug in pd.read_hdf() where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the key argument was set to the name of the dataset. (GH13231)
• Bug in .rolling() that allowed a negative integer window in construction of the Rolling() object, but would later fail on aggregation (GH13383)
• Bug in Series indexing with tuple-valued data and a numeric index (GH13509)
• Bug in printing pd.DataFrame where unusual elements with the object dtype were causing segfaults (GH13717)
• Bug in ranking Series which could result in segfaults (GH13445)
• Bug in various index types, which did not propagate the name of passed index (GH12309)
• Bug in DatetimeIndex, which did not honour the copy=True (GH13205)
• Bug in DatetimeIndex.is_normalized returns incorrectly for normalized date_range in case of local timezones (GH13459)
• Bug in pd.concat and .append may coerce datetime64 and timedelta to object dtype containing python built-in datetime or timedelta rather than Timestamp or Timedelta (GH13626)
• Bug in PeriodIndex.append may raises AttributeError when the result is object dtype (GH13221)
• Bug in CategoricalIndex.append may accept normal list (GH13626)
• Bug in pd.concat and .append with the same timezone get reset to UTC (GH7795)
• Bug in Series and DataFrame .append raises AmbiguousTimeError if data contains datetime near DST boundary (GH13626)
• Bug in DataFrame.to_csv() in which float values were being quoted even though quotations were specified for non-numeric values only (GH12922, GH13259)
• Bug in DataFrame.describe() raising ValueError with only boolean columns (GH13898)
• Bug in MultiIndex slicing where extra elements were returned when level is non-unique (GH12896)
• Bug in .str.replace does not raise TypeError for invalid replacement (GH13438)
• Bug in MultiIndex.from_arrays which didn’t check for input array lengths matching (GH13599)
• Bug in `cartesian_product` and `MultiIndex.from_product` which may raise with empty input arrays (GH12258)

• Bug in `pd.read_csv()` which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances (GH13703)

• Bug in `pd.read_csv()` which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` (GH12224)

• Bug in `pd.read_csv()` which caused BOM files to be incorrectly parsed by not ignoring the BOM (GH4793)

• Bug in `pd.read_csv()` with `engine='python'` which raised errors when a numpy array was passed in for `usecols` (GH12546)

• Bug in `pd.read_csv()` where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter (GH14066)

• Bug in `pd.read_csv()` with `engine='python'` in which NaN values weren’t being detected after data was converted to numeric values (GH13314)

• Bug in `pd.read_csv()` in which the `nrows` argument was not properly validated for both engines (GH10476)

• Bug in `pd.read_csv()` with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly (GH13274)

• Bug in `pd.read_csv()` with `engine='python'` in which trailing NaN values were not being parsed (GH13320)

• Bug in `pd.read_csv()` with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 (GH13398)

• Bug in `pd.read_csv()` that prevents `usecols` kwarg from accepting single-byte unicode strings (GH13219)

• Bug in `pd.read_csv()` that prevents `usecols` from being an empty set (GH13402)

• Bug in `pd.read_csv()` in the C engine where the NULL character was not being parsed as NULL (GH14012)

• Bug in `pd.read_csv()` with `engine='c'` in which NULL `quotechar` was not accepted even though `quoting` was specified as None (GH13411)

• Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric (GH13411)

• Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data (GH3404)

• Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF_xx, utf_xx) raised `UnicodeDecodeError` (GH13549)

• Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were `None`. (GH13940)

• Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. (GH13940)

• Bug in `pd.pivot_table()` where margins_name is ignored when `aggfunc` is a list (GH13354)

• Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` (GH13598)

• Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` (GH13603)

• Bug in `Series arithmetic raises TypeError` if it contains datetime-like as object dtype (GH13043)
• Bug `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
• Bug `Series.fillna()` and `Series.dropna()` don’t affect to `Period('NaT')` (GH13737)
• Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a category dtyped `Series` (GH14021)
• Bug in extension dtype creation where the created types were not is/identical (GH13285)
• Bug in `.resample(...)` where incorrect warnings were triggered by IPython introspection (GH13618)
• Bug in NaT-`Period` raises `AttributeError` (GH13071)
• Bug in `Series` comparison may output incorrect result if rhs contains NaT (GH9005)
• Bug in `Series` and `Index` comparison may output incorrect result if it contains NaT with object dtype (GH13592)
• Bug in `Period` addition raises `TypeError` if `Period` is on right hand side (GH13069)
• Bug in `Period` and `Series` or `Index` comparison raises `TypeError` (GH13200)
• Bug in `pd.set_eng_float_format()` that would prevent NaN and Inf from formatting (GH11981)
• Bug in `.unstack` with Categorical dtype resets .ordered to True (GH13249)
• Clean some compile time warnings in datetime parsing (GH13607)
• Bug in `factorize` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)
• Bug in `.set_index` raises `AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)
• Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
• Bug in `pd.read_hdf()` returns incorrect result when a DataFrame with a categorical column and a query which doesn’t match any values (GH13792)
• Bug in `.iloc` when indexing with a non lex-sorted MultiIndex (GH13797)
• Bug in `.loc` when indexing with date strings in a reverse sorted `DatetimeIndex` (GH14316)
• Bug in `Series` comparison operators when dealing with zero dim NumPy arrays (GH13006)
• Bug in `.combine_first` may return incorrect dtype (GH7630, GH10567)
• Bug in `groupby` where apply returns different result depending on whether first result is None or not (GH12824)
• Bug in `groupby(...).nth()` where the group key is included inconsistently if called after `.head()` / `.tail()` (GH12839)
• Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the formatters key word (GH10690)
• Bug in `DataFrame.iterrows()`, not yielding a `Series` subclass if defined (GH13977)
• Bug in `pd.to_numeric` when errors='coerce' and input contains non-hashable objects (GH13324)
• Bug in invalid `Timedelta` arithmetic and comparison may raise `ValueError` rather than `TypeError` (GH13624)
• Bug in invalid datetime parsing in to_datetime and `DatetimeIndex` may raise `TypeError` rather than `ValueError` (GH11169, GH11287)
• Bug in `Index` created with tz-aware `Timestamp` and mismatched tz option incorrectly coerces timezone (GH13692)
• Bug in `Series` when setting a slice with a `np.timedelta64` (GH14155)
• Bug in Index raises `OutOfBoundsDatetime` if datetime exceeds `datetime64[ns]` bounds, rather than coercing to object dtype (GH13663)
• Bug in Index may ignore specified `datetime64` or `timedelta64` passed as dtype (GH13981)
• Bug in RangeIndex can be created without no arguments rather than raises `TypeError` (GH13793)
• Bug in `.value_counts()` raises `OutOfBoundsDatetime` if data exceeds `datetime64[ns]` bounds (GH13663)
• Bug in DatetimeIndex may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` (GH9114)
• Bug in Series creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values (GH13876)
• Bug in resample with timedelta data where data was casted to float (GH13119).
• Bug in `pd.isnull()` `pd.notnull()` raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
• Bug in `pd.merge()` may raise `TypeError` if input datetime-like has other unit than `ns` (GH13389)
• Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if tz was set (GH13884)
• Bug in Categorical.remove_unused_categories() changes `.codes` dtype to platform int (GH13261)
• Bug in `groupby` with `as_index=False` returns all NaN’s when grouping on multiple columns including a categorical one (GH13204)
• Bug in `df.groupby(...)[[...]]` where `getitem` with `Int64Index` raised an error (GH13731)
• Bug in `pd.read_gbq()` could throw `ImportError`: No module named discovery as a result of a naming conflict with another python package called `apiclient` (GH13454)
• Bug in Index.union returns an incorrect result with a named empty index (GH13432)
• Bugs in Index.difference and DataFrame.join raise in Python3 when using mixed-integer indexes (GH13432, GH12814)
• Bug in subtract tz-aware `datetime.datetime` from tz-aware `datetime64` series (GH14088)
• Bug in `.to_excel()` when DataFrame contains a MultiIndex which contains a label with a NaN value (GH13511)
• Bug in invalid frequency offset string like “D1”, “-2-3H” may not raise `ValueError` (GH13930)
• Bug in concat and groupby for hierarchical frames with `RangeIndex` levels (GH13542).
• Bug in `Series.str.contains()` for Series containing only NaN values of object dtype (GH14171)
• Bug in `agg()` function on groupby dataframe changes dtype of `datetime64[ns]` column to float64 (GH12821)
• Bug in using NumPy ufunc with PeriodIndex to add or subtract integer raise IncompatibleFrequency. Note that using standard operator like + or - is recommended, because standard operators use more efficient path (GH13980)

• Bug in operations on NaT returning float instead of datetime64[ns] (GH12941)

• Bug in Series flexible arithmetic methods (like .add()) raises ValueError when axis=None (GH13894)

• Bug in DataFrame.to_csv() with MultiIndex columns in which a stray empty line was added (GH6618)

• Bug in DatetimeIndex, TimedeltaIndex and PeriodIndex.equals() may return True when input isn’t Index but contains the same values (GH13107)

• Bug in assignment against datetime with timezone may not work if it contains datetime near DST boundary (GH14146)

• Bug in pd.eval() and HDFStore query truncating long float literals with python 2 (GH14241)

• Bug in Index raises KeyError displaying incorrect column when column is not in the df and columns contains duplicate values (GH13822)

• Bug in Period and PeriodIndex creating wrong dates when frequency has combined offset aliases (GH13874)

• Bug in .to_string() when called with an integer line_width and index=False raises an Unbound-LocalError exception because idx referenced before assignment.

• Bug in eval() where the resolvers argument would not accept a list (GH14095)

• Bugs in stack, get_dummies, make_axis_dummies which don’t preserve categorical dtypes in (multi)indexes (GH13854)

• PeriodIndex can now accept list and array which contains pd.NaT (GH13430)

• Bug in df.groupby where .median() returns arbitrary values if grouped dataframe contains empty bins (GH13629)

• Bug in Index.copy() where name parameter was ignored (GH13430)

1.13 v0.18.1 (May 3, 2016)

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

• .groupby(...) has been enhanced to provide convenient syntax when working with .rolling(..), .expanding(..) and .resample(..) per group, see here

• pd.to_datetime() has gained the ability to assemble dates from a DataFrame, see here

• Method chaining improvements, see here.

• Custom business hour offset, see here.

• Many bug fixes in the handling of sparse, see here

• Expanded the Tutorials section with a feature on modern pandas, courtesy of @TomAugsburger. (GH13045).
What’s new in v0.18.1

- **New features**
  - Custom Business Hour
  - `.groupby(..)` syntax with window and resample operations
  - Method chaining improvements
    - `.where()` and `.mask()`
    - `.loc[]`, `.iloc[]`, `.ix[]`
    - `[]` indexing
  - Partial string indexing on `DateTimeIndex` when part of a `MultiIndex`
  - Assembling Datetimes
  - Other Enhancements
- **Sparse changes**
- **API changes**
  - `.groupby(..).nth()` changes
  - numpy function compatibility
  - Using `.apply` on groupby resampling
  - Changes in `read_csv` exceptions
  - `to_datetime` error changes
  - Other API changes
  - Deprecations
- **Performance Improvements**
- **Bug Fixes**

### 1.13.1 New features

#### 1.13.1.1 Custom Business Hour

The `CustomBusinessHour` is a mixture of `BusinessHour` and `CustomBusinessDay` which allows you to specify arbitrary holidays. For details, see Custom Business Hour (GH11514)

```python
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```python
In [4]: dt = datetime(2014, 1, 17, 15)
```

(continues on next page)
Tuesday after MLK Day (Monday is skipped because it’s a holiday)

```python
In [6]: dt + bhour_us * 2
Out[6]: Timestamp('2014-01-20 09:00:00')
```

### 1.13.1.2 `.groupby()` syntax with window and resample operations

`.groupby()` has been enhanced to provide convenient syntax when working with `.rolling()`, `.expanding()` and `.resample()` per group, see (GH12486, GH12738).

You can now use `.rolling()` and `.expanding()` as methods on groupbys. These return another deferred object (similar to what `.rolling()` and `.expanding()` do on ungrouped pandas objects). You can then operate on these `RollingGroupby` objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```python
                          'B': np.arange(40)})
In [8]: df.groupby('A').apply(lambda x: x.rolling(4).B.mean())
Out[9]:
   A
0  1   NaN
1  1   NaN
2  1   NaN
3  1   1.5
4  1   2.5
5  1   3.5
6  1   4.5
```

(continues on next page)
Now you can do:

```python
In [10]: df.groupby('A').rolling(4).B.mean()
Out[10]:
   A
0  0  NaN
  1  NaN
  2  NaN
  3  1.5
  4  2.5
  5  3.5
  6  4.5
... 
3  33  NaN
  34  NaN
  35  33.5
  36  34.5
  37  35.5
  38  36.5
  39  37.5
Name: B, Length: 40, dtype: float64
```

For `.resample()` type of operations, previously you would have to:

```python
In [11]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
                           ....:               periods=4,
                           ....:               freq='W'),
                           ....:               'group': [1, 1, 2, 2],
                           ....:               'val': [5, 6, 7, 8]}).set_index('date')

In [12]: df
Out[12]:
   group  val
date
2016-01-03  1   5
2016-01-10  1   6
2016-01-17  2   7
2016-01-24  2   8
```

```python
In [13]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())
Out[13]:
   group  val
group date
1  2016-01-03  1   5
    2016-01-04  1   5
    2016-01-05  1   5
```
Now you can do:

```python
In [14]: df.groupby('group').resample('1D').ffill()
Out[14]:
       group  val
  group date
1  2016-01-03  1  5
   2016-01-04  1  5
   2016-01-05  1  5
   2016-01-06  1  5
   2016-01-07  1  5
   2016-01-08  1  5
   2016-01-09  1  5
... ... ...
2  2016-01-18  2  7
   2016-01-19  2  7
   2016-01-20  2  7
   2016-01-21  2  7
   2016-01-22  2  7
   2016-01-23  2  7
   2016-01-24  2  8
```

[16 rows x 2 columns]

1.13.1.3 Method chaining improvements

The following methods/indexers now accept a callable. It is intended to make these more useful in method chains, see the documentation. (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[]`, `.iloc[]` and `.ix[]`
- `[]` indexing

`.where()` and `.mask()`

These can accept a callable for the condition and other arguments.
In [15]: df = pd.DataFrame({'A': [1, 2, 3],
                      'B': [4, 5, 6],
                      'C': [7, 8, 9]})

In [16]: df.where(lambda x: x > 4, lambda x: x + 10)
Out[16]:
   A  B  C
0  5 14  7
1 12  5  8
2 13  6  9

.loc[], .iloc[], .ix[]

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or
anything which is valid for these indexer's input.

# callable returns bool indexer
In [17]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[17]:
   B  C
0  5  8
1  6  9

# callable returns list of labels
In [18]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]
Out[18]:
   A  B
0  2  5
1  3  6

[] indexing

Finally, you can use a callable in [] indexing of Series, DataFrame and Panel. The callable must return a valid input
for [] indexing depending on its class and index type.

In [19]: df[lambda x: 'A']
Out[19]:
   0  1
   1  2
   2  3
Name: A, dtype: int64

Using these methods / indexers, you can chain data selection operations without using temporary variable.

In [20]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [21]: (bb.groupby(['year', 'team'])
              .sum()
              .loc[lambda df: df.r > 100]
       )
Out[21]:

(continues on next page)
### 1.13.1.4 Partial string indexing on `DateTimeIndex` when part of a `MultiIndex`

Partial string indexing now matches on `DateTimeIndex` when part of a `MultiIndex` (GH10331)

```
In [22]: dft2 = pd.DataFrame(np.random.randn(20, 1),
                         columns=['A'],
                         index=pd.MultiIndex.from_product([pd.date_range('20130101', periods=10, freq='12H'), ['a', 'b']]))
```

```
In [23]: dft2
```

```
Out[23]:
A
2013-01-01 00:00:00 a   0.156998
   b   -0.571455
2013-01-01 12:00:00 a   1.057633
   b   -0.791489
2013-01-02 00:00:00 a   -0.524627
   b    0.071878
2013-01-02 12:00:00 a   1.910759
   b   -0.276646
```

(continues on next page)
On other levels

```
In [25]: idx = pd.IndexSlice

In [26]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [27]: dft2
```

```
Out[27]:
    A
   a  2013-01-01 00:00:00  0.156998
       2013-01-01 12:00:00  1.057633
       2013-01-02 00:00:00 -0.524627
       2013-01-02 12:00:00  1.910759
       2013-01-03 00:00:00  0.513082
       2013-01-03 12:00:00  1.043945
       2013-01-04 00:00:00  1.459927
       ... ...  
   b  2013-01-02 12:00:00  0.787965
       2013-01-03 00:00:00 -0.546416
       2013-01-03 12:00:00  2.107785
       2013-01-04 00:00:00  1.015405
       2013-01-04 12:00:00 -0.675521
       2013-01-05 00:00:00  0.688972
       2013-01-05 12:00:00  1.924533
```

```
[20 rows x 1 columns]
```

```
In [28]: dft2.loc[idx[:, '2013-01-05'], :]
```

```
Out[28]:
    A
   a  2013-01-05 00:00:00  0.440266
      2013-01-05 12:00:00 -0.276646
   b  2013-01-05 00:00:00  0.688972
      2013-01-05 12:00:00  1.924533
```

```
[20 rows x 1 columns]
```

### 1.13.1.5 Assembling Datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in DataFrame or a dict. (GH8158).

```
In [29]: df = pd.DataFrame({'year': [2015, 2016],
                      'month': [2, 3],
                      'day': [4, 5],
                      'hour': [23, 12]})
```
Assembling using the passed frame.

```python
In [31]: pd.to_datetime(df)
Out[31]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```python
In [32]: pd.to_datetime(df[['year', 'month', 'day']])
Out[32]:
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

### 1.13.1.6 Other Enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine (GH12958)
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` (GH12175)
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way (GH11852)
- `pd.read_msgpack()` now always gives writeable ndarrays even when compression is used (GH12359).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack (GH12573)
- `.to_json()` now supports `NDFrames` that contain categorical and sparse data (GH10778)
- `interpolate()` now supports `method='akima'` (GH7588).
- `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions (GH12655)
- Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. (GH11128)
- `Index.take` now handles `allow_fill` and `fill_value` consistently (GH12631)

```python
In [33]: idx = pd.Index([1., 2., 3., 4.], dtype='float')

# default, allow_fill=True, fill_value=None
In [34]: idx.take([2, -1])
Out[34]: Float64Index([3.0, 4.0], dtype='float64')
```

(continues on next page)
In [35]: idx.take([2, -1], fill_value=True)

Out[35]: Float64Index([3.0, nan], dtype='float64')

Index now supports .str.get_dummies() which returns MultiIndex, see Creating Indicator Variables (GH10008, GH10103)

In [36]: idx = pd.Index(['a|b', 'a|c', 'b|c'])

In [37]: idx.str.get_dummies('|')

Out[37]: MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
labels=[[1, 1, 0], [1, 0, 1], [0, 1, 1]],
names=['a', 'b', 'c'])

- pd.crosstab() has gained a normalize argument for normalizing frequency tables (GH12569). Examples in the updated docs here.
- .resample(..).interpolate() is now supported (GH12925)
- .isin() now accepts passed sets (GH12988)

1.13.2 Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

SparseArray.take now returns a scalar for scalar input, SparseArray for others. Furthermore, it handles a negative indexer with the same rule as Index (GH10560, GH12796)

In [38]: s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])

In [39]: s.take(0)

Out[39]: nan

In [40]: s.take([1, 2, 3])

[1.0, 2.0]

- Bug in SparseSeries[] indexing with Ellipsis raises KeyError (GH9467)
- Bug in SparseArray[] indexing with tuples are not handled properly (GH12966)
- Bug in SparseSeries.loc[] with list-like input raises TypeError (GH10560)
- Bug in SparseSeries.iloc[] with scalar input may raise IndexError (GH10560)
- Bug in SparseSeries.loc[], .iloc[] with slice returns SparseArray, rather than SparseSeries (GH10560)
- Bug in SparseDataFrame.loc[], .iloc[] may results in dense Series, rather than SparseSeries (GH12787)
- Bug in SparseArray addition ignores fill_value of right hand side (GH12910)
- Bug in SparseArray mod raises AttributeError (GH12910)
• Bug in SparseArray pow calculates 1 ** np.nan as np.nan which must be 1 (GH12910)
• Bug in SparseArray comparison output may incorrect result or raise ValueError (GH12971)
• Bug in SparseSeries.__repr__ raises TypeError when it is longer than max_rows (GH10560)
• Bug in SparseSeries.shape ignores fill_value (GH10452)
• Bug in SparseSeries and SparseArray may have different dtype from its dense values (GH12908)
• Bug in SparseSeries.reindex incorrectly handle fill_value (GH12797)
• Bug in SparseArray.to_frame() results in DataFrame, rather than SparseDataFrame (GH9850)
• Bug in SparseSeries.value_counts() does not count fill_value (GH6749)
• Bug in SparseArray.to_dense() does not preserve dtype (GH10648)
• Bug in SparseArray.to_dense() incorrectly handle fill_value (GH12797)
• Bug in pd.concat() of SparseSeries results in dense (GH10536)
• Bug in pd.concat() of SparseDataFrame incorrectly handle fill_value (GH9765)
• Bug in pd.concat() of SparseDataFrame may raise AttributeError (GH12174)
• Bug in SparseArray.shift() may raise NameError or TypeError (GH12908)

1.13.3 API changes

1.13.3.1 .groupby(..).nth() changes

The index in .groupby(..).nth() output is now more consistent when the as_index argument is passed (GH11039):

```python
In [41]: df = DataFrame({'A': ['a', 'b', 'a'],
                   'B': [1, 2, 3]})

In [42]: df
Out[42]:
   A  B
0  a  1
1  b  2
2  a  3

Previous Behavior:

In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
   0  1
   1  2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
   0  1
   1  2
Name: B, dtype: int64

New Behavior:
```
In [43]: df.groupby('A', as_index=True)['B'].nth(0)
Out[43]:
   A
a 1
b 2
Name: B, dtype: int64

In [44]: df.groupby('A', as_index=False)['B'].nth(0)
Out[44]:
   0 1
   1 2
Name: B, dtype: int64

Furthermore, previously, a .groupby would always sort, regardless if sort=False was passed with .nth().

In [45]: np.random.seed(1234)
In [46]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])
In [47]: df['c'] = np.random.randint(0, 4, 100)

Previous Behavior:

In [4]: df.groupby('c', sort=True).nth(1)
Out[4]:
   a   b
c  
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [5]: df.groupby('c', sort=False).nth(1)
Out[5]:
   a   b
   c  
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

New Behavior:

In [48]: df.groupby('c', sort=True).nth(1)
Out[48]:
   a   b
   c  
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [49]: df.groupby('c', sort=False).nth(1)
   →
Out[49]:
   →
   a   b
   →
   c
(continues on next page)
1.13.3.2 numpy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their numpy counterparts has been greatly increased by augmenting the signatures of the pandas methods so as to accept arguments that can be passed in from numpy, even if they are not necessarily used in the pandas implementation (GH12644, GH12638, GH12687)

- `.searchsorted()` for Index and TimedeltaIndex now accept a sorter argument to maintain compatibility with numpy’s `searchsorted` function (GH12238)
- Bug in numpy compatibility of `np.round()` on a Series (GH12600)

An example of this signature augmentation is illustrated below:

```python
In [50]: sp = pd.SparseDataFrame([1, 2, 3])
In [51]: sp
Out[51]:
   0  1  2  3
0   0  1  2  3
```

Previous behaviour:

```python
In [2]: np.cumsum(sp, axis=0)
...: TypeError: cumsum() takes at most 2 arguments (4 given)
```

New behaviour:

```python
In [52]: np.cumsum(sp, axis=0)
Out[52]:
   0  1  2  3
0   0  1  2  3
1   3  6  9
2   6
```

1.13.3.3 Using `.apply` on groupby resampling

Using `.apply` on resampling groupby operations (using a `pd.TimeGrouper`) now has the same output types as similar `.apply` calls on other groupby operations. (GH11742).

```python
In [53]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']), 'value': [10, 13]})
In [54]: df
Out[54]:
   date  value
0  10/10  10
1  11/10  13
```

(continues on next page)
Previous behavior:

```python
In [1]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
...:     .sum())
Out[1]:
...:
TypeError: cannot concatenate a non-NDFrame object

# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value']].
...:     .sum())
Out[2]:
date
2000-10-31 value 10
2000-11-30 value 13
dtype: int64
```

New behavior:

```python
# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
...:     .sum())
Out[55]:
date
2000-10-31 10
2000-11-30 13
Freq: M, dtype: int64

# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value
...:     ']].sum())
Out[56]:
value
date
2000-10-31 10
2000-11-30 13
```

### 1.13.3.4 Changes in `read_csv` exceptions

In order to standardize the `read_csv` API for both the c and python engines, both will now raise an `EmptyDataError`, a subclass of `ValueError`, in response to empty columns or header (GH12493, GH12506)

Previous behaviour:

```python
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...:
ValueError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...:
StopIteration
```

New behaviour:
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...
    pandas.io.common.EmptyDataError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...
    pandas.io.common.EmptyDataError: No columns to parse from file

In addition to this error change, several others have been made as well:

- CParserError now sub-classes ValueError instead of just a Exception (GH12551)
- A CParserError is now raised instead of a generic Exception in read_csv when the c engine cannot parse a column (GH12506)
- A ValueError is now raised instead of a generic Exception in read_csv when the c engine encounters a NaN value in an integer column (GH12506)
- A ValueError is now raised instead of a generic Exception in read_csv when true_values is specified, and the c engine encounters an element in a column containing unencodable bytes (GH12506)
- pandas.parser.OverflowError exception has been removed and has been replaced with Python’s built-in OverflowError exception (GH12506)
- pd.read_csv() no longer allows a combination of strings and integers for the usecols parameter (GH12678)

1.13.3.5 to_datetime error changes

Bugs in pd.to_datetime() when passing a unit with convertible entries and errors='coerce' or non-convertible with errors='ignore'. Furthermore, an OutOfBoundsDatetime exception will be raised when an out-of-range value is encountered for that unit when errors='raise'. (GH11758, GH13052, GH13059)

Previous behaviour:

In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long

New behaviour:

In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'
1.13.3.6 Other API changes

- `.swaplevel()` for Series, DataFrame, Panel, and MultiIndex now features defaults for its first two parameters i and j that swap the two innermost levels of the index. (GH12934)
- `.searchsorted()` for Index and TimedeltaIndex now accept a sorter argument to maintain compatibility with numpy’s searchsorted function (GH12238)
- Period and PeriodIndex now raises IncompatibleFrequency error which inherits ValueError rather than raw ValueError (GH12615)
- Series.apply for category dtype now applies the passed function to each of the .categories (and not the .codes), and returns a category dtype if possible (GH12473)
- read_csv will now raise a TypeError if parse_dates is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
- The default for .query()/.eval() is now engine=None, which will use numexpr if it’s installed; otherwise it will fallback to the python engine. This mimics the pre-0.18.1 behavior if numexpr is installed (and which, previously, if numexpr was not installed, .query()/.eval() would raise). (GH12749)
- pd.show_versions() now includes pandas_datareader version (GH12740)
- Provide a proper __name__ and __qualname__ attributes for generic functions (GH12021)
- pd.concat(ignore_index=True) now uses RangeIndex as default (GH12695)
- pd.merge() and DataFrame.join() will show a UserWarning when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)
- Compat with scipy > 0.17 for deprecated piecewise_polynomial interpolation method; support for the replacement from_derivatives method (GH12887)

1.13.3.7 Deprecations

- The method name Index.sym_diff() is deprecated and can be replaced by Index. symmetric_difference() (GH12591)
- The method name Categorical.sort() is deprecated in favor of Categorical.sort_values() (GH12882)

1.13.4 Performance Improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in .groupby().cumcount() (GH11039)
- Improved memory usage in pd.read_csv() when using skiprows=an_integer (GH13005)
- Improved performance of DataFrame.to_sql when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of Period construction and time series plotting (GH12903, GH11831).
- Improved performance of .str.encode() and .str.decode() methods (GH13008)
- Improved performance of to_numeric if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with IntIndex (GH13036)
1.13.5 Bug Fixes

- The `usecols` parameter in `pd.read_csv` is now respected even when the lines of a CSV file are not even (GH12203)

- Bug in `groupby.transform(...)` when `axis=1` is specified with a non-monotonic ordered index (GH12713)

- Bug in `Period` and `PeriodIndex` creation raises `KeyError` if `freq="Minute"` is specified. Note that “Minute” freq is deprecated in v0.17.0, and recommended to use `freq="T"` instead (GH11854)

- Bug in `.resample(...).count()` with a `PeriodIndex` always raising a `TypeError` (GH12774)

- Bug in `.resample(...)` with a `PeriodIndex` casting to a `DatetimeIndex` when empty (GH12868)

- Bug in printing data which contains `Period` with different `freq` raises `ValueError` (GH12615)

- Bug in `Series` construction with `Categorical` and `dtype='category'` is specified (GH12574)

- Bugs in concatenation with a coercable dtype was too aggressive, resulting in different dtypes in output formatting when an object was longer than `display.max_rows` (GH12411, GH12045, GH11594, GH10571, GH12211)

- Bug in `float_format` option with option not being validated as a callable. (GH12706)

- Bug in `GroupBy.filter` when `dropna=False` and no groups fulfilled the criteria (GH12768)

- Bug in `__name__` of ` cum*` functions (GH12021)

- Bug in `.astype()` of a `Float64Inde/Int64Index` to an `Int64Index` (GH12881)

- Bug in roundtripping an integer based index in `.to_json()/read_json()` when `orient='index'` (the default) (GH12866)

- Bug in plotting `Categorical` dtypes cause error when attempting stacked bar plot (GH13019)

- Compat with >= numpy 1.11 for `NaT` comparisons (GH12969)

- Bug in `.drop()` with a non-unique `MultiIndex`. (GH12701)

- Bug in `.concat` of `datetime` tz-aware and naive DataFrames (GH12467)

- Bug in correctly raising a `ValueError` in `.resample(...).fillna(...)` when passing a non-string (GH12952)

- Bug fixes in various encoding and header processing issues in `pd.read_sas()` (GH12659, GH12654, GH12647, GH12809)

- Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` (GH12569).

- Potential segfault in `DataFrame.to_json` when serialising `datetime.time` (GH11473).

- Potential segfault in `DataFrame.to_json` when attempting to serialise 0d array (GH11299).

- Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of `category`, `sparse`, and `datetime64[ns, tz]` dtypes (GH10778).

- Bug in `DataFrame.to_json` with unsupported dtype not passed to default handler (GH12554).

- Bug in `.align` not returning the sub-class (GH12983)

- Bug in aligning a `Series` with a `DataFrame` (GH13037)

- Bug in `ABCPanel` in which `Panel4D` was not being considered as a valid instance of this generic type (GH12810)
- Bug in consistency of .name on .groupby().apply(). cases (GH12363)
- Bug in Timestamp.__repr__ that caused pprint to fail in nested structures (GH12622)
- Bug in Timedelta.min and Timedelta.max, the properties now report the true minimum/maximum timedeltas as recognized by pandas. See the documentation. (GH12727)
- Bug in .quantile() with interpolation may coerce to float unexpectedly (GH12772)
- Bug in .quantile() with empty Series may return scalar rather than empty Series (GH12772)
- Bug in .loc with out-of-bounds in a large indexer would raise IndexError rather than KeyError (GH12527)
- Bug in resampling when using a TimedeltaIndex and .asfreq(), would previously not include the final fencepost (GH12926)
- Bug in equality testing with a Categorical in a DataFrame (GH12564)
- Bug in GroupBy.first(), .last() returns incorrect row when TimeGrouper is used (GH7453)
- Bug in pd.read_csv() with the c engine when specifying skiprows with newlines in quoted items (GH10911, GH12775)
- Bug in DataFrame timezone lost when assigning tz-aware datetime Series with alignment (GH12981)
- Bug in .value_counts() when normalize=True and dropna=True where nulls still contributed to the normalized count (GH12558)
- Bug in Series.value_counts() loses name if its dtype is category (GH12835)
- Bug in Series.value_counts() loses timezone info (GH12835)
- Bug in Series.value_counts(normalize=True) with Categorical raises UnboundLocalError (GH12835)
- Bug in Panel.fillna() ignoring inplace=True (GH12633)
- Bug in pd.read_csv() when specifying names, usecols, and parse_dates simultaneously with the c engine (GH9755)
- Bug in pd.read_csv() when specifying delim_whitespace=True and lineterminator simultaneously with the c engine (GH12912)
- Bug in Series.rename, DataFrame.rename and DataFrame.rename_axis not treating Series as mappings to relabel (GH12623).
- Clean in .rolling.min and .rolling.max to enhance dtype handling (GH12373)
- Bug in groupby where complex types are coerced to float (GH12902)
- Bug in Series.map raises TypeError if its dtype is category or tz-aware datetime (GH12473)
- Bugs on 32bit platforms for some test comparisons (GH12972)
- Bug in index coercion when falling back from RangeIndex construction (GH12893)
- Better error message in window functions when invalid argument (e.g. a float window) is passed (GH12669)
- Bug in slicing subclassed DataFrame defined to return subclassed Series may return normal Series (GH11559)
- Bug in .str accessor methods may raise ValueError if input has name and the result is DataFrame or MultiIndex (GH12617)
- Bug in DataFrame.last_valid_index() and DataFrame.first_valid_index() on empty frames (GH12800)
• Bug in CategoricalIndex.get_loc returns different result from regular Index (GH12531)
• Bug in PeriodIndex.resample where name not propagated (GH12769)
• Bug in date_range closed keyword and timezones (GH12684).
• Bug in pd.concat raises AttributeError when input data contains tz-aware datetime and timedelta (GH12620)
• Bug in pd.concat did not handle empty Series properly (GH11082)
• Bug in .plot.bar alignment when width is specified with int (GH12979)
• Bug in fill_value is ignored if the argument to a binary operator is a constant (GH12723)
• Bug in pd.read_html() when using bs4 flavor and parsing table with a header and only one column (GH9178)
• Bug in .pivot_table when margins=True and dropna=True where nulls still contributed to margin count (GH12577)
• Bug in .pivot_table when dropna=False where table index/column names disappear (GH12133)
• Bug in pd.crosstab() when margins=True and dropna=False which raised (GH12642)
• Bug in Series.name when name attribute can be a hashable type (GH12610)
• Bug in .describe() resets categorical columns information (GH11558)
• Bug where loffset argument was not applied when calling resample().count() on a timeseries (GH12725)
• pd.read_excel() now accepts column names associated with keyword argument names (GH12870)
• Bug in pd.to_numeric() with Index returns np.ndarray, rather than Index (GH12777)
• Bug in pd.to_numeric() with datetime-like may raise TypeError (GH12777)
• Bug in pd.to_numeric() with scalar raises ValueError (GH12777)

1.14 v0.18.0 (March 13, 2016)

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas >= 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 (GH7718, GH11273)

Warning: numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (>= 2.1 and >= 2.4.6). (GH12489)

Highlights include:
• Moving and expanding window functions are now methods on Series and DataFrame, similar to .groupby, see here.
• Adding support for a RangeIndex as a specialized form of the Int64Index for memory savings, see here.
• API breaking change to the .resample method to make it more .groupby like, see here.
• Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a TypeError, see here.
• The .to_xarray() function has been added for compatibility with the xarray package, see here.
• The read_sas function has been enhanced to read sas7bdat files, see here.
• Addition of the .str.extractall() method, and API changes to the .str.extract() method and .str.cat() method.
• pd.test() top-level nose test runner is available (GH4327).

Check the API Changes and deprecations before updating.

What’s new in v0.18.0

• New features
  – Window functions are now methods
  – Changes to rename
  – Range Index
  – Changes to str.extract
  – Addition of str.extractall
  – Changes to str.cat
  – Datetimelike rounding
  – Formatting of Integers in FloatIndex
  – Changes to dtype assignment behaviors
  – to_xarray
  – Latex Representation
  – pd.read_sas() changes
  – Other enhancements

• Backwards incompatible API changes
  – NaT and Timedelta operations
  – Changes to msgpack
  – Signature change for .rank
  – Bug in QuarterBegin with n=0
  – Resample API
    * Downsampling
    * Upsampling
    * Previous API will work but with deprecations
  – Changes to eval
  – Other API Changes
  – Deprecations
1.14.1 New features

1.14.1.1 Window functions are now methods

Window functions have been refactored to be methods on Series/DataFrame objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of .groupby. See the full documentation here (GH11603, GH12373)

```python
In [1]: np.random.seed(1234)
In [2]: df = pd.DataFrame({'A': range(10), 'B': np.random.randn(10)})
In [3]: df
Out[3]:
   A   B
0  0  0.471435
1  1 -1.190976
2  2  1.432707
3  3 -0.312652
4  4 -0.720589
5  5  0.887163
6  6  0.859588
7  7 -0.636524
8  8  0.015696
9  9 -2.242685
```

Previous Behavior:

```python
In [8]: pd.rolling_mean(df, window=3)
FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be removed in a future version, replace with DataFrame.rolling(window=3, center=False).mean()
Out[8]:
    A   B
0  NaN  NaN
1  NaN  NaN
2  1  0.237722
3  2 -0.023640
4  3  0.133155
5  4 -0.048693
6  5  0.342054
7  6  0.370076
8  7  0.079587
9  8 -0.954504
```

New Behavior:

```python
In [4]: r = df.rolling(window=3)
```
These show a descriptive repr

```
In [5]: r
Out[5]: Rolling [window=3, center=False, axis=0]
```

with tab-completion of available methods and properties.

```
In [9]: r.
   ...: r.A r.agg r.apply r.count r.exclusions r.max r.
   ...: r.median r.name r.skew r.sum
   ...: r.B r.aggregate r.corr r.cov r.kurt r.mean r.
   ...: r.min r.quantile r.std r.var
```

The methods operate on the `Rolling` object itself

```
In [6]: r.mean()
Out[6]:
   A    B
  ---  ---
  0  NaN  NaN
  1 NaN   NaN
  2  1.0  0.237722
  3  2.0 -0.023640
  4  3.0  0.133155
  5  4.0 -0.048693
  6  5.0  0.342054
  7  6.0  0.370076
  8  7.0  0.079587
  9  8.0 -0.954504
```

They provide `getitem` accessors

```
In [7]: r['A'].mean()
Out[7]:
   0  NaN
   1  NaN
   2  1.0
   3  2.0
   4  3.0
   5  4.0
   6  5.0
   7  6.0
   8  7.0
   9  8.0
Name: A, dtype: float64
```

And multiple aggregations

```
In [8]: r.agg({'A' : ['mean','std'],
   ...: 'B' : ['mean','std']})
Out[8]:
   A         B
  ---  ---
  0 NaN    NaN   NaN   NaN
  1 NaN    NaN   NaN   NaN
  2  1.0   0.237722  1.327364
  3  2.0 -0.023640  1.335505
  4  3.0  0.133155  1.143778
```

(continues on next page)
5 4.0 1.0 -0.048693 0.835747
6 5.0 1.0 0.342054 0.920379
7 6.0 1.0 0.370076 0.871850
8 7.0 1.0 0.079587 0.750099
9 8.0 1.0 -0.954504 1.162285

1.14.1.2 Changes to rename

Series.rename and NDFrame.rename_axis can now take a scalar or list-like argument for altering the Series or axis name, in addition to their old behaviors of altering labels. (GH9494, GH11965)

```
In [9]: s = pd.Series(np.random.randn(5))

In [10]: s.rename('newname')
Out[10]:
0    1.150036
1     0.991946
2     0.953324
3    -2.021255
4    -0.334077
Name: newname, dtype: float64

In [11]: df = pd.DataFrame(np.random.randn(5, 2))

In [12]: (df.rename_axis("indexname")
       ....: .rename_axis("columns_name", axis="columns")
       ....:)
Out[12]:
       columns_name       0  1
   indexname
0           0.002118  0.405453
1           0.289092  1.321158
2          -1.546906 -0.202646
3           -0.655969  0.193421
4            0.553439  1.318152
```

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a label to a new label. This continues to work as before for function or dict-like values.

1.14.1.3 Range Index

A RangeIndex has been added to the Int64Index sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python range object (xrange in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to Int64Index if needed.

This will now be the default constructed index for NDFrame objects, rather than previous an Int64Index. (GH939, GH12070, GH12071, GH12109, GH12888)

Previous Behavior:

```
In [3]: s = pd.Series(range(1000))

In [4]: s.index
```

(continues on next page)
Out[4]:
Int64Index([ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
         990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
length=1000)

In [6]: s.index.nbytes
Out[6]: 8000

New Behavior:

In [13]: s = pd.Series(range(1000))
In [14]: s.index
Out[14]: RangeIndex(start=0, stop=1000, step=1)
In [15]: s.index.nbytes
Out[15]: 80

1.14.1.4 Changes to str.extract

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the `expand` argument was added to extract.

- **expand=False**: it returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- **expand=True**: it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user.

Currently the default is `expand=None` which gives a `FutureWarning` and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/DataFrame) but in a future version of pandas this will be changed to expand=True (return DataFrame)
Out[1]:
       0  1
0      1  NaN
1      2  NaN
dtype: object

Extracting a regular expression with one group returns a Series if `expand=False`.

In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=False)
Out[16]:
       0  1  2
0      1  NaN
1      2  NaN
dtype: object

It returns a DataFrame with one column if `expand=True`.

1.14. v0.18.0 (March 13, 2016)
Calling on an Index with a regex with exactly one capture group returns an Index if expand=False.

In [18]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'])

In [19]: s.index
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')

In [20]: s.index.str.extract('(?P<letter>[a-zA-Z])', expand=False)
Out[20]: Index(['A', 'B', 'C'], dtype='object', name='letter')

It returns a DataFrame with one column if expand=True.

In [21]: s.index.str.extract('(?P<letter>[a-zA-Z])', expand=True)
Out[21]:
   letter
0    A
1    B
2    C

Calling on an Index with a regex with more than one capture group raises ValueError if expand=False.

>>> s.index.str.extract('(?P<letter>[a-zA-Z])([0-9]+)', expand=False)
ValueError: only one regex group is supported with Index

It returns a DataFrame if expand=True.

In [22]: s.index.str.extract('(?P<letter>[a-zA-Z])([0-9]+)', expand=True)
Out[22]:
   letter  1
0    A   11
1    B   22
2    C   33

In summary, extract (expand=True) always returns a DataFrame with a row for every subject string, and a column for every capture group.

1.14.1.5 Addition of str.extractall

The .str.extractall method was added (GH11386). Unlike extract, which returns only the first match.

In [23]: s = pd.Series(['ala2', 'b1', 'c1'], ['A', 'B', 'C'])

In [24]: s
Out[24]:
     A    ala2
     B     b1
     C      c1
    dtype: object

(continues on next page)
The `extractall` method returns all matches.

```
In [26]: s.str.extractall("(?P<letter>[ab])(?P<digit>\d)")
```

```
Out[26]:
      letter digit    match
     A      0   a    1
     1      1   a    2
     B      0   b    1
```

### 1.14.1.6 Changes to `str.cat`

The method `.str.cat()` concatenates the members of a Series. Before, if NaN values were present in the Series, calling `.str.cat()` on it would return NaN, unlike the rest of the Series.``.str.* API. This behavior has been amended to ignore NaN values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```
In [27]: pd.Series(['a','b',np.nan,'c']).str.cat(sep=' ')
```

```
' a  b  c'
```

```
In [28]: pd.Series(['a','b',np.nan,'c']).str.cat(sep=' ', na_rep='?')
```

```
' a  b  ?  c'
```

```
In [2]: pd.Series(['a','b',np.nan,'c']).str.cat(' ')
ValueError: Did you mean to supply a `sep` keyword?
```

### 1.14.1.7 Datetimelike rounding

`DatetimeIndex`, `Timestamp`, `TimedeltaIndex`, `Timedelta` have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)
```

```
In [30]: dr
Out[30]:
dtype=’datetime64[ns]’, freq=’D’)
```

```
In [31]: dr.round(’s’)
```
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
  '2013-01-03 09:12:56'],
  dtype='datetime64[ns]', freq=None)

# Timestamp scalar
In [32]: dr[0]
Out[32]: Timestamp('2013-01-01 09:12:56.123400', freq='D')

In [33]: dr[0].round('10s')
Out[33]: Timestamp('2013-01-01 09:13:00')

Tz-aware are rounded, floored and ceiled in local times

In [34]: dr = dr.tz_localize('US/Eastern')

In [35]: dr
Out[35]: DatetimeIndex(['2013-01-01 09:12:56-05:00',
  '2013-01-02 09:12:56-05:00',
  '2013-01-03 09:12:56-05:00'],
  dtype='datetime64[ns, US/Eastern]', freq='D')

In [36]: dr.round('s')
Out[36]: DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
  '2013-01-03 09:12:56-05:00'],
  dtype='datetime64[ns, US/Eastern]', freq=None)

Timedeltas

In [37]: t = timedelta_range('1 days 2 hr 13 min 45 us',periods=3,freq='d')

In [38]: t
Out[38]: TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
  '3 days 02:13:00.000045'],
  dtype='timedelta64[ns]', freq='D')

In [39]: t.round('10min')
Out[39]: TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'],
  dtype='timedelta64[ns]', freq=None)

# Timedelta scalar
In [40]: t[0]
Out[40]: Timedelta('1 days 02:13:00.000045')

In [41]: t[0].round('2h')
Out[41]: Timedelta('1 days 02:00:00')

In addition, .round(), .floor() and .ceil() will be available thru the .dt accessor of Series.
In [42]: s = pd.Series(dr)

In [43]: s
Out[43]:
0  2013-01-01 09:12:56.123400-05:00
1  2013-01-02 09:12:56.123400-05:00
2  2013-01-03 09:12:56.123400-05:00
dtype: datetime64[ns, US/Eastern]

In [44]: s.dt.round('D')
Out[44]:
\[
\begin{array}{l}
0  2013-01-01 00:00:00-05:00 \\
1  2013-01-02 00:00:00-05:00 \\
2  2013-01-03 00:00:00-05:00 \\
\end{array}
\]
dtype: datetime64[ns, US/Eastern]

1.14.1.8 Formatting of Integers in FloatIndex

Integers in FloatIndex, e.g. 1., are now formatted with a decimal point and a 0 digit, e.g. 1.0 (GH11713) This change not only affects the display to the console, but also the output of IO methods like .to_csv or .to_html.

Previous Behavior:

In [2]: s = pd.Series([1,2,3], index=np.arange(3.))

In [3]: s
Out[3]:
0  1
1  2
2  3
dtype: int64

In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

In [5]: print(s.to_csv(path=None))
0,1
1,2
2,3

New Behavior:

In [45]: s = pd.Series([1,2,3], index=np.arange(3.))

In [46]: s
Out[46]:
0.0  1
1.0  2
2.0  3
dtype: int64

In [47]: s.index
Out[47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')

(continues on next page)
In [48]: print(s.to_csv(path=None))
→0,1
1.0,2
2.0,3

1.14.1.9 Changes to dtype assignment behaviors

When a DataFrame’s slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous Behavior:

In [5]: df = pd.DataFrame({'a': [0, 1, 1],
                      'b': pd.Series([100, 200, 300], dtype='uint32')})

In [7]: df.dtypes
Out[7]:
a     int64
b    uint32
dtype: object

In [8]: ix = df['a'] == 1
In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']
In [11]: df.dtypes
Out[11]:
a     int64
b    uint32
dtype: object

New Behavior:

In [49]: df = pd.DataFrame({'a': [0, 1, 1],
                      'b': pd.Series([100, 200, 300], dtype='uint32')})

In [50]: df.dtypes
Out[50]:
a     int64
b    uint32
dtype: object

In [51]: ix = df['a'] == 1
In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']
In [53]: df.dtypes
Out[53]:
a     int64
b    uint32
dtype: object

When a DataFrame’s integer slice is partially updated with a new slice of floats that could potentially be downcasted to integer without losing precision, the dtype of the slice will be set to float instead of integer.
Previous Behavior:

```python
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                      columns=list('abc'),
                      index=[[4,4,8], [8,10,12]])

In [5]: df
Out[5]:
     a  b  c
4  8  1  2
10 4  5  6
  8 12  7  8

In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out[8]:
     a  b  c
4  8  1  2
10 4  5  1
  8 12  7  9
```

New Behavior:

```python
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                      columns=list('abc'),
                      index=[[4,4,8], [8,10,12]])

In [55]: df
Out[55]:
     a  b  c
4  8  1  2
10 4  5  6
  8 12  7  9

In [56]: df.loc[4, 'c'] = np.array([0., 1.])

In [57]: df
Out[57]:
     a  b  c
4  8  1  2 0.0
10 4  5  1.0
  8 12  7  9.0
```

1.14.1.10 to_xarray

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the .to_xarray() method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the xarray full-documentation here.

```python
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))

In [2]: p.to_xarray()
Out[2]:
(continues on next page)```
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11]],
       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]])
Coordinates:
* items  (items) int64 0 1
* major_axis (major_axis) int64 0 1 2
* minor_axis (minor_axis) int64 0 1 2 3

1.14.1.11 Latex Representation

DataFrame has gained a .__repr_latex__() method in order to allow for conversion to latex in a ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option pd.display.latex.repr=True (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement pd.display.latex.repr=True in the first cell to have the contained DataFrame output also stored as latex.

The options display.latex.escape and display.latex.longtable have also been added to the configuration and are used automatically by the to_latex method. See the available options docs for more info.

1.14.1.12 pd.read_sas() changes

read_sas has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see here. (GH4052)

1.14.1.13 Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in Series.to_string (GH11729)
- read_excel now supports s3 urls of the format s3://bucketname/filename (GH11447)
- add support for AWS_S3_HOST env variable when reading from s3 (GH12198)
- A simple version of Panel.round() is now implemented (GH11763)
- For Python 3.x, round(DataFrame), round(Series), round(Panel) will work (GH11763)
- sys.getsizeof(obj) returns the memory usage of a pandas object, including the values it contains (GH11597)
- Series gained an is_unique attribute (GH11946)
- DataFrame.quantile and Series.quantile now accept interpolation keyword (GH10174).
- Added DataFrame.style.format for more flexible formatting of cell values (GH11692)
- DataFrame.select_dtypes now allows the np.float16 typecode (GH11990)
- pivot_table() now accepts most iterables for the values parameter (GH12017)
• Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see here
• HDFStore is now iterable: for k in store is equivalent to for k in store.keys() (GH12221).
• Add missing methods/fields to .dt for Period (GH8848)
• The entire codebase has been PEP-ified (GH12096)

1.14.2 Backwards incompatible API changes

• the leading whitespaces have been removed from the output of .to_string(index=False) method (GH11833)
• the out parameter has been removed from the Series.round() method. (GH11763)
• DataFrame.round() leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
• DataFrame.head(0) and DataFrame.tail(0) return empty frames, rather than self. (GH11937)
• Series.head(0) and Series.tail(0) return empty series, rather than self. (GH11937)
• to_msgpack and read_msgpack encoding now defaults to 'utf-8'. (GH12170)
• the order of keyword arguments to text file parsing functions (.read_csv(), .read_table(), .read_fwf()) changed to group related arguments. (GH11555)
• NaTType.isoformat now returns the string 'NaT' to allow the result to be passed to the constructor of Timestamp. (GH12300)

1.14.2.1 NaT and Timedelta operations

NaT and Timedelta have expanded arithmetic operations, which are extended to Series arithmetic where applicable. Operations defined for datetime64[ns] or timedelta64[ns] are now also defined for NaT (GH11564). NaT now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
Out[59]: NaT

In [60]: pd.NaT / 2
Out[60]: NaT

In [61]: pd.NaT * np.nan
Out[61]: NaT
```

NaT defines more arithmetic operations with datetime64[ns] and timedelta64[ns].

```
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

NaT may represent either a datetime64[ns] null or a timedelta64[ns] null. Given the ambiguity, it is treated as a timedelta64[ns], which allows more operations to succeed.
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [64]: pd.NaT + pd.NaT
Out[64]: NaT

# same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')

as opposed to

In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'

However, when wrapped in a Series whose dtype is datetime64[ns] or timedelta64[ns], the dtype information is respected.

In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction,
but the operator [__add__] was passed

In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0  NaT
dtype: timedelta64[ns]

Timedelta division by floats now works.

In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')

Subtraction by Timedelta in a Series by a Timestamp works (GH11925)

In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out[69]:
0  1 days
1  2 days
2  3 days
dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0  2011-12-31
1  2011-12-30
2  2011-12-29
dtype: datetime64[ns]

NaT.isoformat() now returns 'NaT'. This change allows pd.Timestamp to rehydrate any timestamp like object from its isoformat (GH12300).

1.14.2.2 Changes to msgpack

Forward incompatible changes in msgpack writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527)

Bugs in to_msgpack and read_msgpack introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

202 Chapter 1. What's New
Warning:

<table>
<thead>
<tr>
<th>Packed with</th>
<th>Can be unpacked with</th>
</tr>
</thead>
<tbody>
<tr>
<td>pre-0.17 / Python 2</td>
<td>any</td>
</tr>
<tr>
<td>pre-0.17 / Python 3</td>
<td>any</td>
</tr>
<tr>
<td>0.17 / Python 2</td>
<td>• ==0.17 / Python 2</td>
</tr>
<tr>
<td></td>
<td>• &gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.17 / Python 3</td>
<td>&gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.18</td>
<td>&gt;= 0.18</td>
</tr>
</tbody>
</table>

0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

1.14.2.3 Signature change for .rank

Series.rank and DataFrame.rank now have the same signature (GH11759)

Previous signature

```python
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                  ascending=True, pct=False)
Out[3]:
          0
0 1
1 2
dtype: float64
```

```python
In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                              method='average', na_option='keep',
                              ascending=True, pct=False)
Out[4]:
     0
  0 1
  1 2
```

New signature

```python
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
                              ....: na_option='keep', ascending=True, pct=False)
Out[71]:
          0
0 1.0
1 2.0
dtype: float64
```

```python
In [72]: pd.DataFrame([0,1]).rank(axis=0, method='average', numeric_only=None,
                              ....: na_option='keep', ascending=True, pct=False)
```

1.14. v0.18.0 (March 13, 2016)
1.14.2.4 Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the \( n \) parameter was 0. (GH11406)

The general semantics of anchored offsets for \( n=0 \) is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

```python
In [73]: d = pd.Timestamp('2014-02-01')
In [74]: d
Out[74]: Timestamp('2014-02-01 00:00:00')
In [75]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[75]: Timestamp('2014-02-01 00:00:00')

In [76]: d + pd.offsets.QuarterBegin(n=0, startingMonth=1)
Out[76]: Timestamp('2014-04-01 00:00:00')
```

For the QuarterBegin offset in previous versions, the date would be rolled backwards if date was in the same month as the quarter start date.

```python
In [3]: d = pd.Timestamp('2014-02-15')
In [4]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[4]: Timestamp('2014-02-01 00:00:00')
```

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like MonthBegin and YearBegin.

```python
In [77]: d = pd.Timestamp('2014-02-15')
In [78]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[78]: Timestamp('2014-05-01 00:00:00')
```

1.14.2.5 Resample API

Like the change in the window functions API above, .resample(...) is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).

```python
In [79]: np.random.seed(1234)
In [80]: df = pd.DataFrame(np.random.rand(10,4),
                                 columns=list('ABCD'),
                                 index=pd.date_range('2010-01-01 09:00:00', periods=10, freq='s'))
In [81]: df
Out[81]:
       A         B         C         D
2010-01-01 09:00:00  0.191519  0.622109  0.437728  0.785359
2010-01-01 09:00:01  0.779976  0.272593  0.276464  0.801872
2010-01-01 09:00:02  0.958139  0.875933  0.357817  0.500995
2010-01-01 09:00:03  0.683463  0.712702  0.370251  0.561196
(continues on next page)
Previous API:

You would write a resampling operation that immediately evaluates. If a how parameter was not provided, it would default to how='mean'.

```
In [6]: df.resample('2s')
Out[6]:
     A     B     C     D
2010-01-01 09:00:00 0.485748 0.447351 0.357096 0.793615
2010-01-01 09:00:02 0.820801 0.794317 0.364034 0.531096
2010-01-01 09:00:04 0.433985 0.314582 0.424104 0.625733
2010-01-01 09:00:06 0.624988 0.609738 0.633165 0.612452
2010-01-01 09:00:08 0.510470 0.534317 0.573201 0.806949
```

You could also specify a how directly

```
In [7]: df.resample('2s', how='sum')
Out[7]:
     A     B     C     D
2010-01-01 09:00:00 0.971495 0.894701 0.714192 1.587231
2010-01-01 09:00:02 1.641602 1.588635 0.728068 1.062191
2010-01-01 09:00:04 0.867969 0.629165 0.633165 0.612452
2010-01-01 09:00:06 1.249976 1.219477 1.266330 1.224904
2010-01-01 09:00:08 1.020940 1.068634 1.146402 1.613897
```

New API:

Now, you can write `df.resample(...)` as a 2-stage operation like `df.groupby(...).`, which yields a Resampler.

```
In [82]: r = df.resample('2s')
In [83]: r
Out[83]: DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, label=left, →convention=start, base=0]
```

Downsampling

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```
In [84]: r.mean()
Out[84]:
     A     B     C     D
2010-01-01 09:00:00 0.485748 0.447351 0.357096 0.793615
2010-01-01 09:00:02 0.820801 0.794317 0.364034 0.531096
2010-01-01 09:00:04 0.433985 0.314582 0.424104 0.625733
2010-01-01 09:00:06 0.624988 0.609738 0.633165 0.612452
2010-01-01 09:00:08 0.510470 0.534317 0.573201 0.806949
```
Furthermore, resample now supports `getitem` operations to perform the resample on specific columns.

```python
In [86]: r[['A','C']].mean()
Out[86]:
A    C
2010-01-01 09:00:00 0.485748 0.357096
2010-01-01 09:00:02 0.820801 0.364034
2010-01-01 09:00:04 0.433985 0.424104
2010-01-01 09:00:06 0.624988 0.633165
2010-01-01 09:00:08 0.510470 0.573201
```

and `.aggregate` type operations.

```python
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
Out[87]:
A   B
2010-01-01 09:00:00 0.485748 0.894701
2010-01-01 09:00:02 0.820801 1.588635
2010-01-01 09:00:04 0.433985 0.633165
2010-01-01 09:00:06 0.624988 1.219477
2010-01-01 09:00:08 0.510470 1.068634
```

These accessors can of course, be combined

```python
In [88]: r[['A','B']].agg(['mean','sum'])
Out[88]:
A      B
mean   sum
2010-01-01 09:00:00 0.485748 0.971495 0.447351 0.894701
2010-01-01 09:00:02 0.820801 1.641602 0.794317 1.588635
2010-01-01 09:00:04 0.433985 0.867969 0.314582 0.633165
2010-01-01 09:00:06 0.624988 1.249976 0.609738 1.219477
2010-01-01 09:00:08 0.510470 1.020940 0.534317 1.068634
```

### Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the `Resampler` objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```python
In [89]: s = pd.Series(np.arange(5,dtype='int64'),
          index=date_range('2010-01-01', periods=5, freq='Q'))

In [90]: s
Out[90]:
2010-03-31  0
(continues on next page)
```
Previously

```python
In [6]: s.resample('M', fill_method='ffill')
Out[6]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, dtype: int64
```

New API

```python
In [91]: s.resample('M').ffill()
Out[91]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, dtype: int64
```

**Note:** In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like `mean`) even though you were upsampling, providing a bit of confusion.

**Previous API will work but with deprecations**

**Warning:** This new API for resample includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the resample operation returns a deferred object. We can intercept operations...
and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')

In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred operation
  use .resample(...).mean() instead of .resample(...)
```

```
Out[6]:
          A         B         C         D
2010-01-01 09:00:00 4.857476 4.473507 3.570960 7.936154
2010-01-01 09:00:02 8.208011 7.943173 3.640340 5.310957
2010-01-01 09:00:04 4.339846 3.145823 4.241039 6.257326
2010-01-01 09:00:06 6.249881 6.097384 6.331650 6.124518
2010-01-01 09:00:08 5.104699 5.343172 5.732009 8.069486
```

However, getting and assignment operations directly on a `Resampler` will raise a `ValueError`:

```
In [7]: r.iloc[0] = 5
ValueError: .resample() is now a deferred operation
  use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the `mean` AND then take the `min` of those results.

```
In [4]: df.resample('2s').min()
```

```
Out[4]:
          A         B         C         D
2010-01-01 09:00:00 0.433985 0.314582 0.357096 0.531096
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

```
Out[92]:
          A         B         C         D
2010-01-01 09:00:00 0.191519 0.272593 0.276464 0.785359
2010-01-01 09:00:02 0.683463 0.712702 0.357817 0.500995
2010-01-01 09:00:04 0.364886 0.013768 0.075381 0.368824
2010-01-01 09:00:06 0.316836 0.568099 0.397203 0.436173
2010-01-01 09:00:08 0.218792 0.143767 0.442141 0.704581
dtype: float64
```

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
```

```
Out[93]:
          A         B         C         D
0 0.433985 0.314582 0.357096 0.531096
dtype: float64
```
1.14.2.6 Changes to eval

In prior versions, new columns assignments in an eval expression resulted in an inplace change to the DataFrame. (GH9297, GH8664, GH10486)

```
In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})
```

```
In [95]: df
Out[95]:
   a  b
0  0  0
1  2.5 1
2  5.0 2
3  7.5 3
4 10.0 4
```

```
In [12]: df.eval('c = a + b')

FutureWarning: eval expressions containing an assignment currently default to operating inplace.
This will change in a future version of pandas, use inplace=True to avoid this warning.
```

```
In [13]: df
Out[13]:
    a  b  c
0  0.0 0  0.0
1  2.5 1  3.5
2  5.0 2  7.0
3  7.5 3 10.5
4 10.0 4 14.0
```

In version 0.18.0, a new inplace keyword was added to choose whether the assignment should be done inplace or return a copy.

```
In [96]: df
Out[96]:
   a  b  c
0  0.0 0  0.0
1  2.5 1  3.5
2  5.0 2  7.0
3  7.5 3 10.5
4 10.0 4 14.0
```

```
In [97]: df.eval('d = c - b', inplace=False)

 In [98]: df
```

(continues on next page)
In [99]: df.eval('d = c - b', inplace=True)

In [100]: df
Out[100]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>1</td>
<td>2.5</td>
<td>1.0</td>
<td>3.5</td>
<td>2.5</td>
</tr>
<tr>
<td>2</td>
<td>5.0</td>
<td>2.0</td>
<td>7.0</td>
<td>5.0</td>
</tr>
<tr>
<td>3</td>
<td>7.5</td>
<td>3.0</td>
<td>10.5</td>
<td>7.5</td>
</tr>
<tr>
<td>4</td>
<td>10.0</td>
<td>4.0</td>
<td>14.0</td>
<td>10.0</td>
</tr>
</tbody>
</table>

Warning: For backwards compatibility, inplace defaults to True if not specified. This will change in a future version of pandas. If your code depends on an inplace assignment you should update to explicitly set inplace=True.

The inplace keyword parameter was also added the query method.

In [101]: df.query('a > 5')
Out[101]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>7.5</td>
<td>3.0</td>
<td>10.5</td>
<td>7.5</td>
</tr>
<tr>
<td>4</td>
<td>10.0</td>
<td>4.0</td>
<td>14.0</td>
<td>10.0</td>
</tr>
</tbody>
</table>

In [102]: df.query('a > 5', inplace=True)

In [103]: df
Out[103]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>7.5</td>
<td>3.0</td>
<td>10.5</td>
<td>7.5</td>
</tr>
<tr>
<td>4</td>
<td>10.0</td>
<td>4.0</td>
<td>14.0</td>
<td>10.0</td>
</tr>
</tbody>
</table>

Warning: Note that the default value for inplace in a query is False, which is consistent with prior versions.

eval has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

In [104]: df
Out[104]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>7.5</td>
<td>3.0</td>
<td>10.5</td>
<td>7.5</td>
</tr>
<tr>
<td>4</td>
<td>10.0</td>
<td>4.0</td>
<td>14.0</td>
<td>10.0</td>
</tr>
</tbody>
</table>

In [105]: df.eval(""
......: e = d + a
......: f = e - 22
......: g = f / 2.0"", inplace=True)
1.14.2.7 Other API Changes

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```python
In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H', periods=10))
In [108]: s.between_time('7:00am', '9:00am')
Out [108]:
2015-01-01 07:00:00    7
2015-01-01 08:00:00    8
2015-01-01 09:00:00    9
Freq: H, dtype: int64
```

This will now raise,

```python
In [2]: s.between_time('20150101 07:00:00','20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.
```

- `.memory_usage()` now includes values in the index, as does `memory_usage` in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (e.g., `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
- `DataFrame.unstack` and `Series.unstack` now take `fill_value` keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting `DataFrame`. As an added benefit, specifying `fill_value` will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for `window functions` and `resampling`, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in `groupby`.
- Statistical functions for `NDFrame` objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for **kwargs (GH12301)
- `.to_latex` and `.to_html` gain a `decimal` parameter like `.to_csv`; the default is `', '` (GH12031)
- More helpful error message when constructing a `DataFrame` with empty data but with indices (GH8020)
- `.describe()` will now properly handle bool dtype as a categorical (GH6625)
- More helpful error message with an invalid .transform with user defined input (GH10165)
- Exponentially weighted functions now allow specifying alpha directly (GH10789) and raise `ValueError` if parameters violate $0 < \alpha \leq 1$ (GH12492)
1.14.2.8 Deprecations

- The functions `pd.rolling_*`, `pd.expanding_*`, and `pd.ewm*` are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) (GH11603)

```python
In [1]: s = pd.Series(range(3))
In [2]: pd.rolling_mean(s,window=2,min_periods=1)
   FutureWarning: pd.rolling_mean is deprecated for Series and
   will be removed in a future version, replace with
   Series.rolling(min_periods=1,window=2,center=False).mean()
Out[2]:
   0    0.0
   1    0.5
   2    1.5
   dtype: float64
```

In [3]: `pd.rolling_cov(s, s, window=2)
   FutureWarning: pd.rolling_cov is deprecated for Series and
   will be removed in a future version, replace with
   Series.rolling(window=2).cov(other=<Series>)
Out[3]:
   0   NaN
   1    0.5
   2    0.5
   dtype: float64

- The `freq` and `how` arguments to the `.rolling`, `.expanding`, and `.ewm` (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. (GH11603).

For example, instead of `s.rolling(window=5,freq='D').max()` to get the max value on a rolling 5 Day window, one could use `s.resample('D').mean().rolling(window=5).max()`, which first resamples the data to daily data, then provides a rolling 5 day window.

- `pd.tseries.frequencies.get_offset_name` function is deprecated. Use offset’s `.freqstr` property as alternative (GH11912)
- `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version (GH6077)
- `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version (GH6077)
- show a FutureWarning rather than a DeprecationWarning on using long-time deprecated syntax in HDFStore.select, where the where clause is not a string-like (GH12027)
- The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib’s style sheets (GH11783).

1.14.2.9 Removal of deprecated float indexers

In GH4892 indexing with floating point numbers on a non-Float64Index was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a TypeError. (GH12165, GH12333)

```python
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])
In [110]: s
```
Out[110]:
4 1
5 2
6 3
dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2
Out[112]:
a 1
b 2
c 3
dtype: int64

Previous Behavior:

# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[2]: 2

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[3]: 2

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[4]: 2

# .ix would coerce 1.0 to the positional 1, and index
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not floating point

In [6]: s2
Out[6]:
a 1
b 10
c 3
dtype: int64

New Behavior:

For iloc, getting & setting via a float scalar will always raise.

In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'> with these indexers [2.0] of <type 'float'>

Other indexers will coerce to a like integer for both getting and setting. The FutureWarning has been dropped for .loc,.ix and [].
and setting

```python
In [115]: s_copy = s.copy()
In [116]: s_copy[5.0] = 10
In [117]: s_copy
Out[117]:
4   1
5  10
6   3
dtype: int64
```

```python
In [118]: s_copy = s.copy()
In [119]: s_copy.loc[5.0] = 10
In [120]: s_copy
Out[120]:
4   1
5  10
6   3
dtype: int64
```

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

```python
In [3]: s2.ix[1.0] = 10
In [4]: s2
Out[4]:
a   1
b   2
c   3
1.0 10
dtype: int64
```

Slicing will also coerce integer-like floats to integers for a non-`Float64Index`.

```python
In [121]: s.loc[5.0:6]
Out[121]:
5   2
6   3
dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```python
In [122]: s.loc[5.1:6]
Out[122]:
6   3
dtype: int64
```

Float indexing on a `Float64Index` is unchanged.
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))

In [124]: s[1.0]
Out[124]: 2

In [125]: s[1.0:2.5]
Out[125]:
1.0  2
2.0  3
dtype: int64

1.14.2.10 Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `rolling().corr(pairwise=True)` (GH4950)
- Removal of `expanding_corr_pairwise` in favor of `expanding().corr(pairwise=True)` (GH4950)
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event (GH12111)
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` (GH6680)
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 (GH6292).
- Removal of the `order` keyword from `.factorize()` (GH6930)

1.14.3 Performance Improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` (GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with whitespace preceding the time zone (GH9714)

1.14.4 Bug Fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
- Regression in `.clip` with tz-aware datetimes (GH11838)
- Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
- Bug in consistency of passing nested dicts to `.groupby(...)`.agg(...) (GH9052)
- Accept unicode in `Timedelta` constructor (GH11995)
• Bug in value label reading for StataReader when reading incrementally (GH12014)
• Bug in vectorized DateOffset when n parameter is 0 (GH11370)
• Compat for numpy 1.11 w.r.t. NaT comparison changes (GH12049)
• Bug in read_csv when reading from a StringIO in threads (GH11790)
• Bug in not treating NaT as a missing value in datetimelikes when factorizing & with Categoricals (GH12077)
• Bug in getitem when the values of a Series were tz-aware (GH12089)
• Bug in Series.str.get_dummies when one of the variables was ‘name’ (GH12180)
• Bug in pd.concat while concatenating tz-aware NaT series. (GH11693, GH11755, GH12217)
• Bug in pd.read_stata with version <= 108 files (GH12232)
• Bug in Series.resample using a frequency of Nano when the index is a DatetimeIndex and contains non-zero nanosecond parts (GH12037)
• Bug in resampling with .nunique and a sparse index (GH12352)
• Removed some compiler warnings (GH12471)
• Work around compat issues with boto in python 3.5 (GH11915)
• Bug in NaT subtraction from Timestamp or DatetimeIndex with timezones (GH11718)
• Bug in subtraction of Series of a single tz-aware Timestamp (GH12290)
• Use compat iterators in PY2 to support .next() (GH12299)
• Bug in Timedelta.round with negative values (GH11690)
• Bug in .loc against CategoricalIndex may result in normal Index (GH11586)
• Bug in DataFrame.info when duplicated column names exist (GH11761)
• Bug in .copy of datetime tz-aware objects (GH11794)
• Bug in Series.apply and Series.map where timedelta64 was not boxed (GH11349)
• Bug in DataFrame.set_index() with tz-aware Series (GH12358)
• Bug in subclasses of DataFrame where AttributeError did not propagate (GH11808)
• Bug groupby on tz-aware data where selection not returning Timestamp (GH11616)
• Bug in pd.read_clipboard and pd.to_clipboard functions not supporting Unicode; upgrade included pyperclip to v1.5.15 (GH9263)
• Bug in DataFrame.query containing an assignment (GH8664)
• Bug in from_msgpack where __contains__() fails for columns of the unpacked DataFrame, if the DataFrame has object columns. (GH11880)
• Bug in .resample on categorical data with TimedeltaIndex (GH12169)
• Bug in timezone info lost when broadcasting scalar datetime to DataFrame (GH11682)
• Bug in Index creation from Timestamp with mixed tz coerces to UTC (GH11488)
• Bug in to_numeric where it does not raise if input is more than one dimension (GH11776)
• Bug in parsing timezone offset strings with non-zero minutes (GH11708)
• Bug in df.plot using incorrect colors for bar plots under matplotlib 1.5+ (GH11614)
• Bug in the `groupbyplot` method when using keyword arguments (GH11805).
• Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` (GH11864)
• Bug in `.loc` result with duplicated key may have `Index` with incorrect dtype (GH11497)
• Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
• Bug in `DataFrame.style` with spurious zeros (GH12134)
• Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
• Bug in `.style.bar` may not rendered properly using specific browser (GH11678)
• Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
• Bug in `DataFrame.round` dropping column index name (GH11986)
• Bug in `.replace` while replacing value in mixed dtype DataFrame (GH11698)
• Bug in `.loc` prevents copying name of passed `Index`, when a new name is not provided (GH11193)
• Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
• Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
• Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
• Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
• Bug in `Int64Index` and `Float64Index` preventing the use of the modulo operator (GH9244)
• Bug in `MultiIndex.drop` for not lexsorted multi-indexes (GH12078)
• Bug in `DataFrame` when masking an empty DataFrame (GH11859)
• Bug in `.plot` potentially modifying the `colors` input when the number of columns didn’t match the number of series provided (GH12039).
• Bug in `Series.plot` failing when index has a `CustomBusinessDay` frequency (GH7222).
• Bug in `.to_sql` for `datetime.time` values with sqlite fallback (GH8341)
• Bug in `read_excel` failing to read data with one column when `squeeze=True` (GH12157)
• Bug in `read_excel` failing to read one empty column (GH12292, GH9002)
• Bug in `.groupby` where a `KeyError` was not raised for a wrong column if there was only one row in the dataframe (GH11741)
• Bug in `.read_csv` with `dtype` specified on empty data producing an error (GH12048)
• Bug in `.read_csv` where strings like '2E' are treated as valid floats (GH12237)
• Bug in building `pandas` with debugging symbols (GH12123)
• Removed `millisecond` property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
• Bug in `Series` constructor with read-only data (GH11502)
• Removed `pandas.util.testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)
• Bug in `.loc` setitem indexer preventing the use of a TZ-aware DatetimeIndex (GH12050)
• Bug in `.style` indexes and multi-indexes not appearing (GH11655)
• Bug in `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize NaT (GH12307).
• Bug in `.skew` and `.kurt` due to roundoff error for highly similar values (GH11974)
• Bug in `Timestamp` constructor where microsecond resolution was lost if HHMMSS were not separated with `:` (GH10041)
• Bug in `buffer_rd_bytes` src->buffer could be freed more than once if reading failed, causing a segfault (GH12098)
• Bug in `crosstab` where arguments with non-overlapping indexes would return a `KeyError` (GH10291)
• Bug in `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a `numpy` dtype (GH12244)
• Bug when initializing categorical series with a scalar value. (GH12336)
• Bug when specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` (GH11934)
• Bug when increasing the buffer size of CSV reader in `read_csv` (GH12494)
• Bug when setting columns of a `DataFrame` with duplicate column names (GH12344)

1.15 v0.17.1 (November 21, 2015)

Note: We are proud to announce that pandas has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of pandas as a world-class open-source project.

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

• Support for Conditional HTML Formatting, see here
• Releasing the GIL on the csv reader & other ops, see here
• Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)

What's new in v0.17.1

• New features
  – Conditional HTML Formatting
• Enhancements
• API changes
  – Deprecations
• Performance Improvements
• Bug Fixes
1.15.1 New features

1.15.1.1 Conditional HTML Formatting

**Warning:** This is a new feature and is under active development. We’ll be adding features and possibly making breaking changes in future releases. Feedback is welcome.

We’ve added experimental support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the `pandas.DataFrame.style`, attribute, an instance of Styler with your data attached.

Here’s a quick example:

```python
In [1]: np.random.seed(123)
In [2]: df = DataFrame(np.random.randn(10, 5), columns=list('abcde'))
In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)
```

We can render the HTML to get the following table.

Styler interacts nicely with the Jupyter Notebook. See the documentation for more.

1.15.2 Enhancements

- DatetimeIndex now supports conversion to strings with `astype(str)` (GH10442)
- Support for compression (gzip/bz2) in `pandas.DataFrame.to_csv()` (GH7615)
- `pd.read_*` functions can now also accept `pathlib.Path` or `py._path.local.LocalPath` objects for the `filepath_or_buffer` argument. (GH1033) - The DataFrame and Series functions `.to_csv()`, `.to_html()` and `.to_latex()` can now handle paths beginning with tildes (e.g. ~/Documents/) (GH11438)
- DataFrame now uses the fields of a namedtuple as columns, if columns are not supplied (GH11181)
- `DataFrame.itertuples()` now returns namedtuple objects, when possible. (GH11269, GH11625)
- Added `axvlines_kwds` to parallel coordinates plot (GH10709)
- Option to `.info()` and `.memory_usage()` to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```python
In [4]: df = DataFrame({'A' : ['foo']]*1000)
In [5]: df['B'] = df['A'].astype('category')

# shows the '+' as we have object dtypes
In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
A 1000 non-null object
B 1000 non-null category
dtypes: category(1), object(1)
memory usage: 9.0+ KB
```

(continues on next page)
# Chapter 1. What's New

---

# we have an accurate memory assessment (but can be expensive to compute this)

```
In [7]: df.info(memory_usage='deep')
```

```python
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
A 1000 non-null object  
B 1000 non-null category  
dtypes: category(1), object(1)  
memory usage: 75.4 KB
```

- **Index** now has a `fillna` method (GH10089)

```
In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out[8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')
```

- Series of type **category** now make `.str.<...>` and `.dt.<...>` accessor methods / properties available, if the categories are of that type. (GH10661)

```
In [9]: s = pd.Series(list('aabb')).astype('category')
In [10]: s
Out[10]:
0   a
1   a
2   b
3   b
dtype: category
Categories (2, object): [a, b]
In [11]: s.str.contains("a")
```

```
True  
0 1 2 3
```

```
In [12]: date = pd.Series(pd.date_range('1/1/2015', periods=5)).astype('category')
In [13]: date
Out[13]:
0   2015-01-01
1   2015-01-02
2   2015-01-03
3   2015-01-04
4   2015-01-05
```

```
```

```
In [14]: date.dt.day
```

(continues on next page)
• **pivot_table** now has a `margins_name` argument so you can use something other than the default of ‘All’ (GH3335)

• Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store (GH11411)

• Pretty printing sets (e.g. in DataFrame cells) now uses set literal syntax (`{x, y}`) instead of Legacy Python syntax (`set([x, y])`) (GH11215)

• Improve the error message in pandas.io.gbq.to_gbq() when a streaming insert fails (GH11285) and when the DataFrame does not match the schema of the destination table (GH11359)

### 1.15.3 API changes

• raise `NotImplementedError` in `Index.shift` for non-supported index types (GH8038)

• `min` and `max` reductions on `datetime64` and `timedelta64` typed series now result in `NaT` and not `nan` (GH11245).

• Indexing with a null key will raise a `TypeError`, instead of a `ValueError` (GH11356)

• `Series.ptp` will now ignore missing values by default (GH11163)

#### 1.15.3.1 Deprecations

• The pandas.io.ga module which implements google-analytics support is deprecated and will be removed in a future version (GH11308)

• Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version (GH11274)

### 1.15.4 Performance Improvements

• Checking monotonic-ness before sorting on an index (GH11080)

• `Series.dropna` performance improvement when its dtype can’t contain `NaN` (GH11159)

• Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` (GH11263)

• Release the GIL on some rolling algos: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` (GH11450)

• Release the GIL when reading and parsing text files in `read_csv`, `read_table` (GH11272)

• Improved performance of `rolling_median` (GH11450)

• Improved performance of `to_excel` (GH11352)

• Performance bug in repr of `Categorical` categories, which was rendering the strings before chopping them for display (GH11305)
• Performance improvement in `Categorical.remove_unused_categories`, (GH11643).
• Improved performance of `Series` constructor with no data and `DatetimeIndex` (GH11433)
• Improved performance of `shift`, `cumprod`, and `cumsum with groupby` (GH4095)

1.15.5 Bug Fixes

• `SparseArray.__iter__()` now does not cause `PendingDeprecationWarning` in `Python 3.5` (GH11622)
• Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
• `Series.sort_index()` now correctly handles the `inplace` option (GH11402)
• Incorrectly distributed .c file in the build on PyPi when reading a csv of floats and passing `na_values=<a scalar>` would show an exception (GH11374)
• Bug in `.to_latex()` output broken when the index has a name (GH10660)
• Bug in HDFStore.append with strings whose encoded length exceeded the max unencoded length (GH11234)
• Bug in merging `datetime64[ns, tz]` dtypes (GH11405)
• Bug in HDFStore.select when comparing with a numpy scalar in a where clause (GH11283)
• Bug in using DataFrame.ix with a multi-index indexer (GH11372)
• Bug in `date_range` with ambiguous endpoints (GH11626)
• Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. (GH10673)
• Bug in tz-conversions with an ambiguous time and `.dt` accessors (GH11295)
• Bug in output formatting when using an index of ambiguous times (GH11619)
• Bug in comparisons of Series vs list-likes (GH11339)
• Bug in DataFrame.replace with a `datetime64[ns, tz]` and a non-compat `to_replace` (GH11326, GH11153)
• Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null(GH11206)
• Bug in list-like indexing with a mixed-integer Index (GH11320)
• Bug in `pivot_table` with `margins=True` when indexes are of `Categorical` dtype (GH10993)
• Bug in DataFrame.plot cannot use hex strings colors (GH10299)
• Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)
• Bug in `pd.eval` where unary ops in a list error (GH11235)
• Bug in `squeeze()` with zero length arrays (GH11230, GH8999)
• Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
• Bug in `DataFrame.pct_change()` not propagating axis keyword on `.fillna` method (GH11150)
• Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter (GH11637)
• Bug in indexing with a range, (GH11652)
• Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
• Bug in `to_sql` using unicode column names giving UnicodeEncodeError with (GH11431).
• Fix regression in setting of `xticks` in `plot` (GH11529).
• Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
• Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
• Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
• Bug in `df.groupby(...).apply(func)` when a func returns a `Series` containing a new datetimelike column (GH11324)
• Bug in `pandas.json` when file to load is big (GH11344)
• Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
• Fixed a bug that prevented the construction of an empty series of dtype `datetime64[ns, tz]` (GH11245).
• Bug in `read_excel` with multi-index containing integers (GH11317)
• Bug in `to_excel` with openpyxl 2.2+ and merging (GH11408)
• Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only datetime is present in data (GH11327)
• Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for DataFrames with boolean and not boolean columns (GH11560)
• Bug in the link-time error caused by `C inline` functions on FreeBSD 10+ (with clang) (GH10510)
• Bug in `DataFrame.to_csv` in passing through arguments for formatting MultiIndexes, including `date_format` (GH7791)
• Bug in `DataFrame.join()` with `how='right'` producing a `TypeError` (GH11519)
• Bug in `Series.quantile` with empty list results has `Index` with `object` dtype (GH11588)
• Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)
• Bug in `Categorical.remove_unused_categories` when having `NaN` values (GH11599)
• Bug in `DataFrame.to_sparse()` loses column names for MultiIndexes (GH11600)
• Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
• Bug in `DataFrame.round()` with `decimals` being a non-unique indexed Series producing extra columns (GH11618)

### 1.16 v0.17.0 (October 9, 2015)

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)
Warning: The pandas.io.data package is deprecated and will be replaced by the pandas-datareader package. This will allow the data modules to be independently updated to your pandas installation. The API for pandas-datareader v0.1.1 is exactly the same as in pandas v0.17.0 (GH8961, GH10861).

After installing pandas-datareader, you can easily change your imports:

```python
from pandas.io import data, wb
```

becomes

```python
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#).
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#).
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#).
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#).
- The default for `to_datetime` will now be to `raise` when presented with unparsable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#).
- The default for `dropna` in HDFStore has changed to `False`, to store by default all rows even if they are all NaN, see [here](#).
- Datetime accessor (dt) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the timedelta in seconds. See [here](#).
- Period and PeriodIndex can handle multiplied freq like 3D, which corresponding to 3 days span. See [here](#).
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518).
- Development support for benchmarking with the Air Speed Velocity library (GH8361).
- Support for reading SAS xport files, see [here](#).
- Documentation comparing SAS to pandas, see [here](#).
- Removal of the automatic TimeSeries broadcasting, deprecated since 0.8.0, see [here](#).
- Display format with plain text can optionally align with Unicode East Asian Width, see [here](#).
- Compatibility with Python 3.5 (GH11097).
- Compatibility with matplotlib 1.5.0 (GH11111).

Check the API Changes and deprecations before updating.

---

What’s new in v0.17.0

- New features
  - Datetime with TZ
  - Releasing the GIL
  - Plot submethods
  - Additional methods for dt accessor
    - `strftime`
* total_seconds
  - Period Frequency Enhancement
  - Support for SAS XPORT files
  - Support for Math Functions in .eval()
  - Changes to Excel with MultiIndex
  - Google BigQuery Enhancements
  - Display Alignment with Unicode East Asian Width
  - Other enhancements

• Backwards incompatible API changes
  - Changes to sorting API
  - Changes to to_datetime and to_timedelta
  * Error handling
  * Consistent Parsing
  - Changes to Index Comparisons
  - Changes to Boolean Comparisons vs. None
  - HDFStore dropna behavior
  - Changes to display.precision option
  - Changes to Categorical.unique
  - Changes to bool passed as header in Parsers
  - Other API Changes
  - Deprecations
  - Removal of prior version deprecations/changes

• Performance Improvements

• Bug Fixes

1.16.1 New features

1.16.1.1 Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously could be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number rows. See the docs for more details. (GH8260, GH10763, GH11034).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

In [1]: df = DataFrame({'A' : date_range('20130101', periods=3),
...:                   'B' : date_range('20130101', periods=3, tz='US/Eastern'),
...:                   'C' : date_range('20130101', periods=3, tz='CET'))
...:

In [2]: df

(continues on next page)
```python
Out[2]:
   A          B          C
0 2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00+01:00
1 2013-01-02 2013-01-02 00:00:00-05:00 2013-01-02 00:00:00+01:00
2 2013-01-03 2013-01-03 00:00:00-05:00 2013-01-03 00:00:00+01:00

In [3]: df.dtypes
A  datetime64[ns]
B  datetime64[ns, US/Eastern]
C  datetime64[ns, CET]
dtype: object
```

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```python
In [4]: df.B
Out[4]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
Name: B, dtype: datetime64[ns, US/Eastern]
```

```python
In [5]: df.B.dt.tz_localize(None)
Out[5]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
Name: B, dtype: datetime64[ns]
```

```
Note: There is a slightly different string repr for the underlying DatetimeIndex as a result of the dtype changes, but functionally these are the same.

Previous Behavior:
```
In [1]: pd.date_range('20130101',periods=3,tz='US/Eastern')
Out[1]: DatetimeIndex([ '2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                        '2013-01-03 00:00:00-05:00'],
                       dtype='datetime64[ns]', freq='D', tz='US/Eastern')
```

```
In [2]: pd.date_range('20130101',periods=3,tz='US/Eastern').dtype
Out[2]: dtype('<M8[ns]')
```

New Behavior:
```
In [8]: pd.date_range('20130101',periods=3,tz='US/Eastern')
Out[8]:
```

1.16.1.2 Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably groupby, nsmallest, value_counts and some indexing operations benefit from this. (GH8882)

For example the groupby expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```python
N = 1000000
ngroups = 10
df = DataFrame({'key' : np.random.randint(0,ngroups,size=N),
                'data' : np.random.randn(N) })

df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. QT), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the dask library.

1.16.1.3 Plot submethods

The Series and DataFrame `.plot()` method allows for customizing plot types by supplying the `kind` keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`:

```python
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])

In [11]: df.plot.bar()
```
As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB>
df.plot.area  df.plot.barh  df.plot.density  df.plot.hist  df.plot.line
  → df.plot.scatter
df.plot.bar  df.plot.box  df.plot.hexbin  df.plot.kde  df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new Plotting API documentation.

### 1.16.1.4 Additional methods for `dt` accessor

**strftime**

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
# DatetimeIndex
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))

In [14]: s
Out[14]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
dtype: datetime64[ns]

In [15]: s.dt.strftime('%Y/%m/%d')
Out[15]:
0  2013/01/01
```

(continues on next page)
1. PeriodIndex

```python
In [16]: s = pd.Series(pd.period_range('20130101', periods=4))
```

```python
In [17]: s
Out[17]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: object
```

```python
In [18]: s.dt.strftime('%Y/%m/%d')
```

```python
Out[18]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

The string format is as the python standard library and details can be found here

**total_seconds**

`pd.Series` of type `timedelta64` has new method `.dt.total_seconds()` returning the duration of the `timedelta` in seconds (GH10817)

```python
# TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))
```

```python
In [20]: s
Out[20]:
0 0 days 00:01:00
1 1 days 00:01:00
2 2 days 00:01:00
3 3 days 00:01:00
dtype: timedelta64[ns]
```

```python
In [21]: s.dt.total_seconds()
```

```python
Out[21]:
0 60.0
1 86460.0
2 172860.0
3 259260.0
dtype: float64
```
1.16.1.5 Period Frequency Enhancement

Period, PeriodIndex and period_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str (GH7811)

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period('2015-08-01', freq='3D')
In [23]: p
Out[23]: Period('2015-08-01', '3D')
In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')
In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')
In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')
In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 00:00:00')
```

You can use the multiplied freq in PeriodIndex and period_range.

```
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')
In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype='period[2D]', freq='2D')
In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype='period[2D]', freq='2D')
```

1.16.1.6 Support for SAS XPORT files

read_sas() provides support for reading SAS XPORT format files. (GH4052).

```
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas('sas_xport.xpt', chunksize=10000)
    do_something(df)
```

See the docs for more details.
1.16.1.7 Support for Math Functions in .eval()

`eval()` now supports calling math functions (GH4893)

```python
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are sin, cos, exp, log, expm1, log1p, sqrt, sinh, cosh, tanh, arcsin, arccos, arctan, arccosh, arcsinh, arctanh, abs and arctan2.

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

1.16.1.8 Changes to Excel with MultiIndex

In version 0.16.2 a DataFrame with MultiIndex columns could not be written to Excel via `to_excel`. That functionality has been added (GH10564), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the MultiIndex in the `header` and `index_col` parameters (GH4679)

See the documentation for more details.

```python
In [31]: df = pd.DataFrame([[1,2,3,4], [5,6,7,8]],
                          columns = pd.MultiIndex.from_product([[ 'foo','bar'], [ 'a','b']]),
                          names = ['col1', 'col2']
                   index = pd.MultiIndex.from_product([[ 'j'], [ 'l', 'k']]),
                          names = ['i1', 'i2']
                   )

In [32]: df
Out[32]:
       col1 foo bar
      col2 a b a b
   i1 i2
 j  1  2  3  4
 k  5  6  7  8

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0,1], index_col=[0,1])

In [35]: df
Out[35]:
       col1 foo bar
      col2 a b a b
   i1 i2
 j  1  2  3  4
 k  5  6  7  8
```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

Old
Warning: Excel files saved in version 0.16.2 or prior that had index names will still able to be read in, but the has_index_names argument must specified to True.

### 1.16.1.9 Google BigQuery Enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the docs for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the gbq module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121)
- The gbq module will now support Python 3 (GH11094).
1.16.1.10 Display Alignment with Unicode East Asian Width

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a DataFrame or Series contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```python
In [36]: df = pd.DataFrame({u'' : ['UK', u''], u'' : ['Alice', u'']})
In [37]: df;
```

```plaintext
   名前 国籍
0  Alice  UK
1  しがく 日本
```

```python
In [38]: pd.set_option('display.unicode.east_asian_width', True)
In [39]: df;
```

```plaintext
   名前 国籍
0  Alice  UK
1  しがく 日本
```

For further details, see [here](#)

1.16.1.11 Other enhancements

- Support for openpyxl >= 2.2. The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```python
In [40]: df1 = pd.DataFrame({'coll':[0,1], 'col_left':['a','b']})
```

(continues on next page)
In [41]: df2 = pd.DataFrame({'col1':[1,2,2],'col_right':[2,2,2]})

In [42]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)

Out[42]:
<table>
<thead>
<tr>
<th></th>
<th>col1</th>
<th>col_left</th>
<th>col_right</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>

For more, see the updated docs

- pd.to_numeric is a new function to coerce strings to numbers (possibly with coercion) (GH11133)
- pd.merge will now allow duplicate column names if they are not merged upon (GH10639).
- pd.pivot will now allow passing index as None (GH3962).
- pd.concat will now use existing Series names if provided (GH10698).

In [43]: foo = pd.Series([1,2], name='foo')

In [44]: bar = pd.Series([1,2])

In [45]: baz = pd.Series([4,5])

Previous Behavior:

In [1]: pd.concat([foo, bar, baz], 1)
Out[1]:
<table>
<thead>
<tr>
<th></th>
<th>foo</th>
<th>bar</th>
<th>baz</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>1</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>

New Behavior:

In [46]: pd.concat([foo, bar, baz], 1)
Out[46]:
<table>
<thead>
<tr>
<th></th>
<th>foo</th>
<th>bar</th>
<th>baz</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>5</td>
</tr>
</tbody>
</table>

- DataFrame has gained the nlargest and nsmallest methods (GH10393)
- Add a limit_direction keyword argument that works with limit to enable interpolate to fill NaN values forward, backward, or both (GH9218, GH10420, GH11115)

In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])

In [48]: ser.interpolate(limit=1, limit_direction='both')
Out[48]:
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>5.0</td>
</tr>
<tr>
<td>2</td>
<td>5.0</td>
</tr>
<tr>
<td>3</td>
<td>7.0</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>11.0</td>
</tr>
<tr>
<td>6</td>
<td>13.0</td>
</tr>
</tbody>
</table>

dtype: float64
• Added a `DataFrame.round` method to round the values to a variable number of decimal places (GH10568).

```python
In [49]: df = pd.DataFrame(np.random.random([3, 3]), columns=['A', 'B', 'C'], index=['first', 'second', 'third'])
....:
In [50]: df
Out[50]:
   A    B    C
first 0.34 0.30 0.42
second 0.68 0.88 0.51
third  0.67 0.59 0.62

In [51]: df.round(2)
   A    B    C
first 0.34 0.30 0.42
second 0.68 0.88 0.51
third  0.67 0.59 0.62

In [52]: df.round({'A': 0, 'C': 2})
   A    B    C
first 0.0 0.30 0.42
second 1.0 0.87 0.51
third  1.0 0.58 0.62
```

• `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see here (GH6511, GH8505)

```python
In [53]: s = pd.Series(['A', 'B', 'C', 'A', 'B', 'D'])
In [54]: s.drop_duplicates()
Out[54]:
0  A
1  B
2  C
5  D
dtype: object

In [55]: s.drop_duplicates(keep='last')
Out[55]:
2  C
3  A
4  B
5  D
dtype: object

In [56]: s.drop_duplicates(keep=False)
   0  A
   1  B
   2  C
   5  D
dtype: object
```

• Reindex now has a `tolerance` argument that allows for finer control of *Limits on filling while reindexing* (GH10411):
In [57]: df = pd.DataFrame({'x': range(5),
   ..........:             't': pd.date_range('2000-01-01', periods=5)})
   ..........:
In [58]: df.reindex([0.1, 1.9, 3.5],
   ..........:       method='nearest',
   ..........:       tolerance=0.2)
   ..........:
Out[58]:
   x   t
0.1 0.0 2000-01-01
1.9 2.0 2000-01-03
3.5 NaN NaT

When used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with a string:

In [59]: df = df.set_index('t')

In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
   ..........:       method='nearest',
   ..........:       tolerance='1 day')
   ..........:
Out[60]:
   x
1999-12-31 0

tolerance is also exposed by the lower level Index.get_indexer and Index.get_loc methods.

• Added functionality to use the base argument when resampling a TimeDeltaIndex (GH10530)
• DatetimeIndex can be instantiated using strings contains NaT (GH7599)
• to_datetime can now accept the yearfirst keyword (GH7599)
• pandas.tseries.offsets larger than the Day offset can now be used with a Series for addition/subtraction (GH10699). See the docs for more details.
• pd.Timedelta.total_seconds() now returns Timedelta duration to ns precision (previously microsecond precision) (GH10939)
• PeriodIndex now supports arithmetic with np.ndarray (GH10638)
• Support pickling of Period objects (GH10439)
• .as_blocks will now take a copy optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
• regex argument to DataFrame.filter now handles numeric column names instead of raising ValueError (GH10384).
• Enable reading gzip compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response (GH8685)
• Enable writing Excel files in memory using StringIO/BytesIO (GH7074)
• Enable serialization of lists and dicts to strings in ExcelWriter (GH8188)
• SQL io functions now accept a SQLAlchemy connectable. (GH7877)
• pd.read_sql and to_sql can accept database URI as con parameter (GH10214)
• read_sql_table will now allow reading from views (GH10750).
• Enable writing complex values to HDFStores when using the table format (GH10447)
• Enable pd.read_hdf to be used without specifying a key when the HDF file contains a single dataset (GH10443)
• pd.read_stata will now read Stata 118 type files. (GH9882)
• msgpack submodule has been updated to 0.4.6 with backward compatibility (GH10581)
• DataFrame.to_dict now accepts orient='index' keyword argument (GH10844).
• DataFrame.apply will return a Series of dicts if the passed function returns a dict and reduce=True (GH8735).
• Allow passing kwargs to the interpolation methods (GH10378).
• Improved error message when concatenating an empty iterable of DataFrame objects (GH9157)
• pd.read_csv can now read bz2-compressed files incrementally, and the C parser can read bz2-compressed files from AWS S3 (GH11070, GH11072).
• In pd.read_csv, recognize s3n:// and s3a:// URLs as designating S3 file storage (GH11070, GH11071).
• Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) (GH11070, GH11073)
• pd.read_csv is now able to infer compression type for files read from AWS S3 storage (GH11070, GH11074).

1.16.2 Backwards incompatible API changes

1.16.2.1 Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).

Here is a summary of the API PRIOR to 0.17.0:
• Series.sort is INPLACE while DataFrame.sort returns a new object.
• Series.order returns a new object
• It was possible to use Series/DataFrame.sort_index to sort by values by passing the by keyword.
• Series/DataFrame.sortlevel worked only on a MultiIndex for sorting by index.

To address these issues, we have revamped the API:

• We have introduced a new method, DataFrame.sort_values(), which is the merger of DataFrame.sort(), Series.sort(), and Series.order(), to handle sorting of values.
• The existing methods Series.sort(), Series.order(), and DataFrame.sort() have been deprecated and will be removed in a future version.
• The by argument of DataFrame.sort_index() has been deprecated and will be removed in a future version.
• The existing method .sort_index() will gain the level keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A * marks items that will show a FutureWarning.

To sort by the values:
To sort by the index:

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Series.sort()</td>
<td>Series.sort_values(inplace=True)</td>
</tr>
<tr>
<td>* DataFrame.sort(columns=...)</td>
<td>DataFrame.sort_values(by=...)</td>
</tr>
</tbody>
</table>

We have also deprecated and changed similar methods in two Series-like classes, `Index` and `Categorical`.

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>* Index.order()</td>
<td>Index.sort_values()</td>
</tr>
<tr>
<td>* Categorical.order()</td>
<td>Categorical.sort_values()</td>
</tr>
</tbody>
</table>

### 1.16.2.2 Changes to `to_datetime` and `to_timedelta`  

**Error handling**

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather than return the original input as in previous versions. (GH10636)

**Previous Behavior:**

```python
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

**New Behavior:**

```python
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format.
```

Of course you can coerce this as well.

```python
In [61]: to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```python
In [62]: to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out[62]: array(['2009-07-31', 'asd'], dtype=object)
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise'|'ignore'|'coerce'`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`.
Consistent Parsing

The string parsing of \texttt{to\_datetime}, \texttt{Timestamp} and \texttt{DatetimeIndex} has been made consistent. (GH7599)

Prior to v0.17.0, \texttt{Timestamp} and \texttt{to\_datetime} may parse year-only datetime-string incorrectly using today’s date, otherwise \texttt{DatetimeIndex} uses the beginning of the year. \texttt{Timestamp} and \texttt{to\_datetime} may raise \texttt{ValueError} in some types of datetime-string which \texttt{DatetimeIndex} can parse, such as a quarterly string.

Previous Behavior:

```python
In [1]: Timestamp('2012Q2')
Traceback
...  
ValueError: Unable to parse 2012Q2

# Results in today's date.
In [2]: Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on \texttt{DatetimeIndex} also.

New Behavior:

```python
In [63]: Timestamp('2012Q2')
Out[63]: Timestamp('2012-04-01 00:00:00')

In [64]: Timestamp('2014')
Out[64]: Timestamp('2014-01-01 00:00:00')

In [65]: DatetimeIndex(['2012Q2', '2014'])
Out [65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]', freq=None)
```

Note: If you want to perform calculations based on today’s date, use \texttt{Timestamp.now()} and \texttt{pandas.tseries.offsets}.

```python
In [66]: import pandas.tseries.offsets as offsets

In [67]: Timestamp.now()
Out [67]: Timestamp('2018-07-05 17:10:40.227744')

In [68]: Timestamp.now() + offsets.DateOffset(years=1)
Out [68]: Timestamp('2019-07-05 17:10:40.228803')
```

1.16.2.3 Changes to Index Comparisons

Operator equal on \texttt{Index} should behavior similarly to \texttt{Series} (GH9947, GH10637)

Starting in v0.17.0, comparing \texttt{Index} objects of different lengths will raise a \texttt{ValueError}. This is to be consistent with the behavior of \texttt{Series}.

Previous Behavior:
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False, True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False

New Behavior:

In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare

Note that this is different from the numpy behavior where a comparison can be broadcast:

In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([ True, False, False], dtype=bool)

or it can return False if broadcasting can not be done:

In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False

1.16.2.4 Changes to Boolean Comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with np.nan, rather than raise TypeError. (GH1079).

In [71]: s = Series(range(3))

In [72]: s.iloc[1] = None

In [73]: s
Out[73]:
0   0.0
1  NaN
2   2.0
dtype: float64

Previous Behavior:

In [5]: s==None
TypeError: Could not compare <type 'NoneType'> type with Series

New Behavior:

In [74]: s==None
Out[74]:
(continues on next page)
Usually you simply want to know which values are null.

```
In [75]: s.isnull()
Out[75]:
   0 False
   1  True
   2 False
dtype: bool
```

**Warning:** You generally will want to use `isnull/notnull` for these types of comparisons, as `isnull/notnull` tells you which elements are null. One has to be mindful that `nan`'s don't compare equal, but `None`'s do. Note that Pandas/numpy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [76]: None == None
Out[76]: True

In [77]: np.nan == np.nan
Out[77]: False
```

### 1.16.2.5 HDFStore dropna behavior

The default behavior for HDFStore write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. (GH9382)

**Previous Behavior:**

```
In [78]: df_with_missing = pd.DataFrame({'col1':[0, np.nan, 2],
                                           'col2':[1, np.nan, np.nan]})

In [79]: df_with_missing
Out[79]:
      col1  col2
   0    0.0   1.0
   1  NaN    NaN
   2    2.0  NaN

In [27]: df_with_missing.to_hdf('file.h5',
           'df_with_missing',
           format='table',
           mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')
```

(continues on next page)
New Behavior:

```
In [80]: df_with_missing.to_hdf('file.h5',
    ....:   'df_with_missing',
    ....:   format='table',
    ....:   mode='w')

In [81]: pd.read_hdf('file.h5', 'df_with_missing')
```

```
Out[81]:
   col1  col2
0    0.0  1.0
1   NaN  NaN
2    2.0  NaN
```

See the docs for more details.

### 1.16.2.6 Changes to `display.precision` option

The `display.precision` option has been clarified to refer to decimal places (GH10451).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```
In [1]: pd.set_option('display.precision', 2)

In [2]: pd.DataFrame({'x': [123.456789]})
```

```
Out[2]:
   x
0 123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```
In [82]: pd.set_option('display.precision', 2)

In [83]: pd.DataFrame({'x': [123.456789]})
```

```
Out[83]:
   x
0 123.46
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

### 1.16.2.7 Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with categories and codes that are unique, rather than returning `np.array` (GH10508)

- unordered category: values and categories are sorted by appearance order.
• ordered category: values are sorted by appearance order, categories keep existing order.

```
In [84]: cat = pd.Categorical(["C", "A", "B", "C"],
    ....:     categories=["A", "B", "C"],
    ....:     ordered=True)
    ....:

In [85]: cat
Out[85]:
[C, A, B, C]
Categories (3, object): [A < B < C]

In [86]: cat.unique()

Out[86]:
[C, A, B]
Categories (3, object): [A < B < C]

In [87]: cat = pd.Categorical(["C", "A", "B", "C"],
    ....:     categories=["A", "B", "C"])
    ....:

In [88]: cat
Out[88]:
[C, A, B, C]
Categories (3, object): [A, B, C]

In [89]: cat.unique()

Out[89]:
[C, A, B]
Categories (3, object): [C, A, B]
```

1.16.2.8 Changes to bool passed as header in Parsers

In earlier versions of pandas, if a bool was passed the header argument of read_csv, read_excel, or read_html it was implicitly converted to an integer, resulting in header=0 for False and header=1 for True (GH6113)

A bool input to header will now raise a TypeError

```
In [29]: df = pd.read_csv('data.csv', header=False)
TypeError: Passing a bool to header is invalid. Use header=None for no header or header=int or list-like of ints to specify the row(s) making up the column names
```

1.16.2.9 Other API Changes

• Line and kde plot with subplots=True now uses default colors, not all black. Specify color='k' to draw all lines in black (GH9894)

• Calling the .value_counts() method on a Series with a categorical dtype now returns a Series with a CategoricalIndex (GH10704)

• The metadata properties of subclasses of pandas objects will now be serialized (GH10553).

• groupby using Categorical follows the same rule as Categorical.unique described above (GH10508)
• When constructing DataFrame with an array of complex64 dtype previously meant the corresponding column was automatically promoted to the complex128 dtype. Pandas will now preserve the itemsize of the input for complex data (GH10952)

• some numeric reduction operators would return ValueError, rather than TypeError on object types that includes strings and numbers (GH11131)

• Passing currently unsupported chunksize argument to read_excel or ExcelFile.parse will now raise Not ImplementedError (GH8011)

• Allow an ExcelFile object to be passed into read_excel (GH11198)

• DatetimeIndex.union does not infer freq if self and the input have None as freq (GH11086)

• NaT's methods now either raise ValueError, or return np.nan or NaT (GH9513)

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>return np.nan</td>
<td>weekday, isoweekday</td>
</tr>
<tr>
<td>return NaT</td>
<td>date, now, replace, to_datetime, today</td>
</tr>
<tr>
<td>return np.datetime64('NaT')</td>
<td>to_datetime64 (unchanged)</td>
</tr>
<tr>
<td>raise ValueError</td>
<td>All other public methods (names not beginning with underscores)</td>
</tr>
</tbody>
</table>

### 1.16.2.10 Deprecations

• For Series the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget_value(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
</tbody>
</table>

• For DataFrame the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i]</td>
</tr>
<tr>
<td>.iget_value(i, j)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.icol(j)</td>
<td>.iloc[:, j]</td>
</tr>
</tbody>
</table>

**Note:** These indexing function have been deprecated in the documentation since 0.11.0.

• Categorical.name was deprecated to make Categorical more numpy.ndarray like. Use Series(cat, name="whatever") instead (GH10482).

• Setting missing values (NaN) in a Categorical's categories will issue a warning (GH10748). You can still have missing values in the values.

• drop_duplicates and duplicated's take_last keyword was deprecated in favor of keep. (GH6511, GH8505)

• Series.nsmallest and nlargest's take_last keyword was deprecated in favor of keep. (GH10792)

• DataFrame.combineAdd and DataFrame.combineMult are deprecated. They can easily be replaced by using the add and mul methods: DataFrame.add(other, fill_value=0) and DataFrame.mul(other, fill_value=1.) (GH10735).
• TimeSeries deprecated in favor of Series (note that this has been an alias since 0.13.0), (GH10890)
• SparsePanel deprecated and will be removed in a future version (GH11157).
• Series.is_time_series deprecated in favor of Series.index.is_all_dates (GH11135)
• Legacy offsets (like 'A@JAN') are deprecated (note that this has been alias since 0.8.0) (GH10878)
• WidePanel deprecated in favor of Panel, LongPanel in favor of DataFrame (note these have been aliases since < 0.11.0), (GH10892)
• DataFrame.convert_objects has been deprecated in favor of type-specific functions pd.to_datetime, pd.to_timestamp and pd.to_numeric (new in 0.17.0) (GH11133).

1.16.2.11 Removal of prior version deprecations/changes

• Removal of na_last parameters from Series.order() and Series.sort(), in favor of na_position. (GH5231)
• Remove of percentile_width from .describe(), in favor of percentiles. (GH7088)
• Removal of colSpace parameter from DataFrame.to_string(), in favor of col_space, circa 0.8.0 version.
• Removal of automatic time-series broadcasting (GH2304)

Previously

```
In [90]: np.random.seed(1234)
In [91]: df = DataFrame(np.random.randn(5,2),columns=list('AB'),index=date_range('20130101',periods=5))
In [92]: df
Out[92]:
     A       B

2013-01-05  0.031393 -2.226989

• Remove table keyword in HDFStore.put/append, in favor of using format= (GH4645)
• Remove kind in read_excel/ExcelFile as its unused (GH4712)
• Remove infer_type keyword from pd.read_html as its unused (GH4770, GH7032)
• Remove offset and timeRule keywords from Series.tshift/shift, in favor of freq (GH4853, GH4864)
• Remove pd.load/pd.save aliases in favor of pd.to_pickle/pd.read_pickle (GH3787)

1.16.3 Performance Improvements

• Development support for benchmarking with the Air Speed Velocity library (GH8361)
• Added vbench benchmarks for alternative ExcelWriter engines and reading Excel files (GH7171)
• Performance improvements in Categorical.value_counts (GH10804)
• Performance improvements in SeriesGroupBy.nunique and SeriesGroupBy.value_counts and SeriesGroupby.transform (GH10820, GH11077)
• Performance improvements in DataFrame.drop_duplicates with integer dtypes (GH10917)
• Performance improvements in DataFrame.duplicated with wide frames. (GH10161, GH11180)
• 4x improvement in timedelta string parsing (GH6755, GH10426)
• 8x improvement in timedelta64 and datetime64 ops (GH6755)
• Significantly improved performance of indexing MultiIndex with slicers (GH10287)
• 8x improvement in iloc using list-like input (GH10791)
• Improved performance of Series.isin for datetimelike/integer Series (GH10287)
• 20x improvement in concat of Categoricals when categories are identical (GH10587)
• Improved performance of to_datetime when specified format string is ISO8601 (GH10178)
• 2x improvement of Series.value_counts for float dtype (GH10821)
• Enable infer_datetime_format in to_datetime when date components do not have 0 padding (GH11142)
• Regression from 0.16.1 in constructing DataFrame from nested dictionary (GH11084)
• Performance improvements in addition/subtraction operations for DateOffset with Series or DatetimeIndex (GH10744, GH11205)
1.16.4 Bug Fixes

- Bug in incorect computation of .mean() on timedelta64[ns] because of overflow (GH9442)
- Bug in .isin on older numpies (GH11232)
- Bug in DataFrame.to_html(index=False) renders unnecessary name row (GH10344)
- Bug in DataFrame.to_latex() the column_format argument could not be passed (GH9402)
- Bug in DatetimeIndex when localizing with NaT (GH10477)
- Bug in Series.dt ops in preserving meta-data (GH10477)
- Bug in preserving NaT when passed in an otherwise invalid to_datetime construction (GH10477)
- Bug in DataFrame.apply when function returns categorical series. (GH9573)
- Bug in to_datetime with invalid dates and formats supplied (GH10154)
- Bug in Index.drop_duplicates dropping name(s) (GH10115)
- Bug in Series.quantile dropping name (GH10881)
- Bug in pd.Series when setting a value on an empty Series whose index has a frequency. (GH10193)
- Bug in pd.Series.interpolate with invalid order keyword values. (GH10633)
- Bug in DataFrame.plot raises ValueError when color name is specified by multiple characters (GH10387)
- Bug in Index construction with a mixed list of tuples (GH10697)
- Bug in DataFrame.reset_index when index contains NaT. (GH10388)
- Bug in ExcelReader when worksheet is empty (GH6403)
- Bug in BinGrouper.group_info where returned values are not compatible with base class (GH10914)
- Bug in clearing the cache on DataFrame.pop and a subsequent inplace op (GH10912)
- Bug in indexing with a mixed-integer Index causing an ImportError (GH10610)
- Bug in Series.count when index has nulls (GH10946)
- Bug in pickling of a non-regular freq DatetimeIndex (GH11002)
- Bug causing DataFrame.where to not respect the axis parameter when the frame has a symmetric shape. (GH9736)
- Bug in Table.select_column where name is not preserved (GH10392)
- Bug in offsets.generate_range where start and end have finer precision than offset (GH9907)
- Bug in pd.rolling_* where Series.name would be lost in the output (GH10565)
- Bug in stack when index or columns are not unique. (GH10417)
- Bug in setting a Panel when an axis has a multi-index (GH10360)
- Bug in USFederalHolidayCalendar where USMemorialDay and USMartinLutherKingJr were incorrect (GH10278 and GH9760)
- Bug in .sample() where returned object, if set, gives unnecessary SettingWithCopyWarning (GH10738)
- Bug in .sample() where weights passed as Series were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. (GH10738)
- Regression fixed in (GH9311, GH6620, GH9345), where groupby with a datetime-like converting to float with certain aggregators (GH10979)
- Bug in DataFrame.interpolate with axis=1 and inplace=True (GH10395)
- Bug in io.sql.get_schema when specifying multiple columns as primary key (GH10385).
- Bug in groupby(sort=False) with datetime-like Categorical raises ValueError (GH10505)
- Bug in groupby(axis=1) with filter() throws IndexError (GH11041)
- Bug in test_categorical on big-endian builds (GH10425)
- Bug in Series.shift and DataFrame.shift not supporting categorical data (GH9416)
- Bug in Series.map using categorical Series raises AttributeError (GH10324)
- Bug in MultiIndex.get_level_values including Categorical raises AttributeError (GH10460)
- Bug in pd.get_dummies with sparse=True not returning SparseDataFrame (GH10531)
- Bug in Index subtypes (such as PeriodIndex) not returning their own type for .drop and .insert methods (GH10620)
- Bug in algos.outer_join_indexer when right array is empty (GH10618)
- Bug in filter (regression from 0.16.0) and transform when grouping on multiple keys, one of which is datetime-like (GH10114)
- Bug in to_datetime and to_timedelta causing Index name to be lost (GH10875)
- Bug in len(DataFrame.groupby) causing IndexError when there’s a column containing only NaNs (GH11016)
- Bug that caused segfault when resampling an empty Series (GH10228)
- Bug inDatetimeIndex and PeriodIndex.value_counts resets name from its result, but retains in result’s Index. (GH10150)
- Bug in pd.eval using numexpr engine coerces 1 element numpy array to scalar (GH10546)
- Bug in pd.concat with axis=0 when column is of dtype category (GH10177)
- Bug in read_msgpack where input type is not always checked (GH10369, GH10630)
- Bug in pd.read_csv with kwargs index_col=False, index_col=[a', 'b'] or dtype (GH10413, GH10467, GH10577)
- Bug in Series.from_csv with header kwarg not setting the Series.name or the Series.index name (GH10483)
- Bug in groupby.var which caused variance to be inaccurate for small float values (GH10448)
- Bug in Series.plot(kind='hist') Y Label not informative (GH10485)
- Bug in read_csv when using a converter which generates a uint8 type (GH9266)
- Bug causes memory leak in time-series line and area plot (GH9003)
- Bug when setting a Panel sliced along the major or minor axes when the right-hand side is a DataFrame (GH11014)
- Bug that returns None and does not raise NotImplementedError when operator functions (e.g. .add) of Panel are not implemented (GH7692)
- Bug in line and kde plot cannot accept multiple colors when subplots=True (GH9804)
• Bug in DataFrame.plot raises ValueError when color name is specified by multiple characters (GH10387)
• Bug in left and right align of Series with MultiIndex may be inverted (GH10665)
• Bug in left and right join of with MultiIndex may be inverted (GH10741)
• Bug in read_stata when reading a file with a different order set in columns (GH10757)
• Bug in Categorical may not representing properly when category contains tz or Period (GH10713)
• Bug in Categorical.__iter__ may not returning correct datetime and Period (GH10713)
• Bug in indexing with a PeriodIndex on an object with a PeriodIndex (GH4125)
• Bug in read_csv with engine='c': EOF preceded by a comment, blank line, etc. was not handled correctly (GH10728, GH10548)
• Reading “famafrench” data via DataReader results in HTTP 404 error because of the website url is changed (GH10591).
• Bug in read_msgpack where DataFrame to decode has duplicate column names (GH9618)
• Bug in io.common.get_filepath_or_buffer which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission (GH10604)
• Bug in vectorised setting of timestamp columns with python datetime.date and numpy datetime64 (GH10408, GH10412)
• Bug in Index.take may add unnecessary freq attribute (GH10791)
• Bug in merge with empty DataFrame may raise IndexError (GH10824)
• Bug in to_latex where unexpected keyword argument for some documented arguments (GH10888)
• Bug in indexing of large DataFrame where IndexError is uncaught (GH10645 and GH10692)
• Bug in read_csv when using the nrows or chunksize parameters if file contains only a header line (GH9535)
• Bug in serialization of category types in HDF5 in presence of alternate encodings. (GH10366)
• Bug in pd.DataFrame when constructing an empty DataFrame with a string dttype (GH9428)
• Bug in pd.DataFrame.diff when DataFrame is not consolidated (GH10907)
• Bug in pd.unique for arrays with the datetime64 or timedelta64 dttype that meant an array with object dttype was returned instead the original dttype (GH9431)
• Bug in Timedelta raising error when slicing from 0s (GH10583)
• Bug in DatetimeIndex.take and TimedeltaIndex.take may not raise IndexError against invalid index (GH10295)
• Bug in Series({np.nan}).astype('M8[ms]'), which now returns Series({pd.NaT}) (GH10747)
• Bug in PeriodIndex.order reset freq (GH10295)
• Bug in date_range when freq divides end as nanos (GH10885)
• Bug in iloc allowing memory outside bounds of a Series to be accessed with negative integers (GH10779)
• Bug in read_msgpack where encoding is not respected (GH10581)
• Bug preventing access to the first index when using iloc with a list containing the appropriate negative integer (GH10547, GH10779)
• Bug in TimedeltaIndex formatter causing error while trying to save DataFrame with TimedeltaIndex using to_csv (GH10833)
• Bug in DataFrame.where when handling Series slicing (GH10218, GH9558)
• Bug where pd.read_gbq throws ValueError when Bigquery returns zero rows (GH10273)
• Bug in to_json which was causing segmentation fault when serializing 0-rank ndarray (GH9576)
• Bug in plotting functions may raise IndexError when plotted on GridSpec (GH10819)
• Bug in plot result may show unnecessary minor ticklabels (GH10657)
• Bug in groupby incorrect computation for aggregation on DataFrame with NaT (E.g first, last, min). (GH10590, GH11010)
• Bug when constructing DataFrame where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)
• Bug in .var() causing roundoff errors for highly similar values (GH10242)
• Bug in DataFrame.plot (subplots=True) with duplicated columns outputs incorrect result (GH10962)
• Bug in Index arithmetic may result in incorrect class (GH10638)
• Bug in date_range results in empty if freq is negative annually, quarterly and monthly (GH11018)
• Bug in DatetimeIndex cannot infer negative freq (GH11018)
• Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
• Bug in Index dtype may not applied properly (GH11017)
• Bug in io.gbq when testing for minimum google api client version (GH10652)
• Bug in DataFrame construction from nested dict with timedelta keys (GH11129)
• Bug in .fillna against may raise TypeError when data contains datetime dtype (GH7095, GH11153)
• Bug in .groupby when number of keys to group by is same as length of index (GH11185)
• Bug in convert_objects where converted values might not be returned if all null and coerce (GH9589)
• Bug in convert_objects where copy keyword was not respected (GH9589)

1.17 v0.16.2 (June 12, 2015)

This is a minor bug-fix release from 0.16.1 and includes a a large number of bug fixes along some new features (pipe() method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

• A new pipe method, see here
• Documentation on how to use numba with pandas, see here

What’s new in v0.16.2

• New features
  – Pipe
### 1.17.1 New features

#### 1.17.1.1 Pipe

We've introduced a new method `DataFrame.pipe()`. As suggested by the name, `pipe` should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```python
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3)
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```python
(df.pipe(h)
 .pipe(g, arg1=1)
 .pipe(f, arg2=2, arg3=3)
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the DataFrame as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of `(function, keyword)` indicating where the DataFrame should flow. For example:

```python
# statsmodels.formula.api as sm
import statsmodels.formula.api as sm

bb = pd.read_csv('data/baseball.csv', index_col='id')
# sm.ols takes (formula, data)
(fg(h(df), arg1=1), arg2=2, arg3=3)
```

```python
In [1]: import statsmodels.formula.api as sm
In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [3]: (bb.query('h > 0')
 .assign(ln_h = lambda df: np.log(df.h))
 .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
 .fit()
 .summary()
)
```

```
Out[3]:
```
The pipe method is inspired by unix pipes, which stream text through processes. More recently dplyr and magrittr have introduced the popular `%>%` pipe operator for R.

See the documentation for more. (GH10129)

1.17.1.2 Other Enhancements

- Added `rsplit` to Index/Series StringMethods (GH10303)
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

Note that the notebook has a toggle output scrolling feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here.

- `axis` parameter of DataFrame.quantile now accepts also index and column. (GH9543)

1.17.2 API Changes

- Holiday now raises NotImplementedError if both offset and observance are used in the constructor instead of returning an incorrect result (GH10217).

1.17.3 Performance Improvements

- Improved Series.resample performance with `dtype=datetime64[ns]` (GH7754)
- Increase performance of str.split when `expand=True` (GH10081)
1.17.4 Bug Fixes

- Bug in `Series.hist` raises an error when a one row Series was given (GH10214)
- Bug where `HDFStore.select` modifies the passed columns list (GH7212)
- Bug in `Categorical` repr with `display.width` of `None` in Python 3 (GH10087)
- Bug in `to_json` with certain orients and a `CategoricalIndex` would segfault (GH10317)
- Bug where some of the nan funcs do not have consistent return dtypes (GH10251)
- Bug in `DataFrame.quantile` on checking that a valid axis was passed (GH9543)
- Bug in `groupby.apply` aggregation for Categorical not preserving categories (GH10138)
- Bug in `to_csv` where `date_format` is ignored if the datetime is fractional (GH10209)
- Bug in `DataFrame.to_json` with mixed data types (GH10289)
- Bug in cache updating when consolidating (GH10264)
- Bug in `mean()` where integer dtypes can overflow (GH10172)
- Bug where `Panel.from_dict` does not set dtype when specified (GH10058)
- Bug in `Index.union` raises `AttributeError` when passing array-likes. (GH10149)
- Bug in `Timestamp`'s`' `microsecond`, `quarter`, `dayofyear`, `week` and `daysinmonth` properties return `np.int32` type, not built-in `int`. (GH10050)
- Bug in `NaT` raises `AttributeError` when accessing to `daysinmonth`, `dayofweek` properties. (GH10096)
- Bug in `Index repr` when using the `max_seq_items=None` setting (GH10182).
- Bug in getting timezone data with `dateutil` on various platforms (GH9059, GH8639, GH9663, GH10121)
- Bug in displaying datetimes with mixed frequencies; display ‘ms’ datetimes to the proper precision. (GH10170)
- Bug in `setitem` where type promotion is applied to the entire block (GH10280)
- Bug in `Series` arithmetic methods may incorrectly hold names (GH10068)
- Bug in `GroupBy.get_group` when grouping on multiple keys, one of which is categorical. (GH10132)
- Bug in `DatetimeIndex` and `TimedeltaIndex` names are lost after timedelta arithmetics (GH9926)
- Bug in `DataFrame` construction from nested `dict` with `datetime64` (GH10160)
- Bug in `Series` construction from `dict` with `datetime64` keys (GH9456)
- Bug in `Series.plot(label="LABEL")` not correctly setting the label (GH10119)
- Bug in `plot` not defaulting to `matplotlib` `axes.grid` setting (GH9792)
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in `engine='python'` for the `read_csv` parser (GH9565)
- Bug in `Series.align` resets name when `fill_value` is specified (GH10067)
- Bug in `read_csv` causing index name not to be set on an empty `DataFrame` (GH10184)
- Bug in `SparseSeries.abs` resets name (GH10241)
- Bug in `TimedeltaIndex` slicing may reset freq (GH10292)
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` (GH6992)
- Bug in `SparseSeries` constructor ignores input data name (GH10258)
• Bug in `Categorical.remove_categories` causing a `ValueError` when removing the NaN category if underlying dtype is floating-point (GH10156)
• Bug where `infer_freq` infers timerule (WOM-5XXX) unsupported by `to_offset` (GH9425)
• Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. (GH9057)
• Bug to handle masking empty `DataFrame` (GH10126).
• Bug where MySQL interface could not handle numeric table/column names (GH10255)
• Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than [ns] (GH10245)
• Bug in `Panel.apply` when the result has ndim=0 (GH10332)
• Bug in `read_hdf` where `auto_close` could not be passed (GH9327).
• Bug in `read_hdf` where open stores could not be used (GH10330).
• Bug in adding empty `DataFrames`, now results in a `DataFrame` that `.equals` an empty `DataFrame` (GH10181).
• Bug in `to_hdf` and `HDFStore` which did not check that complib choices were valid (GH4582, GH8874).

1.18 v0.16.1 (May 11, 2015)

This is a minor bug-fix release from 0.16.0 and includes a a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

• Support for a `CategoricalIndex`, a category based index, see here
• New section on how-to-contribute to `pandas`, see here
• Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see here
• New method `sample` for drawing random samples from `Series`, `DataFrames` and `Panels`. See here
• The default `Index` printing has changed to a more uniform format, see here
• `BusinessHour` datetime-offset is now supported, see here
• Further enhancement to the `.str` accessor to make string operations easier, see here

What’s new in v0.16.1

• **Enhancements**
  – `CategoricalIndex`
  – `Sample`
  – **String Methods Enhancements**
  – **Other Enhancements**
• **API changes**
  – **Deprecations**
1.18.1 Enhancements

1.18.1.1 CategoricalIndex

We introduce a CategoricalIndex, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a Categorical (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a DataFrame/Series with a category dtype would convert this to regular object-based Index.

```python
In [1]: df = DataFrame({'A' : np.arange(6),
                   'B' : Series(list('aabbca')).astype('category',
                   categories=list('cab'))
                   }

In [2]: df
Out[2]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [3]: df.dtypes
Out[3]:
   A  int64
   B  category
dtype: object

In [4]: df.B.cat.categories
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create a CategoricalIndex

```python
In [5]: df2 = df.set_index('B')

In [6]: df2.index
Out[6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
                        ordered=False, name='B', dtype='category')
```

indexing with `__getitem__`, `.iloc`, `.loc`, `.ix` works similarly to an Index with duplicates. The indexers MUST be in the category or the operation will raise.

Warning: In pandas 0.17.0, the sub-package pandas.io.data will be removed in favor of a separately installable package (GH8961).
In [7]: df2.loc['a']
Out[7]:
   A  B
  a  0  1
  a  5

and preserves the CategoricalIndex

In [8]: df2.loc['a'].index
Out[8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
  name='B', dtype='category')

sorting will order by the order of the categories

In [9]: df2.sort_index()
Out[9]:
   A  B
  c  4
  a  0
  a  1
  a  5
  b  2
  b  3

groupby operations on the index will preserve the index nature as well

In [10]: df2.groupby(level=0).sum()
Out[10]:
   A  B
  c  4
  a  6
  b  5

In [11]: df2.groupby(level=0).sum().index
Out[11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
  name='B', dtype='category')

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the PASSED Categorical dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

In [12]: df2.reindex(['a','e'])
Out[12]:
   A  B
  a  0.0
  a  1.0
  a  5.0
  e  NaN

In [13]: df2.reindex(['a','e']).index
Out[13]: Index(['a', 'a', 'e'], dtype='object', name='B')
In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))  
Out[14]:  
    A  
   a 0.0  
   a 1.0  
   a 5.0  
  e NaN  
In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index  
Out[15]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'],  
                      ordered=False, name='B', dtype='category')  

See the documentation for more. (GH7629, GH10038, GH10039)

1.18.1.2 Sample

Series, DataFrames, and Panels now have a new method: sample(). The method accepts a specific number of rows or columns to return, or a fraction of the total number or rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. (GH2419)

In [1]: example_series = Series([0, 1, 2, 3, 4, 5])  
# When no arguments are passed, returns 1  
In [2]: example_series.sample()  
Out[2]:  
3 3  
dtype: int64  
# One may specify either a number of rows:  
In [3]: example_series.sample(n=3)  
Out[3]:  
5 5  
1 1  
4 4  
dtype: int64  
# Or a fraction of the rows:  
In [4]: example_series.sample(frac=0.5)  
Out[4]:  
4 4  
1 1  
0 0  
dtype: int64  
# weights are accepted.  
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]  
In [6]: example_series.sample(n=3, weights=example_weights)  
Out[6]:  
2 2  
3 3  
5 5  
(continues on next page)
dtype: int64

# weights will also be normalized if they do not sum to one,
# and missing values will be treated as zeros.
In [8]: example_weights2 = [0.5, 0, 0, None, np.nan]

In [9]: example_series.sample(n=1, weights=example_weights2)
Out[9]:
0 0
dtype: int64

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

In [9]: df = DataFrame({'col1':[9,8,7,6], 'weight_column':[0.5, 0.4, 0.1, 0]})

In [10]: df.sample(n=3, weights='weight_column')
Out[10]:
col1 weight_column
0 9 0.5
1 8 0.4
2 7 0.1

1.18.1.3 String Methods Enhancements

Continuing from v0.16.0, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (.str accessor) to Index (GH9068)

  The .str accessor is now available for both Series and Index.

In [11]: idx = Index([' jack', 'jill ', ' jesse ', 'frank'])

In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

One special case for the .str accessor on Index is that if a string method returns bool, the .str accessor will return a np.array instead of a boolean Index (GH8875). This enables the following expression to work naturally:

In [13]: idx = Index(['a1', 'a2', 'b1', 'b2'])

In [14]: s = Series(range(4), index=idx)

In [15]: s
Out[15]:
a1 0
a2 1
b1 2
b2 3
dtype: int64

In [16]: idx.str.startswith('a')

Out[16]: array([ True, False, False, False], dtype=bool)

(continues on next page)
In [17]: s[s.index.str.startswith('a')]
   →
a1  0
a2  1
dtype: int64

- The following new methods are accessible via `.str` accessor to apply the function to each value. (GH9766, GH9773, GH10031, GH10045, GH10052)

<table>
<thead>
<tr>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>capitalize()</td>
</tr>
<tr>
<td>swapcase()</td>
</tr>
<tr>
<td>normalize()</td>
</tr>
<tr>
<td>partition()</td>
</tr>
<tr>
<td>rpartition()</td>
</tr>
<tr>
<td>index()</td>
</tr>
<tr>
<td>rindex()</td>
</tr>
<tr>
<td>translate()</td>
</tr>
</tbody>
</table>

- `split` now takes `expand` keyword to specify whether to expand dimensionality. `return_type` is deprecated. (GH9847)

In [18]: s = Series(['a,b', 'a,c', 'b,c'])

# return Series
In [19]: s.str.split(',')
Out[19]:
0  [a, b]
1  [a, c]
2  [b, c]
dtype: object

# return DataFrame
In [20]: s.str.split(',', expand=True)

In [21]: idx = Index(['a,b', 'a,c', 'b,c'])

# return Index
In [22]: idx.str.split(',', expand=True)

# return MultiIndex
In [23]: idx.str.split(',', expand=True)

- Improved `extract` and `get_dummies` methods for `Index.str` (GH9980)

1.18.1.4 Other Enhancements

- `BusinessHour` offset is now supported, which represents business hours starting from 09:00 - 17:00 on `BusinessDay` by default. See `Here` for details. (GH7905)
In [24]: from pandas.tseries.offsets import BusinessHour
In [25]: Timestamp('2014-08-01 09:00') + BusinessHour()
Out[25]: Timestamp('2014-08-01 10:00:00')

In [26]: Timestamp('2014-08-01 07:00') + BusinessHour()
Out[26]: Timestamp('2014-08-01 10:00:00')

In [27]: Timestamp('2014-08-01 16:30') + BusinessHour()
Out[27]: Timestamp('2014-08-04 09:30:00')

- DataFrame.diff now takes an axis parameter that determines the direction of differencing (GH9727)
- Allow clip, clip_lower, and clip_upper to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an axis parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
- DataFrame.mask() and Series.mask() now support same keywords as where (GH8801)
- drop function can now accept errors keyword to suppress ValueError raised when any of label does not exist in the target data. (GH6736)

In [28]: df = DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])
In [29]: df.drop(['A', 'X'], axis=1, errors='ignore')
Out[29]:
   B     C
0  1.058969 -0.397840
1  1.047579  1.045938
2 -0.122092  0.124713

- Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
- Allow conversion of values with dtype datetime64 or timedelta64 to strings using astype(str) (GH9757)
- get_dummies function now accepts sparse keyword. If set to True, the return DataFrame is sparse, e.g. SparseDataFrame. (GH8823)
- Period now accepts datetime64 as value input. (GH9054)
- Allow timedelta string conversion when leading zero is missing from time definition, ie 0:00:00 vs 00:00:00. (GH9570)
- Allow Panel.shift with axis='items' (GH9890)
- Trying to write an excel file now raises NotImplementedError if the DataFrame has a MultiIndex instead of writing a broken Excel file. (GH9794)
- Allow Categorical.add_categories to accept Series or np.array. (GH9927)
- Add/delete str/dt/cat accessors dynamically from __dir__. (GH9910)
- Add normalize as a dt accessor method. (GH10047)
- DataFrame and Series now have _constructor_expanddim property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see here
- pd.lib.infer_dtypes now returns 'bytes' in Python 3 where appropriate. (GH10032)
1.18.2 API changes

- When passing in an ax to df.plot(..., ax=ax), the sharex kwarg will now default to False. The result is that the visibility of xlabels and xticklabels will not anymore be changed. You have to do that by yourself for the right axes in your figure or set sharex=True explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in ax kwarg), then the default is still sharex=True and the visibility changes are applied.

- assign() now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)

- By default, read_csv and read_table will now try to infer the compression type based on the file extension. Set compression=None to restore the previous behavior (no decompression). (GH9770)

1.18.2.1 Deprecations

- Series.str.split's return_type keyword was removed in favor of expand (GH9847)

1.18.3 Index Representation

The string representation of Index and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than display.max_seq_items; if lots of items (> display.max_seq_items) will show a truncated display (the head and tail of the data). The formatting for MultiIndex is unchanges (a multi-line wrapped display). The display width responds to the option display.max_seq_items, which is defaulted to 100. (GH6482)

Previous Behavior

```python
In [2]: pd.Index(range(4),name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104),name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, ...
| 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, ...
| 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, ...
| 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, ...
| 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype=
| int64')

In [4]: pd.date_range('20130101',periods=4,name='foo',tz='US/Eastern')
Out[4]: <class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern

In [5]: pd.date_range('20130101',periods=104,name='foo',tz='US/Eastern')
Out[5]: <class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-04-14 00:00:00-04:00]
Length: 104, Freq: D, Timezone: US/Eastern
```

New Behavior

```python
In [30]: pd.set_option('display.width', 80)

In [31]: pd.Index(range(4), name='foo')
Out[31]: RangeIndex(start=0, stop=4, step=1, name='foo')
```
In [32]: pd.Index(range(30), name='foo')
Out[32]: RangeIndex(start=0, stop=30, step=1, name='foo')

In [33]: pd.Index(range(104), name='foo')
Out[33]: RangeIndex(start=0, stop=104, step=1, name='foo')

In [34]: pd.CategoricalIndex(['a','bb','ccc','dddd'], ordered=True, name='foobar')
Out[34]: CategoricalIndex(['a', 'bb', 'ccc', 'dddd'], categories=['a', 'bb', 'ccc', 'dddd'], ordered=True, name='foobar', dtype='category')

In [35]: pd.CategoricalIndex(['a','bb','ccc','dddd']*10, ordered=True, name='foobar')
Out[35]: CategoricalIndex(['a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd'], categories=['a', 'bb', 'ccc', 'dddd'], ordered=True, name='foobar', dtype='category')

In [36]: pd.CategoricalIndex(['a','bb','ccc','dddd']*100, ordered=True, name='foobar')
Out[36]: CategoricalIndex(['a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd', 'a', 'bb', 'ccc', 'dddd'], length=400)

In [37]: pd.date_range('20130101',periods=4, name='foo', tz='US/Eastern')
Out[37]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                   '2013-01-03 00:00:00-05:00', '2013-01-04 00:00:00-05:00'],
                   dtype='datetime64[ns, US/Eastern]', name='foo', freq='D')

In [38]: pd.date_range('20130101',periods=25, freq='D')
Out[38]: DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
                   '2013-01-25'],
                   dtype='datetime64[ns]', freq='D')

In [39]: pd.date_range('20130101',periods=104, name='foo', tz='US/Eastern')
1.18.4 Performance Improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of pd.lib.max_len_string_array by 5-7x (GH10024)

1.18.5 Bug Fixes

- Bug where labels did not appear properly in the legend of DataFrame.plot(), passing label= arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in read_csv where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in scatter_matrix draws unexpected axis ticklabels (GH5662)
- Fixed bug in StataWriter resulting in changes to input DataFrame upon save (GH9795).
- Bug in transform causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in equals causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple pd.Grouper where one is non-time based (GH10063)
- Bug in read_sql_table error when reading postgres table with timezone (GH7139)
- Bug in DataFrame slicing may not retain metadata (GH9776)
- Bug where TimedeltaIndex were not properly serialized in fixed HDFStore (GH9635)
- Bug with TimedeltaIndex constructor ignoring name when given another TimedeltaIndex as data (GH10025).
- Bug in DataFrameFormatter._get_formatted_index with not applying max_colwidth to the DataFrame index (GH7856)
- Bug in .loc with a read-only ndarray data source (GH10043)
- Bug in groupby.apply() that would raise if a passed user defined function either returned only None (for all input). (GH9685)
• Always use temporary files in pytables tests (GH9992)
• Bug in plotting continuously using secondary_y may not show legend properly. (GH9610, GH9779)
• Bug in DataFrame.plot(kind="hist") results in TypeError when DataFrame contains non-numeric columns (GH9853)
• Bug where repeated plotting of DataFrame with a DatetimeIndex may raise TypeError (GH9852)
• Bug in setup.py that would allow an incompat cython version to build (GH9827)
• Bug in plotting secondary_y incorrectly attaches right_ax property to secondary axes specifying itself recursively. (GH9861)
• Bug in Series.quantile on empty Series of type Datetime or Timedelta (GH9675)
• Bug in where causing incorrect results when upcasting was required (GH9731)
• Bug in FloatArrayFormatter where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given display.precision (GH9764)
• Fixed bug where DataFrame.plot() raised an error when both color and style keywords were passed and there was no color symbol in the style strings (GH9671)
• Not showing a DeprecationWarning on combining list-likes with an Index (GH10083)
• Bug in read_csv and read_table when using skip_rows parameter if blank lines are present. (GH9832)
• Bug in read_csv() interprets index_col=True as 1 (GH9798)
• Bug in index equality comparisons using == failing on Index/MultiIndex type incompatibility (GH9785)
• Bug in which SparseDataFrame could not take nan as a column name (GH8822)
• Bug in to_msgpack and read_msgpack zlib and blosc compression support (GH9783)
• Bug GroupBy.size doesn’t attach index name properly if grouped by TimeGrouper (GH9925)
• Bug causing an exception in slice assignments because length_of_indexer returns wrong results (GH9995)
• Bug in csv parser causing lines with initial whitespace plus one non-space character to be skipped. (GH9710)
• Bug in C csv parser causing spurious NaNs when data started with newline followed by whitespace. (GH10022)
• Bug causing elements with a null group to spill into the final group when grouping by a Categorical (GH9603)
• Bug where .iloc and .loc behavior is not consistent on empty dataframes (GH9964)
• Bug in invalid attribute access on a TimedeltaIndex incorrectly raised ValueError instead of AttributeError (GH9680)
• Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. Series(Categorical(list("abc"), ordered=True)) > "d". This returned False for all elements, but now raises a TypeError. Equality comparisons also now return False for == and True for !.=. (GH9848)
• Bug in DataFrame __setitem__ when right hand side is a dictionary (GH9874)
• Bug in where when dtype is datetime64/timedelta64, but dtype of other is not (GH9804)
• Bug in MultiIndex.sortlevel() results in unicode level name breaks (GH9856)
• Bug in which groupby.transform incorrectly enforced output dtypes to match input dtypes. (GH9807)
• Bug in DataFrame constructor when columns parameter is set, and data is an empty list (GH9939)
• Bug in bar plot with \texttt{log=True} raises \texttt{TypeError} if all values are less than 1 (GH9905)
• Bug in horizontal bar plot ignores \texttt{log=True} (GH9905)
• Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)
• Bug where dividing a dataframe containing values of type \texttt{Decimal} by another \texttt{Decimal} would raise. (GH9787)
• Bug where using DataFrames \texttt{asfreq} would remove the name of the index. (GH9885)
• Bug causing extra index point when resample BM/BQ (GH9756)
• Changed caching in \texttt{AbstractHolidayCalendar} to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
• Fixed latex output for multi-indexed dataframes (GH9778)
• Bug causing an exception when setting an empty range using \texttt{DataFrame.loc} (GH9596)
• Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
• Bug in \texttt{transform} and \texttt{filter} when grouping on a categorical variable (GH9921)
• Bug in \texttt{transform} when groups are equal in number and dtype to the input index (GH9700)
• Google BigQuery connector now imports dependencies on a per-method basis. (GH9713)
• Updated BigQuery connector to no longer use deprecated \texttt{oauth2client.tools.run()} (GH8327)
• Bug in subclassed \texttt{DataFrame}. It may not return the correct class, when slicing or subsetting it. (GH9632)
• Bug in \texttt{.median()} where non-float null values are not handled correctly (GH10040)
• Bug in \texttt{Series.fillna()} where it raises if a numerically convertible string is given (GH10092)

1.19 v0.16.0 (March 22, 2015)

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• \texttt{DataFrame.assign} method, see \texttt{here}
• \texttt{Series.to_coo/from_coo} methods to interact with \texttt{scipy.sparse}, see \texttt{here}
• Backwards incompatible change to \texttt{Timedelta} to conform the \texttt{.seconds} attribute with \texttt{datetime.timedelta}, see \texttt{here}
• Changes to the \texttt{.loc} slicing API to conform with the behavior of \texttt{.ix} see \texttt{here}
• Changes to the default for ordering in the \texttt{Categorical} constructor, see \texttt{here}
• Enhancement to the \texttt{.str} accessor to make string operations easier, see \texttt{here}
• The \texttt{pandas.tools.rplot}, \texttt{pandas.sandbox.qtpandas} and \texttt{pandas.rpy} modules are deprecated. We refer users to external packages like \texttt{seaborn}, \texttt{pandas-qt} and \texttt{rpy2} for similar or equivalent functionality, see \texttt{here}

Check the \texttt{API Changes} and \texttt{deprecations} before updating.
What’s new in v0.16.0

- **New features**
  - DataFrame Assign
  - Interaction with scipy.sparse
  - String Methods Enhancements
  - Other enhancements
- **Backwards incompatible API changes**
  - Changes in Timedelta
  - Indexing Changes
  - Categorical Changes
  - Other API Changes
  - Deprecations
  - Removal of prior version deprecations/changes
- **Performance Improvements**
- **Bug Fixes**

1.19.1 New features

1.19.1.1 DataFrame Assign

Inspired by dplyr’s `mutate` verb, DataFrame has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. The new values are inserted, and the entire DataFrame (with all original and new columns) is returned.

```
In [1]: iris = read_csv('data/iris.data')

In [2]: iris.head()
Out[2]:
   SepalLength  SepalWidth  PetalLength  PetalWidth     Name
0       5.1        3.5         1.4        0.2   Iris-setosa
1       4.9        3.0         1.4        0.2   Iris-setosa
2       4.7        3.2         1.3        0.2   Iris-setosa
3       4.6        3.1         1.5        0.2   Iris-setosa
4       5.0         3.6         1.4        0.2   Iris-setosa

In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
```

```
  SepalLength  SepalWidth  PetalLength  PetalWidth     Name  sepal_ratio
0       5.1        3.5         1.4        0.2   Iris-setosa  0.686275
1       4.9        3.0         1.4        0.2   Iris-setosa  0.612245
2       4.7        3.2         1.3        0.2   Iris-setosa  0.680851
3       4.6        3.1         1.5        0.2   Iris-setosa  0.673913
4       5.0         3.6         1.4        0.2   Iris-setosa  0.720000
```
Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```
In [4]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

```
Out[4]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.686275</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.612245</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.680851</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.673913</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.720000</td>
</tr>
</tbody>
</table>
```

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```
In [5]: (iris.query('SepalLength > 5')
    ...: .assign(SepalRatio = lambda x: x.SepalWidth / x.SepalLength,
    ...:           PetalRatio = lambda x: x.PetalWidth / x.PetalLength)
    ...: .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
```

```
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x1c41df41d0>
```

See the documentation for more. (GH9229)

1.19.1.2 Interaction with scipy.sparse

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods (GH8048) for converting to and from `scipy.sparse.coo_matrix` instances (see here). For example, given a SparseSeries with MultiIndex we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```
In [6]: from numpy import nan

In [7]: s = Series([3.0, nan, 1.0, 3.0, nan, nan])

In [8]: s.index = MultiIndex.from_tuples([(1, 2, 'a', 0),
    ...:             (1, 2, 'a', 1),
    ...:             (1, 1, 'b', 0),
    ...:             (1, 1, 'b', 1),
    ...:             (2, 1, 'b', 0),
    ...: ])
```

(continues on next page)
...:                (2, 1, 'b', 1)),
...:            names=['A', 'B', 'C', 'D'])

In [9]: s
Out[9]:
A B C D
1 2 a 0 3.0
1 NaN
1 b 0 1.0
1 3.0
2 1 b 0 NaN
1 NaN
dtype: float64

# SparseSeries
In [10]: ss = s.to_sparse()

In [11]: ss
Out[11]:
A B C D
1 2 a 0 3.0
1 NaN
1 b 0 1.0
1 3.0
2 1 b 0 NaN
1 NaN
dtype: float64

BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 2], dtype=int32)

In [12]: A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
.....:                column_levels=['C', 'D'],
.....:                sort_labels=False)

In [13]: A
Out[13]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
    with 3 stored elements in COOrdinate format>

In [14]: A.todense()

\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n\n...
The `from_coo` method is a convenience method for creating a SparseSeries from a `scipy.sparse.coo_matrix`:

```python
In [17]: from scipy import sparse

In [18]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])),
                           shape=(3, 4))

In [19]: A
Out[19]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
   with 3 stored elements in COOrdinate format>

In [20]: A.todense()
→
matrix([[ 0., 0., 1., 2.],
         [ 3., 0., 0., 0.],
         [ 0., 0., 0., 0.]])

In [21]: ss = SparseSeries.from_coo(A)

In [22]: ss
Out[22]:
0 2 1.0
3 2.0
1 0 3.0
dtype: float64
BlockIndex
Block locations: array([0], dtype=int32)
Block lengths: array([3], dtype=int32)
```

### 1.19.1.3 String Methods Enhancements

- Following new methods are accesible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. (GH9282, GH9352, GH9386, GH9387, GH9439)

<table>
<thead>
<tr>
<th>Methods</th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>isalnum()</td>
<td>isalpha()</td>
<td>isdigit()</td>
<td>isdigit()</td>
<td>isspace()</td>
<td></td>
</tr>
<tr>
<td>islower()</td>
<td>isupper()</td>
<td>istitle()</td>
<td>isnumeric()</td>
<td>isdecimal()</td>
<td></td>
</tr>
<tr>
<td>find()</td>
<td>rfind()</td>
<td>ljust()</td>
<td>rjust()</td>
<td>zfill()</td>
<td></td>
</tr>
</tbody>
</table>

```python
In [23]: s = Series(['abcd', '3456', 'EFGH'])

In [24]: s.str.isalpha()
Out[24]:
0   True
1  False
2   True
dtype: bool

In [25]: s.str.find('ab')
→
0
```

(continues on next page)
• Series.str.pad() and Series.str.center() now accept fillchar option to specify filling character (GH9352)

```
In [26]: s = Series(["12", '300', '25'])

In [27]: s.str.pad(5, fillchar=' _')
Out [27]:
0 ___12
1 __300
2 ___25
dtype: object
```

• Added Series.str.slice_replace(), which previously raised NotImplementedError (GH8888)

```
In [28]: s = Series(['ABCD', 'EFGH', 'IJK'])

In [29]: s.str.slice_replace(1, 3, 'X')
Out [29]:
0 AXD
1 EXH
2 IX

dtype: object
```

```
# replaced with empty char
In [30]: s.str.slice_replace(0, 1)
Out [30]:
0 BCD
1 FGH
2 JK

dtype: object
```

1.19.1.4 Other enhancements

• Reindex now supports method='nearest' for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [31]: df = pd.DataFrame({'x': range(5)})

In [32]: df.reindex([0.2, 1.8, 3.5], method='nearest')
Out [32]:
         x
0.2  0
1.8  2
3.5  4
```

This method is also exposed by the lower level Index.get_indexer and Index.get_loc methods.

• The read_excel() function’s sheetname argument now accepts a list and None, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls',sheetname=['Sheet1',3])
```
- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs here (GH9493).
- Paths beginning with ~ will now be expanded to begin with the user’s home directory (GH9066)
- Added time interval selection in get_data_yahoo (GH9071)
- Added Timestamp.to_datetime64() to complement Timedelta.to_timedelta64() (GH9255)
- tseries.frequencies.to_offset() now accepts Timedelta as input (GH9064)
- Lag parameter was added to the autocorrelation method of Series, defaults to lag-1 autocorrelation (GH9192)
- Timedelta will now accept nanoseconds keyword in constructor (GH9273)
- SQL code now safely escapes table and column names (GH8986)
- Added auto-complete for Series.str.<tab>, Series.dt.<tab> and Series.cat.<tab> (GH9322)
- Index.get_indexer now supports method='pad' and method='backfill' even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
- Index.asof now works on all index types (GH9258).
- A verbose argument has been augmented in io.read_excel(), defaults to False. Set to True to print sheet names as they are parsed. (GH9450)
- Added days_in_month (compatibility alias daysinmonth) property to Timestamp, DatetimeIndex, Period, PeriodIndex, and Series.dt (GH9572)
- Added decimal option in to_csv to provide formatting for non-’.’ decimal separators (GH781)
- Added normalize option for Timestamp to normalized to midnight (GH8794)
- Added example for DataFrame import to R using HDF5 file and rhdf5 library. See the documentation for more (GH9636).

1.19.2 Backwards incompatible API changes

1.19.2.1 Changes in Timedelta

In v0.15.0 a new scalar type Timedelta was introduced, that is a sub-class of datetime.timedelta. Mentioned here was a notice of an API change w.r.t. the .seconds accessor. The intent was to provide a user-friendly set of accessors that give the ‘natural’ value for that unit, e.g. if you had a Timedelta('1 day, 10:11:12'), then .seconds would return 12. However, this is at odds with the definition of datetime.timedelta, which defines .seconds as 10 * 3600 + 11 * 60 + 12 == 36672.

So in v0.16.0, we are restoring the API to match that of datetime.timedelta. Further, the component values are still available through the .components accessor. This affects the .seconds and .microseconds accessors, and removes the .hours, .minutes, .milliseconds accessors. These changes affect TimedeltaIndex and the Series .dt accessor as well. (GH9185, GH9139)

Previous Behavior

```python
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [3]: t.days
Out[3]: 1
```

(continues on next page)
In [4]: t.seconds
Out[4]: 12

In [5]: t.microseconds
Out[5]: 123

New Behavior

In [33]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [34]: t.days
Out[34]: 1
In [35]: t.seconds
Out[35]: 36672
In [36]: t.microseconds
Out[36]: 100123

Using .components allows the full component access

In [37]: t.components
Out[37]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100, microseconds=123, nanoseconds=0)
In [38]: t.components.seconds
Out[38]: 12

1.19.2.2 Indexing Changes

The behavior of a small sub-set of edge cases for using .loc have changed (GH8613). Furthermore we have improved the content of the error messages that are raised:

• Slicing with .loc where the start and/or stop bound is not found in the index is now allowed; this previously would raise a KeyError. This makes the behavior the same as .ix in this case. This change is only for slicing, not when indexing with a single label.

In [39]: df = DataFrame(np.random.randn(5,4),
....:    columns=list('ABCD'),
....:    index=date_range('20130101',periods=5))
In [40]: df
Out[40]:
   A          B         C        D
2013-01-01 -0.322795  0.841675  2.390961  0.076200
2013-01-02 -0.566446  0.036142 -2.074978  0.247792
2013-01-03 -0.897157 -0.136795  0.018289  0.755414
2013-01-04  0.215269  0.841009 -1.445810 -1.401973
2013-01-05 -0.100918 -0.548242 -0.144620  0.354020

In [41]: s = Series(range(5),[-2,-1,1,2,3])
In [42]: s

(continues on next page)
Previous Behavior

In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'

In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'

New Behavior

In [43]: df.loc['2013-01-02':'2013-01-10']
Out[43]:
   A      B      C      D
2013-01-02 -0.566446 0.036142 -2.074978 0.247792
2013-01-03 -0.897157 -0.136795 0.018289 0.755414
2013-01-04  0.215269  0.841009 -1.445810 -1.401973
2013-01-05 -0.100918 -0.548242 -0.144620  0.354020

In [44]: s.loc[-10:3]
   →
   -2  0
   -1  1
   1  2
   2  3
   3  4
Out[44]:
   0  1  2  3
-2  0  1  2
-1  1  2  3
  1  2  3  4
dtype: int64

• Allow slicing with float-like values on an integer index for .ix. Previously this was only enabled for .loc:

Previous Behavior

In [8]: s.ix[-1.0:2]
TypeError: the slice start value [-1.0] is not a proper indexer for this index

New Behavior

In [2]: s.ix[-1.0:2]
Out[2]:
   0  1  2  3
-2  0  1  2
-1  1  2  3
   1  2  3  4
dtype: int64

• Provide a useful exception for indexing with an invalid type for that index when using .loc. For example trying to use .loc on an index of type DatetimeIndex or PeriodIndex or TimedeltaIndex, with an integer (or a float).
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [4]: df.loc[2:3]
KeyError: 'start bound [2] is not the [index]'

New Behavior

In [4]: df.loc[2:3]
TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with <type 'int'> keys

1.19.2.3 Categorical Changes

In prior versions, Categoricals that had an unspecified ordering (meaning no ordered keyword was passed) were defaulted as ordered Categoricals. Going forward, the ordered keyword in the Categorical constructor will default to False. Ordering must now be explicit.

Furthermore, previously you could change the ordered attribute of a Categorical by just setting the attribute, e.g. cat.ordered=True; This is now deprecated and you should use cat.as_ordered() or cat.as_unordered(). These will by default return a new object and not modify the existing object. (GH9347, GH9190)

Previous Behavior

In [3]: s = Series([0,1,2], dtype='category')
In [4]: s
Out[4]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]
In [5]: s.cat.ordered
Out[5]: True
In [6]: s.cat.ordered = False
In [7]: s
Out[7]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]

New Behavior

In [45]: s = Series([0,1,2], dtype='category')
In [46]: s
Out[46]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]
In [47]: s.cat.ordered
Out[47]: False

In [48]: s = s.cat.as_ordered()

In [49]: s
Out[49]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [50]: s.cat.ordered
Out[50]: True

# you can set in the constructor of the Categorical
In [51]: s = Series(Categorical([0,1,2], ordered=True))

In [52]: s
Out[52]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [53]: s.cat.ordered
Out[53]: True

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling .astype(). These are passed directly to the constructor.

In [54]: s = Series(['a','b','c','a']).astype('category', ordered=True)

In [55]: s
Out[55]:
0  a
1  b
2  c
3  a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = Series(['a','b','c','a']).astype('category', categories=list('abcdef'), ordered=False)

In [57]: s
Out[57]:
0  a
1  b
2  c
1.19.4 Other API Changes

- Index.duplicated now returns np.array(dtype=bool) rather than Index(dtype=object) containing bool values. (GH8875)

- DataFrame.to_json now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

  Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

  ```
  In [2]: pd.DataFrame({"i": [1,2], "f": [3.0, 4.2]}).to_json()
  Out[2]: \'{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}\'
  ```

  Now each column is serialised using its correct dtype:

  ```
  In [2]: pd.DataFrame({"i": [1,2], "f": [3.0, 4.2]}).to_json()
  Out[2]: \'{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}\'
  ```

- DatetimeIndex, PeriodIndex and TimedeltaIndex.summary now output the same format. (GH9116)

- TimedeltaIndex.freqstr now output the same string format as DatetimeIndex. (GH9116)

- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib’s axhline or axvline methods (GH9088).

- Series accessors .dt, .cat and .str now raise AttributeError instead of TypeError if the series does not contain the appropriate type of data (GH9617). This follows Python’s built-in exception hierarchy more closely and ensures that tests like hasattr(s, 'cat') are consistent on both Python 2 and 3.

- Series now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to bool.

  Previous Behavior

  ```
  In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
  Out[2]:
  a  True
  b  True
  c  True
  d  True
dtype: bool
  ```

  New Behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

  ```
  In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
  Out[2]:
  a  4
  b  5
c  6
  ```
• During division involving a Series or DataFrame, 0/0 and 0//0 now give np.nan instead of np.inf. (GH9144, GH8445)

Previous Behavior

```python
In [2]: p = pd.Series([0, 1])
In [3]: p / 0
Out[3]:
   0   inf
   1   inf
 dtype: float64

In [4]: p // 0
Out[4]:
   0   inf
   1   inf
 dtype: float64
```

New Behavior

```python
In [54]: p = pd.Series([0, 1])
In [55]: p / 0
Out[55]:
   0  NaN
   1   inf
 dtype: float64

In [56]: p // 0
Out[56]:
   0  NaN
   1   inf
 dtype: float64
```

• Series.values_counts and Series.describe for categorical data will now put NaN entries at the end. (GH9443)

• Series.describe for categorical data will now give counts and frequencies of 0, not NaN, for unused categories (GH9443)

• Due to a bug fix, looking up a partial string label with DatetimeIndex.asof now includes values that match the string, even if they are after the start of the partial string label (GH9258).

Old behavior:

```python
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

Fixed behavior:

```python
In [57]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[57]: Timestamp('2000-02-28 00:00:00')
```
1.19.2.5 Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code using `rplot` to `seaborn`: `rplot docs`.

- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt` (GH9615).

- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed thru the `rpy2` project (GH9602).

- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. (GH9094)

- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. (GH9094)

1.19.2.6 Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s rows and cols keyword arguments were removed in favor of index and columns (GH6581).

- `DataFrame.to_excel` and `DataFrame.to_csv` cols keyword argument was removed in favor of columns (GH6581).

- Removed `convert_dummies` in favor of `get_dummies` (GH6581).

- Removed `value_range` in favor of `describe` (GH6581).

1.19.3 Performance Improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like (GH9126).

- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. (GH9037)

- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values (GH9125)

- Improved the speed of `nunique` by calling `unique` instead of `value_counts` (GH9129, GH7771)

- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately (GH9136)

- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument (GH9163)

- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds (GH9151)

- Performance improvements in multi-key groupby (GH9429)

- Performance improvements in `MultiIndex.sortlevel` (GH9445)

- Performance and memory usage improvements in `DataFrame.duplicated` (GH9398)
• Cythonized Period (GH9440)
• Decreased memory usage on to_hdf (GH9648)

1.19.4 Bug Fixes

• Changed .to_html to remove leading/trailing spaces in table body (GH4987)
• Fixed issue using read_csv on s3 with Python 3 (GH9452)
• Fixed compatibility issue in DatetimeIndex affecting architectures where numpy.int_ defaults to numpy.int32 (GH9493)
• Bug in Panel indexing with an object-like (GH9140)
• Bug in the returned Series.dt.components index was reset to the default index (GH9247)
• Bug in Categorical.__getitem__/__setitem__ with listlike input getting incorrect results from indexer coercion (GH9469)
• Bug in partial setting with a DatetimeIndex (GH9478)
• Bug in groupby for integer and datetime64 columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
• Fixed bug in to_sql when mapping a Timestamp object column (datetime column with timezone info) to the appropriate sqlalchemy type (GH9085).
• Fixed bug in to_sql dtype argument not accepting an instantiated SQLAlchemy type (GH9083).
• Bug in .loc partial setting with a np.datetime64 (GH9516)
• Incorrect dtypes inferred on datetimelike looking Series & on .xs slices (GH9477)
• Items in Categorical.unique() (and s.unique() if s is of dtype category) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
• Fixed bug on big endian platforms which produced incorrect results in StataReader (GH8688).
• Bug in MultiIndex.has_duplicates when having many levels causes an indexer overflow (GH9075, GH5873)
• Bug in pivot and unstack where nan values would break index alignment (GH4862, GH7401, GH7403, GH7405, GH7466, GH9497)
• Bug in left join on multi-index with sort=True or null values (GH9210).
• Bug in MultiIndex where inserting new keys would fail (GH9250).
• Bug in groupby when key space exceeds int64 bounds (GH9096).
• Bug in unstack with TimedeltaIndex or DatetimeIndex and nulls (GH9491).
• Bug in rank where comparing floats with tolerance will cause inconsistent behaviour (GH8365).
• Fixed character encoding bug in read stata and StataReader when loading data from a URL (GH9231).
• Bug in adding offsets.Nano to other offsets raises TypeError (GH9284)
• Bug in DatetimeIndex iteration, related to (GH8890), fixed in (GH9100)
• Bugs in resample around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. (GH5172, GH8744, GH8653, GH9173, GH9468).
• Bug in binary operator method (eg .mul()) alignment with integer levels (GH9463).
• Bug in boxplot, scatter and hexbin plot may show an unnecessary warning (GH8877)
• Bug in subplot with `layout` kw may show unnecessary warning (GH9464)
• Bug in using grouper functions that need passed thru arguments (e.g. axis), when using wrapped function (e.g. `fillna`), (GH9221)
• `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor (GH9099)
• Bug in `read_csv` when using `skiprows` on a file with CR line endings with the `c` engine. (GH9079)
• `isnull` now detects `NaT` in `PeriodIndex` (GH9129)
• Bug in `groupby .nth()` with a multiple column groupby (GH8979)
• Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly (GH9280)
• Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results (GH9184)
• Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing (GH9512)
• Fixed division by zero error for `Series.kurt()` when all values are equal (GH9197)
• Fixed issue in the `xlsxwriter` engine where it added a default ‘General’ format to cells if no other format was applied. This prevented other row or column formatting being applied. (GH9167)
• Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. (GH9082)
• Bug where `wide_to_long` would modify the input stubnames list (GH9204)
• Bug in `to_sql` not storing float64 values using double precision. (GH9009)
• `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) (GH9272).
• Regression in merging Categorical and object dtypes (GH9426)
• Bug in `read_csv` with buffer overflows with certain malformed input files (GH9205)
• Bug in `groupby` MultiIndex with missing pair (GH9049, GH9344)
• Fixed bug in `Series.groupby` where grouping on MultiIndex levels would ignore the sort argument (GH9444)
• Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of Categorical columns. (GH8868)
• Fixed bug with reading CSV files from Amazon S3 on python 3 raising a TypeError (GH9452)
• Bug in the Google BigQuery reader where the ‘jobComplete’ key may be present but False in the query results (GH8728)
• Bug in `Series.values_counts` with excluding `NaN` for categorical type `Series` with `dropna=True` (GH9443)
• Fixed missing numeric_only option for `DataFrame.std/var/sem` (GH9201)
• Support constructing `Panel` or `Panel4D` with scalar data (GH8285)
• `Series` text representation disconnected from `max_rows/max_columns` (GH7508).
• Series number formatting inconsistent when truncated (GH8532).

Previous Behavior

In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0     1
1     1
2     1
...  
127  0.9999
128  1.0000
129  1.0000
Length: 130, dtype: float64

New Behavior

0   1.0000
1   1.0000
2   1.0000
3   1.0000
4   1.0000
...  
125  1.0000
126  1.0000
127  0.9999
128  1.0000
129  1.0000
dtype: float64

• A Spurious SettingWithCopy Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a SettingWithCopy Warning.

In [1]: df1 = DataFrame({'x': Series(['a','b','c']), 'y': Series(['d','e','f'])})
In [2]: df2 = df1[['x']]
In [3]: df2['y'] = ['g', 'h', 'i']

1.20 v0.15.2 (December 12, 2014)

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

• Enhancements
• API Changes
• Performance Improvements
• Bug Fixes
1.20.1 API changes

- Indexing in MultiIndex beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```python
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
                      'joe':['x', 'x', 'z', 'y'],
                      'jolie':np.random.rand(4)}).set_index(['jim', 'joe'])

In [2]: df
Out[2]:
      jolie
    jim joe
0  x  0.123943
   x  0.119381
1  z  0.738523
   y  0.587304

In [3]: df.index.lexsort_depth
    →1
# in prior versions this would raise a KeyError
# will now show a PerformanceWarning
In [4]: df.loc[(1, 'z')]
    →
      jolie
    jim joe
1  z  0.738523
# lexically sorting

In [5]: df2 = df.sort_index()

In [6]: df2
Out[6]:
      jolie
    jim joe
0  x  0.123943
   x  0.119381
1  y  0.587304
   z  0.738523

In [7]: df2.index.lexsort_depth
    →2

In [8]: df2.loc[(1, 'z')]
    →
      jolie
    jim joe
1  z  0.738523
```

- Bug in unique of Series with category dtype, which returned all categories regardless whether they were “used” or not (see GH8559 for the discussion). Previous behaviour was to return all categories:
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [4]: cat
Out[4]:
[a, b, a]
Categories (3, object): [a < b < c]

In [5]: cat.unique()
Out[5]: array(['a', 'b', 'c'], dtype=object)

Now, only the categories that do effectively occur in the array are returned:

In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [10]: cat.unique()
Out[10]: [a, b]
Categories (2, object): [a, b]

• Series.all and Series.any now support the level and skipna parameters. Series.all, Series.any, Index.all, and Index.any no longer support the out and keepdims parameters, which existed for compatibility with ndarray. Various index types no longer support the all and any aggregation functions and will now raise TypeError. (GH8302).

• Allow equality comparisons of Series with a categorical dtype and object dtype; previously these would raise TypeError (GH8938)

• Bug in NDFrame: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named y existed, data.y would return the attribute, while data.y = z would update the column (GH8994)

In [11]: data = pd.DataFrame({'x': [1, 2, 3]})

In [12]: data.y = 2

In [13]: data['y'] = [2, 4, 6]

In [14]: data
Out[14]:
   x  y
0  1  2
1  2  4
2  3  6

# this assignment was inconsistent
In [15]: data.y = 5

Old behavior:

In [6]: data.y
Out[6]: 2

In [7]: data['y'].values
Out[7]: array([5, 5, 5])

New behavior:
In [16]: data.y
Out[16]: 5

In [17]: data['y'].values
Out[17]: array([2, 4, 6])

• Timestamp('now') is now equivalent to Timestamp.now() in that it returns the local time rather than UTC. Also, Timestamp('today') is now equivalent to Timestamp.today() and both have tz as a possible argument. (GH9000)

• Fix negative step support for label-based slices (GH8753)

Old behavior:

In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
Out[1]:
a 0
b 1
c 2
dtype: int64

In [2]: s.loc['c':'a':-1]
Out[2]:
c 2
dtype: int64

New behavior:

In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])

In [19]: s.loc['c':'a':-1]
Out[19]:
c 2
b 1
a 0
dtype: int64

1.20.2 Enhancements

Categorical enhancements:

• Added ability to export Categorical data to Stata (GH8633). See here for limitations of categorical variables exported to Stata data files.

• Added flag order_categoricals to StataReader and read_stata to select whether to order imported categorical data (GH8836). See here for more information on importing categorical variables from Stata data files.

• Added ability to export Categorical data to/to from HDF5 (GH7621). Queries work the same as if it was an object array. However, the category dtype data is stored in a more efficient manner. See here for an example and caveats w.r.t. prior versions of pandas.

• Added support for searchsorted() on Categorical class (GH8420).

Other enhancements:

• Added the ability to specify the SQL type of columns when writing a DataFrame to a database (GH8778). For example, specifying to use the sqlalchemy String type instead of the default Text type for string columns:
from sqlalchemy.types import String

data.to_sql('data_dtype', engine, dtype={'Col_1': String})

• Series.all and Series.any now support the level and skipna parameters (GH8302):

In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])

In [21]: s.any(level=0)
Out[21]:
0  True
1  False
dtype: bool

• Panel now supports the all and any aggregation functions. (GH8302):

In [22]: p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)

In [23]: p.all()
Out[23]:
     0  1  2  3
0   True  True  True  True
1   True  True  False  True
2   True  True  True  True
3   True  True  False  True
4   True  True  True  True

• Added support for utcfromtimestamp(), fromtimestamp(), and combine() on Timestamp class (GH5351).

• Added Google Analytics (pandas.io.ga) basic documentation (GH8835). See here.

• Timedelta arithmetic returns NotImplemented in unknown cases, allowing extensions by custom classes (GH8813).

• Timedelta now supports arithmetic with numpy.ndarray objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).

• Added Timedelta.to_timedelta64() method to the public API (GH8884).

• Added gbq.generate_bq_schema() function to the gbq module (GH8325).

• Series now works with map objects the same way as generators (GH8909).

• Added context manager to HDFStore for automatic closing (GH8791).

• to_datetime gains an exact keyword to allow for a format to not require an exact match for a provided format string (if its False). exact defaults to True (meaning that exact matching is still the default) (GH8904)

• Added axvlines boolean option to parallel_coordinates plot function, determines whether vertical lines will be printed, default is True

• Added ability to read table footers to read_html (GH8552)

• to_sql now infers datatypes of non-NA values for columns that contain NA values and have dtype object (GH8778).

1.20.3 Performance

• Reduce memory usage when skiprows is an integer in read_csv (GH8681)
- **Performance** boost for `to_datetime` conversions with a passed `format=`, and the `exact=False` (GH8904)

### 1.20.4 Bug Fixes

- **Bug in** `concat` of `Series` with `category` `dtype` which were coercing to `object`. (GH8641)
- **Bug in** `Timestamp-Timestamp` not returning a `Timedelta` type and date-like-date-like ops with timezones (GH8865)
- Made consistent a timezone mismatch exception (either tz operated with `None` or incompatible timezone), will now return `TypeError` rather than `ValueError` (a couple of edge cases only), (GH8865)
- **Bug in** using a `pd.Grouper(key=...)` with no level/axis or level only (GH8795, GH8866)
- **Bug** in using a `pd.Grouper(key=...)` with no level/axis or level only (GH8795, GH8866)
- **Bug in** `Timestamp-Timestamp` not returning a `Timedelta` type and date-like-date-like ops with timezones (GH8865)
- **Report a** `TypeError` when invalid/no parameters are passed in a `groupby` (GH8015)
- **Bug in** packaging pandas with `py2app/cx_Freeze` (GH8602, GH8831)
- **Bug in** `df.groupby` signatures that didn’t include `*args` or `**kwargs` (GH8733).
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)
- **Bug in** slicing a multi-index with an empty list and at least one boolean indexer (GH8781)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo (GH8761).
- `Timedelta` `kwargs` may now be numpy ints and floats (GH8757).
- Fixed several outstanding bugs for `Timedelta` arithmetic and comparisons (GH8813, GH5963, GH5436).
- `sql_schema` now generates dialect appropriate `CREATE TABLE` statements (GH8697)
- `slice` string method now takes step into account (GH8754)
- **Bug in** `BlockManager` where setting values with different type would break block integrity (GH8850)
- **Bug in** `DatetimeIndex` when using `time` `object` as key (GH8667)
- **Bug in** `merge` where how='left' and sort=False would not preserve left frame order (GH7331)
- **Bug in** `MultiIndex.reindex` where reindexing at level would not reorder labels (GH4088)
- **Bug in** certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)
- Regression in `DatetimeIndex` iteration with a Fixed/Local offset timezone (GH8890)
- **Bug in** `to_datetime` when parsing a nanoseconds using the `%f` format (GH8989)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- **Fix:** The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- **Fixed division by 0** when reading big csv files in python 3 (GH8621)
- **Bug in** outputting a `Multindex` with `to_html`, `index=False` which would add an extra column (GH8452)
- **Imported categorical variables** from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined `.size` attribute across `NDFrame` objects to provide compat with numpy >= 1.9.1; buggy with `np.array_split` (GH8846)
• Skip testing of histogram plots for matplotlib <= 1.2 (GH8648).
• Bug where `get_data_google` returned object dtypes (GH3995)
• Bug in `DataFrame.stack(..., dropna=False)` when the DataFrame’s columns is a MultiIndex whose labels do not reference all its levels. (GH8844)
• Bug in that Option context applied on `__enter__` (GH8514)
• Bug in resample that causes a ValueError when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
• Bug where `DataFrame.plot(kind='scatter')` fails when checking if an np.array is in the DataFrame (GH8852)
• Bug in `pd.infer_freq/DataFrame.inferred_freq` that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
• Bug where index name was still used when plotting a series with `use_index=False` (GH8558).
• Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
• Bug in `MultiIndex` where `__contains__` returns wrong result if index is not lexically sorted or unique (GH7724)
• BUG CSV: fix problem with trailing whitespace in skipped rows, (GH8679), (GH8661), (GH8983)
• Regression in `Timestamp` does not parse ‘Z’ zone designator for UTC (GH8771)
• Bug in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
• Fixed ValueError raised by `cummin/cummax` when datetime64 Series contains NaT. (GH8965)
• Bug in `DataReader` returns object dtype if there are missing values (GH8980)
• Bug in plotting if `sharex` was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
• Bug where passing a unit to the `TimedeltaIndex` constructor applied the to nano-second conversion twice. (GH9011).
• Bug in plotting of a period-like array (GH9012)

1.21 v0.15.1 (November 9, 2014)

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

• Enhancements
• API Changes
• Bug Fixes

1.21.1 API changes

• `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously -1). (GH8689)
In [1]: s = Series(date_range('20130101', periods=5, freq='D'))

In [2]: s.iloc[2] = np.nan

In [3]: s
Out[3]:
0 2013-01-01
1 2013-01-02
2 NaT
3 2013-01-04
4 2013-01-05
dtype: datetime64[ns]

previous behavior:

In [6]: s.dt.hour
Out[6]:
0 0
1 0
2 -1
3 0
4 0
dtype: int64

current behavior:

In [4]: s.dt.hour
Out[4]:
0 0.0
1 0.0
2 NaN
3 0.0
4 0.0
dtype: float64

• groupby with as_index=False will not add erroneous extra columns to result (GH8582):

In [5]: np.random.seed(2718281)

In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)),
...: columns=['jim', 'joe'])

In [7]: df.head()
Out[7]:
   jim  joe
0   61   81
1   96   49
2   55   65
3   72   51
4   77   12

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))
In [4]: df.groupby(ts, as_index=False).max()
Out[4]:
         NaN  jim  joe
0      0.0  72.0  83.0
1      5.0  77.0  84.0
2     10.0  96.0  65.0

current behavior:

In [9]: df.groupby(ts, as_index=False).max()
Out[9]:
         jim  joe
0      72.0  83.0
1      77.0  84.0
2     96.0  65.0

• groupby will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})

In [11]: df
Out[11]:
         jim  joe
0       0.0   5.0
1       1.0   6.0
2       2.0   7.0
3       3.0   8.0
4       4.0   9.0

In [12]: gr = df.groupby(df['jim'] < 2)

previous behavior (excludes 1st column from output):

In [4]: gr.apply(sum)
Out[4]:

       joe
jim
False  24.0
True   11.0

current behavior:

In [13]: gr.apply(sum)
Out[13]:

       jim  joe
       jim
jim
False  9.0  24.0
True   1.0   11.0

• Support for slicing with monotonic decreasing indexes, even if start or stop is not found in the index (GH7860):

In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])

In [15]: s
Out[15]:
4    a

(continues on next page)
previous behavior:

```
In [8]: s.loc[3.5:1.5]
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
Out[16]:
3  b
2  c
dtype: object
```

• `io.data.Options` has been fixed for a change in the format of theYahoo Options page (GH8612), (GH8741)

**Note:** As a result of a change in Yahoo’s option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsMMYY` and `putsMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

– The expiry parameter can now be a single date or a list-like object containing dates.

– A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options
In [18]: aapl = Options('aapl','yahoo')
In [19]: aapl.get_call_data().iloc[0:5,0:1]
Out[19]:
   Strike  Expiry          Type Symbol         Last
     80  2014-11-14    call AAPL141114C00080000  29.05
     84  2014-11-14    call AAPL141114C00084000  24.80
     85  2014-11-14    call AAPL141114C00085000  24.05
     86  2014-11-14    call AAPL141114C00086000  22.76
     87  2014-11-14    call AAPL141114C00087000  21.74
In [20]: aapl.expiry_dates
Out[20]:
[datetime.date(2014, 11, 14),
  datetime.date(2014, 11, 15),
]```
pandas: powerful Python data analysis toolkit, Release 0.23.2

```python
datetime.date(2014, 11, 22),
datetime.date(2014, 11, 28),
datetime.date(2014, 12, 5),
datetime.date(2014, 12, 12),
datetime.date(2014, 12, 20),
datetime.date(2015, 1, 17),
datetime.date(2015, 2, 20),
datetime.date(2015, 4, 17),
datetime.date(2015, 7, 17),
datetime.date(2016, 1, 15),
datetime.date(2017, 1, 20)]
```

```python
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5,0:1]
Out[21]:
```

<table>
<thead>
<tr>
<th>Strike</th>
<th>Expiry</th>
<th>Type</th>
<th>Symbol</th>
<th>Last</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
<td>2014-11-22</td>
<td>call</td>
<td>AAPL141122C00109000</td>
<td>1.48</td>

</tbody>
</table>

- pandas now also registers the `datetime64` dtype in matplotlib’s units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

### 1.21.2 Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

```python
In [17]: from collections import deque
In [18]: df1 = pd.DataFrame([1, 2, 3])
In [19]: df2 = pd.DataFrame([4, 5, 6])
```

previous behavior:

```python
In [7]: pd.concat(deque((df1, df2)))
 TypeError: first argument must be a list-like of pandas objects, you passed an object of type "deque"
```

current behavior:

```python
In [20]: pd.concat(deque((df1, df2)))
Out[20]:
```

<table>
<thead>
<tr>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>2</td>
<td>3</td>
<td>0</td>
<td>4</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>2</td>
<td>6</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```
• Represent MultiIndex labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the reported memory usage was incorrect as it didn’t show the usage for the memory occupied by the underlying data array. (GH8456)

```python
In [21]: dfi = DataFrame(1,index=pd.MultiIndex.from_product([['a'],range(1000)]),
       →columns=['A'])
```

previous behavior:

```python
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out[1]:
Index 8000 # took about 24008 bytes in < 0.15.1
A 8000
dtype: int64
```

current behavior:

```python
In [22]: dfi.memory_usage(index=True)
Out [22]:
Index 52080
A 8000
dtype: int64
```

• Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).
• Added option to select columns when importing Stata files (GH7935)
• Qualify memory usage in DataFrame.info() by adding + if it is a lower bound (GH8578)
• Raise errors in certain aggregation cases where an argument such as numeric_only is not handled (GH8592).
• Added support for 3-character ISO and non-standard country codes in io.wb.download() (GH8482)
• World Bank data requests now will warn/raise based on an errors argument, as well as a list of hard-coded country codes and the World Bank’s JSON response. In prior versions, the error messages didn’t look at the World Bank’s JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
• Added option to Series.str.split() to return a DataFrame rather than a Series (GH8428)
• Added option to df.info(null_counts=None|True|False) to override the default display options and force showing of the null-counts (GH8701)

1.21.3 Bug Fixes

• Bug in unpickling of a CustomBusinessDay object (GH8591)
• Bug in coercing Categorical to a records array, e.g. df.to_records() (GH8626)
• Bug in Categorical not created properly with Series.to_frame() (GH8626)
• Bug in coercing in astype of a Categorical of a passed pd.Categorical (this now raises TypeError correctly), (GH8626)
• Bug in cut/qcut when using Series and retbins=True (GH8589)
• Bug in writing Categorical columns to an SQL database with to_sql (GH8624).
• Bug in comparing Categorical of datetime raising when being compared to a scalar datetime (GH8687)
• Bug in selecting from a Categorical with .iloc (GH8623)
• Bug in groupby-transform with a Categorical (GH8623)
• Bug in duplicated/drop_duplicates with a Categorical (GH8623)
• Bug in Categorical reflected comparison operator raising if the first argument was a numpy array scalar (e.g. np.int64) (GH8658)
• Bug in Panel indexing with a list-like (GH8710)
• Compat issue is DataFrame.dtypes when options.mode.use_inf_as_null is True (GH8722)
• Bug in read_csv, dialect parameter would not take a string (GH8703)
• Bug in slicing a multi-index level with an empty-list (GH8737)
• Bug in numeric index operations of add/sub with Float/Index Index with numpy arrays (GH8608)
• Bug in setitem with empty indexer and unwanted coercion of dtypes (GH8669)
• Bug in ix/loc block splitting on setitem (manifests with integer-like dtypes, e.g. datetime64) (GH8607)
• Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
• Bug when indexing a Float64Index with np.nan on numpy 1.7 (GH8980).
• Fix shape attribute for MultiIndex (GH8609)
• Bug in GroupBy where a name conflict between the grouper and columns would break groupby operations (GH7115, GH8112)
• Fixed a bug where plotting a column y and specifying a label would mutate the index name of the original DataFrame (GH8494)
• Fix regression in plotting of a DatetimeIndex directly with matplotlib (GH8614).
• Bug in date_range where partially-specified dates would incorporate current date (GH6961)
• Bug in Setting by indexer to a scalar value with a mixed-dtype Panel4d was failing (GH8702)
• Bug where DataReader's would fail if one of the symbols passed was invalid. Now returns data for valid symbols and np.nan for invalid (GH8494)
• Bug in get_quote_yahoo that wouldn’t allow non-float return values (GH5229).

1.22 v0.15.0 (October 18, 2014)

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas >= 0.15.0 will no longer support compatibility with NumPy versions < 1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy >= 1.7.0 (GH7711)

• Highlights include:
  – The Categorical type was integrated as a first-class pandas type, see here
  – New scalar type Timedelta, and a new index type TimedeltaIndex, see here
– New datetimelike properties accessor .dt for Series, see Datetimelike Properties
– New DataFrame default display for df.info() to include memory usage, see Memory Usage
– read_csv will now by default ignore blank lines when parsing, see here
– API change in using Indexes in set operations, see here
– Enhancements in the handling of timezones, see here
– A lot of improvements to the rolling and expanding moment functions, see here
– Internal refactoring of the Index class to no longer sub-class ndarray, see Internal Refactoring
– dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)
– Split indexing documentation into Indexing and Selecting Data and MultiIndex / Advanced Indexing
– Split out string methods documentation into Working with Text Data

• Check the API Changes and deprecations before updating
• Other Enhancements
• Performance Improvements
• Bug Fixes

Warning: In 0.15.0 Index has internally been refactored to no longer sub-class ndarray but instead subclass PandasObject, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the Internal Refactoring)

Warning: The refactorings in Categorical changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use Categorical directly, please audit your code before updating to this pandas version and change it to use the from_codes() constructor. See more on Categorical here

1.22.1 New features

1.22.1.1 Categoricals in Series/DataFrame

Categorical can now be included in Series and DataFrames and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the categorical introduction and the API documentation.

In [1]: df = DataFrame({"id": [1, 2, 3, 4, 5, 6], "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e ∧']})

In [2]: df["grade"] = df["raw_grade"].astype("category")

In [3]: df["grade"]
Out[3]:
   0  a
   1  b

(continues on next page)
Name: grade, dtype: category
Categories (3, object): [a, b, e]

# Rename the categories
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

# Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [6]: df["grade"]
Out[6]:
0 very good
1 good
2 good
3 very good
4 very good
5 very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

In [7]: df.sort_values("grade")

In [8]: df.groupby("grade").size()
1.22.1.2 TimedeltaIndex/Scalar

We introduce a new scalar type Timedelta, which is a subclass of \texttt{datetime.timedelta}, and behaves in a similar manner, but allows compatibility with \texttt{np.timedelta64} types as well as a host of custom representation, parsing, and attributes. This type is very similar to how \texttt{Timestamp} works for datetimes. It is a nice-API box for the type. See the \texttt{docs}. (GH3009, GH4533, GH8209, GH8187, GH8190, GH7869, GH7661, GH8345, GH8471)

\begin{table}[h]
\centering
\begin{tabular}{|l|}
\hline
\textbf{Warning:} Timedelta scalars (and TimedeltaIndex) component fields are \textit{not the same} as the component fields on a \texttt{datetime.timedelta} object. For example, \texttt{.seconds} on a \texttt{datetime.timedelta} object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas \texttt{Timedelta} breaks out hours, minutes, microseconds and nanoseconds separately. \\
\hline
\end{tabular}
\end{table}

\begin{verbatim}
# Timedelta accessor
In [9]: tds = Timedelta('31 days 5 min 3 sec')

In [10]: tds.minutes
Out[10]: 5L

In [11]: tds.seconds
Out[11]: 3L

# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
\end{verbatim}

\textbf{Note:} this is no longer true starting from v0.16.0, where full compatibility with \texttt{datetime.timedelta} is introduced. See the \texttt{0.16.0 whatstnew entry}

\begin{table}[h]
\centering
\begin{tabular}{|l|}
\hline
\textbf{Warning:} Prior to 0.15.0 \texttt{pd.to_timedelta} would return a Series for list-like/Series input, and a \texttt{np.timedelta64} for scalar input. It will now return a TimedeltaIndex for list-like input, Series for Series input, and Timedelta for scalar input.

The arguments to \texttt{pd.to_timedelta} are now (\texttt{arg,unit='ns',box=True,coerce=False}), previously were (\texttt{arg,box=True,unit='ns'}) as these are more logical.

\end{tabular}
\end{table}

Construct a scalar

\begin{verbatim}
In [9]: Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: Timedelta('15.5us')
Out[10]: Timedelta('0 days 00:00:00.000015')

In [11]: Timedelta('1 hour 15.5us')
Out[11]: Timedelta('0 days 01:00:00.000015')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: Timedelta('-1us')
Out[12]: Timedelta('-1 days +23:59:59.999999')
\end{verbatim}

(continues on next page)
# a NaT

```
In [13]: Timedelta('nan')
NaT
```

Access fields for a `Timedelta`

```
In [14]: td = Timedelta('1 hour 3m 15.5us')
In [15]: td.seconds
Out[15]: 3780
In [16]: td.microseconds
Out[16]: 16
In [17]: td.nanoseconds
Out[17]: 500
```

Construct a `TimedeltaIndex`

```
In [18]: TimedeltaIndex(['1 days','1 days, 00:00:05',
                      ....:  np.timedelta64(2,'D'),timedelta(days=2,seconds=2))])
```

Constructing a `TimedeltaIndex` with a regular range

```
In [19]: timedelta_range('1 days',periods=5,freq='D')
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
                      dtype='timedelta64[ns]', freq='D')
In [20]: timedelta_range(start='1 days',end='2 days',freq='30T')
Out[20]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                        '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                        '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                        '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                        '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                        '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                        '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                        '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                        '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                        '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                        '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                        '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                        '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                        '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                        '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                        '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                        '2 days 00:00:00'],
                       dtype='timedelta64[ns]', freq='30T')
```
You can now use a TimedeltaIndex as the index of a pandas object

```python
In [21]: s = Series(np.arange(5),
                   index=timedelta_range('1 days', periods=5, freq='s'))

In [22]: s
Out[22]:
    1 days 00:00:00    0
    1 days 00:00:01    1
    1 days 00:00:02    2
    1 days 00:00:03    3
    1 days 00:00:04    4
Freq: S, dtype: int64
```

You can select with partial string selections

```python
In [23]: s['1 day 00:00:02']
Out[23]: 2

In [24]: s['1 day':'1 day 00:00:02']
Out[24]:
    1 days 00:00:00    0
    1 days 00:00:01    1
    1 days 00:00:02    2
Freq: S, dtype: int64
```

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

```python
In [25]: tdi = TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [27]: dti = date_range('20130101', periods=3)

In [28]: dti.tolist()
Out[28]: [Timestamp('2013-01-01 00:00:00', freq='D'),
          Timestamp('2013-01-02 00:00:00', freq='D'),
          Timestamp('2013-01-03 00:00:00', freq='D')]

In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

- iteration of a Series e.g. list(Series(...)) of timedelta64[ns] would prior to v0.15.0 return np.timedelta64 for each element. These will now be wrapped in Timedelta.

### 1.2.2.1.3 Memory Usage

Implemented methods to find memory usage of a DataFrame. See the FAQ for more. (GH6852).
A new display option `display.memory_usage` (see Options and Settings) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```python
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
          'complex128', 'object', 'bool']

In [32]: n = 5000

In [33]: data = dict{ (t, np.random.randint(100, size=n).astype(t))
          for t in dtypes}

In [34]: df = DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
    int64 5000 non-null int64
    float64 5000 non-null float64
    datetime64[ns] 5000 non-null datetime64[ns]
    timedelta64[ns] 5000 non-null timedelta64[ns]
    complex128 5000 non-null complex128
    object 5000 non-null object
    bool 5000 non-null bool
categorical 5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
˓→object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```python
In [37]: df.memory_usage(index=True)
Out[37]:
Index     80
int64  40000
float64 40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128 80000
object  40000
bool  5000
 categorical 10920
dtype: int64
```

### 1.22.1.4 .dt accessor

Series has gained an accessor to succinctly return datetime like properties for the values of the Series, if its a datetime/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the docs

```python
# datetime
In [38]: s = Series(date_range('20130101 09:10:12', periods=4))
```
In [39]: s
Out[39]:
0 2013-01-01 09:10:12
1 2013-01-02 09:10:12
2 2013-01-03 09:10:12
3 2013-01-04 09:10:12
dtype: datetime64[ns]

In [40]: s.dt.hour
Out[40]:
0 9
1 9
2 9
3 9
dtype: int64

In [41]: s.dt.second
Out[41]:
0 12
1 12
2 12
3 12
dtype: int64

In [42]: s.dt.day
Out[42]:
0 1
1 2
2 3
3 4
dtype: int64

In [43]: s.dt.freq
Out[43]: 'D'

This enables nice expressions like this:

In [44]: s[s.dt.day==2]
Out[44]:
1 2013-01-02 09:10:12
dtype: datetime64[ns]

You can easily produce tz aware transformations:

In [45]: stz = s.dt.tz_localize('US/Eastern')

In [46]: stz
Out[46]:
0 2013-01-01 09:10:12-05:00
1 2013-01-02 09:10:12-05:00
2 2013-01-03 09:10:12-05:00
3 2013-01-04 09:10:12-05:00
You can also chain these types of operations:

```
In [48]: stz.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[48]:
0  2013-01-01 04:10:12-05:00
1  2013-01-02 04:10:12-05:00
2  2013-01-03 04:10:12-05:00
3  2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

The `.dt` accessor works for period and timedelta dtypes.

```
In [49]: s = Series(period_range('20130101', periods=4, freq='D'))
In [50]: s
Out[50]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
3  2013-01-04
dtype: object
In [51]: s.dt.year
Out[51]:
0  2013
1  2013
2  2013
3  2013
dtype: int64
In [52]: s.dt.day
Out[52]:
0  1
1  2
2  3
3  4
dtype: int64
```

```
In [53]: s = Series(timedelta_range('1 day 00:00:05', periods=4, freq='s'))
In [54]: s
Out[54]:
0  1 days 00:00:05
1  1 days 00:00:06
2  1 days 00:00:07
3  1 days 00:00:08
```
dtype: timedelta64[ns]

In [55]: s.dt.days

→ 0 1
   1 1
   2 1
   3 1
dtype: int64

In [56]: s.dt.seconds

→ 0 5
   1 6
   2 7
   3 8
dtype: int64

In [57]: s.dt.components

→  days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
   0  1  0  0  5  0  0  0
   1  1  0  0  6  0  0  0
   2  1  0  0  7  0  0  0
   3  1  0  0  8  0  0  0

1.22.1.5 Timezone handling improvements

- `tz_localize(None)` for tz-aware Timestamp and DatetimeIndex now removes timezone holding local time, previously this resulted in Exception or TypeError (GH7812)

In [58]: ts = Timestamp('2014-08-01 09:00', tz='US/Eastern')

In [59]: ts
Out[59]: Timestamp('2014-08-01 09:00:00-04:00', tz='US/Eastern')

In [60]: ts.tz_localize(None)

→ Timestamp('2014-08-01 09:00:00')

In [61]: didx = DatetimeIndex(start='2014-08-01 09:00', freq='H', periods=10, tz=→'US/Eastern')

In [62]: didx
Out[62]: DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
   '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
   '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
   '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
   '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
dtype='datetime64[ns, US/Eastern]', freq='H')
In [63]: didx.tz_localize(None)

Datet imeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00', '2014-08-01 11:00:00', '2014-08-01 12:00:00', '2014-08-01 13:00:00', '2014-08-01 14:00:00', '2014-08-01 15:00:00', '2014-08-01 16:00:00', '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
dtype='datetime64[ns]', freq='H')

• tz_localize now accepts the ambiguous keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, 'NaT' for setting transition times to NaT, 'infer' for inferring DST/non-DST, and 'raise' (default) for an AmbiguousTimeError to be raised. See the docs for more details (GH7943)

• DataFrame.tz_localize and DataFrame.tz_convert now accepts an optional level argument for localizing a specific level of a MultiIndex (GH7846)

• Timestamp.tz_localize and Timestamp.tz_convert now raise TypeError in error cases, rather than Exception (GH8025)

• a timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone (rather than being a naive datetime64[ns]) as object dtype (GH8411)

• Timestamp.__repr__ displays dateutil.tz.tzoffset info (GH7907)

1.22.1.6 Rolling/Expanding Moments improvements

• rolling_min(), rolling_max(), rolling_cov(), and rolling_corr() now return objects with all NaN when len(arg) < min_periods <= window rather than raising. (This makes all rolling functions consistent in this behavior). (GH7766)

Prior to 0.15.0

In [64]: s = Series([10, 11, 12, 13])

In [15]: rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)

New behavior

In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out[4]:
0   NaN
1   NaN
2   NaN
3   NaN
dtype: float64

• rolling_max(), rolling_min(), rolling_sum(), rolling_mean(), rolling_median(), rolling_std(), rolling_var(), rolling_skew(), rolling_kurt(), rolling_quantile(), rolling_cov(), rolling_corr(), rolling_corr_pairwise(), rolling_window(), and rolling_apply() with center=True previously would return a result of the same structure as the input arg with NaN in the final (window-1)/2 entries.

Now the final (window-1)/2 entries of the result are calculated as if the input arg were followed by (window-1)/2 NaN values (or with shrinking windows, in the case of rolling_apply()). (GH7925, GH8269)
Prior behavior (note final value is NaN):

```python
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out[7]:
0   1
1   3
2   6
3  NaN
dtype: float64
```

New behavior (note final value is $5 = \sum([2, 3, \text{NaN}])$):

```python
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out[7]:
0   1
1   3
2   6
3   5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode ($\text{mean=True}$) so that the calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated without weighting (i.e. ‘boxcar’). See the note on normalization for further details. (GH7618)

Behavior prior to 0.15.0:

```python
In [39]: rolling_window(s, window=3, win_type='triang', center=True)
Out[39]:
0   NaN
1  6.583333
2  6.883333
3  6.683333
4   NaN
dtype: float64
```

New behavior

```python
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out[10]:
0   NaN
1   9.875
2  10.325
3  10.025
4   NaN
dtype: float64
```

- Removed `center` argument from all `expanding_` functions (see list), as the results produced when `center=True` did not make much sense. (GH7925)
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. (GH8279)
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and `rolling_std()`. These functions’ support of a `ddof` argument (with a default value of 1) was previously undocumented. (GH8064)
• `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*()` and `expanding_*()` functions do: a given result entry will be NaN if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to NaN the `min_periods` entries starting with the first non-NaN value. (GH7977)

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```
In [66]: s = Series([1, None, None, None, 2, 3])
In [51]: ewma(s, com=3., min_periods=2)
Out[51]:
0    NaN
1    NaN
2    1.000000
3    1.000000
4    1.571429
5    2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```
In [2]: pd.ewma(s, com=3., min_periods=2)
Out[2]:
0    NaN
1    NaN
2    NaN
3    NaN
4    1.759644
5    2.383784
dtype: float64
```

• `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See Exponentially weighted moment functions for details. (GH7911)

• `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```
In [7]: pd.ewma(Series([None, 1., 8.]), com=2.)
Out[7]:
0  1.0
1  5.2
dtype: float64
```

```
In [8]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=True)  # pre-0.15.0 behavior
Out[8]:
0  1.0
1  1.0
2  5.2
dtype: float64
```

```
In [9]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=False)  # new default
(continues on next page)
```
Out[9]:
0  1.000000
1  1.000000
2  5.846154
dtype: float64

**Warning:** By default (ignore_na=False) the ewm*() functions’ weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly ignore_na=True.

- Bug in expanding_cov(), expanding_corr(), rolling_cov(), rolling_cor(), ewmcov(), and ewmcorr() returning results with columns sorted by name and producing an error for non-unique columns: now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with pairwise=False, where behavior is unchanged) (GH7542)
- Bug in rolling_count() and expanding_*() functions unnecessarily producing error message for zero-length data (GH8056)
- Bug in rolling_apply() and expanding_apply() interpreting min_periods=0 as min_periods=1 (GH8080)
- Bug in expanding_std() and expanding_var() for a single value producing a confusing error message (GH7900)
- Bug in rolling_std() and rolling_var() for a single value producing 0 rather than NaN (GH7900)
- Bug in ewmstd(), ewmvol(), ewmvar(), and ewmcorr() calculation of de-biasing factors when bias=False (the default). Previously an incorrect constant factor was used, based on adjust=True, ignore_na=True, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual \(N/(N-1)\) factor). In particular, for a single point a value of NaN is returned when bias=False, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for ewmvar(..., bias=False), and the corresponding debiasing factors:

```
In [67]: s = Series([1., 2., 0., 4.])
In [89]: ewmvar(s, com=2., bias=False)
Out[89]:
0   -2.775558e-16
1     3.000000e-01
2     9.556787e-01
3    3.585799e+00
dtype: float64
In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
Out[90]:
0     1.25
1     1.25
2     1.25
3     1.25
dtype: float64
```

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):
```python
In [14]: pd.ewmvar(s, com=2., bias=False)
Out[14]:
0    NaN
1   0.500000
2   1.210526
3   4.089069
dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out[15]:
0   NaN
1  2.083333
2  1.583333
3  1.425439
dtype: float64
```

See *Exponentially weighted moment functions* for details. (GH7912)

### 1.22.1.7 Improvements in the sql io module

- Added support for a `chunksize` parameter to `to_sql` function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a `schema` to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

  ```python
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
  ```

- Added support for writing NaN values with `to_sql` (GH2754).
- Added support for writing datetime64 columns with `to_sql` for all database flavors (GH7103).

### 1.22.2 Backwards incompatible API changes

#### 1.22.2.1 Breaking changes

API changes related to `Categorical` (see *here* for more details):

- The `Categorical` constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

  An old function call like (prior to 0.15.0):

  ```python
  pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
  ```

  will have to adapted to the following to keep the same behaviour:
In [2]: pd.Categorical.from_codes([0,1,0,2,1], categories=['a', 'b', 'c'])
Out[2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]

API changes related to the introduction of the Timedelta scalar (see above for more details):

- Prior to 0.15.0 to_timedelta() would return a Series for list-like/Series input, and a np.
timedelta64 for scalar input. It will now return a TimedeltaIndex for list-like input, Series for
Series input, and Timedelta for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview above.

Other notable API changes:

- Consistency when indexing with .loc and a list-like indexer when no values are found.

In [68]: df = DataFrame([['a'], ['b']],index=[1,2])
In [69]: df
Out[69]:
   0
  0 a
  1 b

In prior versions there was a difference in these two constructs:

- df.loc[[3]] would return a frame reindexed by 3 (with all np.nan values)
- df.loc[[3],:] would raise KeyError.

Both will now raise a KeyError. The rule is that at least 1 indexer must be found when using a list-like and .loc (GH7999)

Furthermore in prior versions these were also different:

- df.loc[[1,3]] would return a frame reindexed by [1,3]
- df.loc[[1,3],:] would raise KeyError.

Both will now return a frame reindex by [1,3]. E.g.

In [3]: df.loc[[1,3]]
Out[3]:
   0
  0 a
  1 a
  3 NaN

In [4]: df.loc[[1,3],:]
Out[4]:
   0
  0 a
  1 a
  3 NaN

This can also be seen in multi-axis indexing with a Panel.

In [70]: p = Panel(np.arange(2*3*4).reshape(2,3,4),
   ....:     items=['ItemA','ItemB'],
   ....:     major_axis=[1,2,3],
   ....:     minor_axis=['A','B','C','D'])
   ....:
(continues on next page)
In [71]: p
Out[71]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D

The following would raise **KeyError** prior to 0.15.0:

In [5]:
Out[5]:
    ItemA  ItemD
   1     3  NaN
   2     7  NaN
   3    11  NaN

Furthermore, `.loc` will raise **KeyError** if no values are found in a multi-index with a list-like indexer:

In [72]: s = Series(np.arange(3, dtype='int64'),
               index=MultiIndex.from_product([['A'], ['foo', 'bar', 'baz']],
                                           names=['one', 'two'])).sort_index()

In [73]: s
Out[73]:
   one   two
   A   bar  1
   baz  2
   foo  0
dtype: int64

In [74]: try:
    ....:    s.loc[['D']]  
    ....: except KeyError as e:
    ....:        print("KeyError: " + str(e))
    ....:        print("\['D' not in index"

• Assigning values to `None` now considers the dtype when choosing an ‘empty’ value (GH7941).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses NaN:

In [75]: s = Series([1, 2, 3])

In [76]: s.loc[0] = None

In [77]: s
Out[77]:
   0  NaN
   1  2.0
   2  3.0
dtype: float64
NaT is now used similarly for datetime containers.

For object containers, we now preserve None values (previously these were converted to NaN values).

```
In [78]: s = Series(['a', 'b', 'c'])
In [79]: s.loc[0] = None
In [80]: s
Out[80]:
0    None
1      b
2      c
dtype: object
```

To insert a NaN, you must explicitly use np.nan. See the docs.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [81]: s = Series([1, 2, 3])
In [82]: s2 = s
In [83]: s += 1.5

Behavior prior to v0.15.0

# the original object
In [5]: s
Out[5]:
0    2.5
1    3.5
2    4.5
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0    1
1    2
2    3
dtype: int64

This is now the correct behavior

# the original object
In [84]: s
Out[84]:
0    2.5
1    3.5
2    4.5
dtype: float64

# a reference to the original object
In [85]: s2
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.2

1 3.5
2 4.5
dtype: float64

• Made both the C-based and Python engines for read_csv and read_table ignore empty lines in input as well as whitespace-filled lines, as long as sep is not whitespace. This is an API change that can be controlled by the keyword parameter skip_blank_lines. See the docs (GH4466)

• A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as object dtype rather than being converted to a naive datetime64[ns] (GH8411).

• Bug in passing a DatetimeIndex with a timezone that was not being retained in DataFrame construction from a dict (GH7822)

  In prior versions this would drop the timezone, now it retains the timezone, but gives a column of object dtype:

  In [86]: i = date_range('1/1/2011', periods=3, freq='10s', tz = 'US/Eastern')
  In [87]: i
  Out[87]:
  DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
  '2011-01-01 00:00:20-05:00'],
  dtype='datetime64[ns, US/Eastern]', freq='10S')
  In [88]: df = DataFrame( {'a' : i } )
  In [89]: df
  Out[89]:
  a
  0 2011-01-01 00:00:00-05:00
  1 2011-01-01 00:00:10-05:00
  2 2011-01-01 00:00:20-05:00

  Previously this would have yielded a column of datetime64 dtype, but without timezone info.

  The behaviour of assigning a column to an existing dataframe as df['a'] = i remains unchanged (this already returned an object column with a timezone).

• When passing multiple levels to stack(), it will now raise a ValueError when the levels aren’t all level names or all level numbers (GH7660). See Reshaping by stacking and unstacking.

• Raise a ValueError in df.to_hdf with ‘fixed’ format, if df has non-unique columns as the resulting file will be broken (GH7761)

• SettingWithCopy raise/warnings (according to the option mode.chained_assignment) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)
• merge, DataFrame.merge, and ordered_merge now return the same type as the left argument (GH7737).

• Previously an enlargement with a mixed-dtype frame would act unlike .append which will preserve dtypes (related GH2578, GH8176):

```python
In [91]: df = DataFrame([[True, 1],[False, 2]],
                        columns=["female","fitness"])
            ....:
            ....:

In [92]: df
Out[92]:
female fitness
0   True   1
1  False   2

In [93]: df.dtypes                                                                 
Out[93]:
female    bool
fitness   int64
dtype: object

# dtypes are now preserved

In [95]: df
Out[95]:
female fitness
0   True   1
1  False   2
2  False   2

In [96]: df.dtypes                                                                 
Out[96]:
female    bool
fitness   int64
dtype: object
```

• Series.to_csv() now returns a string when path=None, matching the behaviour of DataFrame.to_csv() (GH8215).

• read_hdf now raises IOError when a file that doesn’t exist is passed in. Previously, a new, empty file was created, and a KeyError raised (GH7715).

• DataFrame.info() now ends its output with a newline character (GH8114)

• Concatenating no objects will now raise a ValueError rather than a bare Exception.

• Merge errors will now be sub-classes of ValueError rather than raw Exception (GH8501)
• **DataFrame.plot** and **Series.plot** keywords are now have consistent orders (GH8037)

### 1.22.2.2 Internal Refactoring

In 0.15.0 Index has internally been refactored to no longer sub-class **ndarray** but instead subclass **PandasObject**, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (GH5080, GH7439, GH7796, GH8024, GH8367, GH7997, GH8522):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See `pickle docs`
- when plotting with a PeriodIndex, the matplotlib internal axes will now be arrays of Period rather than a PeriodIndex (this is similar to how a DatetimeIndex passes arrays of datetimes now)
- MultiIndexes will now raise similarly to other pandas objects w.r.t. truth testing, see here (GH7897).
- When plotting a DatetimeIndex directly with matplotlib’s plot function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a datetime64). **UPDATE** This is fixed in 0.15.1, see here.

### 1.22.2.3 Deprecations

- The attributes **Categorical labels** and **levels** attributes are deprecated and renamed to **codes** and **categories**.
- The **outtype** argument to `pd.DataFrame.to_dict` has been deprecated in favor of **orient**. (GH7840)
- The **convert_dummies** method has been deprecated in favor of **get_dummies** (GH8140)
- The **infer_dst** argument in `tz_localize` will be deprecated in favor of **ambiguous** to allow for more flexibility in dealing with DST transitions. Replace **infer_dst=True** with **ambiguous='infer'** for the same behavior (GH7943). See the docs for more details.
- The top-level **pd.value_range** has been deprecated and can be replaced by `.describe()` (GH8481)
- The **Index** set operations `+` and `-` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `-` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` (GH8226)

```
# +
Index(['a', 'b', 'c']) + Index(['b', 'c', 'd'])
# should be replaced by
Index(['a', 'b', 'c']).union(Index(['b', 'c', 'd']))

# -
Index(['a', 'b', 'c']) - Index(['b', 'c', 'd'])
# should be replaced by
Index(['a', 'b', 'c']).difference(Index(['b', 'c', 'd']))
```

- The **infer_types** argument to `read_html()` now has no effect and is deprecated (GH7762, GH7032).

### 1.22.2.4 Removal of prior version deprecations/changes

- Remove **DataFrame.delevel** method in favor of **DataFrame.reset_index**
### 1.22.3 Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for bool, uint8, uint16 and uint32 datatypes in `to_stata` (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`. (GH7858)
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to True. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have `object` data type. (GH8045)

Enhancements in the plotting functions:

- Added `layout` keyword to `DataFrame.plot`. You can pass a tuple of `(rows, columns)`, one of which can be `-1` to automatically infer (GH6667, GH8071).
- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` (GH5353, GH6970, GH7069)
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` (GH7780)
- Histogram from `DataFrame.plot` with `kind='hist'` (GH7809), See the docs.
- Boxplot from `DataFrame.plot` with `kind='box'` (GH7998), See the docs.

Other:

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see here (GH8002, GH8044)
- Added `searchsorted` method to `Series` objects (GH7447)
- `describe()` on mixed-types DataFrames is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See the docs (GH8164).

```
In [97]: df = DataFrame(['catA': ['foo', 'foo', 'bar'] * 8,
    ....:             'catB': ['a', 'b', 'c', 'd'] * 6,
    ....:             'numC': np.arange(24),
    ....:             'numD': np.arange(24.) + .5})

In [98]: df.describe(include=['object'])
Out[98]:
     catA  catB
   count   24   24
   unique  2   4
   top    foo  a
   freq   16   6

In [99]: df.describe(include=['number', 'object'], exclude=['float'])
```

(continues on next page)
Requesting all columns is possible with the shorthand ‘all’

```
In [100]: df.describe(include='all')
Out[100]:
         catA      catB  numC  numD
       count       24    24.000000  24.000000
       unique     2       4    NaN    NaN
        top       foo     a    NaN    NaN
        freq      16       6    NaN    NaN
       mean       NaN    NaN   11.500000  12.000000
       std        NaN    NaN    7.071068  7.071068
       min        NaN    NaN    0.000000  0.500000
       25%        NaN    NaN    5.750000  6.250000
       50%        NaN    NaN   11.500000  12.000000
       75%        NaN    NaN   17.250000  17.750000
       max        NaN    NaN   23.000000  23.500000
```

Without those arguments, `describe` will behave as before, including only numerical columns or, if none are, only categorical columns. See also the `docs`

- Added `split` as an option to the `orient` argument in `pd.DataFrame.to_dict`. (GH7840)
- The `get_dummies` method can now be used on DataFrames. By default only categorical columns are encoded as 0’s and 1’s, while other columns are left untouched.

```
In [101]: df = DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
                          'C': [1, 2, 3]})
```

```
In [102]: pd.get_dummies(df)
Out[102]:
     C   A_a   A_b   B_b   B_c
0  1  1.00  0.00  0.00  1.00
1  2  0.00  1.00  0.00  1.00
2  3  0.00  0.00  1.00  0.00
```

- `PeriodIndex` supports `resolution` as the same as `DatetimeIndex` (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple `nth` values (GH7910)
# get the first, 4th, and last date index for each month
In [105]: df.groupby((df.index.year, df.index.month)).nth([0, 3, -1])
Out[105]:
   a  b
2014 4 1 1
    4 1 1
    4 1 1
    5 1 1
    5 1 1
    5 1 1
    6 1 1
    6 1 1
    6 1 1

- Period and PeriodIndex supports addition/subtraction with timedelta-likes (GH7966)

  If Period freq is D, H, T, S, L, U, N, Timedelta-like can be added if the result can have same freq. Otherwise, only the same offsets can be added.

  In [106]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
     
  In [107]: idx
Out[107]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

  In [108]: idx + pd.offsets.Hour(2)
      
  In [109]: idx + pd.offsets.Hour(2)

  In [110]: idx = pd.period_range('2014-07', periods=5, freq='M')
     
  In [111]: idx
Out[111]:
            dtype='period[M]', freq='M')

  In [112]: idx + pd.offsets.MonthEnd(3)

- Added experimental compatibility with openpyxl for versions >= 2.0. The DataFrame.to_excel method engine keyword now recognizes openpyxl1 and openpyxl2 which will explicitly require openpyxl v1 and v2 respectively, failing if the requested version is not available. The openpyxl engine is a now a meta-engine that automatically uses whichever version of openpyxl is installed. (GH7177)
• DataFrame.fillna can now accept a DataFrame as a fill value (GH8377)

• Passing multiple levels to stack() will now work when multiple level numbers are passed (GH7660). See Reshaping by stacking and unstacking.

• set_names(), set_labels(), and set_levels() methods now take an optional level keyword argument to all modification of specific level(s) of a MultiIndex. Additionally set_names() now accepts a scalar string value when operating on an Index or on a specific level of a MultiIndex (GH7792)

```
In [113]: idx = MultiIndex.from_product([['a'], range(3), list('pqr')], names=['foo', 'bar', 'baz'])

In [114]: idx.set_names('qux', level=0)
Out[114]: MultiIndex(levels=[['a'], [0, 1, 2], ['p', 'q', 'r']], labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0, 1, 2, 0, 1, 2, 0, 1, 2]], names=['qux', 'bar', 'baz'])

In [115]: idx.set_names(['qux','corge'], level=[0,1])

In [116]: idx.set_levels(['a','b','c'], level='bar')

In [117]: idx.set_levels([['a','b','c'],[1,2,3]], level=[1,2])
```

• Index.isin now supports a level argument to specify which index level to use for membership tests (GH7892, GH7890)

```
In [1]: idx = MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [2]: idx.values
Out[2]: array([0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')], dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([ True, False, True, True, False, True], dtype=bool)

• Index now supports duplicated and drop_duplicates. (GH4060)

```
In [118]: idx = Index([1, 2, 3, 4, 1, 2])
```
In [119]: idx
Out[119]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [120]: idx.duplicated()
Out[120]: array([False, False, False, True, True], dtype=bool)

In [121]: idx.drop_duplicates()
Out[121]: Int64Index([1, 2, 3, 4], dtype='int64')

• add copy=True argument to pd.concat to enable pass thru of complete blocks (GH8252)
• Added support for numpy 1.8+ data types (bool_, int_, float_, string_) for conversion to R dataframe (GH8400)

1.22.4 Performance

• Performance improvements in DatetimeIndex.__iter__ to allow faster iteration (GH7683)
• Performance improvements in Period creation (and PeriodIndex setitem) (GH5155)
• Improvements in Series.transform for significant performance gains (revised) (GH6496)
• Performance improvements in StataReader when reading large files (GH8040, GH8073)
• Performance improvements in StataWriter when writing large files (GH8079)
• Performance and memory usage improvements in multi-key groupby (GH8128)
• Performance improvements in groupby .agg and .apply where builtins max/min were not mapped to numpy/cythonized versions (GH7722)
• Performance improvement in writing to sql (to_sql) of up to 50% (GH8208).
• Performance benchmarking of groupby for large value of ngroups (GH6787)
• Performance improvement in CustomBusinessDay,CustomBusinessMonth (GH8236)
• Performance improvement for MultiIndex.values for multi-level indexes containing datetimes (GH8543)

1.22.5 Bug Fixes

• Bug in pivot_table, when using margins and a dict aggfunc (GH8349)
• Bug in read_csv where squeeze=True would return a view (GH8217)
• Bug in checking of table name in read_sql in certain cases (GH7826).
• Bug in DataFrame.groupby where Grouper does not recognize level when frequency is specified (GH7885)
• Bug in multiindexes dtypes getting mixed up when DataFrame is saved to SQL table (GH8021)
• Bug in Series 0-division with a float and integer operand dtypes (GH7785)
• Bug in Series.astype("unicode") not calling unicode on the values correctly (GH7758)
• Bug in DataFrame.as_matrix() with mixed datetime64[ns] and timedelta64[ns] dtypes (GH7778)
• Bug in **HDFStore.select_column()** not preserving UTC timezone info when selecting a **DatetimeIndex** (GH7777)

• Bug in **to_datetime** when format='%Y%m%d' and coerce=True are specified, where previously an object array was returned (rather than a coerced time-series with NaT), (GH7930)

• Bug in **DatetimeIndex** and **PeriodIndex** in-place addition and subtraction cause different result from normal one (GH6527)

• Bug in adding and subtracting **PeriodIndex with PeriodIndex** raise **TypeError** (GH7741)

• Bug in **combine_first** with **PeriodIndex data raises TypeError** (GH3367)

• Bug in multi-index slicing with missing indexers (GH7866)

• Bug in multi-index slicing with various edge cases (GH8132)

• Regression in multi-index indexing with a non-scalar type object (GH7914)

• Bug in **Timestamp comparisons with == and int64 dtype** (GH8058)

• Bug in pickles contains **DateOffset may raise AttributeError when normalize attribute is referred internally** (GH7748)

• Bug in **Panel when using major_xs and copy=False is passed** (deprecation warning fails because of missing warnings) (GH8152).

• Bug in picking deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there’s only one block there’s no ambiguity (GH7794)

• Bug in putting a **PeriodIndex into a Series would convert to int64 dtype, rather than object of Periods** (GH7932)

• Bug in **HDFStore iteration when passing a where** (GH8014)

• Bug in **DataFrameGroupby.transform when transforming with a passed non-sorted key** (GH8046, GH8430)

• Bug in repeated timeseries line and area plot may result in **ValueError or incorrect kind** (GH7733)

• Bug in inference in a **MultiIndex with datetime.date inputs** (GH7888)

• Bug in **get where an IndexError would not cause the default value to be returned** (GH7725)

• Bug in offsets.apply, rollforward and rollback may reset nanosecond (GH7697)

• Bug in offsets.apply, rollforward and rollback may raise **AttributeError if Timestamp has dateutil tzinfo** (GH7697)

• Bug in sorting a multi-index frame with a **Float64Index** (GH8017)

• Bug in **inconsistent panel setitem with a rhs of a DataFrame for alignment** (GH7763)

• Bug in **is_superperiod and is_subperiod cannot handle higher frequencies than S** (GH7760, GH7772, GH7803)

• Bug in **32-bit platforms with Series.shift** (GH8129)

• Bug in **PeriodIndex.unique returns int64 np.ndarray** (GH7540)

• Bug in groupby.apply with a non-affecting mutation in the function (GH8467)

• Bug in **DataFrame.reset_index which has MultiIndex contains PeriodIndex or DateTimeIndex with tz raises ValueError** (GH7746, GH7793)

• Bug in **DataFrame.plot with subplots=True may draw unnecessary minor xticks and yticks** (GH7801)
- Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816)
- Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858)
- Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords (GH7844)
- Bug in `DatetimeIndex.value_counts` doesn’t preserve tz (GH7735)
- Bug in `PeriodIndex.value_counts` results in `Int64Index` (GH7735)
- Bug in `DataFrame.join` when doing left join on index and there are multiple matches (GH5391)
- Bug in `GroupBy.transform()` where int groups with a transform that didn’t preserve the index were incorrectly truncated (GH7972)
- Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` (GH7929)
- Bug in `groupby` error message when a DataFrame grouping column is duplicated (GH7511)
- Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly (GH7762, GH7032)
- Bug in `Series.str.cat` with an index which was filtered as to not include the first item (GH7857)
- Bug in `Timestamp` cannot parse nanosecond from string (GH7878)
- Bug in `Timestamp` with string offset and tz results incorrect (GH7833)
- Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results (GH7798)
- Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with tz raises IndexError (GH7880)
- Bug in `alignment` with TimeOps and non-unique indexes (GH8363)
- Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn’t (GH7870)
- Bug in `date_range()`/`DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901)
- Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949)
- Bug in `area` plot draws legend with incorrect `alpha` when `stacked=True` (GH8027)
- `Period` and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations (GH7740)
- Bug in `Holiday` with no offset or observance (GH7987)
- Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` (GH7982)
- Bug in `DateOffset` around Daylight Savings Time produces unexpected results (GH5175)
- Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 (GH8019)
- Bug in installation where `html_encoding/*_.html` wasn’t installed and therefore some tests were not running correctly (GH7927)
- Bug in `read_html` where `bytes` objects were not tested for `in _read` (GH7927)
- Bug in `DataFrame.stack()` when one of the column levels was a datelike (GH8039)
• Bug in broadcasting numpy scalars with DataFrame (GH8116)
• Bug in pivot_table performed with nameless index and columns raises KeyError (GH8103)
• Bug in DataFrame.plot(kind='scatter') draws points and errorbars with different colors when the color is specified by c keyword (GH8081)
• Bug in Float64Index where iat and at were not testing and were failing (GH8092).
• Bug in DataFrame.boxplot() where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).
• Bug in read_csv where line comments were not handled correctly given a custom line terminator or delim_whitespace=True (GH8122).
• Bug in read_html where empty tables caused a StopIteration (GH7575)
• Bug in casting when setting a column in a same-dtype block (GH7704)
• Bug in accessing groups from a GroupBy when the original grouper was a tuple (GH8121).
• Bug in .at that would accept integer indexers on a non-integer index and do fallback (GH7814)
• Bug with kde plot and NaNs (GH8182)
• Bug in GroupBy.count with float32 data type were nan values were not excluded (GH8169).
• Bug with stacked barplots and NaNs (GH8175).
• Bug in resample with non evenly divisible offsets (e.g. ‘7s’) (GH8371)
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug with DatetimeIndex.asof incorrectly matching partial strings and returning the wrong date (GH8245).
• Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
• Bug in DataFrame.__setitem__ that caused errors when setting a dataframe column to a sparse array (GH8131)
• Bug where DataFrame.boxplot() failed when entire column was empty (GH8181).
• Bug with messed variables in radviz visualization (GH8199).
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug in to_clipboard that would clip long column data (GH8305)
• Bug in DataFrame terminal display: Setting max_column/max_rows to zero did not trigger auto-resizing of dfs to fit terminal width/height (GH7180).
• Bug in OLS where running with “cluster” and “nw_lags” parameters did not work correctly, but also did not throw an error (GH5884).
• Bug in DataFrame.dropna that interpreted non-existent columns in the subset argument as the ‘last column’ (GH8303)
• Bug in Index.intersection on non-monotonic non-unique indexes (GH8362).
• Bug in masked series assignment where mismatching types would break alignment (GH8387)
• Bug in NDFrame.equals gives false negatives with dtype=object (GH8437)
• Bug in assignment with indexer where type diversity would break alignment (GH8258)
pandas: powerful Python data analysis toolkit, Release 0.23.2

- Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray (GH6552)
- Regression in `NDFrame.loc` indexing when rows/columns were converted to Float64Index if target was an empty list/ndarray (GH7774)
- Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted (GH8444)
- Bug in item assignment of a `DataFrame` with multi-index columns where right-hand-side columns were not aligned (GH7655)
- Suppress FutureWarning generated by NumPy when comparing object arrays containing NaN for equality (GH7065)
- Bug in `DataFrame.eval()` where the dtype of the `not` operator (~) was not correctly inferred as `bool`.

1.23 v0.14.1 (July 11, 2014)

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  - Support for dateutil timezones (see docs).
  - Support for ignoring full line comments in the `read_csv()` text parser.
  - New documentation section on `Options and Settings`.
  - Lots of bug fixes.

- Enhancements
- API Changes
- Performance Improvements
- Experimental Changes
- Bug Fixes

1.23.1 API changes

- Openpyxl now raises a ValueError on construction of the openpyxl writer instead of warning on pandas import (GH7284).
- For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` (GH7242)
- `Period` objects no longer raise a `TypeError` when compared using `==` with another object that isn’t a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn’t a `Period` `False` is returned. (GH7376)
• Previously, the behaviour on resetting the time or not in offsets.apply, rollforward and rollback operations differed between offsets. With the support of the normalize keyword for all offsets (see below) with a default value of False (preserve time), the behaviour changed for certain offsets (BusinessMonthBegin, MonthEnd, BusinessMonthEnd, CustomBusinessMonthEnd, BusinessYearBegin, LastWeekOfMonth, FY5253Quarter, LastWeekOfMonth, Easter):

```python
from pandas.tseries import offsets

d = pd.Timestamp('2014-01-01 09:00')

# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: Timestamp('2014-01-31 00:00:00')

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with normalize=True

# new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')

In [2]: d + offsets.MonthEnd(normalize=True)
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

• Add back #N/A N/A as a default NA value in text parsing, (regression from 0.12) (GH5521)

• Raise a TypeError on inplace-setting with a .where and a non np.nan value as this is inconsistent with a set-item expression like df[mask] = None (GH7656)

### 1.23.2 Enhancements

• Add dropna argument to `value_counts` and `nunique` (GH5569).

• Add `select_dtypes()` method to allow selection of columns based on dtype (GH7316). See the docs.

• All offsets supports the normalize keyword to specify whether offsets.apply, rollforward and rollback resets the time (hour, minute, etc) or not (default False, preserves time) (GH7156):

```python
import pandas.tseries.offsets as offsets

day = offsets.Day()

In [5]: day.apply(Timestamp('2014-01-01 09:00'))
Out[5]: Timestamp('2014-01-02 09:00:00')

In [6]: day = offsets.Day(normalize=True)

In [7]: day.apply(Timestamp('2014-01-01 09:00'))
Out[7]: Timestamp('2014-01-02 00:00:00')
```

• PeriodIndex is represented as the same format as DatetimeIndex (GH7601)

• StringMethods now work on empty Series (GH7242)

• The file parsers `read_csv` and `read_table` now ignore line comments provided by the parameter `comment`, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)
• Add **NotImplementedError** for simultaneous use of **chunksize** and **nrows** for read_csv() (GH6774).

• Tests for basic reading of public S3 buckets now exist (GH7281).

• read_html now sports an **encoding** argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).

• read_excel now supports reading from URLs in the same way that read_csv does. (GH6809)

• Support for dateutil timezones, which can now be used in the same way as pytz timezones across pandas. (GH4688)

```python
In [8]: rng = date_range('3/6/2012 00:00', periods=10, freq='D',
                      tz='dateutil/Europe/London')

In [9]: rng.tz
Out[9]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See the docs.

• Implemented **sem** (standard error of the mean) operation for Series, DataFrame, Panel, and Groupby (GH6897)

• Add **nlargest** and **nsmallest** to the Series groupby whitelist, which means you can now use these methods on a SeriesGroupBy object (GH7053).

• All offsets apply, rollforward and rollback can now handle np.datetime64, previously results in ApplyTypeError (GH7452)

• **Period** and **PeriodIndex** can contain NaT in its values (GH7485)

• Support pickling Series, DataFrame and Panel objects with non-unique labels along **item** axis (index, columns and items respectively) (GH7370).

• Improved inference of datetime/timedelta with mixed null objects. Regression from 0.13.1 in interpretation of an object Index with all null elements (GH7431)

### 1.23.3 Performance

• Improvements in dtype inference for numeric operations involving yielding performance gains for dtypes: int64, timedelta64, datetime64 (GH7223)

• Improvements in Series.transform for significant performance gains (GH6496)

• Improvements in DataFrame.transform with ufuncs and built-in grouper functions for significant performance gains (GH7383)

• Regression in groupby aggregation of datetime64 dtypes (GH7555)

• Improvements in MultiIndex.from_product for large iterables (GH7627)

### 1.23.4 Experimental

• pandas.io.data.Options has a new method, get_all_data method, and now consistently returns a multi-indexed DataFrame (GH5602)

• io.gbq.read_gbq and io.gbq.to_gbq were refactored to remove the dependency on the Google bq.py command line client. This submodule now uses httplib2 and the Google apiclient and oauth2client API client libraries which should be more stable and, therefore, reliable than bq.py. See the docs. (GH6937).
1.23.5 Bug Fixes

- Bug in DataFrame.where with a symmetric shaped frame and a passed other of a DataFrame (GH7506)
- Bug in Panel indexing with a multi-index axis (GH7516)
- Regression in datetime-like slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in setitem with list-of-lists and single vs mixed types (GH7551)
- Bug in timeops with non-aligned Series (GH7500)
- Bug in timedelta inference when assigning an incomplete Series (GH7592)
- Bug in groupby .nth with a Series and integer-like column name (GH7559)
- Bug in Series.get with a boolean accessor (GH7407)
- Bug in value_counts where NaT did not qualify as missing (NaN) (GH7423)
- Bug in to_timedelta that accepted invalid units and misinterpreted ‘m/h’ (GH7611, GH6423)
- Bug in line plot doesn’t set correct xlim if secondary_y=True (GH7459)
- Bug in grouped hist and scatter plots use old figsize default (GH7394)
- Bug in plotting subplots with DataFrame.plot, hist clears passed ax even if the number of subplots is one (GH7391)
- Bug in plotting subplots with DataFrame.boxplot with by kw raises ValueError if the number of subplots exceeds 1 (GH7391)
- Bug in subplots displays ticklabels and labels in different rule (GH5897)
- Bug in Panel.apply with a multi-index as an axis (GH7469)
- Bug in DatetimeIndex.insert doesn’t preserve name and tz (GH7299)
- Bug in DatetimeIndex.asobject doesn’t preserve name (GH7299)
- Bug in multi-index slicing with datetime-like ranges (strings and Timestamps), (GH7429)
- Bug in Index.min and max doesn’t handle nan and NaT properly (GH7261)
- Bug in PeriodIndex.min/max results in int (GH7609)
- Bug in resample where fill_method was ignored if you passed how (GH2073)
- Bug in TimeGrouper doesn’t exclude column specified by key (GH7227)
- Bug in DataFrame and Series bar and barh plot raises TypeError when bottom and left keyword is specified (GH7226)
- Bug in DataFrame.hist raises TypeError when it contains non numeric column (GH7277)
- Bug in Index.delete does not preserve name and freq attributes (GH7302)
- Bug in DataFrame.query() / eval where local string variables with the @ sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in Float64Index which didn’t allow duplicates (GH7149).
- Bug in DataFrame.replace() where truthy values were being replaced (GH7140).
- Bug in StringMethods.extract() where a single match group Series would use the matcher’s name instead of the group name (GH7313).
- Bug in isnull() when mode.use_inf_as_null == True where isnull wouldn’t test True when it encountered an inf/-inf (GH7315).
- Bug in inferred_freq results in None for eastern hemisphere timezones (GH7310)
- Bug in Easter returns incorrect date when offset is negative (GH7195)
- Bug in broadcasting with .div, integer dtypes and divide-by-zero (GH7325)
- Bug in CustomBusinessDay.apply raises NameError when np.datetime64 object is passed (GH7196)
- Bug in MultiIndex.append, concat and pivot_table don’t preserve timezone (GH6606)
- Bug in .loc with a list of indexers on a single-multi index level (that is not nested) (GH7349)
- Bug in Series.map when mapping a dict with tuple keys of different lengths (GH7333)
- Bug all StringMethods now work on empty Series (GH7242)
- Fix delegation of read_sql to read_sql_query when query does not contain ‘select’ (GH7324).
- Bug where a string column name assignment to a DataFrame with a Float64Index raised a TypeError during a call to np.isnan (GH7366).
- Bug where NDFrame.replace() didn’t correctly replace objects with Period values (GH7379).
- Bug in .ix getitem should always return a Series (GH7150)
- Bug in multi-index slicing with incomplete indexers (GH7399)
- Bug in multi-index slicing with a step in a sliced level (GH7400)
- Bug where negative indexers in DatetimeIndex were not correctly sliced (GH7408)
- Bug where NaT wasn’t repr’d correctly in a MultiIndex (GH7406, GH7409).  
- Bug where bool objects were converted to nan in convert_objects (GH7416).
- Bug in quantile ignoring the axis keyword argument (GH7306)
- Bug where nanops._maybe_null_out doesn’t work with complex numbers (GH7353)
- Bug in several nanops functions when axis==0 for 1-dimensional nan arrays (GH7354)
- Bug where nanops.nanmedian doesn’t work when axis==None (GH7352)
- Bug where nanops._has_infs doesn’t work with many dtypes (GH7357)
- Bug in StataReader.data where reading a 0-observation dta failed (GH7369)
- Bug in StataReader when reading Stata 13 (117) files containing fixed width strings (GH7360)
- Bug in StataWriter where encoding was ignored (GH7286)
- Bug in DatetimeIndex comparison doesn’t handle NaT properly (GH7529)
- Bug in passing input with tzinfo to some offsets apply, rollforward or rollback resets tzinfo or raises ValueError (GH7465)
- Bug in DatetimeIndex.to_period, PeriodIndex.asobject, PeriodIndex.to_timestamp doesn’t preserve name (GH7485)
- Bug in DatetimeIndex.to_period and PeriodIndex.to_timestamp handle NaT incorrectly (GH7228)
- Bug in offsets.apply, rollforward and rollback may return normal datetime (GH7502)
- Bug in resample raises ValueError when target contains NaT (GH7227)
- Bug in Timestamp.tz_localize resets nanosecond info (GH7534)
- Bug in DatetimeIndex.asobject raises ValueError when it contains NaT (GH7539)
• Bug in Timestamp.__new__ doesn’t preserve nanosecond properly (GH7610)
• Bug in Index.astype(float) where it would return an object dtype Index (GH7464).
• Bug in DataFrame.reset_index loses tz (GH3950)
• Bug in DatetimeIndex.freqstr raises AttributeError when freq is None (GH7606)
• Bug in GroupBy.size created by TimeGrouper raises AttributeError (GH7453)
• Bug in single column bar plot is misaligned (GH7498).
• Bug in area plot with tz-aware time series raises ValueError (GH7471)
• Bug in non-monotonic Index.union may preserve name incorrectly (GH7458)
• Bug in DatetimeIndex.intersection doesn’t preserve timezone (GH4690)
• Bug in rolling_var where a window larger than the array would raise an error (GH7297)
• Bug with last plotted timeseries dictating xlim (GH2960)
• Bug with secondary_y axis not being considered for timeseries xlim (GH3490)
• Bug in Float64Index assignment with a non scalar indexer (GH7586)
• Bug in pandas.core.strings.str_contains does not properly match in a case insensitive fashion when regex=False and case=False (GH7505)
• Bug in expanding_cov, expanding_corr, rolling_cov, and rolling_corr for two arguments with mismatched index (GH7512)
• Bug in to_sql taking the boolean column as text column (GH7678)
• Bug in grouped hist doesn’t handle rot kw and sharex kw properly (GH7234)
• Bug in .loc performing fallback integer indexing with object dtype indices (GH7496)
• Bug (regression) in PeriodIndex constructor when passed Series objects (GH7701).

1.24 v0.14.0 (May 31, 2014)

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

• Highlights include:
  – Officially support Python 3.4
  – SQL interfaces updated to use sqlalchemy, See Here.
  – Display interface changes, See Here
  – MultiIndexing Using Slicers, See Here.
  – Ability to join a singly-indexed DataFrame with a multi-indexed DataFrame, see Here
  – More consistency in groupby results and more flexible groupby specifications, See Here
  – Holiday calendars are now supported in CustomBusinessDay, see Here
  – Several improvements in plotting functions, including: hexbin, area and pie plots, see Here.
  – Performance doc section on I/O operations, See Here

• Other Enhancements

• API Changes
  • Text Parsing API Changes
  • Groupby API Changes
  • Performance Improvements
  • Prior Deprecations
  • Deprecations
  • Known Issues
  • Bug Fixes

**Warning:** In 0.14.0 all NDFrame based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container’s labels. This should not have any visible user/API behavior changes (GH6745)

### 1.24.1 API changes

• `read_excel` uses 0 as the default sheet (GH6573)

• `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` (GH6296, GH6299). This could result in an empty axis (e.g. an empty DataFrame being returned)

```
In [1]: df1 = DataFrame(np.random.randn(5,2),columns=list('AB'))

In [2]: df1
Out[2]:
     A    B
0  1.58  -0.438
1 -0.403  -0.781
2 -0.142   0.542
3  0.371  -0.252
4  0.79  1.667

In [3]: df1.iloc[:,2:3]

Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [4]: df1.iloc[:,1:3]

     B
0  -0.438
1  -0.781
2   0.542
3  -0.252
4   1.667
```

(continues on next page)
In [5]: df1.iloc[4:6]

\[
\begin{array}{cc}
\text{A} & \text{B} \\
4 & 0.787484 & 1.666563 \\
\end{array}
\]

These are out-of-bounds selections

\[
\begin{array}{l}
dfl.iloc[[4,5,6]]
\text{IndexError: positional indexers are out-of-bounds}

dfl.iloc[:,4]
\text{IndexError: single positional indexer is out-of-bounds}
\end{array}
\]

- Slicing with negative start, stop & step values handles corner cases better (GH6531):
  - `df.iloc[:-len(df)]` is now empty
  - `df.iloc[len(df)::1]` now enumerates all elements in reverse

- The `DataFrame.interpolate()` keyword downcast default has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).

- When converting a dataframe to HTML it used to return `Empty DataFrame`. This special case has been removed, instead a header with the column names is returned (GH6062).

- `Series` and `Index` now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on `Index` types as well. The `Series.weekday` property from is removed from `Series` for API consistency. Using a `DatetimeIndex/PeriodIndex` method on a `Series` will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).

- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DateTimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DateTimeIndex / Timestamp` (GH4565, GH6998)

- Local variable usage has changed in `pandas.eval()/DataFrame.eval()/DataFrame.query()` (GH5987). For the `DataFrame` methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is `not` a column you must still refer to it with the `@` prefix.
  - You can have an expression like `df.query('a < a')` with no complaints from `pandas` about ambiguity of the name `a`.
  - The top-level `pandas.eval()` function does not allow you use the `@` prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn’t necessary anymore.

- Define and document the order of column vs index names in `query/eval` (GH6676)

- `concat` will now concatenate mixed `Series` and `DataFrames` using the `Series` name or numbering columns as needed (GH2385). See the docs

- Slicing and advanced/boolean indexing operations on `Index` classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)
Previously, the above operation would return `Int64Index`. If you’d like to do this manually, use `Index.astype()`

```
In [9]: i[[0,1,2]].astype(np.int_)
Out [9]: Int64Index([1, 2, 3], dtype='int64')
```

• `set_index` no longer converts MultiIndexes to an Index of tuples. For example, the old behavior returned an Index in this case (GH6459):

```
# Old behavior, casted MultiIndex to an Index
In [10]: tuple_ind
Out [10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')

In [11]: df_multi.set_index(tuple_ind)
Out [11]:
       0 1
(a, c) 0.471435 -1.190976
(a, d) 1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588  0.636524
```

# New behavior
```
In [12]: mi

MultiIndex(levels=[['a', 'b'], ['c', 'd']],
           labels=[[0, 0, 1, 1], [0, 1, 0, 1]])

In [13]: df_multi.set_index(mi)
```

```
       0 1
a c  0.471435 -1.190976
d  1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588  0.636524
```

This also applies when passing multiple indices to `set_index`:

```
# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out [14]:
       0 1
(a, c) (a, c) 0.471435 -1.190976
(a, d) (a, d) 1.432707 -0.312652
(b, c) (b, c) -0.720589  0.887163
(b, d) (b, d)  0.859588  0.636524
```
# New output, 4-level MultiIndex
```
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out[15]:
   0    1
a c a c  0.471435 -1.190976
   a d a d  1.432707  0.312652
b c b c -0.720589  0.887163
d b d b   0.859588 -0.636524
```

- **pairwise** keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`, `ewmcov`, `ewmcorr`, `expanding_cov`, `expanding_corr` to allow the calculation of moving window covariance and correlation matrices (GH4950). See *Computing rolling pairwise covariances and correlations* in the docs.

```
In [1]: df = DataFrame(np.random.randn(10,4),columns=list('ABCD'))
In [4]: covs = pd.rolling_cov(df[['A','B','C']], df[['B','C','D']], 5, pairwise=True)
In [5]: covs[df.index[-1]]
```

```
   B    C    D
A  0.035310  0.326593 -0.505430
B  0.137748 -0.006888 -0.005383
C -0.006888  0.861040  0.020762
```

- `Series.iteritems()` is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added **nunique** and **value_counts** functions to `Index` for counting unique elements. (GH6734)
- `stack` and `unstack` now raise a `ValueError` when the `level` keyword refers to a non-unique item in the `Index` (previously raised a `KeyError`). (GH6738)
- `drop` unused order argument from `Series.sort`; args now are in the same order as `Series.order`; add `na_position` arg to conform to `Series.order` (GH6847)
- default sorting algorithm for `Series.order` is now `quicksort`, to conform with `Series.sort` (and `numpy` defaults)
- add `inplace` keyword to `Series.order/sort` to make them inverses (GH6859)
- `DataFrame.sort` now places NaNs at the beginning or end of the sort according to the `na_position` parameter. (GH3917)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added `factorize` functions to `Index` and `Series` to get indexer and unique values (GH7090)
- `describe` on a `DataFrame` with a mix of `Timestamp` and string like objects returns a different `Index` (GH7088). Previously the index was unintentionally sorted.
- Arithmetic operations with only `bool` dtypes now give a warning indicating that they are evaluated in Python space for `+`, `-`, and `*` operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```
x = pd.Series(np.random.rand(10) > 0.5)
y = True
x + y  # warning generated: should do x | y instead
```

1.24. v0.14.0 (May 31, 2014) 331
x / y  # this raises because it doesn't make sense

NotImplementedError: operator '/' not implemented for bool dtypes

- In HDFStore, select_as_multiple will always raise a KeyError, when a key or the selector is not found (GH6177)
- df['col'] = value and df.loc[:, 'col'] = value are now completely equivalent; previously the .loc would not necessarily coerce the dtype of the resultant series (GH6149)
- dtypes and ftypes now return a series with dtype=object on empty containers (GH5740)
- df.to_csv will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- pd.infer_freq() will now raise a TypeError if given an invalid Series/Index type (GH6407, GH6463)
- A tuple passed to DataFrame.sort_index will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- all offset operations now return Timestamp types (rather than datetime), Business/Week frequencies were incorrect (GH4069)
- to_excel now converts np.inf into a string representation, customizable by the inf_rep keyword argument (Excel has no native inf representation) (GH6782)
- Replace pandas.compat.scipy.scoreatpercentile with numpy.percentile (GH6810)
- .quantile on a datetime[ns] series now returns Timestamp instead of np.datetime64 objects (GH6810)
- change AssertionError to TypeError for invalid types passed to concat (GH6583)
- Raise a TypeError when DataFrame is passed an iterator as the data argument (GH5357)

1.24.2 Display Changes

- The default way of printing large DataFrames has changed. DataFrames exceeding max_rows and/or max_columns are now displayed in a centrally truncated view, consistent with the printing of a pandas.Series (GH5603).

In previous versions, a DataFrame was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.options.display.max_rows = 6
In [4]: pd.options.display.max_columns = 6
In [5]: index = pd.DatetimeIndex(start='2001-01-01',freq='D',periods=10)
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)),index=index)
Out[6]:
   0   1   2   3   4   5
2001-01-01  0   1   2   3   4   5 ...
2001-01-02 10  11  12  13  14  15 ...
2001-01-03 20  21  22  23  24  25 ...
2001-01-04 30  31  32  33  34  35 ...
2001-01-05 40  41  42  43  44  45 ...
2001-01-06 50  51  52  53  54  55 ...
          ... ... ... ... ... ...
[10 rows x 10 columns]

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)),index=index)
Out[24]:
   0   1   2   3   4   5
2001-01-01  0   1   2   3   4   5 ...
2001-01-02 10  11  12   7   8   9 ...
2001-01-03 20  21  22  23  24  25 ...
2001-01-04 30  31  32  33  34  35 ...
2001-01-05 40  41  42  43  44  45 ...
2001-01-06 50  51  52  53  54  55 ...
          ... ... ... ... ... ...
2001-01-08 70  71  72  73  74  75 ...
2001-01-09 80  81  82  83  84  85 ...
2001-01-10 90  91  92  93  94  95 ...
[10 rows x 10 columns]

• allow option 'truncate' for display.show_dimensions to only show the dimensions if the frame is truncated (GH6547).

The default for display.show_dimensions will now be truncate. This is consistent with how Series display length.

In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1,5), index=[0,1,2,3,4], columns=[0,1,2,3,4])
# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
                   'display.show_dimensions', 'truncate'):
                   print(dfd)
                   ....:
                   ....:
(continues on next page)
Regression in the display of a MultiIndexed Series with display.max_rows is less than the length of the series (GH7101)

Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the large_repr set to ‘info’ (GH7105)

The verbose keyword in DataFrame.info(), which controls whether to shorten the info representation, is now None by default. This will follow the global setting in display.max_info_columns. The global setting can be overridden with verbose=True or verbose=False.

Fixed a bug with the info repr not honoring the display.max_info_columns setting (GH6939)

Offset/freq info now in Timestamp __repr__ (GH4553)

### 1.24.3 Text Parsing API Changes

read_csv() / read_table() will now be noiser w.r.t invalid options rather than falling back to the PythonParser.

- Raise ValueError when sep specified with delim_whitespace=True in read_csv() / read_table() (GH6607)
- Raise ValueError when engine='c' specified with unsupported options in read_csv() / read_table() (GH6607)
- Raise ValueError when fallback to python parser causes options to be ignored (GH6607)
- Produce ParserWarning on fallback to python parser when no options are ignored (GH6607)
- Translate sep=’\s+’ to delim_whitespace=True in read_csv() / read_table() if no other C-unsupported options specified (GH6607)

### 1.24.4 Groupby API Changes

More consistent behaviour for some groupby methods:

- groupby head and tail now act more like filter rather than an aggregation:
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [20]: g = df.groupby('A')
In [21]: g.head(1)  # filters DataFrame
Out[21]:
   A  B
0  1  2
2  5  6

In [22]: g.apply(lambda x: x.head(1))  # used to simply fall-through
Out[22]:
   A  B
A  1  2
5  6

• groupby head and tail respect column selection:

In [23]: g[['B']].head(1)
Out[23]:
   B
0  2
2  6

• groupby nth now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See the docs.

Reducing

In [24]: df = DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [25]: g = df.groupby('A')
In [26]: g.nth(0)
Out[26]:
   B
A
1  NaN
5  6.0

# this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
   B
A
1  4.0
5  6.0

# this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
   B
A
1  4.0
5  6.0
Filtering

```python
In [29]: gf = df.groupby('A',as_index=False)
In [30]: gf.nth(0)
Out[30]:
   A  B
0  1  NaN
2  5  6.0
In [31]: gf.nth(0, dropna='any')
```

- `groupby` will now not return the grouped column for non-cython functions (GH5610, GH5614, GH6732), as its already the index

```python
In [32]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])
In [33]: g = df.groupby('A')
In [34]: g.count()
Out[34]:
   A  B
0  1  1
1  5  2
In [35]: g.describe()
```

- passing `as_index` will leave the grouped column in-place (this is not change in 0.14.0)

```python
In [36]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])
In [37]: g = df.groupby('A',as_index=False)
In [38]: g.count()
Out[38]:
   A  B
0  1  1
1  5  2
In [39]: g.describe()
```

(continues on next page)
• Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See the docs. (GH3794)

• Better propagation/preservation of Series names when performing groupby operations:
  – `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
  – If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates `DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

### 1.24.5 SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on included dialects).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```python
In [40]: from sqlalchemy import create_engine
# Create your connection.
In [41]: engine = create_engine('sqlite:///:memory:)
```

This engine can then be used to write or read data to/from this database:

```python
In [42]: df = pd.DataFrame({'A': [1,2,3], 'B': ['a', 'b', 'c']})
In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```python
In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A  B
0  a  1
1  b  2
2  c  3
```

or by specifying a sql query:
Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the index keyword (default is True).
- specify the column label to use when writing the index with index_label.
- specify string columns to parse as datetimes with the parse_dates keyword in read_sql_query() and read_sql_table().

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: tquery, uquery, read_frame, frame_query, write_frame.

**Warning:** The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).

### 1.24.6 MultiIndexing Using Slicers

In 0.14.0 we added a new way to slice multi-indexed objects. You can slice a multi-index by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, labels, and boolean indexers.

You can use slice(None) to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as slice(None).

As usual, both sides of the slicers are included as this is label indexing.

See the docs See also issues (GH6134, GH4036, GH3057, GH2598, GH5641, GH7106)

**Warning:** You should specify all axes in the .loc specifier, meaning the indexer for the index and for the columns. Their are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

```
df.loc[{'slice('A1','A3'),.....},:]  
```

rather than this:

```
df.loc[{'slice('A1','A3'),.....}]  
```

**Warning:** You will need to make sure that the selection axes are fully lexsorted!
In [46]: def mklbl(prefix, n):
    .....:      return ["%s%s" % (prefix, i) for i in range(n)]
    .....:

In [47]: index = MultiIndex.from_product([mklbl('A', 4),
    .....:           mklbl('B', 2),
    .....:           mklbl('C', 4),
    .....:           mklbl('D', 2)])
    .....:

In [48]: columns = MultiIndex.from_tuples([('a', 'foo'), ('a', 'bar'),
    .....:           ('b', 'foo'), ('b', 'bah')],
           names=['lvl0', 'lvl1'])
           .....:

In [49]: df = DataFrame(np.arange(len(index) * len(columns)).reshape((len(index),
    .....:           len(columns))),
           index=index,
           columns=columns).sort_index().sort_index(axis=1)
           .....:

In [50]: df

Out[50]:
lvl0  a  b
lvl1  bar  foo  bah  foo
A0  B0  C0  D0  1  0  3  2
D1  5  4  7  6
C1  D0  9  8  11  10
D1  13  12  15  14
C2  D0  17  16  19  18
D1  21  20  23  22
C3  D0  25  24  27  26
...  ...  ...  ...  ...
A3  B1  C0  D1  229  228  231  230
C1  D0  233  232  235  234
D1  237  236  239  238
C2  D0  241  240  243  242
D1  245  244  247  246
C3  D0  249  248  251  250
D1  253  252  255  254
[64 rows x 4 columns]

Basic multi-index slicing using slices, lists, and labels.

In [51]: df.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]

Out[51]:
lvl0  a  b
lvl1  bar  foo  bah  foo
A1  B0  C1  D0  73  72  75  74
D1  77  76  79  78
C3  D0  89  88  91  90
D1  93  92  95  94
B1  C0  D1  105  104  107  106
D1  109  108  111  110
C3  D0  121  120  123  122
...  ...  ...  ...
(continues on next page)
You can use a `pd.IndexSlice` to shortcut the creation of these slices

```
In [52]: idx = pd.IndexSlice

In [53]: df.loc[idx,:,:,['C1','C3'],idx[:,'foo']]
Out [53]:
   lvl0  lvl1
  a   b   foo   foo
A0  B0  C0  D0    8   10
    D1  12  14
  C3  D0  24  26
    D1  28  30
B1  C0  D0  40  42
    D1  44  46
  C3  D0  56  58
...  ...  ...  ...  ...
A3  B0  C0  D1  204  206
    C3  D0  216  218
    D1  220  222
B1  C0  D0  232  234
    D1  236  238
  C3  D0  248  250
    D1  252  254
```

[32 rows x 2 columns]

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [54]: df.loc[['A1',slice(None),'foo']]
Out [54]:
   lvl0  lvl1
  a   b   foo   foo
A0  B0  C0  D0    64   66
    D1  68  70
  C1  D0  72  74
    D1  76  78
C2  D0  80  82
    D1  84  86
  C3  D0  88  90
...  ...  ...  ...  ...
B1  C0  D1  100  102
  C1  D0  104  106
    D1  108  110
  C2  D0  112  114
    D1  116  118
  C3  D0  120  122
    D1  124  126
```

(continues on next page)
Using a boolean indexer you can provide selection related to the values.

```python
In [56]: mask = df[('a','foo')]>200
In [57]: df.loc[idx[mask,:,['C1','C3']],idx[:, 'foo']]
```

```
Out[57]:
  lvl0  a  b
  lvl1 foo foo
      A0  B0  C1  D0 8 10
          D1  12 14
          C3  D0 24 26
          D1  28 30
      B1  C1  D0 40 42
          D1  44 46
          C3  D0 56 58
      ... ... ... ...
      A3  B0  C1  D1 204 206
          C3  D0 216 218
          D1  220 222
      B1  C1  D0 232 234
          D1  236 238
          C3  D0 248 250
          D1  252 254
[32 rows x 2 columns]
```

You can also specify the axis argument to .loc to interpret the passed slicers on a single axis.

```python
In [58]: df.loc(axis=0)[:,:,['C1','C3']]
```

```
Out[58]:
  lvl0  a  b
  lvl1  bar  foo  bah  foo
      A0  B0  C1  D0 9  8 11 10
          D1  13 12 15 14
          C3  D0 25 24 27 26
          D1  29 28 31 30
      B1  C1  D0 41 40 43 42
          D1  45 44 47 46
          C3  D0 57 56 59 58
      ... ... ... ... ...
      A3  B0  C1  D1 205 204 207 206
```
Furthermore you can set the values using these methods

```
In [59]: df2 = df.copy()

In [60]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [61]: df2
```

```
Out[61]:
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You can use a right-hand-side of an alignable object as well.

```
In [62]: df2 = df.copy()

In [63]: df2.loc[idx[::, :, ['C1', 'C3']]] = df2*1000

In [64]: df2
```

```
Out[64]:
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

... ... ... ...

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(continues on next page)
1.24.7 Plotting

- Hexagonal bin plots from DataFrame.plot with kind='hexbin' (GH5478), See the docs.
- DataFrame.plot and Series.plot now supports area plot with specifying kind='area' (GH6656), See the docs
- Pie plots from Series.plot and DataFrame.plot with kind='pie' (GH6976), See the docs.
- Plotting with Error Bars is now supported in the .plot method of DataFrame and Series objects (GH3796, GH6834), See the docs.
- DataFrame.plot and Series.plot now support a table keyword for plotting matplotlib.Table, See the docs. The table keyword can receive the following values.
  - False: Do nothing (default).
  - True: Draw a table using the DataFrame or Series called plot method. Data will be transposed to meet matplotlib's default layout.
  - DataFrame or Series: Draw matplotlib.table using the passed data. The data will be drawn as displayed in print method (not transposed automatically). Also, helper function pandas.tools.plotting.table is added to create a table from DataFrame and Series, and add it to an matplotlib.Axes.
- plot(legend='reverse') will now reverse the order of legend labels for most plot kinds. (GH6014)
- Line plot and area plot can be stacked by stacked=True (GH6656)
- Following keywords are now acceptable for DataFrame.plot() with kind='bar' and kind='barh':
  - width: Specify the bar width. In previous versions, static value 0.5 was passed to matplotlib and it cannot be overwritten. (GH6604)
  - align: Specify the bar alignment. Default is center (different from matplotlib). In previous versions, pandas passes align='edge' to matplotlib and adjust the location to center by itself, and it results align keyword is not applied as expected. (GH4525)
  - position: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). (GH6604)

Because of the default align value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using set_xlim, set_ylim, etc. In this cases, please modify your script to meet with new coordinates.

- The parallel_coordinates() function now takes argument color instead of colors. A FutureWarning is raised to alert that the old colors argument will not be supported in a future release. (GH6956)
- The parallel_coordinates() and andrews_curves() functions now take positional argument frame instead of data. A FutureWarning is raised if the old data argument is used by name. (GH6956)
• DataFrame.boxplot() now supports layout keyword (GH6769)
• DataFrame.boxplot() has a new keyword argument, return_type. It accepts 'dict', 'axes', or 'both', in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

1.24.8 Prior Version Deprecations/Changes

There are prior version deprecations that are taking effect as of 0.14.0.
• Remove DateRange in favor of DatetimeIndex (GH6816)
• Remove column keyword from DataFrame.sort (GH4370)
• Remove precision keyword from set_eng_float_format() (GH395)
• Remove force_unicode keyword from DataFrame.to_string(), DataFrame.to_latex(), and DataFrame.to_html(); these function encode in unicode by default (GH2224, GH2225)
• Remove nanRep keyword from DataFrame.to_csv() and DataFrame.to_string() (GH275)
• Remove unique keyword from HDFStore.select_column() (GH3256)
• Remove inferTimeRule keyword from Timestamp.offset() (GH391)
• Remove name keyword from get_data_yahoo() and get_data_google() (commit b921d1a)
• Remove offset keyword from DatetimeIndex constructor (commit 3136390)
• Remove time_rule from several rolling-moment statistical functions, such as rolling_sum() (GH1042)
• Removed neg – boolean operations on numpy arrays in favor of inv ~, as this is going to be deprecated in numpy 1.9 (GH6960)

1.24.9 Deprecations

• The pivot_table()/DataFrame.pivot_table() and crosstab() functions now take arguments index and columns instead of rows and cols. A FutureWarning is raised to alert that the old rows and cols arguments will not be supported in a future release (GH5505)
• The DataFrame.drop_duplicates() and DataFrame.duplicated() methods now take argument subset instead of cols to better align with DataFrame.dropna(). A FutureWarning is raised to alert that the old cols arguments will not be supported in a future release (GH6680)
• The DataFrame.to_csv() and DataFrame.to_excel() functions now take argument columns instead of cols. A FutureWarning is raised to alert that the old cols arguments will not be supported in a future release (GH6645)
• Indexers will warn FutureWarning when used with a scalar indexer and a non-floating point Index (GH4892, GH6960)

```python
# non-floating point indexes can only be indexed by integers / labels
In [1]: Series(1,np.arange(5))[3.0]
  pandas/core/index.py:469: FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
     →Int64Index
Out[1]: 1

In [2]: Series(1,np.arange(5)).iloc[3.0]
  pandas/core/index.py:469: FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
     →Int64Index
Out[2]: 1
```
(continues on next page)
In [3]: Series(1, np.arange(5)).iloc[3.0:4]
   pandas/core/index.py:527: FutureWarning: slice indexers when using iloc should be integers and not floating point
Out[3]:
   3  1
   dtype: int64

# these are Float64Indexes, so integer or floating point is acceptable
In [4]: Series(1, np.arange(5.))[3]
Out[4]: 1

In [5]: Series(1, np.arange(5.))[3.0]
Out[6]: 1

• Numpy 1.9 compat w.r.t. deprecation warnings (GH6960)
• Panel.shift() now has a function signature that matches DataFrame.shift(). The old positional argument lags has been changed to a keyword argument periods with a default value of 1. A FutureWarning is raised if the old argument lags is used by name. (GH6910)
• The order keyword argument of factorize() will be removed. (GH6926).
• Remove the copy keyword from DataFrame.xs(), Panel.major_xs(), Panel.minor_xs(). A view will be returned if possible, otherwise a copy will be made. Previously the user could think that copy=False would ALWAYS return a view. (GH6894)
• The parallel_coordinates() function now takes argument color instead of colors. A FutureWarning is raised to alert that the old colors argument will not be supported in a future release. (GH6956)
• The parallel_coordinates() and andrews_curves() functions now take positional argument frame instead of data. A FutureWarning is raised if the old data argument is used by name. (GH6956)
• The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).
• The following io.sql functions have been deprecated: tquery, uquery, read_frame, frame_query, write_frame.
• The percentile_width keyword argument in describe() has been deprecated. Use the percentiles keyword instead, which takes a list of percentiles to display. The default output is unchanged.
• The default return type of boxplot() will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing return_type='axes' to boxplot.

1.24.10 Known Issues

• OpenPyXL 2.0.0 breaks backwards compatibility (GH7169)

1.24.11 Enhancements

• DataFrame and Series will create a MultiIndex object if passed a tuples dict, See the docs (GH3323)
In [65]: Series({('a', 'b'): 1, ('a', 'a'): 0,  
    ....:  ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})  
    ....:  
Out[65]:  
    a b 1  
a 0 2  
c 3  
b a 4  
    dtype: int64

In [66]: DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},  
    ....:  ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},  
    ....:  ('a', 'c'): {('A', 'B'): 5, ('A', 'C'): 6},  
    ....:  ('b', 'a'): {('A', 'C'): 7, ('A', 'B'): 8},  
    ....:  ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})

...

Out[66]:  
    a b  
    b a  
    c a  
    b  
    NaNaNaNNaNNaN NaN

• Added the sym_diff method to Index (GH5543)

• DataFrame.to_latex now takes a longtable keyword, which if True will return a table in a longtable environment. (GH6617)

• Add option to turn off escaping in DataFrame.to_latex (GH6472)

• pd.read_clipboard will, if the keyword sep is unspecified, try to detect data copied from a spreadsheet and parse accordingly. (GH6223)

• Joining a singly-indexed DataFrame with a multi-indexed DataFrame (GH3662)  

See the docs. Joining multi-index DataFrames on both the left and right is not yet supported ATM.

In [67]: household = DataFrame(dict(household_id = [1,2,3],  
    ....:  male = [0,1,0],  
    ....:  wealth = [196087.3,316478.7,294750]),  
    ....:  columns = ['household_id','male','wealth'])  
    ....:  ).set_index('household_id')  
    ....:

</table>

• `quotechar`, `doublequote`, and `escapechar` can now be specified when using `DataFrame.to_csv` (GH5414, GH4528)

• Partially sort by only the specified levels of a MultiIndex with the `sort_remaining` boolean kwarg. (GH3984)

• Added `to_julian_date` to `TimeStamp` and `DatetimeIndex`. The Julian Date is used primarily in astronomy and represents the number of days from noon, January 1, 4713 BC. Because nanoseconds are used to define the time in pandas the actual range of dates that you can use is 1678 AD to 2262 AD. (GH4041)

• `DataFrame.to_stata` will now check data for compatibility with Stata data types and will upcast when needed. When it is not possible to losslessly upcast, a warning is issued (GH6327)

• `DataFrame.to_stata` and `StataWriter` will accept keyword arguments `time_stamp` and `data_label` which allow the time stamp and dataset label to be set when creating a file. (GH6545)

• `pandas.io.gbq` now handles reading unicode strings properly. (GH5940)

• `Holidays Calendars` are now available and can be used with the `CustomBusinessDay` offset (GH6719)

• `Float64Index` is now backed by a `float64` dtype ndarray instead of an `object` dtype array (GH4741).

• Implemented `Panel.pct_change` (GH6904)

• Added how option to rolling-moment functions to dictate how to handle resampling: `rolling_max()` defaults to max, `rolling_min()` defaults to min, and all others default to mean (GH6297)

• `CustomBusinessMonthBegin` and `CustomBusinessMonthEnd` are now available (GH6866)
• **Series.quantile()** and **DataFrame.quantile()** now accept an array of quantiles.
• **describe()** now accepts an array of percentiles to include in the summary statistics (GH4196)
• **pivot_table** can now accept `Grouper` by index and columns keywords (GH6913)

```python
In [72]: import datetime
In [73]: df = DataFrame(
   ....:     'Branch': ['A A A A A B'].split(),
   ....:     'Buyer': ['Carl Mark Carl Carl Joe Joe'].split(),
   ....:     'Quantity': [1, 3, 5, 1, 8, 1],
   ....:     'Date': [datetime.datetime(2013,11,1,13,0),
               datetime.datetime(2013,9,1,13,0),
               datetime.datetime(2013,10,1,20,0),
               datetime.datetime(2013,9,1,13,0),
               datetime.datetime(2013,10,1,20,0),
               datetime.datetime(2013,10,1,20,0)],
   ....:     'PayDay': [datetime.datetime(2013,10,4,0,0),
                 datetime.datetime(2013,9,5,20,0),
                 datetime.datetime(2013,10,7,20,0),
                 datetime.datetime(2013,9,5,10,0)]
   ....: )
```

```python
In [74]: df
Out[74]:
  Branch Buyer Quantity Date PayDay
0     A  Carl      1 2013-11-01 13:00:00 2013-10-04 00:00:00
1     A  Mark      3 2013-09-01 13:05:00 2013-10-15 13:05:00
2     A  Carl      5 2013-10-01 20:00:00 2013-09-05 20:00:00

2013-09-30                                NaN        NaN        NaN
2013-10-31                                6.0        NaN        1.0
2013-11-30                                NaN        9.0        NaN
```

• Arrays of strings can be wrapped to a specified width (`str.wrap`) (GH6999)
• Add `nsmallest()` and `Series.nlargest()` methods to `Series`, See the docs (GH3960)
• **PeriodIndex** fully supports partial string indexing like `DatetimeIndex` (GH7043)

```python
In [76]: prng = period_range('2013-01-01 09:00', periods=100, freq='H')
In [77]: ps = Series(np.random.randn(len(prng)), index=prng)
In [78]: ps
```

- **read_excel** can now read milliseconds in Excel dates and times with xlrd >= 0.9.3. (GH5945)
- **pd.stats.moments.rolling_var** now uses Welford’s method for increased numerical stability (GH6817)
- **pd.expanding_apply** and **pd.rolling_apply** now take args and kwargs that are passed on to the func (GH6289)
- **DataFrame.rank()** now has a percentage rank option (GH5971)
- **Series.rank()** now has a percentage rank option (GH5971)
- **Series.rank()** and **DataFrame.rank()** now accept method='dense' for ranks without gaps (GH6514)
- Support passing **encoding** with xlwt (GH3710)
- Refactor **Block classes** removing **Block.items** attributes to avoid duplication in item handling (GH6745, GH6988).
- Testing statements updated to use specialized asserts (GH6175)
1.24.12 Performance

- Performance improvement when converting DatetimeIndex to floating ordinals using DatetimeConverter (GH6636)
- Performance improvement for DataFrame.shift (GH5609)
- Performance improvement in indexing into a multi-indexed Series (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of DataFrame construction with certain offsets, by removing faulty caching (e.g. MonthEnd, BusinessMonthEnd), (GH6479)
- Improve performance of CustomBusinessDay (GH6584)
- Improve performance of slice indexing on Series with string keys (GH6341, GH6372)
- Performance improvement for DataFrame.from_records when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in timedelta conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing take_2d (GH6749)
- GroupBy.count() is now implemented in Cython and is much faster for large numbers of groups (GH7016).

1.24.13 Experimental

There are no experimental changes in 0.14.0

1.24.14 Bug Fixes

- Bug in Series ValueError when index doesn’t match data (GH6532)
- Prevent segfault due to MultiIndex not being supported in HDFStore table format (GH1848)
- Bug in pd.DataFrame.sort_index where mergesort wasn’t stable when ascending=False (GH6399)
- Bug in pd.tseries.frequencies.to_offset when argument has leading zeroes (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing Timestamp/to_datetime for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)
- Bug in .xs with a Series multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a DatetimeIndex with a specified frequency (GH6273, GH6274)
- Bug in eval where type-promotion failed for large expressions (GH6205)
- Bug in interpolate with inplace=True (GH6281)
- HDFStore.remove now handles start and stop (GH6177)
- HDFStore.select_as_multiple handles start and stop the same way as select (GH6177)
- HDFStore.select_as_coordinates and select_column works with a where clause that results in filters (GH6177)
• Regression in join of non_unique_indexes (GH6329)
• Issue with groupby agg with a single function and a mixed-type frame (GH6337)
• Bug in DataFrame.replace() when passing a non-bool to_replace argument (GH6332)
• Raise when trying to align on different levels of a multi-index assignment (GH3738)
• Bug in setting complex dtypes via boolean indexing (GH6345)
• Bug in TimeGrouper/resample when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
• Bug in index name propagation in TimeGrouper/resample (GH4161)
• TimeGrouper has a more compatible API to the rest of the groupers (e.g. groups was missing) (GH3881)
• Bug in multiple grouping with a TimeGrouper depending on target column order (GH6764)
• Bug in pd.eval when parsing strings with possible tokens like ' & ' (GH6351)
• Bug correctly handle placements of -inf in Panels when dividing by integer 0 (GH6178)
• DataFrame.shift with axis=1 was raising (GH6371)
• Disabled clipboard tests until release time (run locally with nosetests -A disabled) (GH6048).
• Bug in DataFrame.replace() when passing a nested dict that contained keys not in the values to be replaced (GH6342)
• str.match ignored the na flag (GH6609).
• Bug in take with duplicate columns that were not consolidated (GH6240)
• Bug in interpolate changing dtypes (GH6290)
• Bug in Series.get was using a buggy access method (GH6383)
• Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313)
• Bug in DataFrame.dropna with duplicate indices (GH6355)
• Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394)
• Float64Index with nans not comparing correctly (GH6401)
• eval/query expressions with strings containing the @ character will now work (GH6366).
• Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418)
• Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
• Perf issue in concatting with empty objects (GH3259)
• Clarify sorting of sym_diff on Index objects with NaN values (GH444)
• Regression in MultiIndex.from_product with a DatetimeIndex as input (GH439)
• Bug in str.extract when passed a non-default index (GH6348)
• Bug in str.split when passed pat=None and n=1 (GH6466)
• Bug in io.data.DataReader when passed "F-F_Momentum_Factor" and data_source="famafrench" (GH6460)
• Bug in sum of a timedelta64 [ns] series (GH6462)
• Bug in resample with a timezone and certain offsets (GH6397)
• Bug in iat/iloc with duplicate indices on a Series (GH6493)
• Bug in read_html where nan’s were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
• Bug in read_html tests where redirected invalid URLs would make one test fail (GH6445).
• Bug in multi-axis indexing using .loc on non-unique indices (GH6504)
• Bug that caused _ref_locs corruption when slice indexing across columns axis of a DataFrame (GH6525)
• Regression from 0.13 in the treatment of numpy datetime64 non-ns dtypes in Series creation (GH6529)
• .names attribute of MultiIndexes passed to set_index are now preserved (GH6459).
• Bug in setitem with a duplicate index and an alignable rhs (GH6541)
• Bug in setitem with .loc on mixed integer Indexes (GH6546)
• Bug in pd.read_stata which would use the wrong data types and missing values (GH6327)
• Bug in DataFrame.to_stata that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
• StataWriter replaces missing values in string columns by empty string (GH6802)
• Inconsistent types in Timestamp addition/subtraction (GH6543)
• Bug in preserving frequency across Timestamp addition/subtraction (GH4547)
• Bug in empty list lookup caused IndexError exceptions (GH6536, GH6551)
• Series.quantile raising on an object dtype (GH6555)
• Bug in .xs with a nan in level when dropped (GH6574)
• Bug in fillna with method='bfill/ffill' and datetime64[ns] dtype (GH6587)
• Bug in sql writing with mixed dtypes possibly leading to data loss (GH6509)
• Bug in Series.pop (GH6600)
• Bug in iloc indexing when positional indexer matched Int64Index of the corresponding axis and no re-ordering happened (GH6612)
• Bug in fillna with limit and value specified
• Bug in DataFrame.to_stata when columns have non-string names (GH4558)
• Bug in compat with np.compress, surfaced in (GH6658)
• Bug in binary operations with a rhs of a Series not aligning (GH6681)
• Bug in DataFrame.to_stata which incorrectly handles nan values and ignores with_index keyword argument (GH6685)
• Bug in resample with extra bins when using an evenly divisible frequency (GH4076)
• Bug in consistency of groupby aggregation when passing a custom function (GH6715)
• Bug in resample when how=None resample freq is the same as the axis frequency (GH5955)
• Bug in downcasting inference with empty arrays (GH6733)
• Bug in obj.blocks on sparse containers dropping all but the last items of same for dtpe (GH6748)
• Bug in unpickling NaT (NaTTtype) (GH4606)
- Bug in `DataFrame.replace()` where regex metacharacters were being treated as regexs even when `regex=False` (GH6777).
- Bug in timedelta ops on 32-bit platforms (GH6808).
- Bug in setting a tz-aware index directly via `.index` (GH6785).
- Bug in `expressions.py` where numexpr would try to evaluate arithmetic ops (GH6762).
- Bug in `Makefile` where it didn’t remove Cython generated C files with `make clean` (GH6768).
- Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166).
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806).
- Regression from 0.13 with `fillna` and a Series on datetime-like (GH6344).
- Bug in adding `np.timedelta64` to `DatetimeIndex` with timezone outputs incorrect results (GH6818).
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value (GH6689).
- Better error message when passing a frequency of ‘MS’ in `Period` construction (GH5332).
- Bug in `Series.__unicode__` when `max_rows=None` and the Series has more than 1000 rows. (GH6863).
- Bug in `groupby.get_group` where a datetlike wasn’t always accepted (GH5267).
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` (GH6914).
- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting `NaT` incorrectly (GH5546).
- Bug in arithmetic operations affecting `NaT` (GH6873).
- Bug in `Series.str.extract` where the resulting Series from a single group match wasn’t renamed to the group name.
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the header kwarg (GH6186).
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678).
- Internal tests for patching `__finalize__` / bug in merge not finalizing (GH6923, GH6927).
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583).
- Bug in C parser with leading whitespace (GH3374).
- Bug in C parser with `delim_whitespace=True` and `\r`-delimited lines.
- Bug in python parser with explicit multi-index in row following column header (GH6893).
- Bug in `Series.rank` and `DataFrame.rank` that caused small floats (<1e-13) to all receive the same rank (GH6886).
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result (GH6952).
- Bug in `sum/mean` on 32-bit platforms on overflows (GH6915).
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. (GH6959).
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` (GH6951).
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` (GH6951).
• Bug in `read_csv` from a filesystem with non-utf-8 encoding (GH6807)
• Bug in `iloc` when setting / aligning (GH6766)
• Bug causing UnicodeEncodeError when `get_dummies` called with unicode values and a prefix (GH6885)
• Bug in timeseries-with-frequency plot cursor display (GH5453)
• Bug surfaced in `groupby.plot` when using a `Float64Index` (GH7025)
• Stopped tests from failing if options data isn’t able to be downloaded from Yahoo (GH7034)
• Bug in `parallel_coordinates` and `radviz` where reordering of class column caused possible color/class mismatch (GH6956)
• Bug in `radviz` and `andrews_curves` where multiple values of ‘color’ were being passed to plotting method (GH6956)
• Bug in `Float64Index.isin()` where containing `nans` would make indices claim that they contained all the things (GH7066).
• Bug in `DataFrame.boxplot` where it failed to use the axis passed as the `ax` argument (GH3578)
• Bug in the `XlsxWriter` and `XlwtWriter` implementations that resulted in datetime columns being formatted without the time (GH7075) were being passed to plotting method
• `read_fwf()` treats `None` in `colspec` like regular python slices. It now reads from the beginning or until the end of the line when `colspec` contains a `None` (previously raised a `TypeError`)
• Bug in cache coherence with chained indexing and slicing; add `_is_view` property to `NDFrame` to correctly predict views; mark `is_copy` on `xs` only if it's an actual copy (and not a view) (GH7084)
• Bug in `DatetimeIndex` creation from string ndarray with `dayfirst=True` (GH5917)
• Bug in `MultiIndex.from_arrays` created from `DatetimeIndex` doesn’t preserve freq and tz (GH7090)
• Bug in `unstack` raises `ValueError` when `MultiIndex` contains `PeriodIndex` (GH4342)
• Bug in boxplot and hist draws unnecessary axes (GH6769)
• Regression in `groupby.nth()` for out-of-bounds indexers (GH6621)
• Bug in `quantile` with datetime values (GH6965)
• Bug in `Dataframe.set_index`, `reindex` and `pivot` don’t preserve `DatetimeIndex` and `PeriodIndex` attributes (GH3950, GH5878, GH6631)
• Bug in `MultiIndex.get_level_values` doesn’t preserve `DatetimeIndex` and `PeriodIndex` attributes (GH7092)
• Bug in `Groupby` doesn’t preserve tz (GH3950)
• Bug in `PeriodIndex` partial string slicing (GH6716)
• Bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to ‘info’ (GH7105)
• Bug in `DatetimeIndex` specifying freq raises `ValueError` when passed value is too short (GH7098)
• Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting (GH6939)
• Bug `PeriodIndex` string slicing with out of bounds values (GH5407)
• Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)
• Bug in `isnull` when applied to 0-dimensional object arrays (GH7176)
• Bug in `query/eval` where global constants were not looked up correctly (GH7178)
• Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer (GH7189)
• Bug in `setitem` with a single value, multi-index and integer indices (GH7190, GH7218)
• Bug in expressions evaluation with reversed ops, showing in `series-dataframe` ops (GH7198, GH7192)
• Bug in multi-axis indexing with > 2 ndim and a multi-index (GH7199)
• Fix a bug where invalid eval/query operations would blow the stack (GH5198)

1.25 v0.13.1 (February 3, 2014)

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
• Will intelligently limit display precision for `datetime/timedelta` formats.
• Enhanced Panel `apply()` method.
• Suggested tutorials in new `Tutorials` section.
• Our pandas ecosystem is growing. We now feature related projects in a new `Pandas Ecosystem` section.
• Much work has been taking place on improving the docs, and a new `Contributing` section has been added.
• Even though it may only be of interest to devs, we <3 our new CI status page: `ScatterCI`.

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having numpy < 1.8, and doing chained assignment on a string-like array. Please review the docs, chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = DataFrame(dict(A = np.array(['foo','bar','bah','foo','bar'])))
In [2]: df['A'].iloc[0] = np.nan

In [3]: df
Out[3]:
   A
0  NaN
1  bar
2  bah
3  foo
4  bar
```

The recommended way to do this type of assignment is:
In [4]: df = DataFrame(dict(A = np.array(['foo','bar','bah','foo','bar'])))

In [5]: df.loc[0,'A'] = np.nan

In [6]: df
Out[6]:
   A
0  NaN
1  bar
2  bah
3  foo
4  bar

1.25.1 Output Formatting Enhancements

• df.info() view now display dtype info per column (GH5682)
• df.info() now honors the option max_info_rows, to disable null counts for large frames (GH5974)

In [7]: max_info_rows = pd.get_option('max_info_rows')

In [8]: df = DataFrame(dict(A = np.random.randn(10),
   ...: B = np.random.randn(10),
   ...: C = date_range('20130101',periods=10)))

In [9]: df.iloc[3:6,[0,2]] = np.nan

# set to not display the null counts
In [10]: pd.set_option('max_info_rows',0)

In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A float64
B float64
C datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0 bytes

# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows',max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A 7 non-null float64
B 10 non-null float64
C 7 non-null datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0 bytes

• Add show_dimensions display option for the new DataFrame repr to control whether the dimensions print.
In [14]: df = DataFrame([[1, 2], [3, 4]])

In [15]: pd.set_option('show_dimensions', False)

In [16]: df
Out[16]:
   0 1
0 1 2
1 3 4

In [17]: pd.set_option('show_dimensions', True)

In [18]: df
Out[18]:
   0 1
0 1 2
1 3 4

[2 rows x 2 columns]

• The ArrayFormatter for datetime and timedelta64 now intelligently limit precision based on the values in the array (GH3401)

Previously output might look like:

<table>
<thead>
<tr>
<th>age</th>
<th>today</th>
<th>diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>00:00:00</td>
<td>00:00:00</td>
</tr>
<tr>
<td>1</td>
<td>00:00:00</td>
<td>00:00:00</td>
</tr>
<tr>
<td></td>
<td>2001-01-01</td>
<td>2013-04-19</td>
</tr>
<tr>
<td></td>
<td>4491 days, 00:00:00</td>
<td>3244 days, 00:00:00</td>
</tr>
</tbody>
</table>

Now the output looks like:

In [19]: df = DataFrame([Timestamp('20010101'),
                      Timestamp('20040601')], columns=['age'])

In [20]: df['today'] = Timestamp('20130419')

In [21]: df['diff'] = df['today']-df['age']

In [22]: df
Out[22]:
     age   today   diff
0 2001-01-01 2013-04-19 4491 days
1 2004-06-01 2013-04-19 3244 days

[2 rows x 3 columns]

1.25.2 API changes

• Add -NaN and -nan to the default set of NA values (GH5952). See NA Values.

• Added Series.str.get_dummies vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

In [23]: s = Series(['a', 'a|b', np.nan, 'a|c'])

(continues on next page)
In [24]: s.str.get_dummies(sep='|')
Out[24]:
a b c
0 1 0 0
1 1 1 0
2 0 0 0
3 1 0 1
[4 rows x 3 columns]

• Added the NDFrame.equals() method to compare if two NDFrames are equal have equal axes, dtypes, and values. Added the array_equivalent function to compare if two ndarrays are equal. NaNs in identical locations are treated as equal. (GH5283) See also the docs for a motivating example.

In [25]: df = DataFrame({'col': ['foo', 0, np.nan]})
In [26]: df2 = DataFrame({'col': [np.nan, 0, 'foo']}, index=[2,1,0])
In [27]: df.equals(df2)
Out[27]: False
In [28]: df.equals(df2.sort_index())
Out[28]: True

In [29]: import pandas.core.common as com
In [30]: com.array_equivalent(np.array([0, np.nan]), np.array([0, np.nan]))
---------------------------------------------------------------------------
AttributeError                      Traceback (most recent call last)
<ipython-input-30-18a036193b45> in
----> 1 com.array_equivalent(np.array([0, np.nan]), np.array([0, np.nan]))

AttributeError: module 'pandas.core.common' has no attribute 'array_equivalent'
In [31]: np.array_equal(np.array([0, np.nan]), np.array([0, np.nan]))
False

• DataFrame.apply will use the reduce argument to determine whether a Series or a DataFrame should be returned when the DataFrame is empty (GH6007).

Previously, calling DataFrame.apply an empty DataFrame would return either a DataFrame if there were no columns, or the function being applied would be called with an empty Series to guess whether a Series or DataFrame should be returned:

In [32]: def applied_func(col):
.....:     print("Apply function being called with: ", col)
.....:     return col.sum()
.....: 
In [33]: empty = DataFrame(columns=['a', 'b'])
In [34]: empty.apply(applied_func)
Apply function being called with: Series([], Length: 0, dtype: float64)
Out[34]:
a  NaN

(continues on next page)
Now, when `apply` is called on an empty DataFrame: if the `reduce` argument is `True` a Series will returned, if it is `False` a DataFrame will be returned, and if it is `None` (the default) the function being applied will be called with an empty series to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a    NaN
b    NaN
Length: 2, dtype: float64

In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []
[0 rows x 2 columns]
```

1.25.3 Prior Version Deprecations/Changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

1.25.4 Deprecations

There are no deprecations of prior behavior in 0.13.1

1.25.5 Enhancements

• `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexical for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

  If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

```
# Try to infer the format for the index column
df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                 infer_datetime_format=True)
```

• `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)

• `MultiIndex.from_product` convenience function for creating a MultiIndex from the cartesian product of a set of iterables (GH6055):

```
In [32]: shades = ['light', 'dark']
In [33]: colors = ['red', 'green', 'blue']
```
In [34]: MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[34]:
MultiIndex(levels=[['dark', 'light'], ['blue', 'green', 'red']], labels=[[1, 1, 1, 0, 0, 0], [2, 1, 0, 2, 1, 0]], names=['shade', 'color'])

• Panel apply() will work on non-ufuncs. See the docs.

In [35]: import pandas.util.testing as tm
In [36]: panel = tm.makePanel(5)
In [37]: panel
Out[37]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
In [38]: panel['ItemA']

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-03</td>
<td>0.694103</td>
<td>1.893534</td>
<td>-1.735349</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.678630</td>
<td>0.639633</td>
<td>1.210384</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.239556</td>
<td>-0.962029</td>
<td>0.797435</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.151227</td>
<td>-2.085266</td>
<td>-0.379811</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.816127</td>
<td>1.930247</td>
<td>0.702562</td>
</tr>
</tbody>
</table>

[5 rows x 4 columns]

Specifying an apply that operates on a Series (to return a single element)

In [39]: panel.apply(lambda x: x.dtype, axis='items')
Out[39]:
A    float64
B    float64
C    float64
D    float64

[5 rows x 4 columns]

A similar reduction type operation

In [40]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[40]:
       ItemA    ItemB     ItemC
A  2.579643  3.062757  0.379252
B  1.416120 -1.960855  0.923558
C  0.595222 -1.079772 -3.118269
D  1.487226 -0.734611 -1.979310

[4 rows x 3 columns]
This is equivalent to

```python
In [41]: panel.sum('major_axis')
Out[41]:
ItemA    ItemB    ItemC
A  2.579643  3.062757  0.379252
B  1.416120 -1.960855  0.923558
C  0.595222 -1.079772 -3.118269
D  1.487226 -0.734611 -1.979310
[4 rows x 3 columns]
```

A transformation operation that returns a Panel, but is computing the z-score across the major_axis

```python
In [42]: result = panel.apply(
    ....:     lambda x: (x-x.mean())/x.std(),
    ....:     axis='major_axis')
    ....:
In [43]: result
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
In [44]: result['ItemA']
```

- Panel `apply()` operating on cross-sectional slabs. (GH1148)

```python
In [45]: f = lambda x: ((x.T-x.mean(1))/x.std(1)).T
In [46]: result = panel.apply(f, axis = ['items','major_axis'])
In [47]: result
Out[47]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
In [48]: result.loc[:,:, 'ItemA']
```

(continues on next page)
This is equivalent to the following

```
In [49]: result = Panel(dict(
      (ax,f(panel.loc[:,:ax]))
      for ax in panel.minor_axis ))

In [50]: result
Out[50]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC

In [51]: result.loc[:,:,'ItemA']
```

```

### 1.25.6 Performance

Performance improvements for 0.13.1
- Series datetime/timedelta binary operations ([GH5801](https://github.com/pandas-dev/pandas/pull/5801))
- `DataFrame` `count/dropna` for `axis=1`
- Series\.str\.contains now has a `regex=False` keyword which can be faster for plain (non-regex) string patterns. ([GH5879](https://github.com/pandas-dev/pandas/pull/5879))
- Series\.str\.extract ([GH5944](https://github.com/pandas-dev/pandas/pull/5944))
- `dtypes/ftypes` methods ([GH5968](https://github.com/pandas-dev/pandas/pull/5968))
- indexing with object dtypes ([GH5968](https://github.com/pandas-dev/pandas/pull/5968))
- `DataFrame\.apply` ([GH6013](https://github.com/pandas-dev/pandas/pull/6013))
- Regression in JSON IO ([GH5765](https://github.com/pandas-dev/pandas/pull/5765))
- Index construction from Series ([GH6150](https://github.com/pandas-dev/pandas/pull/6150))
1.25.7 Experimental
There are no experimental changes in 0.13.1

1.25.8 Bug Fixes
See V0.13.1 Bug Fixes for an extensive list of bugs that have been fixed in 0.13.1.
See the full release notes or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

1.26 v0.13.0 (January 3, 2014)
This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.
Highlights include:
- support for a new index type Float64Index, and other Indexing enhancements
- HDFStore has a new string based syntax for query specification
- support for new methods of interpolation
- updated timedelta operations
- a new string manipulation method extract
- Nanosecond support for Offsets
- isin for DataFrames

Several experimental features are added, including:
- new eval/query methods for expression evaluation
- support for msgpack serialization
- an i/o interface to Google’s BigQuery

There are several new or updated docs sections including:
- Comparison with SQL, which should be useful for those familiar with SQL but still learning pandas.
- Comparison with R, idiom translations from R to pandas.
- Enhancing Performance, ways to enhance pandas performance with eval/query.

**Warning:** In 0.13.0 Series has internally been refactored to no longer sub-class ndarray but instead subclass NDFrame, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See Internal Refactoring

1.26.1 API changes
- read_excel now supports an integer in its sheetname argument giving the index of the sheet to read in (GH4301).
- Text parser now treats anything that reads like inf ("inf", "Inf", "-Inf", "iNf", etc.) as infinity. (GH4220, GH4219), affecting read_table, read_csv, etc.

- pandas now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s six library into compat. (GH4384, GH4375, GH4372)

- pandas.util.compat and pandas.util.py3compat have been merged into pandas.compat. pandas.compat now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of range, filter, map and zip, plus other necessary elements for Python 3 compatibility. lmap, lzip, lrange and lfilter all produce lists instead of iterators, for compatibility with numpy, subscripting and pandas constructors.(GH4384, GH4375, GH4372)

- Series.get with negative indexers now returns the same as [] (GH4390)

- Changes to how Index and MultiIndex handle metadata (levels, labels, and names)(GH4039):

```python
# previously, you would have set levels or labels directly
index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
index = index.set_levels([1, 2, 3, 4], [1, 2, 4, 4])

# similarly, for names, you can rename the object
# but setting names is not deprecated
index = index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
index.set_names(["bob", "cranberry"], inplace=True)
```

- All division with NDFrame objects is now truedivision, regardless of the future import. This means that operating on pandas objects will by default use floating point division, and return a floating point dtype. You can use // and floordiv to do integer division.

**Integer division**

```python
In [3]: arr = np.array([1, 2, 3, 4])
In [4]: arr2 = np.array([5, 3, 2, 1])
In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])
In [6]: Series(arr) // Series(arr2)
Out[6]:
   0    0
  1    0
  2    1
  3    4
dtype: int64
```

**True Division**

```python
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
   0    0.200000
  1    0.666667
  2    1.500000
```

(continues on next page)
• Infer and downcast dtype if downcast='infer' is passed to fillna/ffill/bfill (GH4604)

• __nonzero__ for all NDFrame objects, will now raise a ValueError, this reverts back to (GH1073, GH4633) behavior. See gotchas for a more detailed discussion.

This prevents doing boolean comparison on entire pandas objects, which is inherently ambiguous. These all will raise a ValueError.

```python
if df:
    ....
df1 and df2
s1 and s2
```

Added the .bool() method to NDFrame objects to facilitate evaluating of single-element boolean Series:

```python
In [1]: Series([True]).bool()
Out[1]: True

In [2]: Series([False]).bool()
Out[2]: False

In [3]: DataFrame([[True]]).bool()
Out[3]: True

In [4]: DataFrame([[False]]).bool()
Out[4]: False
```

• All non-Index NDFrames (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)

• Series and DataFrame now have a mode() method to calculate the statistical mode(s) by axis/Series. (GH5367)

• Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option mode.chained_assignment, allowed options are raise/warn/None. See the docs.

```python
In [5]: dfc = DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```python
In [7]: dfc.loc[0]['A'] = 1111
Traceback (most recent call last)
  ...  
SettingWithCopyWarning:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.
In [8]: dfc.loc[0, 'A'] = 11

In [9]: dfc
Out[9]:
     A  B
0   11  1
1  bbb  2
2   ccc  3

[3 rows x 2 columns]

• Panel.reindex has the following call signature Panel.reindex(items=None, major_axis=None, minor_axis=None, **kwargs) to conform with other NDFrame objects. See Internal Refactoring for more information.

• Series.argmin and Series.argmax are now aliased to Series.idxmin and Series.idxmax. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

1.26.2 Prior Version Deprecations/Changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

• Remove deprecated Factor (GH3650)
• Remove deprecated set_printoptions/reset_printoptions (GH3046)
• Remove deprecated _verbose_info (GH3215)
• Remove deprecated read_clipboard/to_clipboard/ExcelFile/ExcelWriter from pandas.io.parsers (GH3717) These are available as functions in the main pandas namespace (e.g. pd.read_clipboard)
• default for tupleize_cols is now False for both to_csv and read_csv. Fair warning in 0.12 (GH3604)
• default for display.max_seq_len is now 100 rather then None. This activates truncated display (“…” of long sequences in various places. (GH3391)

1.26.3 Deprecations

Deprecated in 0.13.0

• deprecated iterkv, which will be removed in a future release (this was an alias of iteritems used to bypass 2to3’s changes). (GH4384, GH4375, GH4372)

• deprecated the string method match, whose role is now performed more idiomatically by extract. In a future release, the default behavior of match will change to become analogous to contains, which returns a boolean indexer. (Their distinction is strictness: match relies on re.match while contains relies on re.search.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument as_indexer=True.

1.26.4 Indexing API Changes

Prior to 0.13, it was impossible to use a label indexer (.loc/.ix) to set a value that was not contained in the index of a particular axis. (GH2578). See the docs

In the Series case this is effectively an appending operation
In [10]: s = Series([1,2,3])

In [11]: s
Out[11]:
0  1
1  2
2  3
Length: 3, dtype: int64

In [13]: s
Out[13]:
0  1.0
1  2.0
2  3.0
5  5.0
Length: 4, dtype: float64

In [14]: dfi = DataFrame(np.arange(6).reshape(3,2),
   ....:     columns=['A','B'])
   ....:

In [15]: dfi
Out[15]:
   A  B
0  0  1
1  2  3
2  4  5
[3 rows x 2 columns]

This would previously KeyError

In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [17]: dfi
Out[17]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
[3 rows x 3 columns]

This is like an append operation.

In [18]: dfi.loc[3] = 5

In [19]: dfi
Out[19]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

(continues on next page)
A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2,4,2),
                   items=['Item1','Item2'],
                   major_axis=pd.date_range('2001/1/12',periods=4),
                   minor_axis=['A','B'],dtype='float64')
```

```
In [21]: p
Out[21]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:,:,'C'] = Series([30,32],index=p.items)
```

```
In [23]: p
Out[23]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C
```

```
In [24]: p.loc[:,:,'C']
```

```
   Item1  Item2
2001-01-12   30.0   32.0
2001-01-13   30.0   32.0
2001-01-14   30.0   32.0
2001-01-15   30.0   32.0
```

1.26.5 Float64Index API Change

- Added a new index type, Float64Index. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes [],ix,loc for scalar indexing and slicing work exactly the same. See the docs, (GH263)

Construction is by default for floating type values.

```
In [25]: index = Index([1.5, 2, 3, 4.5, 5])
In [26]: index
Out[26]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [27]: s = Series(range(5),index=index)
In [28]: s
```

(continues on next page)
Scalar selection for [], `.ix`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

The only positional indexing is via `iloc`

A scalar index that is not found will raise `KeyError`

Slicing is ALWAYS on the values of the index, for [], `.ix`, `.loc` and ALWAYS positional with `iloc`

In float indexes, slicing using floats are allowed
Indexing on other index types are preserved (and positional fallback for [], ix), with the exception, that floating point slicing on indexes on non Float64Index will now raise a TypeError.

In [1]: Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type
→(Int64Index)

In [1]: Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
→(Int64Index)

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

In [3]: Series(range(5))[3.0]
Out[3]:

1.26.6 HDFStore API Changes

• Query Format Changes. A much more string-like query format is now supported. See the docs.

In [37]: path = 'test.h5'

In [38]: dfq = DataFrame(randn(10,4),
    ....: columns=list('ABCD'),
    ....: index=date_range('20130101',periods=10))
    ....:

In [39]: dfq.to_hdf(path,'dfq',format='table',data_columns=True)

Use boolean expressions, with in-line function evaluation.

In [40]: read_hdf(path,'dfq',
    ....: where="index>Timestamp('20130104') & columns=['A', 'B']")
    ....:

Out[40]:

Use an inline column reference

In [41]: read_hdf(path,'dfq',
    ....: where="A>0 or C>0")
    ....:

Out[41]:

(continues on next page)
• the **format** keyword now replaces the **table** keyword; allowed values are **fixed(f)** or **table(t)** the same defaults as prior < 0.13.0 remain, e.g. put implies fixed format and append implies table format. This default format can be set as an option by setting **io.hdf.default_format**.

```
In [42]: path = 'test.h5'
In [43]: df = pd.DataFrame(np.random.randn(10,2))
In [44]: df.to_hdf(path,'df_table',format='table')
In [45]: df.to_hdf(path,'df_table2',append=True)
In [46]: df.to_hdf(path,'df_fixed')
In [47]: with pd.HDFStore(path) as store: ....:     print(store) ....: <class 'pandas.io.pytables.HDFStore'> File path: test.h5
```

• Significant table writing performance improvements

• handle a passed **Series** in table format (**GH4330**)  

• can now serialize a **timedelta64 [ns]** dtype in a table (**GH3577**), See the docs.

• added an **is_open** property to indicate if the underlying file handle is_open; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) (**GH4409**)  

• a close of a HDFStore now will close that instance of the HDFStore but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of HDFStore referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise ClosedFileError

```
In [48]: path = 'test.h5'
In [49]: df = DataFrame(randn(10,2))
In [50]: store1 = HDFStore(path)
In [51]: store2 = HDFStore(path)
In [52]: store1.append('df',df)
```

(continues on next page)
In [53]: store2.append('df2', df)

In [54]: store1

Out[54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [55]: store2

Out[55]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [56]: store1.close()

In [57]: store2

Out[57]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [58]: store2.close()

In [59]: store2

Out[59]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

- removed the _quiet attribute, replace by a DuplicateWarning if retrieving duplicate rows from a table (GH4367)
- removed the warn argument from open. Instead a PossibleDataLossError exception will be raised if you try to use mode='w' with an OPEN file handle (GH4367)
- allow a passed locations array or mask as a where condition (GH4467). See the docs for an example.
- add the keyword dropna=True to append to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option io.hdf.dropna_table (GH4625)
- pass thru store creation arguments; can be used to support in-memory stores

**1.26.7 DataFrame repr Changes**

The HTML and plain text representations of DataFrame now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view (GH4886, GH5550). This makes the representation more consistent as small DataFrames get larger.
To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

### 1.26.8 Enhancements

- `df.to_clipboard()` learned a new excel keyword that let’s you paste df data directly into excel (enabled by default). (GH5070).
- `read_html` now raises a `URLError` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes `records` as a possible outtype. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handing in `get_dummies` (GH4446) with `dummy_na`

```
# previously, nan was erroneously counted as 2 here
# now it is not counted at all
In [60]: get_dummies([1, 2, np.nan])
Out[60]:
   1.0  2.0
 0   1   0
 1   0   1
 2   0   0

[3 rows x 2 columns]
```

```
# unless requested
In [61]: get_dummies([1, 2, np.nan], dummy_na=True)
Out[61]:
   1.0  2.0   NaN
 0   1   0   0
 1   0   1   0
 2   0   0   1

[3 rows x 3 columns]
```

- `timedelta64[ns]` operations. See the docs.
Warning: Most of these operations require numpy >= 1.7

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard timedelta format (produced by `to_csv`) into a timedelta type (`np.timedelta64` in nanoseconds).

```python
In [62]: to_timedelta('1 days 06:05:01.00003')
Out[62]: Timedelta('1 days 06:05:01.000030')

In [63]: to_timedelta('15.5us')
Out[63]: Timedelta('0 days 00:00:00.000015')

In [64]: to_timedelta(['1 days 06:05:01.00003','15.5us','nan'])
Out[64]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT], dtype='timedelta64[ns]', freq=None)

In [65]: to_timedelta(np.arange(5),unit='s')
Out[65]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'], dtype='timedelta64[ns]', freq=None)

In [66]: to_timedelta(np.arange(5),unit='d')
Out[66]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)
```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` dtyped Series. This is frequency conversion. See the docs for the docs.

```python
In [67]: from datetime import timedelta

In [68]: td = Series(date_range('20130101',periods=4))-Series(date_range('20121201',periods=4))

In [69]: td[2] += np.timedelta64(timedelta(minutes=5,seconds=3))

In [70]: td[3] = np.nan

In [71]: td
Out[71]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3  NaT
Length: 4, dtype: timedelta64[ns]

# to days
In [72]: td / np.timedelta64(1,'D')
```

(continues on next page)
Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```
In [76]: td * -1
Out[76]:
0   -31 days +00:00:00
1   -31 days +00:00:00
2   -32 days +23:54:57
3      NaT
Length: 4, dtype: timedelta64[ns]
```

```
In [77]: td * Series([1,2,3,4])
Out[77]:
0   31 days 00:00:00
1   62 days 00:00:00
2   93 days 00:15:09
3      NaT
Length: 4, dtype: timedelta64[ns]
```

Absolute DateOffset objects can act equivalently to `timedeltas`

```
In [78]: from pandas import offsets

In [79]: td + offsets.Minute(5) + offsets.Milli(5)
Out[79]:
0   31 days 00:05:00.005000
1   31 days 00:05:00.005000
2   31 days 00:10:03.005000
```

(continues on next page)
Fillna is now supported for timedeltas

```
In [80]: td.fillna(0)
Out[80]:
0   31 days 00:00:00
1   31 days 00:00:00
2   31 days 00:05:03
3     0 days 00:00:00
Length: 4, dtype: timedelta64[ns]

In [81]: td.fillna(timedelta(days=1, seconds=5))
```

You can do numeric reduction operations on timedeltas.

```
In [82]: td.mean()
Out[82]: Timedelta('31 days 00:01:41')

In [83]: td.quantile(.1)
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for scipy >= 0.11.0) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See scipy docs. (GH4298)
- DataFrame constructor now accepts a numpy masked record array (GH3478)
- The new vectorized string method `extract` return regular expression matches more conveniently.

```
In [84]: Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out[84]:
0   a 1
1   b 2
2   NaN
[3 rows x 1 columns]

Elements that do not match return NaN. Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```
In [85]: Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)')
Out[85]:
0   a 1
1   b 2
2  NaN NaN
```

(continues on next page)
Elements that do not match return a row of NaN. Thus, a Series of messy strings can be converted into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects.

Named groups like

```python
In [86]: Series(['a1', 'b2', 'c3']).str.extract(
    ....:    '(?P<letter>[ab])(?P<digit>\d)')
Out[86]:
    letter digit
   0    a    1
   1    b    2
   2  NaN   NaN
```

and optional groups can also be used.

```python
In [87]: Series(['a1', 'b2', '3']).str.extract(
    ....:    '(?P<letter>[ab]?)(?P<digit>\d)')
Out[87]:
    letter digit
   0    a    1
   1    b    2
   2  NaN    3
```

- `read_stata` now accepts Stata 13 format (GH4291)
- `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function (GH4488).
- support for nanosecond times as an offset

**Warning:** These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```python
In [88]: date_range('2013-01-01', periods=5, freq='5N')
Out[88]:
DatetimeIndex([ '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
   dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset
In [89]: date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
Out[89]:
DatetimeIndex(['2013-01-01 00:00:00',
                '2013-01-01 00:00:00.000000005',
                '2013-01-01 00:00:00.000000010',
                '2013-01-01 00:00:00.000000015',
                '2013-01-01 00:00:00.000000020'],
dtype='datetime64[ns]', freq='5N')

Timestamps can be modified in the nanosecond range

In [90]: t = Timestamp('20130101 09:01:02')
In [91]: t + pd.tseries.offsets.Nano(123)
Out[91]: Timestamp('2013-01-01 09:01:02.000000123')

• A new method, `isin` for DataFrames, which plays nicely with boolean indexing. The argument to `isin`, what we’re comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See the docs for more.

To get the rows where any of the conditions are met:

In [92]: dfi = DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})
In [93]: dfi
Out[93]:
  A B
0 1 a
1 2 b
2 3 f
3 4 n

[4 rows x 2 columns]

In [94]: other = DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})
In [95]: mask = dfi.isin(other)
In [96]: mask
Out[96]:
  A   B
0  True False
1  False False
2   True  True
3  False  False

[4 rows x 2 columns]

In [97]: dfi[mask.any(1)]

→
  A B
0 1 a
2 3 f

[2 rows x 2 columns]

• Series now supports a `to_frame` method to convert it to a single-column DataFrame (GH5164)

• All R datasets listed here http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html can now be
loaded into Pandas objects

```python
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see [the docs](#)
- `DatetimeIndex` is now in the API documentation, see [the docs](#)
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See [the docs](#)
- Added PySide support for the qtpandas DataFrameModel and DataFrameWidget.
- Python csv parser now supports usecols (GH4335)
- Frequencies gained several new offsets:
  - `LastWeekOfMonth` (GH4637)
  - `FY5253`, and `FY5253Quarter` (GH4511)
- DataFrame has a new `interpolate` method, similar to Series (GH4434, GH1892)

```python
In [98]: df = DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
                   'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
...
In [99]: df.interpolate()
```

Additionally, the method argument to `interpolate` has been expanded to include 'nearest', 'zero', 'slinear', 'quadratic', 'cubic', 'barycentric', 'krogh', 'piecewise_polynomial', 'pchip', 'polynomial', 'spline'. The new methods require scipy. Consult the Scipy reference guide and documentation for more information about when the various methods are appropriate. See [the docs](#).

Interpolate now also accepts a `limit` keyword argument. This works similar to `fillna`'s limit:

```python
In [100]: ser = Series([1, 3, np.nan, np.nan, np.nan, 11])
In [101]: ser.interpolate(limit=2)
```

1.26. v0.13.0 (January 3, 2014) 379
• Added `wide_to_long` panel data convenience function. See the docs.

```
In [102]: np.random.seed(123)

In [103]: df = pd.DataFrame({
     ....:     "A1970" : ["a", "b", "c"],
     ....:     "A1980" : ["d", "e", "f"],
     ....:     "B1970" : [2.5, 1.2, 0.7],
     ....:     "B1980" : [3.2, 1.3, 0.1],
     ....:     "X" : dict(zip(range(3), np.random.randn(3)))
     ....:     })

In [104]: df["id"] = df.index

In [105]: df
Out[105]:
0     a     d     2.5    3.2 -1.085631 0
1     b     e     1.2    1.3  0.997345 1
2     c     f     0.7    0.1  0.282978 2

[3 rows x 6 columns]

In [106]: wide_to_long(df, ["A", "B"], i="id", j="year")

<table>
<thead>
<tr>
<th>id year</th>
<th>X</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1970</td>
<td>-1.085631 a 2.5</td>
<td></td>
<td></td>

<td>0.282978 f 0.1</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[6 rows x 3 columns]

• `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. (GH4313)

• `DataFrame.plot` will scatter plot x versus y by passing `kind='scatter'` (GH2215)

• Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)

1.26.9 Experimental

• The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,
# eval with NumExpr backend

```python
In [109]: %timeit pd.eval('df1 + df2 + df3 + df4')
8.07 ms +- 212 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

# pure Python evaluation

```python
In [110]: %timeit df1 + df2 + df3 + df4
11.4 ms +- 752 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the [docs](#).

- Similar to pandas.eval, DataFrame has a new DataFrame.eval method that evaluates an expression in the context of the DataFrame. For example,

  ```python
  In [111]: df = DataFrame(randn(10, 2), columns=['a', 'b'])
  In [112]: df.eval('a + b')
  Out[112]:
   0   -0.685204
   1    1.589745
   2    0.325441
   3   -1.784153
   4    0.432893
   5    0.171850
   6    1.895919
   7    3.065587
   8   -0.092759
   9    1.391365
Length: 10, dtype: float64
  ```

- `query()` method has been added that allows you to select elements of a DataFrame using a natural query syntax nearly identical to Python syntax. For example,

  ```python
  In [113]: n = 20
  In [114]: df = DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c'])
  In [115]: df.query('a < b < c')
  Out[115]:
    a  b  c
   11 1   5  8
   15 8  16 19
  [2 rows x 3 columns]
  ```

selects all the rows of df where `a < b < c` evaluates to `True`. For more details see the [docs](#).

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See [docs](#).

**Warning**: Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```python
In [116]: df = DataFrame(np.random.rand(5,2),columns=list('AB'))
```

(continues on next page)
In [117]: df.to_msgpack('foo.msg')

In [118]: pd.read_msgpack('foo.msg')
Out[118]:
   A     B
0 0.251082 0.017357
1 0.347915 0.929879
2 0.546233 0.203368
3 0.064942 0.031722
4 0.355309 0.524575

[5 rows x 2 columns]

In [119]: s = Series(np.random.rand(5), index=date_range('20130101', periods=5))

In [120]: pd.to_msgpack('foo.msg', df, s)

In [121]: pd.read_msgpack('foo.msg')
Out[121]:
   A     B
0 0.251082 0.017357
1 0.347915 0.929879
2 0.546233 0.203368
3 0.064942 0.031722
4 0.355309 0.524575
Freq: D, Length: 5, dtype: float64

You can pass iterator=True to iterator over the unpacked results

In [122]: for o in pd.read_msgpack('foo.msg', iterator=True):
    print(o)
    
    A     B
    0 0.251082 0.017357
    1 0.347915 0.929879
    2 0.546233 0.203368
    3 0.064942 0.031722
    4 0.355309 0.524575
    
    [5 rows x 2 columns]
    2013-01-01 0.227025
    2013-01-02 0.383282
    2013-01-03 0.193225
    2013-01-04 0.110977
    Freq: D, Length: 5, dtype: float64

• pandas.io.gbq provides a simple way to extract from, and load data into, Google’s BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. See the docs
from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicdata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.

query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC""

# Fetch the result set for this query
# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = xxxxxxxxx;

df = gbq.read_gbq(query, project_id = projectid)

# Use pandas to process and reshape the dataset

df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pandas.concat([df2.min(), df2.mean(), df2.max()],
                                 axis=1,keys=['Min Tem', "Mean Temp", "Max Temp"])

The resulting DataFrame is:

```
> df3
       Min Tem  Mean Temp  Max Temp
MONTH
 1   -53.336667   39.827892   89.770968
 2   -49.837500   43.685219   93.437932
 3   -77.926087   48.708355   96.099998
 4   -82.892858   55.070087   97.317240
 5   -92.378261   61.428117  102.042856
 6   -77.703334   65.858888  102.900000
 7   -87.821428  68.169663  106.510714
 8   -89.431999  68.614215  105.500000
 9   -86.611112  63.436935  107.142856
 10  -78.209677  56.880838  92.103333
 11  -50.125000  48.861228  94.996428
 12  -50.332258  42.286879  94.396774
```

Warning: To use this module, you will need a BigQuery account. See <https://cloud.google.com/products/big-query> for details.

As of 10/10/13, there is a bug in Google’s API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.
1.26.10 Internal Refactoring

In 0.13.0 there is a major refactor primarily to subclass Series from NDFrame, which is the base class currently for DataFrame and Panel, to unify methods and behaviors. Series formerly subclassed directly from ndarray. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a Series if passed a Series as an argument. This seems only to affect np.ones_like, np.empty_like, np.diff and np.where. These now return ndarrays.

```python
In [123]: s = Series([1,2,3,4])

Numpy Usage

In [124]: np.ones_like(s)
Out[124]: array([1, 1, 1, 1])

In [125]: np.diff(s)
Out[125]: array([1, 1, 1])

In [126]: np.where(s>1,s,np.nan)
Out[126]: array([ nan, 2., 3., 4.])
```

Pandonic Usage

```python
In [127]: Series(1,index=s.index)
Out[127]:
0 1
1 1
2 1
3 1
Length: 4, dtype: int64

In [128]: s.diff()
Out[128]:
0 NaN
1 1.0
2 1.0
3 1.0
Length: 4, dtype: float64

In [129]: s.where(s>1)
Out[129]:
0 NaN
1 2.0
2 3.0
3 4.0
Length: 4, dtype: float64
```

- Passing a Series directly to a cython function expecting an ndarray type will no long work directly, you must pass Series.values, See Enhancing Performance
- Series(0.5) would previously return the scalar 0.5, instead this will return a 1-element Series
- This change breaks rpy2<=2.3.8. an Issue has been opened against rpy2 and a workaround is detailed in GH5698. Thanks @JanSchulz.
• Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with pd.read_pickle, see Pickling.

• Refactor of series.py/frame.py/panel.py to move common code to generic.py
  – added _setup_axes to created generic NDFrame structures
  – moved methods
    * from_axes, _wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop
    * _iter__, keys, _contains__, _len__, _neg__, _invert__
    * convert_objects, as_blocks, as_matrix, values
    * __getstate__, __setstate__ (compat remains in frame/panel)
    * __getattr__, __setattr__
    * _indexed_same, reindex_like, align, where, mask
    * fillna, replace (Series replace is now consistent with DataFrame)
    * filter (also added axis argument to selectively filter on a different axis)
    * reindex, reindex_axis, take
    * truncate (moved to become part of NDFrame)

• These are API changes which make Panel more consistent with DataFrame
  – swapaxes on a Panel with the same axes specified now return a copy
  – support attribute access for setting
  – filter supports the same API as the original DataFrame filter

• Reindex called with no arguments will now return a copy of the input object

• TimeSeries is now an alias for Series. the property is_time_series can be used to distinguish (if desired)

• Refactor of Sparse objects to use BlockManager
  – Created a new block type in internals, SparseBlock, which can hold multi-dtypes and is non-consolidatable. SparseSeries and SparseDataFrame now inherit more methods from there hierarchy (Series/DataFrame), and no longer inherit from SparseArray (which instead is the object of the SparseBlock)
  – Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  – Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  – enable setitem on SparseSeries for boolean/integer/slices
  – SparsePanels implementation is unchanged (e.g. not using BlockManager, needs work)

• added ftypes method to Series/DataFrame, similar to dtypes, but indicates if the underlying is sparse/dense (as well as the dtype)

• All NDFrame objects can now use __finalize__() to specify various values to propagate to new objects from an existing one (e.g. name in Series will follow more automatically now)

• Internal type checking is now done via a suite of generated classes, allowing isinstance(value, klass) without having to directly import the klass, courtesy of @jtratner
• Bug in Series update where the parent frame is not updating its cache based on changes (GH4080) or types (GH3217), fillna (GH3386)
• Indexing with dtype conversions fixed (GH4463, GH4204)
• Refactor Series.reindex to core/generic.py (GH4604, GH4618), allow method= in reindexing on a Series to work
• Series.copy no longer accepts the order parameter and is now consistent with NDFrame copy
• Refactor rename methods to core/generic.py; fixes Series.rename for (GH4605), and adds rename with the same signature for Panel
• Refactor clip methods to core/generic.py (GH4798)
• Refactor of _get_numeric_data/_get_bool_data to core/generic.py, allowing Series/Panel functionality
• Series (for index) / Panel (for items) now allow attribute access to its elements (GH1903)

```
In [130]: s = Series([1,2,3],index=list('abc'))

In [131]: s.b
Out[131]: 2

In [132]: s.a = 5

In [133]: s
Out[133]:
   a 5
   b 2
   c 3
Length: 3, dtype: int64
```

1.26.11 Bug Fixes

See V0.13.0 Bug Fixes for an extensive list of bugs that have been fixed in 0.13.0.

See the full release notes or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

1.27 v0.12.0 (July 24, 2013)

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write multi-indexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via filter, and a revamped replace routine that accepts regular expressions.

1.27.1 API changes

• The I/O API is now much more consistent with a set of top level reader functions accessed like pd.read_csv() that generally return a pandas object.
  - read_csv
- read_excel
- read_hdf
- read_sql
- read_json
- read_html
- read_stata
- read_clipboard

The corresponding writer functions are object methods that are accessed like df.to_csv()

- to_csv
- to_excel
- to_hdf
- to_sql
- to_json
- to_html
- to_stata
- to_clipboard

- Fix modulo and integer division on Series,DataFrames to act similarly to float dtypes to return np.nan or np.inf as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes differently.

```
In [1]: p = DataFrame({'first': [4,5,8], 'second': [0,0,3]})
In [2]: p % 0
Out[2]:
   first  second
0   NaN    NaN
1   NaN    NaN
2   NaN    NaN
[3 rows x 2 columns]
In [3]: p % p
    →
   first  second
0   0.0    NaN
1   0.0    NaN
2   0.0    0.0
[3 rows x 2 columns]
In [4]: p / p
    →
   first  second
0   1.0    NaN
1   1.0    NaN
2   1.0    1.0
```

• Add squeeze keyword to groupby to allow reduction from DataFrame -> Series if groups are unique. This
is a Regression from 0.10.1. We are reverting back to the prior behavior. This means groupby will return the
same shaped objects whether the groups are unique or not. Revert this issue (GH2893) with (GH3596).
In [6]: df2 = DataFrame([{"val1": 1, "val2" : 20}, {"val1":1, "val2": 19},
...:
{"val1":1, "val2": 27}, {"val1":1, "val2": 12}])
...:
In [7]: def func(dataf):
...:
return dataf["val2"]
...:

- dataf["val2"].mean()

# squeezing the result frame to a series (because we have unique groups)

• Raise on iloc when boolean indexing with a label based indexer mask e.g. a boolean Series, even with integer
labels, will raise. Since iloc is purely positional based, the labels on the Series are not alignable (GH3631)
This case is rarely used, and there are plently of alternatives. This preserves the iloc API to be purely positional
based.
In [10]: df = DataFrame(lrange(5), list('ABCDE'), columns=['a'])
In [11]: mask = (df.a%2 == 0)
In [12]: mask
Out[12]:
A
True
(continues on next page)

388

Chapter 1. What’s New


df.iloc[mask] will raise a ValueError

- The `raise_on_error` argument to plotting functions is removed. Instead, plotting functions raise a `TypeError` when the `dtype` of the object is `object` to remind you to avoid `object` arrays whenever possible and thus you should cast to an appropriate numeric `dtype` if you need to plot something.

- Add `colormap` keyword to DataFrame plotting methods. Accepts either a matplotlib colormap object (ie, `matplotlib.cm.jet`) or a string name of such an object (ie, 'jet'). The colormap is sampled to select the color for each column. Please see `Colormaps` for more information. (GH3860)

- `DataFrame.interpolate()` is now deprecated. Please use `DataFrame.fillna()` and `DataFrame.replace()` instead. (GH3582, GH3675, GH3676)

- the `method` and `axis` arguments of `DataFrame.replace()` are deprecated

- `DataFrame.replace`'s `infer_types` parameter is removed and now performs conversion by default. (GH3907)

- Add the keyword `allow_duplicates` to `DataFrame.insert` to allow a duplicate column to be inserted if True, default is False (same as prior to 0.12) (GH3679)

- Implement `__nonzero__` for NDFrame objects (GH3691, GH3696)

- IO api

  - added top-level function `read_excel` to replace the following. The original API is deprecated and will be removed in a future version

```python
from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])
```
With

```python
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

- added top-level function `read_sql` that is equivalent to the following

```python
from pandas.io.sql import read_frame
read_frame(....)
```

- DataFrame.to_html and DataFrame.to_latex now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to object, and `timedelta64[ns]` to object/int (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a Series and return an `empty` Series when performed on a DataFrame similar to performing these operations on, for example, a DataFrame of slice objects:
  - sum, prod, mean, std, var, skew, kurt, corr, and cov
- `read_html` now defaults to None when reading, and falls back on bs4 + html5lib when lxml fails to parse. a list of parsers to try until success is also valid
- The internal pandas class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the baseclass for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

### 1.27.2 I/O Enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return DataFrames, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a single parser backend: BeautifulSoup4 + html5lib See the docs

You can use `pd.read_html()` to read the output from DataFrame.to_html() like so

```python
In [15]: df = DataFrame({'a': range(3), 'b': list('abc')})

In [16]: print(df)
a b
0 0 a
1 1 b
2 2 c
[3 rows x 2 columns]
In [17]: html = df.to_html()
In [18]: alist = pd.read_html(html, index_col=0)
In [19]: print(df == alist[0])
a b
```

(continues on next page)
Note that **alist** here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

- `pd.read_html()` no longer performs hard conversion of date strings (GH3656).

**Warning:** You may have to install an older version of BeautifulSoup4, [See the installation docs](#).

- Added module for reading and writing Stata files: `pandas.io.stata` (GH1512) accessible via `read_stata` top-level function for reading, and `to_stata` DataFrame method for writing, [See the docs](#).
- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` DataFrame method for writing, [See the docs](#) various issues (GH1226, GH3804, GH3876, GH3867, GH1305)
- **MultiIndex** column support for reading and writing csv format files
  - The **header option** in `read_csv` now accepts a list of the rows from which to read the index.
  - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading **MultiIndex** columns via a list of tuples. The default in 0.12 is to write lists of tuples and **not** interpret list of tuples as a **MultiIndex** column.

  Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default to write and read **MultiIndex** columns will be in the new format. (GH3571, GH1651, GH3141)
- **If an index_col is not specified** (e.g. you don’t have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be lost.

```python
In [20]: from pandas.util.testing import makeCustomDataframe as mkdf
In [21]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
In [22]: df.to_csv('mi.csv')
In [23]: print(open('mi.csv').read())
C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,
  R_l0_g0,R_l1_g0,R0C0,R0C1,R0C2
  R_l0_g1,R_l1_g1,R1C0,R1C1,R1C2
  R_l0_g2,R_l1_g2,R2C0,R2C1,R2C2
  R_l0_g3,R_l1_g3,R3C0,R3C1,R3C2
  R_l0_g4,R_l1_g4,R4C0,R4C1,R4C2

In [24]: pd.read_csv('mi.csv', header=[0,1,2,3], index_col=[0,1])
```

(continues on next page)
• Support for HDFStore (via PyTables 3.0.0) on Python3

• Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for `tables`

```python
In [25]: path = 'store_iterator.h5'

In [26]: DataFrame(randn(10,2)).to_hdf(path,'df',table=True)

In [27]: for df in read_hdf(path,'df', chunksize=3):
    ....:     print df
    ....:
     0  1
  0  0.713216 -0.778461
  1 -0.661062  0.862877
  2  0.344342  0.149565
     0  1
  3 -0.626968 -0.875772
  4 -0.930687 -0.218983
  5  0.949965 -0.442354
     0  1
  6 -0.402985  1.113358
  7 -0.241527  0.670477
  8  0.049355  0.632633
     0  1
  9 -1.502767 -1.225492
```

• `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters

### 1.27.3 Other Enhancements

• `DataFrame.replace()` now allows regular expressions on contained `Series` with object dtype. See the examples section in the regular docs *Replacing via String Expression*

For example you can do

```python
In [25]: df = DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})

In [26]: df.replace(regex=r'\s*\..\s*', value=np.nan)
Out[26]:
       a  b
 0   a  1
 1   b  2
```

(continues on next page)
[4 rows x 2 columns]

to replace all occurrences of the string '. ' with zero or more instances of surrounding whitespace with NaN. Regular string replacement still works as expected. For example, you can do

```
In [27]: df.replace('.', np.nan)
Out[27]:
  a  b
0  a  1
1  b  2
2  NaN  3
3  NaN  4
[4 rows x 2 columns]
```

to replace all occurrences of the string '. ' with NaN.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame.
- `pd.set_option()` now allows N option, value pairs (GH3667).
  
  Let's say that we had an option 'a.b' and another option 'b.c'. We can set them at the same time:

```
In [28]: pd.get_option('a.b')
Out[28]: 2

In [29]: pd.get_option('b.c')
Out[29]: 3

In [30]: pd.set_option('a.b', 1, 'b.c', 4)

In [31]: pd.get_option('a.b')
Out[31]: 1

In [32]: pd.get_option('b.c')
Out[32]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [33]: sf = Series([1, 1, 2, 3, 3, 3])

In [34]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[34]:
          3
3  3
4  3
5  3
Length: 3, dtype: int64
```

The argument of `filter` must a function that, applied to the group as a whole, returns True or False. Another useful operation is filtering out elements that belong to groups with only a couple members.
In [35]:
dff = DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})

In [36]:
dff.groupby('B').filter(lambda x: len(x) > 2)
Out[36]:
     A  B
0    2  b
1    3  b
2    4  b
3    5  b

[4 rows x 2 columns]

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

In [37]:
dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[37]:
     A  B
0  NaN NaN
1  NaN NaN
2  2.0  b
3  3.0  b
4  4.0  b
5  5.0  b
6  NaN NaN
7  NaN NaN

[8 rows x 2 columns]

- Series and DataFrame hist methods now take a figsize argument (GH3834)
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
- Timestamp.min and Timestamp.max now represent valid Timestamp instances instead of the default datetime.min and datetime.max (respectively), thanks @SleepingPills
- read_html now raises when no tables are found and BeautifulSoup==4.2.0 is detected (GH4214)

### 1.27.4 Experimental Features

- Added experimental CustomBusinessDay class to support DateOffsets with custom holiday calendars and custom weekmasks. (GH2301)

Note: This uses the numpy.busdaycalendar API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.

In [38]:
   from pandas.tseries.offsets import CustomBusinessDay

In [39]:
   from datetime import datetime

# As an interesting example, let's look at Egypt where
# a Friday-Saturday weekend is observed.
In [40]:
   weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
# add that for a couple of years
In [41]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01 →')]

In [42]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_ →egypt)

In [43]: dt = datetime(2013, 4, 30)

In [44]: print (dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [45]: dts = date_range(dt, periods=5, freq=bday_egypt)

In [46]: print(Series(dts.weekday, dts).map(Series('Mon Tue Wed Thu Fri Sat Sun'. →split())))
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, Length: 5, dtype: object

1.27.5 Bug Fixes

- Plotting functions now raise a TypeError before trying to plot anything if the associated objects have have a
dtype of object (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric
arrays if possible so that you can still plot, for example, an object array with floats. This happens before any
drawing takes place which eliminates any spurious plots from showing up.

- fillna methods now raise a TypeError if the value parameter is a list or tuple.

- Series.str now supports iteration (GH3638). You can iterate over the individual elements of each string in
the Series. Each iteration yields yields a Series with either a single character at each index of the original
Series or NaN. For example,

In [47]: strs = 'go', 'bow', 'joe', 'slow'

In [48]: ds = Series(strs)

In [49]: for s in ds.str:
   ....:     print(s)
   ....:
0  g
1  b
2  j
3  s
Length: 4, dtype: object
0  o
1  o
2  o
3  l
Length: 4, dtype: object
0  NaN
1  w
(continues on next page)
The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being NaN. Here since 'slow' is the longest string and there are no other strings with the same length 'w' is the only non-null string in the yielded `Series`.

- HDFStore
  - will retain index attributes (freq.tz.name) on recreation (GH3499)
  - will warn with an `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  - support datelike columns with a timezone as data_columns (GH2852)

- Non-unique index support clarified (GH3468).
  - Fix assigning a new index to a duplicate index in a DataFrame would fail (GH3468)
  - Fix construction of a DataFrame with a duplicate index
  - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) (GH2194)
  - `applymap` on a DataFrame with a non-unique index now works (removed warning) (GH2786), and fix (GH3230)
  - Fix to `.csv` to handle non-unique columns (GH3495)
  - Duplicate indexes with getitem will return items in the correct order (GH3455, GH3457) and handle missing elements like unique indices (GH3561)
  - Duplicate indexes with and empty DataFrame.from_records will return a correct frame (GH3562)
  - Concat to produce a non-unique columns when duplicates are across dtypes is fixed (GH3602)
  - Allow insert/delete to non-unique columns (GH3679)
  - Non-unique indexing with a slice via `loc` and friends fixed (GH3659)
  - Allow insert/delete to non-unique columns (GH3679)
- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added takeable argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)

- `DataFrame.from_records` did not accept empty recarrays (GH3682)
- `read_html` now correctly skips tests (GH3741)
- Fixed a bug where `DataFrame.replace` with a compiled regular expression in the `to_replace` argument wasn’t working (GH3907)
- Improved network test decorator to catch `IOError` (and therefore `URLError` as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets where open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in test_yahoo, test_google where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- `Series.hist` will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN DataFrame would barf on a 1xN mask (GH4071)
- Fixed running of `tox` under python3 where the pickle import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where `sharex` and `sharey` were not being passed to `grouped_hist` (GH4089)
- Fixed bug in `DataFrame.replace` where a nested dict wasn’t being iterated over when `regex=False` (GH4115)
- Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
- Fixed bug in `PandasAutoDateLocator` where `invert_xaxis` triggered incorrectly `MilliSecondLocator` (GH3990)
- Fixed bug in plotting that wasn’t raising on invalid colormap for matplotlib 1.1.1 (GH4215)
- Fixed the legend displaying in `DataFrame.plot` (`kind='kde'`) (GH4216)
- Fixed bug where Index slices weren’t carrying the name attribute (GH4226)
- Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
- Fixed bug where `html5lib` wasn’t being properly skipped (GH4265)
- Fixed bug where `get_data_famafrench` wasn’t using the correct file edges (GH4281)

See the full release notes or issue tracker on GitHub for a complete list.

1.28  v0.11.0 (April 22, 2013)

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.
There is a new section in the documentation, 10 Minutes to Pandas, primarily geared to new users.

There is a new section in the documentation, Cookbook, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now Recommended Dependencies

1.28.1 Selection Choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- .loc is strictly label based, will raise KeyError when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a label of the index. This use is not an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']
  - A slice object with labels 'a':'f', (note that contrary to usual python slices, both the start and the stop are included!)
  - A boolean array

  See more at Selection by Label

- .iloc is strictly integer position based (from 0 to length-1 of the axis), will raise IndexError when the requested indicies are out of bounds. Allowed inputs are:
  - An integer e.g. 5
  - A list or array of integers [4, 3, 0]
  - A slice object with ints 1:7
  - A boolean array

  See more at Selection by Position

- .ix supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. .ix is the most general and will support any of the inputs to .loc and .iloc, as well as support for floating point label schemes. .ix is especially useful when dealing with mixed positional and label based hierarchial indexes.

  As using integer slices with .ix have different behavior depending on whether the slice is interpreted as position based or label based, it’s usually better to be explicit and use .iloc or .loc.

  See more at Advanced Indexing and Advanced Hierarchical.

1.28.2 Selection Deprecations

Starting in version 0.11.0, these methods may be deprecated in future versions.

- irow
- icol
- iget_value

See the section Selection by Position for substitutes.
1.28.3 Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

```python
In [1]: df1 = DataFrame(randn(8, 1), columns = ['A'], dtype = 'float32')
In [2]: df1
Out[2]:
     A
0  1.392665
1 -0.123497
2 -0.402761
3 -0.246604
4 -0.288433
5 -0.763434
6  2.069526
7 -1.203569
[8 rows x 1 columns]
In [3]: df1.dtypes
→
A  float32
Length: 1, dtype: object
In [4]: df2 = DataFrame(dict( A = Series(randn(8),dtype='float16'),
                      B = Series(randn(8)),
                      C = Series(randn(8),dtype='uint8') ))
In [5]: df2
Out[5]:
     A       B       C
0  0.591797 -0.038605   0
1  0.841309 -0.460478   1
2 -0.500977 -0.310458   0
3 -0.816406  0.866493 254
4 -0.207031  0.245972   0
5 -0.664062  0.319442 255
6  0.580566  1.378512   1
7 -0.965820  0.292502 255
[8 rows x 3 columns]
In [6]: df2.dtypes
→
A  float16
B  float64
C   uint8
Length: 3, dtype: object
# here you get some upcasting
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

(continues on next page)
In [8]: df3
Out[8]:
    A       B       C
0  1.98446  -0.03861  0.0
1  0.71781  -0.46048  1.0
2 -0.90374  -0.31046  0.0
3 -1.06301  0.86649  254.0
4 -0.49547  0.24597  0.0
5 -1.42749  0.31944  1.0
6  2.65009  1.37851  1.0
7 -2.16939  0.29250  255.0

[8 rows x 3 columns]

In [9]: df3.dtypes

A  float32
B  float64
C  float64
Length: 3, dtype: object

1.2.8.4 Dtype Conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

In [10]: df3.values.dtype
Out[10]: dtype('float64')

Conversion

In [11]: df3.astype('float32').dtypes
Out[11]:
A  float32
B  float32
C  float32
Length: 3, dtype: object

Mixed Conversion

In [12]: df3['D'] = '1.'

In [13]: df3['E'] = '1'

In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
A  float32
B  float64
C  float64
D  float64
E  int64
Length: 5, dtype: object

# same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')
In [16]: `df3['E'] = df3['E'].astype('int32')`

In [17]: `df3.dtypes`
Out[17]:
A  float32
B  float64
C  float64
D  float16
E  int32
Length: 5, dtype: object

Forcing Date coercion (and setting NaT when not datelike)

In [18]: `from datetime import datetime`

In [19]: `s = Series([datetime(2001,1,1,0,0), 'foo', 1.0, 1, ....:
   ....:    Timestamp('20010104'), '20010105'],dtype='O')
   ....:
In [20]: `s.convert_objects(convert_dates='coerce')`
Out[20]:
0    2001-01-01
1      NaT
2      NaT
3      NaT
4    2001-01-04
5    2001-01-05
Length: 6, dtype: datetime64[ns]

1.28.5 Dtype Gotchas

Platform Gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of int64 and float64, regardless of platform. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they WILL be respected, however (GH2837)

The following will all result in int64 dtypes

In [21]: `DataFrame([1,2],columns=['a']).dtypes`
Out[21]:
a  int64
Length: 1, dtype: object

In [22]: `DataFrame({'a' : [1,2] }).dtypes`

In [23]: `DataFrame({'a' : 1 }, index=range(2)).dtypes`
Keep in mind that `DataFrame(np.array([1,2]))` **WILL** result in `int32` on 32-bit platforms!

**Upcasting Gotchas**

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where `nans` are not introduced.

```
In [24]: dfi = df3.astype('int32')

In [25]: dfi['D'] = dfi['D'].astype('int64')

In [26]: dfi
Out[26]:
A  B  C  D  E
0  1  0  0  1  1
1  0  0  1  1  1
2  0  0  0  1  1
3 -1  0  254 1  1
4  0  0  0  1  1
5 -1  0  1  1  1
6  2  1  1  1  1
7 -2  0  255 1  1

[8 rows x 5 columns]
```

```
In [27]: dfi.dtypes

Out[27]:
A  int32
B  int32
C  int32
D  int64
E  int32
Length: 5, dtype: object
```

```

### 1.28.6 Datetimes Conversion

Datet ime64[ns] columns in a DataFrame (or a Series) allow the use of np.nan to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore datetime64[ns] columns are created by default, when passed datetimelike objects (this change was introduced in 0.10.1) (GH2809, GH2810)

```python
In[37]: df = DataFrame(randn(6,2),date_range('20010102',periods=6),columns=['A','B'])
In[38]: df['timestamp'] = Timestamp('20010103')
In[39]: df
```
Out[39]:

In [49]: s = s.astype('O')
1.28.7 API changes

- Added `to_series()` method to indices, to facilitate the creation of indexers (GH3275)
- HDFStore
  - added the method `select_column` to select a single column from a table as a Series.
  - deprecated the `unique` method, can be replicated by `select_column(key, column).unique()`
  - `min_itemsize` parameter to `append` will now automatically create `data_columns` for passed keys

1.28.8 Enhancements

- Improved performance of `df.to_csv()` by up to 10x in some cases. (GH3059)
- Numexpr is now a **Recommended Dependencies**, to accelerate certain types of numerical and boolean operations
- Bottleneck is now a **Recommended Dependencies**, to accelerate certain types of `nan` operations
- HDFStore
  - support `read_hdf/to_hdf` API similar to `read_csv/to_csv`

```
In [52]: df = DataFrame(dict(A=lrange(5), B=lrange(5)))
In [53]: df.to_hdf('store.h5','table',append=True)
In [54]: read_hdf('store.h5', 'table', where = ['index>2'])
```

- provide dotted attribute access to `get` from stores, e.g. `store.df == store['df']`
- new keywords `iterator=boolean, and chunksize=number_in_a_chunk` are provided to support iteration on `select` and `select_as_multiple` (GH3076)

- You can now select timestamps from an `unordered` timeseries similarly to an `ordered` timeseries (GH2437)
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series (GH3070)
In [55]: idx = date_range("2001-10-1", periods=5, freq='M')

In [56]: ts = Series(np.random.rand(len(idx)), index=idx)

Freq: D, Name: B, Length: 4, dtype: float64

• In pd.io.data.Options,
- Fix bug when trying to fetch data for the current month when already past expiry.
- Now using lxml to scrape html instead of BeautifulSoup (lxml was faster).
- New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply calls and puts. Also works for future expiry months and save the instance variable as callsMMYY or putsMMYY, where MMYY are, respectively, the month and year of the option’s expiry.
- Options.get_near_stock_price now allows the user to specify the month for which to get relevant options data.
- Options.get_forward_data now has optional kwargs near and above_below. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from Options.get_near_stock_price instead of Options.get_xxx_data() (GH2758).

- Cursor coordinate information is now displayed in time-series plots.
- added option display.max_seq_items to control the number of elements printed per sequence pprinting it. (GH2979)
- added option display.chop_threshold to control display of small numerical values. (GH2739)
- added option display.max_info_rows to prevent verbose_info from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- value_counts() now accepts a “normalize” argument, for normalized histograms. (GH2710).
- DataFrame.from_records now accepts not only dicts but any instance of the collections.Mapping ABC.
- added option display.mpl_style providing a sleeker visual style for plots. Based on https://gist.github.com/huyng/816622 (GH3075).
- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- to_html() now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes & in addition to < and >. (GH2919)

See the full release notes or issue tracker on GitHub for a complete list.

1.29 v0.10.1 (January 22, 2013)

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the inplace option has been reverted and deprecation warnings added.

1.29.1 API changes

- Functions taking an inplace option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data (GH2700)
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception (GH2640)
- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
- DatetimeIndex.unique now returns a DatetimeIndex with the same name and
pandas: powerful Python data analysis toolkit, Release 0.23.2

- timezone instead of an array (GH2563)

### 1.29.2 New features

- MySQL support for database (contribution from Dan Allan)

### 1.29.3 HDFStore

You may need to upgrade your existing data files. Please visit the compatibility section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```python
In [1]: store = HDFStore('store.h5')
In [2]: df = DataFrame(randn(8, 3), index=date_range('1/1/2000', periods=8),
...:     columns=['A', 'B', 'C'])
...:
In [3]: df['string'] = 'foo'
In [4]: df.loc[df.index[4:6], 'string'] = np.nan
In [5]: df.loc[df.index[7:9], 'string'] = 'bar'
In [6]: df['string2'] = 'cool'
In [7]: df
Out[7]:
   A     B     C    string    string2
0 2000-01-01  1.885136 -0.183873  foo    cool
1 2000-01-02  0.180759 -1.117089  foo    cool
2 2000-01-03 -0.294467 -0.591411  foo    cool
3 2000-01-04  3.127110  1.451130  foo    cool
4 2000-01-05 -0.242846  1.195819  NaN    cool
5 2000-01-06  0.820521 -0.281201  NaN    cool
6 2000-01-07 -0.034086  0.252394  foo    cool
7 2000-01-08 -2.290958 -1.601262  bar    cool
[8 rows x 5 columns]
```

# on-disk operations
```
In [8]: store.append('df', df, data_columns = ['B','C','string','string2'])
In [9]: store.select('df', "B>0 and string=='foo'")
Out[9]:
   A     B     C    string    string2
0 2000-01-04  3.127110  1.451130  foo    cool
1 2000-01-07 -0.034086  0.252394  foo    cool
[2 rows x 5 columns]
```

# this is in-memory version of this type of selection
```
In [10]: df[(df.B > 0) & (df.string == 'foo')]
```

(continues on next page)
Retrieving unique values in an indexable or data column.

```python
# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df','index').unique()
store.unique('df','index')
store.unique('df','string')
```

You can now store `datetime64` in data columns

```python
In [11]: df_mixed = df.copy()
In [12]: df_mixed['datetime64'] = Timestamp('20010102')
In [13]: df_mixed.loc[df_mixed.index[3:4], ['A','B']] = np.nan
In [14]: store.append('df_mixed', df_mixed)
In [15]: df_mixed1 = store.select('df_mixed')
In [16]: df_mixed1
```

```
A     B     C     string    string2       datetime64
2000-01-01 1.885136 -0.183873 2.550850  foo   cool   2001-01-02
2000-01-02 0.180759 -1.117089 0.061462  foo   cool   2001-01-02
2000-01-03 -0.294467 -0.591411 -0.876691  foo   cool   2001-01-02
2000-01-04 NaN    NaN    0.045152  foo   cool   2001-01-02
2000-01-05 -0.242846 1.195819 1.533294  NaN   cool   2001-01-02
2000-01-06 0.820521 -0.281201 1.651561  NaN   cool   2001-01-02
2000-01-07 -0.034086 0.252394 -0.498772  foo   cool   2001-01-02
2000-01-08 -2.290958 -1.601262 -0.256718  bar   cool   2001-01-02
```

```
[8 rows x 6 columns]
```

```python
In [17]: df_mixed1.get_dtype_counts()
```

```python
float64    3
object     2
datetime64[ns]  1
Length: 3, dtype: int64
```

You can pass columns keyword to select to filter a list of the return columns, this is equivalent to passing a `Term('columns',list_of_columns_to_filter)`

```python
In [18]: store.select('df',columns = ['A','B'])
```

```
   A     B
2000-01-01 1.885136 -0.183873
2000-01-02 0.180759 -1.117089
2000-01-03 -0.294467 -0.591411
(continues on next page)```

Enhancements

- HDFStore now can read native PyTables table format tables
- You can pass nan\_rep = 'my\_nan\_rep' to append, to change the default nan representation on disk (which converts to/from np.nan), this defaults to nan.
- You can pass index to append. This defaults to True. This will automagically create indices on the indexables and data columns of the table
- You can pass chunksize=an integer to append, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass expectedrows=an integer to the first append, to set the TOTAL number of expectedrows that PyTables will expect. This will optimize read/write performance.
- Select now supports passing start and stop to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers (GH2698)
- Allow DataFrame.merge to handle combinatorial sizes too large for 64-bit integer (GH2690)
- Series now has unary negation (-series) and inversion (~series) operators (GH2686)
- DataFrame.plot now includes a logx parameter to change the x-axis to log scale (GH2327)
- Series arithmetic operators can now handle constant and ndarray input (GH2574)
- ExcelFile now takes a kind argument to specify the file type (GH2613)
- A faster implementation for Series.str methods (GH2602)

Bug Fixes

- HDFStore tables can now store float32 types correctly (cannot be mixed with float64 however)
- Fixed Google Analytics prefix when specifying request segment (GH2713).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets (GH2687).
- Fixed groupby bug resulting in segfault when passing in MultiIndex (GH2706)
- Fixed bug where passing a Series with datetime64 values into to\_datetime results in bogus output values (GH2699)
- Fixed bug in pattern in HDFStore expressions when pattern is not a valid regex (GH2694)
- Fixed performance issues while aggregating boolean data (GH2692)
• When given a boolean mask key and a Series of new values, Series __setitem__ will now align the incoming values with the original Series (GH2686)
• Fixed MemoryError caused by performing counting sort on sorting MultiIndex levels with a very large number of combinatorial values (GH2684)
• Fixed bug that causes plotting to fail when the index is a DatetimeIndex with a fixed-offset timezone (GH2683)
• Corrected businessday subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend (GH2680)
• Fixed C file parser behavior when the file has more columns than data (GH2668)
• Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified usecols value
• DataFrames with numerical or datetime indices are now sorted prior to plotting (GH2609)
• Fixed DataFrame.from_records error when passed columns, index, but empty records (GH2633)
• Several bug fixed for Series operations when dtype is datetime64 (GH2689, GH2629, GH2626)

See the full release notes or issue tracker on GitHub for a complete list.

1.30 v0.10.0 (December 17, 2012)

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

1.30.1 File parsing new features

The delimited file parsing engine (the guts of read_csv and read_table) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:
• Much-improved Unicode handling via the encoding option.
• Column filtering (usecols)
• Dtype specification (dtype argument)
• Ability to specify strings to be recognized as True/False
• Ability to yield NumPy record arrays (as_recarray)
• High performance delim_whitespace option
• Decimal format (e.g. European format) specification
• Easier CSV dialect options: escapechar, lineterminator, quotechar, etc.
• More robust handling of many exceptional kinds of files observed in the wild
1.30.2 API changes

Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame’s columns and broadcast down the rows, except in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: Special cases aren’t special enough to break the rules). Here’s what I’m talking about:

```
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4),
   ...:                     index=pd.date_range('1/1/2000', periods=6))

In [3]: df
Out[3]:
   0   1   2   3

   → 2000-01-04  0.0  0.564293 0.236399  1.199839
```
Altered resample default behavior

The default time series resample binning behavior of daily D and higher frequencies has been changed to closed='left', label='left'. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
In [2]: series = Series(np.arange(len(dates)), index=dates)
In [3]: series

Freq: D, dtype: int64
```
• Infinity and negative infinity are no longer treated as NA by isnull and notnull. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the mode.use_inf_as_null option:

```python
In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])
In [7]: pd.isnull(s)
Out[7]:
0   False
1   False
2   False
3   False
Length: 4, dtype: bool
In [8]: s.fillna(0)
Out[8]:
0   1.500000
1   inf
2   3.400000
3   -inf
Length: 4, dtype: float64
In [9]: pd.set_option('use_inf_as_null', True)
In [10]: pd.isnull(s)
Out[10]:
0   False
1   True
2   False
3   True
Length: 4, dtype: bool
In [11]: s.fillna(0)
Out[11]:
0   1.5
1   0.0
2   3.4
3   0.0
Length: 4, dtype: float64
In [12]: pd.reset_option('use_inf_as_null')
```

• Methods with the inplace option now all return None instead of the calling object. E.g. code written like df = df.fillna(0, inplace=True) may stop working. To fix, simply delete the unnecessary variable assignment.

• pandas.merge no longer sorts the group keys (sort=False) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnec-
The default column names for a file with no header have been changed to the integers 0 through $N - 1$. This is to create consistency with the DataFrame constructor with no columns specified. The v0.9.0 behavior (names $X_0, X_1, \ldots$) can be reproduced by specifying `prefix='X'`:

```python
In [6]: data= 'a,b,c
1,Yes,2
3,No,4'
In [7]: print(data)
a,b,c
1,Yes,2
3,No,4
In [8]: pd.read_csv(StringIO(data), header=None)
Out[8]:
   0  1  2
0  a  b  c
1  1  Yes 2
2  3  No  4
[3 rows x 3 columns]
In [9]: pd.read_csv(StringIO(data), header=None, prefix='X')
→ X0 X1 X2
0  a  b  c
1  1  Yes 2
2  3  No  4
[3 rows x 3 columns]
```

Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```python
In [10]: print(data)
a,b,c
1,Yes,2
3,No,4
In [11]: pd.read_csv(StringIO(data))
Out[11]:
a  b  c
0  1  Yes 2
1  3  No  4
[2 rows x 3 columns]
In [12]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
Out[12]:
a  b  c
0  1  True 2
1  3  False 4
[2 rows x 3 columns]
```

The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It’s better to do post-processing using the `replace` function instead.
• Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```python
In [13]: s = Series([np.nan, 1., 2., np.nan, 4])
In [14]: s
Out[14]:
0 NaN
1 1.0
2 2.0
3 NaN
4 4.0
Length: 5, dtype: float64

In [15]: s.fillna(0)
Out[15]:
0 0.0
1 1.0
2 2.0
3 0.0
4 4.0
Length: 5, dtype: float64

In [16]: s.fillna(method='pad')
Out[16]:
0 NaN
1 1.0
2 2.0
3 2.0
4 4.0
Length: 5, dtype: float64
```

Convenience methods `ffill` and `bfill` have been added:

```python
In [17]: s.ffill()
Out[17]:
0 NaN
1 1.0
2 2.0
3 2.0
4 4.0
Length: 5, dtype: float64
```

• `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame

```python
In [18]: def f(x):
    ....:     return Series([ x, x**2 ], index = ['x', 'x^2'])
    ....:

In [19]: s = Series(np.random.rand(5))
In [20]: s
Out[20]:
0 0.717478
1 0.815199
(continues on next page)
New API functions for working with pandas options (GH2097):

- get_option / set_option - get/set the value of an option. Partial names are accepted. -
  reset_option - reset one or more options to their default value. Partial names are accepted. -
  describe_option - print a description of one or more options. When called with no arguments. print all registered options.

Note: set_printoptions/ reset_printoptions are now deprecated (but functioning), the print op-

tions now live under “display.XYZ”. For example:

```
In [22]: get_option("display.max_rows")
Out[22]: 15
```

- to_string() methods now always return unicode strings (GH2224).

### 1.30.3 New features

#### 1.30.4 Wide DataFrame Printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by
default:

```
In [23]: wide_frame = DataFrame(randn(5, 16))
In [24]: wide_frame
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>...</th>
<th>11</th>
<th>12</th>
</tr>
</thead>
<tbody>
<tr>

<td>0.314510</td>
</tr>
</tbody>
</table>
(continues on next page)
The old behavior of printing out summary information can be achieved via the `expand_frame_repr` print option:

```
In [25]: pd.set_option('expand_frame_repr', False)
In [26]: wide_frame
Out[26]:
   0   1   2   3   4   5   6   7
--|---|---|---|---|---|---|---|--
0  1.180274 -0.834179 -0.583599 -1.201796 -0.882554 1.209871
1  0.441522 0.191356 1.180274 -0.834179 0.703043 0.166568
2  0.441522 -0.316864 -0.017062 1.570114 -0.880096 0.235532
3  0.441522 -0.316864 -0.017062 1.570114 -0.880096 0.235532
```

The width of each line can be changed via `line_width` (80 by default):

```
In [27]: pd.set_option('line_width', 40)
```

```
OptionError Traceback (most recent call last)

</table>

[8 rows x 5 columns]

In [57]: df1.get_dtype_counts()
• performance improvements on table writing
• support for arbitrarily indexed dimensions
• SparseSeries now has a density property (GH2384)
• enable Series.str.strip/lstrip/rstrip methods to take an input argument to strip arbitrary characters (GH2411)
• implement value_vars in melt to limit values to certain columns and add melt to pandas namespace (GH2412)

Bug Fixes
• added Term method of specifying where conditions (GH1996).
• del store['df'] now call store.remove('df') for store deletion
• deleting of consecutive rows is much faster than before
• min_itemsize parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
• indexing support via create_table_index (requires PyTables >= 2.3) (GH698).
• appending on a store would fail if the table was not first created via put
• fixed issue with missing attributes after loading a pickled dataframe (GH2431)
• minor change to select and remove: require a table ONLY if where is also provided (and not None)

Compatibility
0.10 of HDFStore is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

1.30.6 N Dimensional Panels (Experimental)

Adding experimental support for Panel4D and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```
In [58]: p4d = Panel4D(randn(2, 2, 5, 4),
....:     labels=['Label1','Label2'],
....:     items=['Item1', 'Item2'],
....:     major_axis=date_range('1/1/2000', periods=5),
....:     minor_axis=['A', 'B', 'C', 'D'])
....:
In [59]: p4d
Out[59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
```
See the full release notes or issue tracker on GitHub for a complete list.

### 1.31 v0.9.1 (November 14, 2012)

This is a bugfix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

#### 1.31.1 New features

- *Series.sort*, *DataFrame.sort*, and *DataFrame.sort_index* can now be specified in a per-column manner to support multiple sort orders (GH928)

```python
In [2]: df = DataFrame(np.random.randint(0, 2, (6, 3)), columns=['A', 'B', 'C'])
In [3]: df.sort(['A', 'B'], ascending=[1, 0])
Out[3]:
   A  B  C
0  0  1  1
1  0  1  1
2  0  0  1
3  1  0  0
4  1  0  0
5  0  0  0
```

- *DataFrame.rank* now supports additional argument values for the *na_option* parameter so missing values can be assigned either the largest or the smallest rank (GH1508, GH2159)

```python
In [1]: df = DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
In [3]: df.rank()
Out[3]:
   A  B  C
0  3.0 1.0 3.0
1  1.0 3.0 2.0
2  NaN NaN NaN
3  NaN NaN NaN
4  NaN NaN NaN
5  2.0 2.0 1.0
[6 rows x 3 columns]
```

```python
In [4]: df.rank(na_option='top')
```

(continues on next page)
DataFrame has new *where* and *mask* methods to select values according to a given boolean mask (GH2109, GH2151)

Dataframe currently supports slicing via a boolean vector the same length as the DataFrame (inside the []). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as *NaN*. This is accomplished via the new method *DataFrame.where*. In addition, *where* takes an optional *other* argument for replacement.
Furthermore, *where* now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.ix` (but on the contents rather than the axis labels)

```python
In [12]: df2 = df.copy()

In [13]: df2[df2[1:4] > 0] = 3

In [14]: df2
Out[14]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-1.101581</td>
<td>1.187831</td>
<td>0.630693</td>
</tr>
<tr>
<td>1</td>
<td>3.000000</td>
<td>3.000000</td>
<td>-0.870464</td>
</tr>
<tr>
<td>2</td>
<td>3.000000</td>
<td>-0.224382</td>
<td>0.642489</td>
</tr>
<tr>
<td>3</td>
<td>3.000000</td>
<td>-1.848369</td>
<td>3.000000</td>
</tr>
<tr>
<td>4</td>
<td>1.235390</td>
<td>1.615529</td>
<td>-0.303272</td>
</tr>
</tbody>
</table>
[5 rows x 3 columns]
```

*DataFrame.mask* is the inverse boolean operation of *where*.

```python
In [15]: df.mask(df<=0)
```

</tbody>
</table>
```

[7 rows x 4 columns]

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)
- DataFrame.dot can now accept ndarrays (GH2042)
- DataFrame.drop now supports non-unique indexes (GH2101)
- Panel.shift now supports negative periods (GH2164)
- DataFrame now support unary ~ operator (GH2110)

### 1.31.2 API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```
In [1]: prng = period_range('2012Q1', periods=2, freq='Q')
```

```
In [2]: s = Series(np.random.randn(len(prng)), prng)
```

```
In [4]: s.resample('M')
```

```
Out[4]:
2012-01 -1.471992
2012-02 NaN
2012-03 NaN
2012-04 NaN
```

(continues on next page)
2012-05 NaN
2012-06 NaN
Freq: M, dtype: float64

- Period.end_time now returns the last nanosecond in the time interval (GH2124, GH2125, GH1764)

```python
In [18]: p = Period('2012')
In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')
```

- File parsers no longer coerce to float or bool for columns that have custom converters specified (GH2184)

```python
In [20]: data = 'A,B,C

00001,001,5
00002,002,6'

In [21]: read_csv(StringIO(data), converters={'A': lambda x: x.strip()})
Out[21]:
   A  B  C
0  00001 1  5
1  00002 2  6
```

See the full release notes or issue tracker on GitHub for a complete list.

### 1.32 v0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for `Series.str`, `to_latex` method to DataFrame, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

#### 1.32.1 New features

- Add `encode` and `decode` for unicode handling to vectorized string processing methods in `Series.str` (GH1706)
- Add `DataFrame.to_latex` method (GH1735)
- Add convenient expanding window equivalents of all rolling_* ops (GH1785)
- Add Options class to pandas.io.data for fetching options data from Yahoo! Finance (GH1748, GH1739)
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight (GH1871)
- Series constructor can now handle generator as input (GH1679)
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input (GH924)
- Enable `skip_footer` parameter in `ExcelFile.parse` (GH1843)
1.32.2 API changes

- The default column names when header=None and no columns names passed to functions like read_csv has changed to be more Pythonic and amenable to attribute access:

```
In [1]: data = '0,0,1
   
1,1,0
   
0,1,0'

In [2]: df = read_csv(StringIO(data), header=None)

In [3]: df
Out[3]:
   0 1 2
0 0 0 1
1 1 1 0
2 0 1 0
[3 rows x 3 columns]
```

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like Series(df[col1], index=df[col2]) that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

```
In [4]: s1 = Series([1, 2, 3])

In [5]: s1
Out[5]:
0 1
1 2
2 3
Length: 3, dtype: int64

In [6]: s2 = Series(s1, index=['foo', 'bar', 'baz'])

In [7]: s2
Out[7]:
foo  NaN
bar  NaN
baz  NaN
Length: 3, dtype: float64
```

- Deprecated day_of_year API removed from PeriodIndex, use dayofyear (GH1723)
- Don’t modify NumPy suppress printoption to True at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by HDFStore (GH1834, GH1824)
- Legacy cruft removed: pandas.stats.misc.quantileTS
- Use ISO8601 format for Period repr: monthly, daily, and on down (GH1776)
- Empty DataFrame columns are now created as object dtype. This will prevent a class of TypeErrors that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) (GH1783)
- Setting parts of DataFrame/Panel using ix now aligns input Series/DataFrame (GH1630)
- first and last methods in GroupBy no longer drop non-numeric columns (GH1809)
• Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type `dict` no longer override default NAs unless `keep_default_na` is set to `false` explicitly (GH1657)
• `DataFrame.dot` will not do data alignment, and also work with Series (GH1915)

See the full release notes or issue tracker on GitHub for a complete list.

1.33 v0.8.1 (July 22, 2012)

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

1.33.1 New features

• Add vectorized string processing methods accessible via `Series.str` (GH620)
• Add option to disable adjustment in EWMA (GH1584)
• Radviz plot (GH1566)
• Parallel coordinates plot
• Bootstrap plot
• Per column styles and secondary y-axis plotting (GH1559)
• New datetime converters millisecond plotting (GH1599)
• Add option to disable "sparse" display of hierarchical indexes (GH1538)
• Series/DataFrame’s `set_index` method can `append levels` to an existing `Index/MultiIndex` (GH1569, GH1577)

1.33.2 Performance improvements

• Improved implementation of rolling min and max (thanks to Bottleneck !)
• Add accelerated 'median' GroupBy option (GH1358)
• Significantly improve the performance of parsing ISO8601-format date strings with `DatetimeIndex` or `to_datetime` (GH1571)
• Improve the performance of GroupBy on single-key aggregations and use with Categorical types
• Significant datetime parsing performance improvements

1.34 v0.8.0 (June 29, 2012)

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy datetime64 dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the full release notes or issue tracker on GitHub for a complete list.
1.34.1 Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

1.34.2 NumPy datetime64 dtype and 1.6 dependency

Time series data are now represented using NumPy’s datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6’s datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy codebases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

1.34.3 Time series changes and improvements

Note: With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

Note: See documentation for overview of pandas timeseries API.

- New datetime64 representation speeds up join operations and data alignment, reduces memory usage, and improve serialization / deserialization performance significantly over datetime.datetime
- High performance and flexible resample method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.
- Revamp of frequency aliases and support for frequency shortcuts like ‘15min’, or ‘1h30min’
- New DatetimeIndex class supports both fixed frequency and irregular time series. Replaces now deprecated DateRange class
- New PeriodIndex and Period classes for representing time spans and performing calendar logic, including the 12 fiscal quarterly frequencies <timeseries.quarterly>. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries codebase. Support for conversion between PeriodIndex and DatetimeIndex
- New Timestamp data type subclasses datetime.datetime, providing the same interface while enabling working with nanosecond-resolution data. Also provides easy time zone conversions.
- Enhanced support for time zones. Add tz_convert and tz_localize methods to TimeSeries and DataFrame. All timestamps are stored as UTC; Timestamps from DatetimeIndex objects with time zone set will be localized to localtime. Time zone conversions are therefore essentially free. User needs to know very little about pytz library now; only time zone names as as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.
- Time series string indexing conveniences / shortcuts: slice years, year and month, and index values with strings
• Enhanced time series plotting: adaptation of scikits.timeseries matplotlib-based plotting code
• New date_range, bdate_range, and period_range factory functions
• Robust frequency inference function infer_freq and inferred_freq property of DatetimeIndex, with option to infer frequency on construction of DatetimeIndex
• to_datetime function efficiently parses array of strings to DatetimeIndex. DatetimeIndex will parse array or list of strings to datetime64
• Optimized support for datetime64-dtype data in Series and DataFrame columns
• New NaT (Not-a-Time) type to represent NA in timestamp arrays
• Optimize Series.asof for looking up “as of” values for arrays of timestamps
• Milli, Micro, Nano date offset objects
• Can index time series with datetime.time objects to select all data at particular time of day (TimeSeries. at_time) or between two times (TimeSeries.between_time)
• Add tshift method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using shift

1.34.4 Other new features

• New cut and qcut functions (like R’s cut function) for computing a categorical variable from a continuous variable by binning values either into value-based (cut) or quantile-based (qcut) bins
• Rename Factor to Categorical and add a number of usability features
• Add limit argument to fillna/reindex
• More flexible multiple function application in GroupBy, and can pass list (name, function) tuples to get result in particular order with given names
• Add flexible replace method for efficiently substituting values
• Enhanced read_csv/read_table for reading time series data and converting multiple columns to dates
• Add comments option to parser functions: read_csv, etc.
• Add dayfirst option to parser functions for parsing international DD/MM/YYYY dates
• Allow the user to specify the CSV reader dialect to control quoting etc.
• Handling thousands separators in read_csv to improve integer parsing.
• Enable unstacking of multiple levels in one shot. Alleviate pivot_table bugs (empty columns being introduced)
• Move to klib-based hash tables for indexing; better performance and less memory usage than Python’s dict
• Add first, last, min, max, and prod optimized GroupBy functions
• New ordered_merge function
• Add flexible comparison instance methods eq, ne, lt, gt, etc. to DataFrame, Series
• Improve scatter_matrix plotting function and add histogram or kernel density estimates to diagonal
• Add ‘kde’ plot option for density plots
• Support for converting DataFrame to R data.frame through rpy2
• Improved support for complex numbers in Series and DataFrame
• Add `pct_change` method to all data structures
• Add `max_colwidth` configuration option for DataFrame console output
• `Interpolate` Series values using index values
• Can select multiple columns from GroupBy
• Add `update` methods to Series/DataFrame for updating values in place
• Add `any` and `all` method to DataFrame

### 1.34.5 New plotting methods

`Series.plot` now supports a `secondary_y` option:

```python
In [1]: plt.figure()
Out[1]: <Figure size 640x480 with 0 Axes>

In [2]: fx['FR'].plot(style='g')
   
Out[2]: <matplotlib.axes._subplots.AxesSubplot at 0x1c376acfd0>

In [3]: fx['IT'].plot(style='k--', secondary_y=True)
   
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3781cb38>
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, `kde` is a new option:

```python
In [4]: s = Series(np.concatenate((np.random.randn(1000),
                          ...
                          np.random.randn(1000) * 0.5 + 3)))

In [5]: plt.figure()
Out[5]: <Figure size 640x480 with 0 Axes>

In [6]: s.hist(normed=True, alpha=0.2)
Out[6]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37c3a588>

In [7]: s.plot(kind='kde')
Out[7]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37c3a588>
```

See the `plotting page` for much more.

### 1.34.6 Other API changes

• Deprecation of `offset`, `time_rule`, and `timeRule` arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

### 1.34.7 Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy’s `datetime64` data type instead of `dtype=object` arrays of Python’s built-in `datetime.datetime` objects. `DateRange` has been
replaced by `DatetimeIndex` but otherwise behaved identically. But, if you have code that converts `DateRange` or `Index` objects that used to contain `datetime.datetime` values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:

```python
In [8]: import datetime

In [9]: rng = date_range('1/1/2000', periods=10)

In [10]: rng[5]
Out[10]: Timestamp('2000-01-06 00:00:00', freq='D')

In [11]: isinstance(rng[5], datetime.datetime)
Out[11]: True

In [12]: rng_asarray = np.asarray(rng)

In [13]: scalar_val = rng_asarray[5]

In [14]: type(scalar_val)
Out[14]: numpy.datetime64
```

Pandas’s `Timestamp` object is a subclass of `datetime.datetime` that has nanosecond support (the nanosecond field store the nanosecond value between 0 and 999). It should substitute directly into any code that used `datetime.datetime` values before. Thus, I recommend not casting `DatetimeIndex` to regular NumPy arrays.

If you have code that requires an array of `datetime.datetime` objects, you have a couple of options. First, the `astype(object)` method of `DatetimeIndex` produces an array of `Timestamp` objects:

```python
In [15]: stamp_array = rng.astype(object)

In [16]: stamp_array
Out[16]:
Index(['2000-01-01 00:00:00', '2000-01-02 00:00:00', '2000-01-03 00:00:00',
'2000-01-04 00:00:00', '2000-01-05 00:00:00', '2000-01-06 00:00:00',
'2000-01-07 00:00:00', '2000-01-08 00:00:00', '2000-01-09 00:00:00',
'2000-01-10 00:00:00'],
dtype='object')

In [17]: stamp_array[5]

→ Timestamp('2000-01-06 00:00:00', freq='D')
```

To get an array of proper `datetime.datetime` objects, use the `to_pydatetime` method:

```python
In [18]: dt_array = rng.to_pydatetime()

In [19]: dt_array
Out[19]:
array([datetime.datetime(2000, 1, 1, 0, 0),
       datetime.datetime(2000, 1, 2, 0, 0),
       datetime.datetime(2000, 1, 3, 0, 0),
       datetime.datetime(2000, 1, 4, 0, 0),
       datetime.datetime(2000, 1, 5, 0, 0),
       datetime.datetime(2000, 1, 6, 0, 0),
       datetime.datetime(2000, 1, 7, 0, 0),
       datetime.datetime(2000, 1, 8, 0, 0),
       datetime.datetime(2000, 1, 9, 0, 0),
       (continues on next page)
```
datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)

In [20]: dt_array[5]
Out[20]:

matplotlib knows how to handle `datetime.datetime` but not `Timestamp` objects. While I recommend that you plot time series using `TimeSeries.plot`, you can either use `to_pydatetime` or register a converter for the `Timestamp` type. See matplotlib documentation for more on this.

```
In [21]: rng = date_range('1/1/2000', periods=10)
In [22]: rng
Out[22]:
```

```
In [23]: np.asarray(rng)
Out[23]:
```

```
In [24]: converted = np.asarray(rng, dtype=object)
In [25]: converted[5]
Out[25]:
```

**Warning:** There are bugs in the user-facing API with the nanosecond `datetime64` unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to `dtype=object` is similarly broken.

```
In [21]: rng = date_range('1/1/2000', periods=10)
In [22]: rng
Out[22]:
```

```
In [23]: np.asarray(rng)
Out[23]:
```

```
In [24]: converted = np.asarray(rng, dtype=object)
In [25]: converted[5]
```

**Trust me: don’t panic.** If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas’s API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you do not work directly with `datetime64` arrays in NumPy 1.6 and only use the pandas API.

Support for non-unique indexes: In the latter case, you may have code inside a `try:... catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

1.35 v.0.7.3 (April 12, 2012)

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the full release notes or issue tracker on GitHub for a complete list.
1.35.1 New features

- New *fixed width file reader*, `read_fwf`
- New `scatter_matrix` function for making a scatter plot matrix

```python
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2)
```

```
import matplotlib.pyplot as plt
plt.show()
```

- Add `stacked` argument to Series and DataFrame's `plot` method for *stacked bar plots*.

```python
df.plot(kind='bar', stacked=True)
```
Add log x and y scaling options to DataFrame.plot and Series.plot

Add kurt methods to Series and DataFrame for computing kurtosis

1.35.2 NA Boolean Comparison API Change

Reverted some changes to how NA values (represented typically as NaN or None) are handled in non-numeric Series:

In [1]: series = Series(['Steve', np.nan, 'Joe'])

In [2]: series == 'Steve'
Out[2]:
0    True
1   False
In comparisons, NA / NaN will always come through as False except with != which is True. Be very careful with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```python
In [4]: mask = series == 'Steve'
In [5]: series[mask & series.notnull()]
Out[5]:
    0  Steve
Length: 1, dtype: object
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

### 1.35.3 Other API Changes

When calling apply on a grouped Series, the return value will also be a Series, to be more consistent with the groupby behavior with DataFrame:

```python
In [6]: df = DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
                          'foo', 'bar', 'foo', 'foo'],
                     'B' : ['one', 'one', 'two', 'three',
                             'two', 'two', 'one', 'three'],
                     'C' : np.random.randn(8), 'D' : np.random.randn(8))
In [7]: df
Out[7]:
   A  B         C         D
0  foo  one -0.841015  0.459840
1   bar  one  0.114219 -0.253040
2  foo  two -0.405617 -0.261128
3   bar  three  1.240678  0.406604
4  foo  two -1.022256  0.406604
5   bar  two  1.525196 -0.882785
6  foo  one  0.520047  1.793331
7  foo  three  0.163834 -0.429688
8 rows x 4 columns
```

```python
In [8]: grouped = df.groupby('A')['C']
In [9]: grouped.describe()
```
**1.36 v.0.7.2 (March 16, 2012)**

This release targets bugs in 0.7.1, and adds a few minor features.

**1.36.1 New features**

- Add additional tie-breaking methods in DataFrame.rank (GH874)
- Add ascending parameter to rank in Series, DataFrame (GH875)
- Add coerce_float option to DataFrame.from_records (GH893)
- Add sort_columns parameter to allow unsorted plots (GH918)
- Enable column access via attributes on GroupBy (GH882)
- Can pass dict of values to DataFrame.fillna (GH661)
- Can select multiple hierarchical groups by passing list of values in .ix (GH134)
- Add axis option to DataFrame.fillna (GH174)
- Add level keyword to drop for dropping values from a level (GH159)

**1.36.2 Performance improvements**

- Use khash for Series.value_counts, add raw function to algorithms.py (GH861)
- Intercept __builtin__.sum in groupby (GH885)

**1.37 v.0.7.1 (February 29, 2012)**

This release includes a few new features and addresses over a dozen bugs in 0.7.0.
1.37.1 New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series align method (GH806, GH807)
- Add `fill_value` option to `reindex`, `align` methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using openpyxl

1.37.2 Performance improvements

- Improve performance and memory usage of `fillna` on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame (GH787)

1.38 v.0.7.0 (February 9, 2012)

1.38.1 New features

- New unified merge function for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)
- New unified concatenation function for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` (GH468, GH479, GH273)
- Can pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
- Can pass list of dicts (e.g., a list of JSON objects) to DataFrame constructor (GH526)
- You can now set multiple columns in a DataFrame via `__getitem__`, useful for transformation (GH342)
- Handle differently-indexed output values in `DataFrame.apply` (GH498)

```
In [1]: df = DataFrame(randn(10, 4))
In [2]: df.apply(lambda x: x.describe())
Out[2]:
   0       1       2       3
count 10.000000 10.000000 10.000000 10.000000
mean  0.424980  0.115056  0.452000 -0.103829
std   0.898046  0.712034  0.867316  0.830197
min  -1.337024 -0.779344 -1.206466 -1.022360
25%  -0.000996 -0.344789 -0.120217 -0.744313
50%   0.860419  0.098422  0.540168 -0.387554
75%   1.094236  0.375137  1.076331  0.674952
max   1.207725  1.601703  1.663859  1.096187
```

(continues on next page)
1.38.2 API Changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how integer indexes are handled with regard to label-based indexing. Here is an example:
In [3]: s = Series(randn(10), index=range(0, 20, 2))

In [4]: s
Out[4]:
   0    0.446246
   2   -0.500268
   4     0.814725
   6    -0.312744
   8    1.098892
  10    1.306330
  12   -0.312744
  14   -0.030890
  16    1.608095
  18   -0.023287
Length: 10, dtype: float64

In [5]: s[0]
Out[5]:
   0.44624598505731339

In [6]: s[2]
Out[6]:
   -0.500268093241102

In [7]: s[4]
Out[7]:
   0.8147247587659604

This is all exactly identical to the behavior before. However, if you ask for a key not contained in the Series, in versions 0.6.1 and prior, Series would fall back on a location-based lookup. This now raises a KeyError:

In [2]: s[1]
KeyError: 1

This change also has the same impact on DataFrame:

In [3]: df = DataFrame(randn(8, 4), index=range(0, 16, 2))

In [4]: df
Out[4]:
   0  1  2  3
  0  0.88427  0.3363 -0.1787  0.03162
  2  0.14451 -0.1415  0.2504  0.58374
  4 -1.44779  -0.9186 -1.4996  0.27163
  6 -0.26598  -2.4184 -0.2658  0.11503
  8  0.58776   0.3144  -0.8566  0.61941
 10  0.10940  -0.7175 -1.0108  0.47990
 12 -1.16919  -0.3087  -0.6049 -0.43544
 14 -0.07337   0.3410  0.0424 -0.16037

In [5]: df.ix[3]
KeyError: 3

In order to support purely integer-based indexing, the following methods have been added:
### Method Description

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series.iget_value(i)</td>
<td>Retrieve value stored at location i</td>
</tr>
<tr>
<td>Series.iget(i)</td>
<td>Alias for iget_value</td>
</tr>
<tr>
<td>DataFrame.irow(i)</td>
<td>Retrieve the i-th row</td>
</tr>
<tr>
<td>DataFrame.icol(j)</td>
<td>Retrieve the j-th column</td>
</tr>
<tr>
<td>DataFrame.iget_value(i, j)</td>
<td>Retrieve the value at row i and column j</td>
</tr>
</tbody>
</table>

#### 1.38.3 API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) unless both the start and endpoint are contained in the index:

```python
In [1]: s = Series(randn(6), index=list('gmkaec'))
In [2]: s
Out[2]:
g -1.182230
m -0.276183
k -0.243550
a  1.628992
e  0.073308
c -0.539890
dtype: float64
```

Then this is OK:

```python
In [3]: s.ix['k':'e']
Out[3]:
k -0.243550
a  1.628992
e  0.073308
dtype: float64
```

But this is not:

```python
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```python
In [4]: s2 = s.sort_index()
In [5]: s2
Out[5]:
a  1.628992
c -0.539890
e  0.073308
g -1.182230
k -0.243550
m -0.276183
dtype: float64
```

```python
In [6]: s2.ix['b':'h']
Out[6]:
c -0.539890
```

(continues on next page)
1.38.4 Changes to Series [ ] operator

As as notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [ ] (i.e. the __getitem__ and __setitem__ methods). The behavior will be the same as passing similar input to ix except in the case of integer indexing:

```python
In [8]: s = Series(randn(6), index=list('acegkm'))

In [9]: s
Out[9]:
a   -0.800734
b   -0.229737
c   -0.781940
d   0.756053
e   -0.159310
f   2.613373
Length: 6, dtype: float64

In [10]: s[['m', 'a', 'c', 'e']]
→
m   -0.159310
a   -0.800734
c   -0.229737
e   -0.781940
Length: 4, dtype: float64

In [11]: s['b':'l']
→
c   -0.229737
e   -0.781940
g   0.756053
k   2.613373
Length: 4, dtype: float64

In [12]: s['c':'k']
→
c   -0.229737
e   -0.781940
g   0.756053
k   2.613373
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing ndarray):

```python
In [13]: s = Series(randn(6), index=range(0, 12, 2))

In [14]: s[[4, 0, 2]]
Out[14]:
a   -0.800734
c   -0.229737
e   -0.781940
g   0.756053
k   2.613373
Length: 4, dtype: float64
```
4  0.022862
0  -0.321246
2  -0.707337
Length: 3, dtype: float64

In [15]: s[1:5]
Out[15]:
   2    -0.707337
   4     0.022862
   6     0.306713
   8   -0.162222
Length: 4, dtype: float64

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

### 1.38.5 Other API Changes

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a DataFrame, an exception will now be raised. Before it was possible to accidentally mutate a DataFrame’s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` (GH316)
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` (GH699)

### 1.38.6 Performance improvements

- **Cythonized GroupBy aggregations** no longer presort the data, thus achieving a significant speedup (GH93). GroupBy aggregations with Python functions significantly sped up by clever manipulation of the ndarray data type in Cython (GH496).
- Better error message in DataFrame constructor when passed column labels don’t match data (GH497)
- Substantially improve performance of multi-GroupBy aggregation when a Python function is passed, reuse ndarray object in Cython (GH496)
- Can store objects indexed by tuples and floats in HDFStore (GH492)
- Don’t print length by default in `Series.to_string`, add `length` option (GH489)
- Improve Cython code for multi-groupby to aggregate without having to sort the data (GH93)
- Improve MultiIndex reindexing speed by storing tuples in the MultiIndex, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of `Series._getitem__` for standard use cases
- Avoid Index dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in setup.py if NumPy not installed
- Use common set of NA-handling operations (sum, mean, etc.) in Panel class also (GH536)
- Default name assignment when calling `reset_index` on DataFrame with a regular (non-hierarchical) index (GH476)
• Use Cythonized groupers when possible in Series/DataFrame stat ops with level parameter passed (GH545)
• Ported skiplist data structure to C to speed up rolling_median by about 5-10x in most typical use cases (GH374)

1.39 v.0.6.1 (December 13, 2011)

1.39.1 New features

• Can append single rows (as Series) to a DataFrame
• Add Spearman and Kendall rank correlation options to Series.corr and DataFrame.corr (GH428)
• Added get_value and set_value methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). set_value is capable of producing an enlarged object.
• Add PyQt table widget to sandbox (GH435)
• DataFrame.align can accept Series arguments and an axis option (GH461)
• Implement new SparseArray and SparseList data structures. SparseSeries now derives from SparseArray (GH463)
• Better console printing options (GH453)
• Implement fast data ranking for Series and DataFrame, fast versions of scipy.stats.rankdata (GH428)
• Implement DataFrame.from_items alternate constructor (GH444)
• DataFrame.convert_objects method for inferring better dtypes for object columns (GH302)
• Add rolling_corr_pairwise function for computing Panel of correlation matrices (GH189)
• Add margins option to pivot_table for computing subgroup aggregates (GH114)
• Add Series.from_csv function (GH482)
• Can pass DataFrame/DataFrame and DataFrame/Series to rolling_corr/rolling_cov (GH #462)
• MultiIndex.get_level_values can accept the level name

1.39.2 Performance improvements

• Improve memory usage of DataFrame.describe (do not copy data unnecessarily) (PR #425)
• Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
• Fix performance regression in cross-sectional count in DataFrame, affecting DataFrame.dropna speed
• Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

1.40 v.0.6.0 (November 25, 2011)

1.40.1 New Features

• Added melt function to pandas.core.reshape
• Added level parameter to group by level in Series and DataFrame descriptive statistics (GH313)
• Added head and tail methods to Series, analogous to to DataFrame (GH296)
• Added Series.isin function which checks if each value is contained in a passed sequence (GH289)
• Added float_format option to Series.to_string
• Added skip_footer (GH291) and converters (GH343) options to read_csv and read_table
• Added drop_duplicates and duplicated functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
• Implemented operators ‘&’, ‘|’, ‘^’, ‘~’ on DataFrame (GH347)
• Added Series.mad, mean absolute deviation
• Added QuarterEnd DateOffset (GH321)
• Added dot to DataFrame (GH65)
• Added orient option to Panel.from_dict (GH359, GH301)
• Added orient option to DataFrame.from_dict
• Added passing list of tuples or list of lists to DataFrame.from_records (GH357)
• Added multiple levels to groupby (GH103)
• Allow multiple columns in by argument of DataFrame.sort_index (GH92, GH362)
• Added fast get_value and put_value methods to DataFrame (GH360)
• Added cov instance methods to Series and DataFrame (GH194, GH362)
• Added kind='bar' option to DataFrame.plot (GH348)
• Added idxmin and idxmax to Series and DataFrame (GH286)
• Added read_clipboard function to parse DataFrame from clipboard (GH300)
• Added nunique function to Series for counting unique elements (GH297)
• Made DataFrame constructor use Series name if no columns passed (GH373)
• Support regular expressions in read_table/read_csv (GH364)
• Added DataFrame.to_html for writing DataFrame to HTML (GH387)
• Added support for MaskedArray data in DataFrame, masked values converted to NaN (GH396)
• Added DataFrame.boxplot function (GH368)
• Can pass extra args, kwds to DataFrame.apply (GH376)
• Implement DataFrame.join with vector on argument (GH312)
• Added legend boolean flag to DataFrame.plot (GH324)
• Can pass multiple levels to stack and unstack (GH370)
• Can pass multiple values columns to pivot_table (GH381)
• Use Series name in GroupBy for result index (GH363)
• Added raw option to DataFrame.apply for performance if only need ndarray (GH309)
• Added proper, tested weighted least squares to standard and panel OLS (GH303)
1.40.2 Performance Enhancements

- **VBENCH** Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the codebase (GH361)
- **VBENCH** Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
- **VBENCH** Improved performance of `MultiIndex.from_tuples`
- **VBENCH** Special Cython matrix iterator for applying arbitrary reduction operations
- **VBENCH + DOCUMENT** Add `raw` option to DataFrame.apply for getting better performance when
- **VBENCH** Faster cythonized count by level in Series and DataFrame (GH341)
- **VBENCH**? Significant GroupBy performance enhancement with multiple keys with many “empty” combinations
- **VBENCH** New Cython vectorized function `map_infer` speeds up Series.apply and Series.map significantly when passed elementwise Python function, motivated by (GH355)
- **VBENCH** Significantly improved performance of Series.order, which also makes np.unique called on a Series faster (GH327)
- **VBENCH** Vastly improved performance of GroupBy on axes with a MultiIndex (GH299)

1.41 v.0.5.0 (October 24, 2011)

1.41.1 New Features

- **Added** DataFrame.align method with standard join options
- **Added** `parse_dates` option to read_csv and read_table methods to optionally try to parse dates in the index columns
- **Added** `nrows`, `chunksize`, and `iterator` arguments to read_csv and read_table. The last two return a new TextParser class capable of lazily iterating through chunks of a flat file (GH242)
- **Added** ability to join on multiple columns in DataFrame.join (GH214)
- **Added** private `_get_duplicates` function to Index for identifying duplicate values more easily (ENH5c)
- **Added** column attribute access to DataFrame.
- **Added** Python tab completion hook for DataFrame columns. (GH233, GH230)
- **Implemented** Series.describe for Series containing objects (GH241)
- **Added** inner join option to DataFrame.join when joining on key(s) (GH248)
- **Implemented** selecting DataFrame columns by passing a list to `__getitem__` (GH253)
- **Implemented** `&` and `|` to intersect / union Index objects, respectively (GH261)
- **Added** pivot_table convenience function to pandas namespace (GH234)
- **Implemented** Panel.rename_axis function (GH243)
- **Implemented** DataFrame will show index level names in console output (GH334)
- **Implemented** Panel.take
- **Added** `set_eng_float_format` for alternate DataFrame floating point string formatting (ENH61)
• *Added* convenience *set_index* function for creating a DataFrame index from its existing columns
• *Implemented* *groupby* hierarchical index level name (GH223)
• *Added* support for different delimiters in *DataFrame.to_csv* (GH244)
• TODO: DOCS ABOUT TAKE METHODS

### 1.41.2 Performance Enhancements

• **VBENCH** Major performance improvements in file parsing functions *read_csv* and *read_table*
• **VBENCH** Added Cython function for converting tuples to ndarray very fast. Speeds up many MultiIndex-related operations
• **VBENCH** Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
• **VBENCH** Improved speed of *DataFrame.xs* on mixed-type DataFrame objects by about 5x, regression from 0.3.0 (GH215)
• **VBENCH** With new *DataFrame.align* method, speeding up binary operations between differently-indexed DataFrame objects by 10-25%.
• **VBENCH** Significantly sped up conversion of nested dict into DataFrame (GH212)
• **VBENCH** Significantly speed up *DataFrame.__repr__* and *count* on large mixed-type DataFrame objects

### 1.42 v.0.4.3 through v0.4.1 (September 25 - October 9, 2011)

#### 1.42.1 New Features

• *Added* Python 3 support using 2to3 (GH200)
• *Added* *name* attribute to *Series*, now prints as part of *Series.__repr__*
• *Added* instance methods *isnull* and *notnull* to *Series* (GH209, GH203)
• *Added* *Series.align* method for aligning two series with choice of join method (ENH56)
• *Added* method *get_level_values* to *MultiIndex* (GH188)
• Set values in mixed-type DataFrame objects via *.ix* indexing attribute (GH135)
• *Added* new *DataFrame methods* *get_dtype_counts* and property *dtypes* (ENHdc)
• *Added* *ignore_index* option to *DataFrame.append* to stack DataFrames (ENH1b)
• *read_csv* tries to *sniff* delimiters using *csv.Sniffer* (GH146)
• *read_csv* can *read* multiple columns into a MultiIndex; *DataFrame‘s to_csv* method writes out a corresponding MultiIndex (GH151)
• *DataFrame.rename* has a new *copy* parameter to *rename* a DataFrame in place (ENHed)
• *Enable* unstacking by name (GH142)
• *Enable* *sortlevel* to work by level (GH141)
1.42.2 Performance Enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of `isnull` and `notnull`, a regression from v0.3.0 (GH187)
- Refactored code related to `DataFrame.join` so that intermediate aligned copies of the data in each `DataFrame` argument do not need to be created. Substantial performance increases result (GH176)
- Substantially improved performance of generic `Index.intersection` and `Index.union`
- Implemented `BlockManager.take` resulting in significantly faster `take` performance on mixed-type `DataFrame` objects (GH104)
- Improved performance of `Series.sort_index`
- Significant groupby performance enhancement: removed unnecessary integrity checks in `DataFrame` internals that were slowing down slicing operations to retrieve groups
- Optimized `_ensure_index` function resulting in performance savings in type-checking `Index` objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into `DataFrame.join` and related functions
The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users. Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

2.1 Plan for dropping Python 2.7

The Python core team plans to stop supporting Python 2.7 on January 1st, 2020. In line with NumPy’s plans, all pandas releases through December 31, 2018 will support Python 2.

The final release before December 31, 2018 will be the last release to support Python 2. The released package will continue to be available on PyPI and through conda.

Starting January 1, 2019, all releases will be Python 3 only.

If there are people interested in continued support for Python 2.7 past December 31, 2018 (either backporting bugfixes or funding) please reach out to the maintainers on the issue tracker.

For more information, see the Python 3 statement and the Porting to Python 3 guide.

2.2 Python version support

Officially Python 2.7, 3.5, 3.6, and 3.7.

2.3 Installing pandas

2.3.1 Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, ...) is with Anaconda, a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for Anaconda can be found here.
A full list of the packages available as part of the Anaconda distribution can be found here.

Another advantage to installing Anaconda is that you don’t need admin rights to install it. Anaconda can install in the user’s home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

### 2.3.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

Conda is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

Miniconda allows you to create a minimal self contained Python installation, and then use the Conda command to install additional packages.

First you will need Conda to be installed and downloading and running the Miniconda will do this for you. The installer can be found here

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```bash
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```bash
source activate name_of_my_env
```

On Windows the command is:

```bash
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```bash
conda install pandas
```

To install a specific pandas version:

```bash
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```bash
conda install ipython
```

To install the full Anaconda distribution:

```bash
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```bash
conda install pip
pip install django
```
2.3.3 Installing from PyPI

pandas can be installed via pip from PyPI.

```bash
pip install pandas
```

2.3.4 Installing with ActivePython

Installation instructions for ActivePython can be found here. Versions 2.7 and 3.5 include pandas.

2.3.5 Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

```none
<table>
<thead>
<tr>
<th>Distribution</th>
<th>Status</th>
<th>Download / Repository Link</th>
<th>Install method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian</td>
<td>stable</td>
<td>official Debian repository</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>Debian &amp; Ubuntu</td>
<td>unstable (latest packages)</td>
<td>NeuroDebian</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>Ubuntu</td>
<td>stable</td>
<td>official Ubuntu repository</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>OpenSuse</td>
<td>stable</td>
<td>OpenSuse Repository</td>
<td><code>zypper in python3-pandas</code></td>
</tr>
<tr>
<td>Fedora</td>
<td>stable</td>
<td>official Fedora repository</td>
<td><code>dnf install python3-pandas</code></td>
</tr>
<tr>
<td>Centos/RHEL</td>
<td>stable</td>
<td>EPEL repository</td>
<td><code>yum install python3-pandas</code></td>
</tr>
</tbody>
</table>
```

However, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it’s recommended to install using the `pip` or `conda` methods described above.

2.3.6 Installing from source

See the contributing documentation for complete instructions on building from the git source tree. Further, see creating a development environment if you wish to create a pandas development environment.

2.4 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the codebase as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` and run:

```bash
>>> import pandas as pd
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TF\Anaconda3\envs\py36\lib\site-packages\pandas
================================== test session starts ==================================
(continues on next page)
2.5 Dependencies

- setuptools: 24.2.0 or higher
- NumPy: 1.9.0 or higher
- python-dateutil: 2.5.0 or higher
- pytz

2.5.1 Recommended Dependencies

- numexpr: for accelerating certain numerical operations. numexpr uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.4.6 or higher.
- bottleneck: for accelerating certain types of nan evaluations. bottleneck uses specialized cython routines to achieve large speedups. If installed, must be Version 1.0.0 or higher.

Note: You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

2.5.2 Optional Dependencies

- Cython: Only necessary to build development version. Version 0.24 or higher.
- SciPy: miscellaneous statistical functions, Version 0.14.0 or higher
- xarray: pandas like handling for > 2 dims, needed for converting Panels to xarray objects. Version 0.7.0 or higher is recommended.
- PyTables: necessary for HDF5-based storage. Version 3.0.0 or higher required, Version 3.2.1 or higher highly recommended.
- Feather Format: necessary for feather-based storage, version 0.3.1 or higher.
- Apache Parquet, either pyarrow (>= 0.4.1) or fastparquet (>= 0.0.6) for parquet-based storage. The snappy and brotli are available for compression support.
- SQLAlchemy: for SQL database support. Version 0.8.1 or higher recommended. Besides SQLAlchemy, you also need a database specific driver. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs. Some common drivers are:
  - psycopg2: for PostgreSQL
• **pymysql**: for MySQL.
• **SQLite**: for SQLite, this is included in Python’s standard library by default.

**matplotlib**: for plotting, Version 1.4.3 or higher.

**For Excel I/O:**

• **xlrd/xlwt**: Excel reading (xlrd) and writing (xlwt)
• **openpyxl**: openpyxl version 2.4.0 for writing .xlsx files (xlrd >= 0.9.0)
• **XlsxWriter**: Alternative Excel writer

**Jinja2**: Template engine for conditional HTML formatting.

**s3fs**: necessary for Amazon S3 access (s3fs >= 0.0.7).

**blosc**: for msgpack compression using blosc

• One of **qtpy** (requires PyQt or PySide), **PyQt5**, **PyQt4**, **pygtk**, **xsel**, or **xclip**: necessary to use `read_clipboard()`. Most package managers on Linux distributions will have `xclip` and/or `xsel` immediately available for installation.

**pandas-gbq**: for Google BigQuery I/O.

**Backports.lzma**: Only for Python 2, for writing to and/or reading from an xz compressed DataFrame in CSV; Python 3 support is built into the standard library.

• One of the following combinations of libraries is needed to use the top-level `read_html()` function:

  Changed in version 0.23.0.

**Note**: If using BeautifulSoup4 a minimum version of 4.2.1 is required

• **BeautifulSoup4** and **html5lib** (Any recent version of html5lib is okay.)
• **BeautifulSoup4** and **lxml**
• **BeautifulSoup4** and **html5lib** and **lxml**
• **Only lxml**, although see *HTML Table Parsing* for reasons as to why you should probably **not** take this approach.

**Warning:**

• if you install **BeautifulSoup4** you must install either **lxml** or **html5lib** or both. **read_html()** will **not** work with only **BeautifulSoup4** installed.

• You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

**Note:**

• if you’re on a system with **apt-get** you can do

```bash
sudo apt-get build-dep python-lxml
```

to get the necessary dependencies for installation of **lxml**. This will prevent further headaches down the line.
Note: Without the optional dependencies, many useful features will not work. Hence, it is highly recommended that you install these. A packaged distribution like Anaconda, ActivePython (version 2.7 or 3.5), or Enthought Canopy may be worth considering.
CHAPTER THREE

CONTRIBUTING TO PANDAS

Table of contents:

• Where to start?
• Bug reports and enhancement requests
• Working with the code
  – Version control, Git, and GitHub
  – Getting started with Git
  – Forking
  – Creating a development environment
    * Installing a C Compiler
    * Creating a Python Environment
    * Creating a Python Environment (pip)

  – Code standards
    * C (cpplint)
    * Python (PEP8)
    * Backwards Compatibility
  – Testing With Continuous Integration
  – Test-driven development/code writing
    * Writing tests
3.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and good first issue where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

Feel free to ask questions on the mailing list or on Gitter.

3.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
```

2. Include the full version string of pandas and its dependencies. You can use the built in function:
3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the pandas community and be open to comments/ideas from others.

### 3.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

#### 3.3.1 Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy’s documentation.
- Matthew Brett’s Pydagogue.

#### 3.3.2 Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

#### 3.3.3 Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```bash
$ git clone https://github.com/your-user-name/pandas.git pandas-yourname
$ cd pandas-yourname
$ git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory pandas-yourname and connects your repository to the upstream (main project) pandas repository.

#### 3.3.4 Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C compiler and Python environment. If you’re making documentation changes, you can skip to Contributing to the documentation but you won’t be able to build the documentation locally before pushing your changes.
3.3.4.1 Installing a C Compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using. Follow the CPython contributing guidelines for getting a compiler installed. You don’t need to do any of the ./configure or make steps; you only need to install the compiler.

For Windows developers, the following links may be helpful.

- https://cowboyprogrammer.org/building-python-wheels-for-windows/
- https://blog.ionelmc.ro/2014/12/21/compiling-python-extensions-on-windows/

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

3.3.4.2 Creating a Python Environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either Anaconda or miniconda
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```bash
# Create and activate the build environment
conda env create -f ci/environment-dev.yaml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .

# Install the rest of the optional dependencies
conda install -c defaults -c conda-forge --file=ci/requirements-optional-conda.txt
```

At this point you should be able to import pandas from your locally built version:

```bash
$ python  # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```
This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```bash
conda info -e
```

To return to your root environment:

```bash
conda deactivate
```

See the full conda docs [here](#).

### 3.3.4.3 Creating a Python Environment (pip)

If you aren’t using conda for you development environment, follow these instructions. You’ll need to have at least python3.5 installed on your system.

```bash
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev
# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r ci/requirements_dev.txt
# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .

# Install additional dependencies
python -m pip install -r ci/requirements-optional-pip.txt
```

### 3.3.5 Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```bash
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```bash
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to pandas. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```bash
git checkout master
git pull upstream master --ff-only
```
When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.

### 3.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

**Documentation:**

- *About the pandas documentation*
- *How to build the pandas documentation*
  - Requirements
  - Building the documentation
  - Building master branch documentation

#### 3.4.1 About the pandas documentation

The documentation is written in reStructuredText, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder pandas/doc/.
  
The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the Numpy Docstring Standard. Follow the pandas docstring guide for detailed instructions on how to write a correct docstring.

#### 3.4.1.1 pandas docstring guide

**Note:** Video tutorial: Pandas docstring guide by Frank Akogun.

**About docstrings and standards**

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.
Next example gives an idea on how a docstring looks like:

```python
def add(num1, num2):
    """
    Add up two integer numbers.
    
    This function simply wraps the `+` operator, and does not
    do anything interesting, except for illustrating what is
    the docstring of a very simple function.
    
    Parameters
    ----------
    num1 : int
        First number to add
    num2 : int
        Second number to add
    
    Returns
    -------
    int
        The sum of `num1` and `num2`
    
    See Also
    --------
    subtract : Subtract one integer from another
    
    Examples
    --------
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring convention is followed. The conventions is explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

Pandas has some helpers for sharing docstrings between related classes, see Sharing Docstrings.

The rest of this document will summarize all the above guides, and will provide additional convention specific to the pandas project.
Writing a docstring

General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. os, list, numpy.abs, datetime.date, True)
- A pandas class (in the form :class:`pandas.Series`)
- A pandas method (in the form :meth:`pandas.Series.sum`)
- A pandas function (in the form :func:`pandas.to_datetime`)

**Note:** To display only the last component of the linked class, method or function, prefix it with ~. For example, :class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.

**Good:**

```python
def add_values(arr):
    
    Add the values in `arr`.
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.
    Some sections are omitted here for simplicity.
    
    return sum(arr)
```

**Bad:**

```python
def func():

    """Some function.
    With several mistakes in the docstring.
    It has a blank like after the signature `def func():`.
    The text 'Some function' should go in the line after the opening quotes of the docstring, not in the same line.
    There is a blank line between the docstring and the first line of code `foo = 1`.
    The closing quotes should be in the next line, not in this one.""

    foo = 1
```

(continues on next page)
Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

**Good:**

```python
def astype(dtype):
    """
    Cast Series type.
    
    This section will provide further details.
    """
    pass
```

**Bad:**

```python
def astype(dtype):
    """
    Casts Series type.
    
    Verb in third-person of the present simple, should be infinitive.
    """
    pass

def astype(dtype):
    """
    Method to cast Series type.
    
    Does not start with verb.
    """
    pass

def astype(dtype):
    """
    Cast Series type
    
    Missing dot at the end.
    """
    pass

def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in the parameter `dtype`.
    
    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```
Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```python
def unstack():
    """
    Pivot a row index to columns.

    When using a multi-index, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.
    """
    pass
```

Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *args and **kwargs, but not self.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *args and **kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When None is a value being used, we will keep the form “str, default None”. For example, in df.to_csv(compression=None), None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use str, optional. Only in cases like func(value=None) and None is being used in the same way as 0 or foo would be used, then we will specify “str, int or None, default None”.

Good:

```python
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.
        """
```
Render the data in the Series as a matplotlib plot of the specified kind.

Parameters

    kind : str
        Kind of matplotlib plot.
    color : str, default 'blue'
        Color name or rgb code.
    **kwargs
        These parameters will be passed to the matplotlib plotting function.

""
    pass

Bad:

```python
class Series:

    def plot(self, kind, **kwargs):
        ""
        Generate a plot.
        Render the data in the Series as a matplotlib plot of the specified kind.

        Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter 'kind' and before the colon, a space is missing.

        Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.

        Finally, the `**kwargs` parameter is missing.

        Parameters

        kind: str
            kind of matplotlib plot
        ""
        pass
```

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For dict and tuple, as more than one type is present, we use the brackets to help read the type (curly brackets for dict and normal brackets for tuple):
– list of int
– dict of {str : int}
– tuple of (str, int, int)
– tuple of (str,)
– set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:
– {0, 10, 25}
– {‘simple’, ‘advanced’}
– {‘low’, ‘medium’, ‘high’}
– {‘cat’, ‘dog’, ‘bird’}

If the type is defined in a Python module, the module must be specified:
– datetime.date
– datetime.datetime
– decimal.Decimal

If the type is in a package, the module must be also specified:
– numpy.ndarray
– scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:
– Series
– DataFrame
– pandas.Index
– pandas.Categorical
– pandas.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:
– array-like
– iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:
– int or float
– float, decimal.Decimal or None
– str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:
– axis : {0 or ‘index’, 1 or ‘columns’, None}, default None
Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    """
    Generate and return a random number.
    The value is sampled from a continuous uniform distribution between 0 and 1.
    Returns
    -------
    float
    Random number generated.
    """
    return random.random()
```

With more than one value:

```python
def random_letters():
    """
    Generate and return a sequence of random letters.
    The length of the returned string is also random, and is also returned.
    Returns
    -------
    length : int
    Length of the returned string.
    letters : str
    String of random letters.
    """
    length = random.randint(1, 10)
    letters = ''.join(random.choice(string.ascii_lowercase) for i in range(length))
    return length, letters
```

If the method yields its value:

```python
def sample_values():
    """
    Generate an infinite sequence of random numbers.
    The values are sampled from a continuous uniform distribution between 0 and 1.
    """
    """
```
Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the `head()` and `tail()` methods. As `tail()` does the equivalent as `head()` but at the end of the `Series` or `DataFrame` instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `iteritems`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.
        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.
        """
        return self.iloc[:5]

Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. >>> is used to present code. ... is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:
class Series:
    def head(self, n=5):
        
        """
        Return the first elements of the Series.
        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.
        """
        Parameters
        ----------
        n : int
            Number of values to return.
        Return
        ------
        pandas.Series
            Subset of the original series with the n first values.
        See Also
        --------
        tail : Return the last n elements of the Series.
        Examples
        --------
        >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon', ...'Lion', 'Monkey', 'Rabbit', 'Zebra'])
        >>> s.head()
        0    Ant
        1    Bear
        2    Cow
        3    Dog
        4    Falcon
        dtype: object
        With the `n` parameter, we can change the number of returned rows:
        >>> s.head(n=3)
        0    Ant
        1    Bear
        2    Cow
        dtype: object
        """
        return self.iloc[:n]

The examples should be as concise as possible. In cases where the complexity of the function requires long
examples, is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in
**this example**.

**Conventions for the examples**

Code in examples is assumed to always start with these two lines which are not shown:

```
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP-8)
and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single Series use the name `s`, and if illustrating with a single DataFrame use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous Series or DataFrame is used, name them `s1, s2, s3...` or `df1, df2, df3...` If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```python
class Series:
    def mean(self):
        """
        Compute the mean of the input.
        """
        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by 'value'.
        """
        Examples
        --------
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.
        """
        Examples
        --------
        >>> s = pd.Series([380., 370., 24., 26],
        ... name='max_speed',
        ... index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
```
contains(self, pattern, case_sensitive=True, na=numpy.nan):
    
    Return whether each value contains 'pattern'.

    In this case, we are illustrating how to use sections, even if the example is simple enough and does not require them.

    Examples
    -------------
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', numpy.nan)
    >>> s.contains(pattern='a')
    0    False
    1    False
    2     True
    3    NaN
    dtype: bool

    **Case sensitivity**

    With 'case_sensitive' set to 'False' we can match 'a' with both 'a' and 'A':

    >>> s.contains(pattern='a', case_sensitive=False)
    0     True
    1    False
    2     True
    3    NaN
    dtype: bool

    **Missing values**

    We can fill missing values in the output using the 'na' parameter:

    >>> s.contains(pattern='a', na=False)
    0    False
    1    False
    2     True
    3     False
    dtype: bool

    pass
to understand.

Try to avoid positional arguments like in `df.method(1)`. They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate))`, but avoid them otherwise.

When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

Examples
--------
>>> import numpy as np
>>> import pandas as pd
>>> df = pd.DataFrame(numpy.random.randn(3, 3),
...                   columns=('a', 'b', 'c'))
>>> df.method(1)
21
>>> df.method(bar=14)
123
***
pass

Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as import pandas as pd and import numpy as np) and define all variables you use in the example.

- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```python
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `...` on the continued lines:

```python
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'], columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```python
>>> pd.to_datetime(['712-01-01'])
Traceback (most recent call last):
OutOfBoundsDatet ime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

3.4. Contributing to the documentation 477
If you want to show that \texttt{s.plot()} returns a matplotlib AxesSubplot object, this will fail the doctest

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```python
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.
        
        Examples
        --------
        .. plot::
            :context: close-figs

            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

## Sharing Docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%(klass)s`. The variables filled in later on using the Substitution decorator. Finally, docstrings can be appended to with the Appender decorator.

In this example, we’ll create a parent docstring normally (this is like pandas.core.generic.NDFrame. Then we’ll have two children (like pandas.core.series.Series and pandas.core.frame.DataFrame). We’ll substitute the children’s class names in this docstring.

```python
class Parent:
    def my_function(self):
        """Apply my function to %(klass)s."""
        ...

class ChildA(Parent):
    @Substitution(klass="ChildA")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
```

(continues on next page)
The resulting docstrings are

```python
>>> print(Parent.my_function.__doc__)
Apply my function to %klass%s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```python
@Appender(template % _shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFramefillna` for an example template, and `pandas.core.series.Seriesfillna` and `pandas.core.generic.framefillna` for the filled versions.

- The tutorials make heavy use of the `ipython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```ipython:: python
    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2
In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

3.4. Contributing to the documentation
• Our API documentation in doc/source/api.rst houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. _templates/autosummary/class.rst. Use this when you want to automatically generate a page for every public method and attribute on the class. The Attributes and Methods sections will be automatically added to the class’ rendered documentation by numpydoc. See DataFrame for an example.

2. _templates/autosummary/class_without_autosummary. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an Attributes and Methods section in the class docstring. See CategoricalIndex for an example.

Every method should be included in a toctree in api.rst, else Sphinx will emit a warning.

Note: The .rst files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit CONTRIBUTING.md directly, but instead make any changes to doc/source/contributing.rst. Then, to generate CONTRIBUTING.md, use pandoc with the following command:

```
pandoc doc/source/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script scripts/validate_docstrings.py can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in doc/source/api.rst (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in doc/source/api.rst that are not actually class methods, and existing methods that are not documented in doc/source/api.rst.

### 3.4.2 How to build the pandas documentation

#### 3.4.2.1 Requirements

First, you need to have a development environment to be able to build pandas (see the docs on creating a development environment above).

#### 3.4.2.2 Building the documentation

So how do you build the docs? Navigate to your local pandas/doc/ directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder pandas/doc/build/html/.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell make.py to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.
For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
pandas/docs/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!

### 3.4.2.3 Building master branch documentation

When pull requests are merged into the pandas master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the Continuous Integration section.

### 3.5 Contributing to the code base

**Code Base:**

- Code standards
  - C (cpplint)
  - Python (PEP8)

3.5.1 Code standards

Writing good code is not just about what you write. It is also about how you write it. During Continuous Integration testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as backwards compatible as possible to avoid mass breakages.

Additional standards are outlined on the code style wiki page.

3.5.1.1 C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-
          --build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-
          --build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run cpplint to double check and make any other style fixes manually.

---

482 Chapter 3. Contributing to pandas
3.5.1.2 Python (PEP8)

*pandas* uses the PEP8 standard. There are several tools to ensure you abide by this standard. Here are some of the more common PEP8 issues:

- we restrict line-length to 79 characters to promote readability
- passing arguments should have spaces after commas, e.g. `foo(arg1, arg2, kw1='bar')`

*Continuous Integration* will run the *flake8* tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself on the diff:

```
% git diff master -u -- "*.py" | flake8 --diff
```

This command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
% git diff master --name-only -- "*.py" | grep "pandas/" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
% git diff master --name-only -- "*.py" | grep "pandas/" | xargs flake8
```

Note that on Windows, these commands are unfortunately not possible because commands like `grep` and `xargs` are not available natively. To imitate the behavior with the commands above, you should run:

```
% git diff master --name-only -- "*.py"
```

This will list all of the Python files that have been modified. The only ones that matter during linting are any whose directory filepath begins with “pandas.” For each filepath, copy and paste it after the *flake8* command as shown below:

```
flake8 <python-filepath>
```

Alternatively, you can install the *grep* and *xargs* commands via the MinGW toolchain, and it will allow you to run the commands above.

3.5.1.3 Backwards Compatibility

Please try to maintain backward compatibility. *pandas* has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the *pandas.util._decorators.deprecate*:

```
from pandas.util._decorators import deprecate
deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:
3.5.2 Testing With Continuous Integration

The pandas test suite will run automatically on Travis-CI, Appveyor, and Circle CI continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for Travis-CI, Appveyor, and CircleCI.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

Note: Each time you push to your fork, a new run of the tests will be triggered on the CI. Appveyor will auto-cancel any non-currently-running tests for that same pull-request. You can enable the auto-cancel feature for Travis-CI here and for CircleCI here.

3.5.3 Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount
of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

**Note:** The earliest supported pytest version is 3.1.0.

### 3.5.3.1 Writing tests

All tests should go into the tests subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The pandas.util.testing module has many special assert functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

### 3.5.3.2 Transitioning to pytest

pandas existing test structure is mostly classed based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature(object):
    ....
```

Going forward, we are moving to a more functional style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
    ....
```
3.5.3.3 Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like test_* and only take arguments that are either fixtures or parameters
- pytest.mark can be used to set metadata on test functions, e.g. skip or xfail.
- using parametrize: allow testing of multiple cases
- to set a mark on a parameter, pytest.param(...) syntax should be used
- fixture, code for object construction, on a per-test basis
- using bare assert for scalars and truth-testing
- tm.assert_series_equal (and its counter part tm.assert_frame_equal), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file test_cool_feature.py and put in an appropriate place in the pandas/tests/ structure.

```python
import pytest
import numpy as np
import pandas as pd
from pandas.util import testing as tm

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@ pytest.mark.parametrize('dtype', ['float32',
    pytest.param('int16', marks=pytest.mark.skip),
    pytest.param('int32',
        marks=pytest.mark.xfail(reason='to show how it works')))]]

def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@ pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@ pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype
    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```
(pandas) bash-3.2$ pytest test_cool_feature.py -v
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.2.1, py-1.4.31, pluggy-0.4.0
collected 11 items

(continues on next page)
```
Tests that we have parametrized are now accessible via the test name, for example we could run these with \(-k\) \texttt{int8} to sub-select \textit{only} those tests which match \texttt{int8}.

```bash
((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.2.1, py-1.4.31, pluggy-0.4.0
collected 11 items
test_cool_feature.py::test_dtypes[int8] PASSED
```

### 3.5.4 Running the test suite

The tests can then be run directly inside your Git clone (without having to install \texttt{pandas}) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using \texttt{pytest-xdist}, one can speed up local testing on multicore machines. To use this feature, you will need to install \texttt{pytest-xdist} via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:
This can significantly reduce the time it takes to locally run tests before submitting a pull request.
For more, see the pytest documentation.

Furthermore one can run

```python
pd.test()
```

with an imported pandas to run tests similarly.

### 3.5.5 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the pandas/asv_bench directory. asv supports both python2 and python3.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

To install asv:

```bash
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```bash
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```bash
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all asv commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```bash
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using \ as a separator. For example:

```bash
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of pandas already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/..` asv [remaining arguments]. You can run benchmarks using an existing Python environment by:
or, to use a specific Python interpreter:

```
asv run -e -E existing:python3.5
```

This will display stderr from the benchmarks, and use your local python that comes from your $PATH.

Information on how to write a benchmark and how to use asv can be found in the asv documentation.

### 3.5.6 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.txt`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regardong documentation above. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 0.21.0
```

This will put the text *New in version 0.21.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

### 3.6 Contributing your changes to pandas

#### 3.6.1 Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
# On branch shiny-new-feature
#
#     modified: /relative/path/to/file-you-added.py
#```

Finally, commit your changes to your local repository with an explanatory message. *Pandas* uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- **ENH**: Enhancement, new functionality
- **BUG**: Bug fix
The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```sh
git commit -m
```

### 3.6.2 Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```sh
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```sh
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin git@github.com:yourname/pandas.git (fetch)
origin git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the pandas project. For that to happen, a pull request needs to be submitted on GitHub.

### 3.6.3 Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – [https://github.com/your-user-name/pandas](https://github.com/your-user-name/pandas)
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be master and shiny-new-feature, respectively.
3.6.4 Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the Pull Request button
3. You can then click on Commits and Files Changed to make sure everything looks okay one last time
4. Write a description of your changes in the Preview Discussion tab
5. Click Send Pull Request.

This request then goes to the repository maintainers, and they will review the code.

3.6.5 Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the Continuous Integration tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/ for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the `stash` docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

3.6.6 Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git checkout shiny-new-feature
git merge upstream/master
git branch -d shiny-new-feature
```

3.6. Contributing your changes to pandas
Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won’t warn you if your feature branch has not actually been merged. The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```
CHAPTER
FOUR

PACKAGE OVERVIEW

*pandas* is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

*pandas* consists of the following elements:

- A set of labeled array data structures, the primary of which are Series and DataFrame.
- Index objects enabling both simple axis indexing and multi-level / hierarchical axis indexing.
- An integrated group by engine for aggregating and transforming data sets.
- Date range generation (date_range) and custom date offsets enabling the implementation of customized frequencies.
- Input/Output tools: loading tabular data from flat files (CSV, delimited, Excel 2003), and saving and loading pandas objects from the fast and efficient PyTables/HDF5 format.
- Memory-efficient “sparse” versions of the standard data structures for storing data that is mostly missing or mostly constant (some fixed value).
- Moving window statistics (rolling mean, rolling standard deviation, etc.).

### 4.1 Data Structures

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Series</td>
<td>1D labeled homogeneously-typed array</td>
</tr>
<tr>
<td>2</td>
<td>DataFrame</td>
<td>General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column</td>
</tr>
</tbody>
</table>

#### 4.1.1 Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguousness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.
For example, with tabular data (DataFrame) it is more semantically helpful to think of the index (the rows) and the columns rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```python
for col in df.columns:
    series = df[col]
    # do something with series
```

### 4.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

### 4.3 Getting Support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

### 4.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you’re interested in contributing, please visit Contributing to pandas webpage.

pandas is a NumFOCUS sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to donate to the project.

### 4.5 Project Governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

### 4.6 Development Team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.
4.7 Institutional Partners

The information about current institutional partners can be found on pandas website page.

4.8 License

THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT HOLDER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: import matplotlib.pyplot as plt
```

### 5.1 Object Creation

See the *Data Structure Intro section.*

Creating a *Series* by passing a list of values, letting pandas create a default integer index:

```
In [4]: s = pd.Series([1,3,5,np.nan,6,8])
In [5]: s
Out[5]:
    0  1.0
    1  3.0
    2  5.0
    3  NaN
    4  6.0
    5  8.0
dtype: float64
```

Creating a *DataFrame* by passing a NumPy array, with a datetime index and labeled columns:

```
In [6]: dates = pd.date_range('20130101', periods=6)
In [7]: dates
Out[7]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
In [8]: df = pd.DataFrame(np.random.randn(6,4), index=dates, columns=list('ABCD'))
In [9]: df
Out[9]:
```

(continues on next page)
Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```python
In [10]: df2 = pd.DataFrame({
    'A' : 1.,
    'B' : pd.Timestamp('20130102'),
    'C' : pd.Series(1,index=list(range(4)),dtype='float32'),
    'D' : np.array([3]*4,dtype='int32'),
    'E' : pd.Categorical(['test','train','test','train'])),
    'F' : 'foo'})
In [11]: df2
Out[11]:
   A     B          C         D        E          F
0  1.0 2013-01-02  1.0 3.0  test  foo
1  1.0 2013-01-02  1.0 3.0  train foo
2  1.0 2013-01-02  1.0 3.0  test  foo
3  1.0 2013-01-02  1.0 3.0  train foo
```

The columns of the resulting DataFrame have different dtypes.

```python
In [12]: df2.dtypes
Out[12]:
A    float64
B  datetime64[ns]
C    float32
D     int32
E  category
F     object
dtype: object
```

If you’re using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here’s a subset of the attributes that will be completed:

```python
In [13]: df2.<TAB>
df2.A            df2 bool
df2.abs          df2.boxplot
df2.add          df2 C
df2.add_prefix   df2 clip
df2.add_suffix   df2.clip_lower
df2.align        df2.clip_upper
df2.all          df2 columns
df2.any          df2 combine
df2.append       df2 combine_first
df2.apply        df2 compound
df2.applymap     df2 consolidate
df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.
5.2 Viewing Data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```
In [14]: df.head()
Out[14]:
          A         B         C         D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -0.044236
2013-01-03  0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05  0.424972  0.567020  0.276232 -0.087401
```

```
In [15]: df.tail(3)
Out[15]:
          A         B         C         D
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
2013-01-05  0.424972  0.567020  0.276232 -0.087401
2013-01-06 -0.673690  0.113648 -1.478427  0.524988
```

Display the index, columns, and the underlying NumPy data:

```
In [16]: df.index
Out[16]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
               dtype='datetime64[ns]', freq='D')

In [17]: df.columns
Out[17]:
Index(['A', 'B', 'C', 'D'], dtype='object')

In [18]: df.values
Out[18]:
array([[ 0.4691, -0.2829, -1.5091, -1.1356],
       [ 1.2121, -0.1732,  0.1192, -0.0442],
       [ 0.8618, -2.1046, -0.4949,  1.0718],
       [ 0.7216, -0.7068, -1.0396,  0.2719],
       [ 0.425 ,  0.567 ,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784,  0.525 ]])
```

describe() shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out[19]:
          A         B         C         D
count   6.000000  6.000000  6.000000  6.000000
mean   0.073711 -0.431125 -0.687758 -0.233103
std    0.843157  0.922818  0.779887  0.973118
min  -0.861849 -2.104569 -1.509059 -1.135632
25%  -0.611510 -0.600794 -1.368714 -1.076610
50%   0.022070 -0.228039 -0.767252 -0.386188
75%   0.658444  0.041933  0.276232  0.461706
max   1.212112  0.567020  0.276232  1.071804
```
Transposing your data:

```
In [20]: df.T
Out[20]:
A      0.469112  1.212112  -0.861849  0.721555  -0.424972  -0.673690
B     -0.282863  -0.173215  -2.104569  -0.706771   0.567020   0.113648
C    -1.509059   0.119209  -0.494929  -1.039575   0.276232  -1.478427
D    -1.135632  -1.044236  1.071804   0.271860  -1.087401   0.524988
```

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
     D     C     B     A
2013-01-01 -1.135632 -1.509059 -0.282863  0.469112
2013-01-02 -1.044236  0.119209 -0.173215  1.212112
2013-01-03  1.071804  -0.494929 -2.104569  -0.861849
2013-01-04  0.271860  -1.039575  -0.706771   0.567020
2013-01-05  1.087401   0.276232  0.567020  -0.424972
2013-01-06  0.524988  -1.478427  0.113648  -0.673690
```

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
      A     B     C     D
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555  -0.706771  -1.039575   0.271860
2013-01-01  0.469112  -0.282863  -1.509059  -1.135632
2013-01-02  1.212112  -0.173215  0.119209  -1.044236
2013-01-06 -0.673690   0.113648  -1.478427   0.524988
2013-01-05  0.424972   0.567020   0.276232  -1.087401
```

5.3 Selection

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation *Indexing and Selecting Data* and *MultiIndex / Advanced Indexing*.

5.3.1 Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
2013-01-01    0.469112
2013-01-02    1.212112
2013-01-03   -0.861849
2013-01-04    0.721555
```

(continues on next page)
Selecting via [], which slices the rows.

```
In [24]: df[0:3]
Out[24]:
   A     B     C     D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [25]: df['20130102':'20130104']
Out[25]:
   A     B     C     D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04  0.721555 -0.706771 -1.039575  0.271860
```

### 5.3.2 Selection by Label

See more in *Selection by Label*.

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
     A     B     C     D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:,['A','B']]
Out[27]:
      A     B
2013-01-01  0.469112 -0.282863
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
2013-01-06 -0.673690  0.113648
```

Showing label slicing, both endpoints are included:

```
In [28]: df.loc['20130102':'20130104',['A','B']]
Out[28]:
      A     B
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
```
Reduction in the dimensions of the returned object:

In [29]:  df.loc['20130102', ['A', 'B']]
Out[29]:
   A    B
Name: 2013-01-02 00:00:00, dtype: float64

For getting a scalar value:

In [30]:  df.loc[dates[0], 'A']
Out[30]:
0.46911229990718628

For getting fast access to a scalar (equivalent to the prior method):

In [31]:  df.at[dates[0], 'A']
Out[31]:
0.46911229990718628

5.3.3 Selection by Position

See more in Selection by Position.

Select via the position of the passed integers:

In [32]:  df.iloc[3]
Out[32]:
   A    B    C    D
2013-01-04  0.721555 -0.706771  0.271860

By integer slices, acting similar to numpy/python:

In [33]:  df.iloc[3:5,0:2]
Out[33]:
   A       B
2013-01-04  0.721555 -0.706771
2013-01-05  0.424972  0.567020

By lists of integer position locations, similar to the numpy/python style:

In [34]:  df.iloc[[1,2,4], [0,2]]
Out[34]:
   A   C
2013-01-02  1.212112  0.119209
2013-01-03 -0.861849 -0.494929
2013-01-05 -0.424972  0.276232

For slicing rows explicitly:

In [35]:  df.iloc[1:3,:]
Out[35]:
   A    B    C    D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
For slicing columns explicitly:

```
In [36]: df.iloc[:,1:3]
Out[36]:
          B     C
2013-01-01 -0.282863 -1.509059
2013-01-02 -0.173215  0.119209
2013-01-03 -2.104569 -0.494929
2013-01-04 -0.706771 -1.039575
2013-01-05  0.567020  0.276232
2013-01-06  0.113648 -1.478427
```

For getting a value explicitly:

```
In [37]: df.iloc[1,1]
Out[37]:
-0.17321464905330858
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1,1]
Out[38]:
-0.17321464905330858
```

### 5.3.4 Boolean Indexing

Using a single column’s values to select data.

```
In [39]: df[df.A > 0]
Out[39]:
          A     B     C     D
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632
2013-01-02 1.212112 -0.173215  0.119209 -1.044236
2013-01-03 0.721555 -0.706771 -1.039575  0.271860
```

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
          A     B     C     D
2013-01-01 0.469112 NaN   NaN   NaN
2013-01-02 1.212112 NaN   0.119209 NaN
2013-01-03 NaN   NaN   NaN   1.071804
2013-01-04 0.721555 NaN   NaN   0.271860
2013-01-05 NaN   0.567020  0.276232 NaN
2013-01-06 NaN   0.113648 NaN   0.524988
```

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()

In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']

In [43]: df2
Out[43]:
          A     B     C     D     E
2013-01-01 0.469112 -0.282863 -1.509059 -1.135632 one
2013-01-02 1.212112 -0.173215  0.119209 -1.044236 one
```

(continues on next page)
5.3.5 Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1,2,3,4,5,6], index=pd.date_range('20130102', periods=6))
```

```
3.5. Setting

Setting values by label:
```
In [48]: df.at[dates[0],'A'] = 0
```

Setting values by position:
```
In [49]: df.iat[0,1] = 0
```

Setting by assigning with a NumPy array:
```
In [50]: df.loc[:,'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.
```
In [51]: df
```
```
<p>| | | | | | |</p>
<table>
<thead>
<tr>

<td></td>
<td></td>
</tr>
</tbody>
</table>
```

A where operation with setting.
In [52]: df2 = df.copy()

In [53]: df2[df2 > 0] = -df2

In [54]: df2

Out[54]:
   A    B     C     D    F
0 0.000000 0.000000 -1.509059 -5  NaN
1 -1.212112 -0.173215 -0.119209 -5  -1.0
2 -0.861849 -2.104569 -0.494929 -5  -2.0
3 -0.721555 -0.706771 -1.039575 -5  -3.0
4 -0.424972 -0.567020 -0.276232 -5  -4.0
5 -0.673690 -0.113648 -1.478427 -5  -5.0

5.4 Missing Data

pandas primarily uses the value \texttt{np.nan} to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])

In [56]: df1.loc[dates[0]:dates[1],'E'] = 1

In [57]: df1

Out[57]:
   A       B   C       D    F  E
0 0.000000 0.000000 -1.509059 5  NaN 1.0
1 1.212112 -0.173215 0.119209 5  1.0 1.0
2 -0.861849 -2.104569 -0.494929 5  2.0  NaN
3 0.721555 -0.706771 -1.039575 5  3.0  NaN

To drop any rows that have missing data.

In [58]: df1.dropna(how='any')

Out[58]:
   A       B   C       D    F  E
0 1.212112 -0.173215 0.119209 5  1.0 1.0

Filling missing data.

In [59]: df1.fillna(value=5)

Out[59]:
   A       B   C       D    F  E
0 0.000000 0.000000 -1.509059 5  5.0 1.0
1 1.212112 -0.173215 0.119209 5  1.0 1.0
2 -0.861849 -2.104569 -0.494929 5  2.0  5.0
3 0.721555 -0.706771 -1.039575 5  3.0  5.0

To get the boolean mask where values are \texttt{nan}.

In [60]: pd.isna(df1)

Out[60]:
   A       B   C       D    F  E
0       False False  False  False  False False
1       False False  False  False  False False
2       False False  False  False  False False
3       False False  False  False  False False
4       False False  False  False  False False

(continues on next page)
5.5 Operations

See the Basic section on Binary Ops.

5.5.1 Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
   A  -0.004474
   B  -0.383981
   C  -0.687758
   D   5.000000
   F   3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01  0.872735
2013-01-02  1.431621
2013-01-03  0.707731
2013-01-04  1.395042
2013-01-05  1.883656
2013-01-06  1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1,3,5,np.nan,6,8], index=dates).shift(2)
In [64]: s
Out[64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03    1.0
2013-01-04    3.0
2013-01-05    5.0
2013-01-06    NaN
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis='index')
```

(continues on next page)
5.5.2 Apply

Applying functions to the data:

```
In [66]: df.apply(np.cumsum)
Out[66]:
          A         B         C         D         F
2013-01-01 0.000000 0.000000 -1.509059  5.000000 NaN
2013-01-02 1.212112 -0.173215 -1.389850 10.000000  1.000000
2013-01-03 0.350263 -2.277784 -1.884779 15.000000  3.000000
2013-01-04 1.071818 -2.984555 -2.924354 20.000000  6.000000
2013-01-05 0.646846 -2.417535 -2.648122 25.000000 10.000000
2013-01-06 -0.026844 -2.303886 -4.126549 30.000000 15.000000
```

```
In [67]: df.apply(lambda x: x.max() - x.min())
    ...:
    ...
    ...
         A  2.073961
         B  2.671590
         C  1.785291
         D  0.000000
         F  4.000000
dtype: float64
```

5.5.3 Histogramming

See more at Histogramming and Discretization.

```
In [68]: s = pd.Series(np.random.randint(0, 7, size=10))
In [69]: s
Out[69]:
0  4
1  2
2  1
3  2
4  6
5  4
6  4
7  6
8  4
9  4
dtype: int64
In [70]: s.value_counts()
```

(continues on next page)
5.5.4 String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

```python
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [72]: s.str.lower()
Out[72]:
   0   a
   1   b
   2   c
   3  aaba
   4   baca
   5   NaN
   6   caba
   7    dog
   8     cat
   dtype: object
```

5.6 Merge

5.6.1 Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

```python
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
   0   1   2   3
0 -0.548702 1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
```
7    -0.932132    1.956030    0.017587   -0.016692
8    -0.575247    0.254161  -1.143704    0.215897
9    1.193555   -0.077118  -0.408530   -0.862495

# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]

In [76]: pd.concat(pieces)
Out[76]:
      0     1     2     3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3  0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.930231  1.956030  0.017587 -0.016692
8  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

5.6.2 Join

SQL style merges. See the Database style joining section.

In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})

In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})

In [79]: left
Out[79]:
   key lval
0  foo   1
1  foo   2

In [80]: right
   key rval
0  foo     4
1  foo     5

In [81]: pd.merge(left, right, on='key')
   key lval  rval
0  foo   1     4
1  foo   1     5
2  foo   2     4
3  foo   2     5

Another example that can be given is:

In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})

In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})

(continues on next page)
5.6.3 Append

Append rows to a dataframe. See the `Appending` section.

In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A','B','C','D'])

In [88]: df
Out[88]:
   A         B         C         D
0  1.346061  1.511763  1.627081 -0.990582
1 -0.441652  1.211526  0.268520  0.024580
2 -1.577585  0.396823 -0.105381 -0.532532
3  1.453749  1.208843 -0.080952 -0.264610
4 -0.727965 -0.589346  0.339969 -0.693205
5 -0.339355  0.593616  0.884345  1.591431
6  0.141809  0.220390  0.435589  0.192451
7 -0.096701  0.803351  1.715071 -0.708758

In [89]: s = df.iloc[3]

In [90]: df.append(s, ignore_index=True)
Out[90]:
   A         B         C         D
0  1.346061  1.511763  1.627081 -0.990582
1 -0.441652  1.211526  0.268520  0.024580
2 -1.577585  0.396823 -0.105381 -0.532532
3  1.453749  1.208843 -0.080952 -0.264610
4 -0.727965 -0.589346  0.339969 -0.693205
5 -0.339355  0.593616  0.884345  1.591431
6  0.141809  0.220390  0.435589  0.192451
7 -0.096701  0.803351  1.715071 -0.708758
8  1.453749  1.208843 -0.080952 -0.264610
5.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the *Grouping section*.

```python
In [91]: df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar', 'foo', 'bar', 'foo', 'foo'],
                      ....:                     'B' : ['one', 'one', 'two', 'three', 'two', 'two', 'one', 'three'],
                      ....:                     'C' : np.random.randn(8),
                      ....:                     'D' : np.random.randn(8))

In [92]: df
Out[92]:
      A  B      C         D
0  foo  one -1.202872 -0.055224
1  bar  one -1.814470  2.395985
2  foo  two  1.018601  1.552825
3  bar  three -0.595447  0.166599
4  foo  two  1.395433  0.047609
5  bar  two -0.392670 -0.136473
6  foo  one  0.007207 -0.561757
7  foo  three  1.928123 -1.623033

Grouping and then applying the `sum()` function to the resulting groups.

```python
In [93]: df.groupby('A').sum()
Out[93]:
     C         D
A
  bar -2.802588  2.426110
  foo  3.146492 -0.639581

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```python
In [94]: df.groupby(['A', 'B']).sum()
Out[94]:
          C         D
A B
bar one -1.814470  2.395985
   three -0.595447  0.166599
   two -0.392670 -0.136473
foo one -1.195665 -0.616981
   three  1.928123 -1.623033
   two  2.414034  1.600434

5.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.
5.8.1 Stack

```python
In [95]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                          'foo', 'foo', 'qux', 'qux'],
                          ['one', 'two', 'one', 'two',
                          'one', 'two', 'one', 'two']]))

In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [98]: df2 = df[:4]

In [99]: df2
Out[99]:
         A       B
first second
bar     one  0.029399 -0.542108
        two  0.282696 -0.087302
baz     one -1.575170  1.771208
        two  0.816482  1.100230

The `stack()` method “compresses” a level in the DataFrame’s columns.

```python
In [100]: stacked = df2.stack()

In [101]: stacked
Out[101]:
         A       B
first second
bar     one    A  0.029399
        B -0.542108
        two   A  0.282696
               B -0.087302
baz     one    A -1.575170
        B  1.771208
        two   A  0.816482
               B  1.100230
dtype: float64

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

```python
In [102]: stacked.unstack()
Out[102]:
         A       B
first second
bar     one  0.029399 -0.542108
        two  0.282696 -0.087302
baz     one -1.575170  1.771208
        two  0.816482  1.100230

In [103]: stacked.unstack(1)

(continues on next page)
5.8.2 Pivot Tables

See the section on **Pivot Tables**.

```python
In [105]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3,
                        'B': ['A', 'B', 'C'] * 4,
                        'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
                        'D': np.random.randn(12),
                        'E': np.random.randn(12)})
```

```python
In [106]: df
Out[106]:
A   B   C   D   E
0   one A   foo 1.418757 -0.179666
1   one B   foo -1.879024 1.291836
2   two C   foo 0.536826 -0.009614
3   three A  bar 1.006160 0.392149
4    one B  bar  -0.029716 0.264599
5    one C  bar  -1.146178 0.057409
6   two A   foo  0.100900 -1.425638
7   three B   foo  1.035018 1.024098
8    one C   foo  0.314665 -0.106062
9    one A  bar  -0.773723 1.824375
10  two B  bar  -1.170653 0.595974
11  three C  bar  0.648740 1.167115
```

We can produce pivot tables from this data very easily:

```python
In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
```

```python
Out[107]:
C    bar   foo
  A  B
one  A  -0.773723  1.418757
     B  -0.029716 -1.879024
     C  -1.146178  0.314665
three A  1.006160   NaN
          B  NaN  -1.035018
          C  0.648740  NaN
two   A  NaN  0.100900
```

5.8. Reshaping
5.9 Time Series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the Time Series section.

In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [110]: ts.resample('5Min').sum()
Out[110]:
2012-01-01  25083
Freq: 5T, dtype: int64

Time zone representation:

In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [113]: ts
Out[113]:
2012-03-06  0.464000
2012-03-07  0.227371
2012-03-08  -0.496922
2012-03-09  0.306389
2012-03-10  -2.290613
Freq: D, dtype: float64
In [114]: ts_utc = ts.tz_localize('UTC')
In [115]: ts_utc
Out[115]:
2012-03-05 19:00:00+00:00  0.464000
2012-03-06 19:00:00+00:00  0.227371
2012-03-08 19:00:00+00:00  -0.496922
2012-03-09 19:00:00+00:00  0.306389
2012-03-10 19:00:00+00:00  -2.290613
Freq: D, dtype: float64

Converting to another time zone:

In [116]: ts_utc.tz_convert('US/Eastern')
Out[116]:
2012-03-05 19:00:00-05:00  0.464000
2012-03-06 19:00:00-05:00  0.227371
2012-03-08 19:00:00-05:00  -0.496922
2012-03-09 19:00:00-05:00  0.306389
2012-03-10 19:00:00-05:00  -2.290613
Freq: D, dtype: float64
Converting between time span representations:

```python
In [117]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [118]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [119]: ts
Out[119]:
2012-01-31  -1.134623
2012-02-29  -1.561819
2012-03-31  -0.260838
2012-04-30   0.281957
2012-05-31   1.523962
Freq: M, dtype: float64
In [120]: ps = ts.to_period()
In [121]: ps
Out[121]:
2012-01    -1.134623
2012-02    -1.561819
2012-03    -0.260838
2012-04     0.281957
2012-05    1.523962
Freq: M, dtype: float64
In [122]: ps.to_timestamp()
Out[122]:
2012-01-01 -1.134623
2012-02-01 -1.561819
2012-03-01 -0.260838
2012-04-01  0.281957
2012-05-01  1.523962
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [123]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [124]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [125]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [126]: ts.head()
Out[126]:
1990-03-01 09:00  -0.902937
1990-06-01 09:00   0.068159
1990-09-01 09:00  -0.057873
1990-12-01 09:00  -0.368204
1991-03-01 09:00  -1.144073
Freq: H, dtype: float64
```

5.9. Time Series
5.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the categorical introduction and the API documentation.

```
In [127]: df = pd.DataFrame({"id":[1,2,3,4,5,6], "raw_grade":["a", 'b', 'b', 'a', 'a', 'e']})
```

Convert the raw grades to a categorical data type.

```
In [128]: df["grade"] = df["raw_grade"].astype("category")
In [129]: df["grade"]
Out[129]:
0  a
1  b
2  b
3  a
4  a
5  e
Name: grade, dtype: category
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to Series.cat.categories is inplace!).

```
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under Series.cat return a new Series by default).

```
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"])
In [132]: df["grade"]
Out[132]:
0  very good
1  good
2  good
3  very good
4  very good
5  very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [133]: df.sort_values(by="grade")
Out[133]:
     id  raw_grade  grade
    5      6      e  very bad
    1      2      b   good
    2      3      b   good
    0      1      a  very good
    3      4      a  very good
    4      5      a  very good
```

Grouping by a categorical column also shows empty categories.
5.11 Plotting

See the Plotting docs.

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:
5.12 Getting Data In/Out

5.12.1 CSV

Writing to a csv file.

In [141]: df.to_csv('foo.csv')

Reading from a csv file.

In [142]: pd.read_csv('foo.csv')

Out[142]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.0</td>
<td>0.0</td>

5.12.3 Excel

Reading and writing to MS Excel.

Writing to an excel file.

5.12. Getting Data In/Out
Reading from an excel file.

```python
In [146]: pd.read_excel('foo.xlsx', 'Sheet1', index_col=None, na_values=['NA'])
Out[146]:
      A         B         C         D
2000-01-01  0.266457  -0.399641  -0.219582  1.186860
2000-01-02  1.170732  -0.345873   1.653061  -0.282953
2000-01-03  1.734933   0.530468   2.060811  -0.515536
2000-01-04  1.555121   1.452620   0.239859  -1.156896
2000-01-05  0.578117   0.511371   0.103552  -2.428202
2000-01-06  0.478344   0.499933  -0.741620  -1.962409
2000-01-07  1.235339  -0.091757  -1.543861  -1.084753
         ...         ...         ...         ...
2002-09-21 -10.390377  -8.727491  -6.399645  30.914107
2002-09-26 -11.856774  -10.671012  -3.216025  29.369368
[1000 rows x 4 columns]
```

### 5.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
    print("I was true")
Traceback
  ...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.
CHAPTER SIX

TUTORIALS

This is a guide to many pandas tutorials, geared mainly for new users.

6.1 Internal Guides

pandas’ own 10 Minutes to pandas.
More complex recipes are in the Cookbook.
A handy pandas cheat sheet.

6.2 pandas Cookbook

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails.

Here are links to the v0.2 release. For an up-to-date table of contents, see the pandas-cookbook GitHub repository. To run the examples in this tutorial, you’ll need to clone the GitHub repository and get IPython Notebook running. See How to use this cookbook.

• A quick tour of the IPython Notebook: Shows off IPython’s awesome tab completion and magic functions.
• Chapter 1: Reading your data into pandas is pretty much the easiest thing. Even when the encoding is wrong!
• Chapter 2: It’s not totally obvious how to select data from a pandas dataframe. Here we explain the basics (how to take slices and get columns)
• Chapter 3: Here we get into serious slicing and dicing and learn how to filter dataframes in complicated ways, really fast.
• Chapter 4: Groupby/aggregate is seriously my favorite thing about pandas and I use it all the time. You should probably read this.
• Chapter 5: Here you get to find out if it’s cold in Montreal in the winter (spoiler: yes). Web scraping with pandas is fun! Here we combine dataframes.
• Chapter 6: Strings with pandas are great. It has all these vectorized string operations and they’re the best. We will turn a bunch of strings containing “Snow” into vectors of numbers in a trice.
• Chapter 7: Cleaning up messy data is never a joy, but with pandas it’s easier.
• Chapter 8: Parsing Unix timestamps is confusing at first but it turns out to be really easy.
• Chapter 9: Reading data from SQL databases.
6.3 Lessons for new pandas users

For more resources, please visit the main repository.

• 01 - Lesson: - Importing libraries - Creating data sets - Creating data frames - Reading from CSV - Exporting to CSV - Finding maximums - Plotting data
• 02 - Lesson: - Reading from TXT - Exporting to TXT - Selecting top/bottom records - Descriptive statistics - Grouping/sorting data
• 03 - Lesson: - Creating functions - Reading from EXCEL - Exporting to EXCEL - Outliers - Lambda functions - Slice and dice data
• 04 - Lesson: - Adding/deleting columns - Index operations
• 05 - Lesson: - Stack/Unstack/Transpose functions
• 06 - Lesson: - GroupBy function
• 07 - Lesson: - Ways to calculate outliers
• 08 - Lesson: - Read from Microsoft SQL databases
• 09 - Lesson: - Export to CSV/EXCEL/TXT
• 10 - Lesson: - Converting between different kinds of formats
• 11 - Lesson: - Combining data from various sources

6.4 Practical data analysis with Python

This guide is a comprehensive introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as follows:

• Munging Data
• Aggregating Data
• Visualizing Data
• Time Series

6.5 Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

• 01 - Getting & Knowing Your Data
• 02 - Filtering & Sorting
• 03 - Grouping
• 04 - Apply
• 05 - Merge
• 06 - Stats
• 07 - Visualization
• 08 - Creating Series and DataFrames
6.6 Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

- Modern Pandas
- Method Chaining
- Indexes
- Performance
- Tidy Data
- Visualization
- Timeseries

6.7 Excel charts with pandas, vincent and xlsxwriter

- Using Pandas and XlsxWriter to create Excel charts

6.8 Video Tutorials

- Pandas: .head() to .tail() (2016) (1:26) GitHub repo

6.9 Various Tutorials

- Wes McKinney’s (pandas BDFL) blog
- Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
- Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- Financial analysis in Python, by Thomas Wiecki
- Intro to pandas data structures, by Greg Reda
- Pandas and Python: Top 10, by Manish Amde
- Pandas Tutorial, by Mikhail Semeniuk
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples
This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 7.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```python
In [1]: df = pd.DataFrame(
    ...:   {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]});
Out[1]:
     AAA  BBB  CCC
0    4    10   100
1    5    20    50
2    6    30   -30
3    7    40   -50
```

#### 7.1.1 if-then...

An if-then on one column

```python
In [2]: df.loc[df.AAA >= 5,'BBB'] = -1; df
Out[2]:
     AAA  BBB  CCC
0    4    10   100
1    5   -1    50
2    6   -1   -30
3    7   -1   -50
```

An if-then with assignment to 2 columns:
In [3]: df.loc[df.AAA >= 5,['BBB','CCC']] = 555; df
Out[3]:
   AAA  BBB  CCC
0  4    10  100
1  5   555  555
2  6   555  555
3  7   555  555

Add another line with different logic, to do the -else
In [4]: df.loc[df.AAA < 5,['BBB','CCC']] = 2000; df
Out[4]:
   AAA  BBB  CCC
0  4   2000  2000
1  5   555  555
2  6   555  555
3  7   555  555

Or use pandas where after you’ve set up a mask
In [6]: df.where(df_mask,-1000)
Out[6]:
   AAA  BBB  CCC
0  4   -1000  2000
1  5    -1000 -1000
2  6   -1000   555
3  7    -1000 -1000

if-then-else using numpy’s where()
In [7]: df = pd.DataFrame(
      ...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
      ...
Out[7]:
   AAA  BBB  CCC
0  4   10   100
1  5   20    50
2  6   30    -30
3  7   40    -50
In [8]: df['logic'] = np.where(df['AAA'] > 5,'high','low'); df

   AAA  BBB  CCC   logic
0  4   10    100  low
1  5   20     50  low
2  6   30    -30  high
3  7   40    -50  high

7.1.2 Splitting

Split a frame with a boolean criterion

526  Chapter 7. Cookbook
In [9]: df = pd.DataFrame(
    ...:
     ('AAA' : [4, 5, 6, 7], 'BBB' : [10, 20, 30, 40], 'CCC' : [100, 50, -30, -50])); df
    ...:
Out[9]:
    AAA  BBB  CCC
   0  4    10   100
   1  5     20    50
   2  6     30   -30
   3  7     40   -50

In [10]: dflow = df[df.AAA <= 5]; dflow

    AAA  BBB  CCC
    0  4    10   100
    1  5     20    50

In [11]: dfhigh = df[df.AAA > 5]; dfhigh

    AAA  BBB  CCC
    2  6     30   -30
    3  7     40   -50

### 7.1.3 Building Criteria

Select with multi-column criteria

In [12]: df = pd.DataFrame(
    ...:
     ('AAA' : [4, 5, 6, 7], 'BBB' : [10, 20, 30, 40], 'CCC' : [100, 50, -30, -50])); df
    ...:
Out[12]:
    AAA  BBB  CCC
   0  4    10   100
   1  5     20    50
   2  6     30   -30
   3  7     40   -50

... and (without assignment returns a Series)

In [13]: newseries = df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']; newseries
Out[13]:
    0  4
    1  5
Name: AAA, dtype: int64

... or (without assignment returns a Series)

In [14]: newseries = df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA']; newseries;

... or (with assignment modifies the DataFrame.)

In [15]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1; df
Out[15]:
    AAA  BBB  CCC
    0  0.1    10   100

### 7.1. Idioms 527
Select rows with data closest to certain value using argsort

```
In [16]: df = pd.DataFrame(  
.....:    {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]}); df  
.....:
Out[16]:  
AAA  BBB  CCC
0  4    10  100  
1  5    20   50  
2  6    30  -30  
3  7    40  -50  

In [17]: aValue = 43.0

In [18]: df.loc[(df.CCC-aValue).abs().argsort()]
Out[18]:  
AAA  BBB  CCC
1  5    20   50  
0  4    10  100  
2  6    30  -30  
3  7    40  -50  
```

Dynamically reduce a list of criteria using a binary operators

```
In [19]: df = pd.DataFrame(  
.....:    {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]}); df  
.....:
Out[19]:  
AAA  BBB  CCC
0  4    10  100  
1  5    20   50  
2  6    30  -30  
3  7    40  -50  

In [20]: Crit1 = df.AAA <= 5.5

In [21]: Crit2 = df.BBB == 10.0

In [22]: Crit3 = df.CCC > -40.0

One could hard code:

```
In [23]: AllCrit = Crit1 & Crit2 & Crit3

... Or it can be done with a list of dynamically built criteria

```

```
In [24]: CritList = [Crit1,Crit2,Crit3]

In [25]: AllCrit = functools.reduce(lambda x,y: x & y, CritList)

In [26]: df[AllCrit]
Out[26]:  
```
### 7.2 Selection

#### 7.2.1 DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```python
In [27]: df = pd.DataFrame(
    ....:     {'AAA': [4, 5, 6, 7], 'BBB': [10, 20, 30, 40], 'CCC': [100, 50, -30, -50]}); df
   ....:
Out[27]:
    AAA  BBB  CCC
   0   4    10  100
   1   5    20   50
   2   6    30  -30
   3   7    40  -50
```

```python
In [28]: df[(df.AAA <= 6) & (df.index.isin([0, 2, 4]))]
```

```
AAA  BBB  CCC
0    4    10  100
2    6    30  -30
```

Use `loc` for label-oriented slicing and `iloc` positional slicing

```python
In [29]: data = {'AAA': [4, 5, 6, 7], 'BBB': [10, 20, 30, 40], 'CCC': [100, 50, -30, -50]}
In [30]: df = pd.DataFrame(data=data, index=['foo', 'bar', 'boo', 'kar']); df
Out[30]:
    AAA  BBB  CCC
  foo    4    10  100
  bar    5    20   50
  boo    6    30  -30
  kar    7    40  -50
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style: exclusive of end)
2. Label-oriented (Non-Python slicing style: inclusive of end)
3. General (Either slicing style: depends on if the slice contains labels or positions)

```python
In [31]: df.loc['bar':'kar']  # Label
Out[31]:
    AAA  BBB  CCC
  bar    5    20   50
  boo    6    30  -30
  kar    7    40  -50
```

(continues on next page)
# Generic

In [32]: df.iloc[0:3]

\n\n→
\nAAA BBB CCC
foo  4  10  100
bar  5  20  50
boo  6  30 -30

In [33]: df.loc['bar':'kar']

\n\n→
\nAAA BBB CCC
bar  5  20  50
boo  6  30 -30
kar  7  40 -50

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [34]: df2 = pd.DataFrame(data=data,index=[1,2,3,4]); # Note index starts at 1.

In [35]: df2.iloc[1:3] # Position-oriented

Out[35]:
\n\nAAA BBB CCC
2   5  20  50
3   6  30 -30

In [36]: df2.loc['1:3'] # Label-oriented

\n\nAAA BBB CCC
1   4  10  100
2   5  20  50
3   6  30 -30

Using inverse operator (~) to take the complement of a mask

In [37]: df = pd.DataFrame(
.....:     ('AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]));
~df

Out[37]:
\n\nAAA BBB CCC
0   4  10  100
1   5  20  50
2   6  30 -30
3   7  40 -50

In [38]: df[~((df.AAA <= 6) & (df.index.isin([0,2,4])))]

\n\nAAA BBB CCC
1   5  20  50
3   7  40 -50
7.2.2 Panels

Extend a panel frame by transposing, adding a new dimension, and transposing back to the original dimensions

```python
In [39]: rng = pd.date_range('1/1/2013', periods=100, freq='D')
In [40]: data = np.random.randn(100, 4)
In [41]: cols = ['A', 'B', 'C', 'D']
In [42]: df1, df2, df3 = pd.DataFrame(data, rng, cols), pd.DataFrame(data, rng, cols),
   → pd.DataFrame(data, rng, cols)
In [43]: pf = pd.Panel({'df1':df1,'df2':df2,'df3':df3});pf
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 4 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to D
In [44]: pf.loc[:,:,'F'] = pd.DataFrame(data, rng, cols);pf

Out[44]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 5 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to F
```

Mask a panel by using np.where and then reconstructing the panel with the new masked values

7.2.3 New Columns

Efficiently and dynamically creating new columns using applymap

```python
In [45]: df = pd.DataFrame({
   ....:     'AAA' : [1,2,1,3],
   ....:     'BBB' : [1,1,2,2],
   ....:     'CCC' : [2,1,3,1]
   ....: }); df
Out[45]:
      AAA  BBB  CCC
0    1    1   2
1    2    1   1
2    1    2   3
3    3    2   1
In [46]: source_cols = df.columns  # or some subset would work too.
In [47]: new_cols = [str(x) + '_cat' for x in source_cols]
In [48]: categories = {1 : 'Alpha', 2 : 'Beta', 3 : 'Charlie'}
In [49]: df[new_cols] = df[source_cols].applymap(categories.get);df
Out[49]:
      AAA  BBB  CCC   AAA_cat  BBB_cat  CCC_cat
0    1    1   2    Alpha      Alpha  Beta
```

(continues on next page)
Keep other columns when using min() with groupby

```python
In [50]: df = pd.DataFrame(
    ....:     {'AAA' : [1,1,1,2,2,2,3,3], 'BBB' : [2,1,3,4,5,1,2,3]}); df
Out[50]:
    AAA  BBB
  0  1    2
  1  1    1
  2  1    3
  3  2    4
  4  2    5
  5  2    1
  6  3    2
  7  3    3
```

Method 1: idxmin() to get the index of the mins

```python
In [51]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
Out[51]:
    AAA  BBB
  1  1    1
  5  2    1
  6  3    2
```

Method 2: sort then take first of each

```python
In [52]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[52]:
    AAA  BBB
  0  1    1
  1  2    1
  2  3    2
```

Notice the same results, with the exception of the index.

### 7.3 MultIndexing

The **multindexing** docs.

Creating a multi-index from a labeled frame

```python
In [53]: df = pd.DataFrame({'row' : [0,1,2],
    ....:     'One_X' : [1.1,1.1,1.1],
    ....:     'One_Y' : [1.2,1.2,1.2],
    ....:     'Two_X' : [1.11,1.11,1.11],
    ....:     'Two_Y' : [1.22,1.22,1.22]}); df
Out[53]:
   row  One_X  One_Y  Two_X  Two_Y
0    0   1.1    1.2  1.11  1.22
```

(continues on next page)
# As Labelled Index

```python
In [54]: df = df.set_index('row');df

Out[54]:

<table>
<thead>
<tr>
<th></th>
<th>One_X</th>
<th>One_Y</th>
<th>Two_X</th>
<th>Two_Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>1.1</td>
<td>1.2</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>0</td>
<td>1.1</td>
<td>1.2</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>1</td>
<td>1.1</td>
<td>1.2</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>2</td>
<td>1.1</td>
<td>1.2</td>
<td>1.11</td>
<td>1.22</td>
</tr>
</tbody>
</table>
```

# With Hierarchical Columns

```python
In [55]: df.columns = pd.MultiIndex.from_tuples((tuple(c.split('_')) for c in df.columns));df

Out[55]:

<table>
<thead>
<tr>
<th></th>
<th>One</th>
<th>Two</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>X</td>
<td>Y</td>
</tr>
<tr>
<td>row</td>
<td>0</td>
<td>1.1</td>
</tr>
<tr>
<td>0</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>1</td>
<td>1.1</td>
<td>1.2</td>
</tr>
<tr>
<td>2</td>
<td>1.1</td>
<td>1.2</td>
</tr>
</tbody>
</table>
```

# Now stack & Reset

```python
In [56]: df = df.stack(0).reset_index(1);df

Out[56]:

<table>
<thead>
<tr>
<th></th>
<th>level_1</th>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>0</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>1</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>1</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>2</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>2</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
</tbody>
</table>
```

# And fix the labels (Notice the label 'level_1' got added automatically)

```python
In [57]: df.columns = ['Sample','All_X','All_Y'];df

Out[57]:

<table>
<thead>
<tr>
<th></th>
<th>Sample</th>
<th>All_X</th>
<th>All_Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>row</td>
<td>0</td>
<td>One</td>
<td>1.10</td>
</tr>
<tr>
<td>0</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>1</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>1</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
<tr>
<td>2</td>
<td>One</td>
<td>1.10</td>
<td>1.20</td>
</tr>
<tr>
<td>2</td>
<td>Two</td>
<td>1.11</td>
<td>1.22</td>
</tr>
</tbody>
</table>
```

### 7.3.1 Arithmetic

Performing arithmetic with a multi-index that needs broadcasting
In [58]: cols = pd.MultiIndex.from_tuples([(x,y) for x in ['A','B','C'] for y in ['O', 'I']])

In [59]: df = pd.DataFrame(np.random.randn(2,6),index=['n','m'],columns=cols); df
Out[59]:
    A  B  C
  nO  1.920906 -0.388231 -2.314394 0.665508 0.402562 0.399555
  mO -1.765956  0.850423  0.388054 0.992312 0.744086 -0.739776

In [60]: df = df.div(df['C'],level=1); df
   A  B  C
  nO I  O I  O I
  mO I  O I  O I

7.3.2 Slicing

Slicing a multi-index with xs

In [61]: coords = [('AA','one'), ('AA','six'), ('BB','one'), ('BB','two'), ('BB','six')]

In [62]: index = pd.MultiIndex.from_tuples(coords)

In [63]: df = pd.DataFrame([11,22,33,44,55],index,['MyData']); df
Out[63]:
     MyData
    AA one  11
    six  22
    BB one  33
two  44
    six  55

To take the cross section of the 1st level and 1st axis the index:

In [64]: df.xs('BB',level=0,axis=0)  #Note : level and axis are optional, and default to zero
Out[64]:
     MyData
   one  33
two  44
    six  55

...and now the 2nd level of the 1st axis.

In [65]: df.xs('six',level=1,axis=0)
Out[65]:
     MyData
AA   22
BB   55

Slicing a multi-index with xs, method #2
In [66]: index = list(itertools.product(['Ada','Quinn','Violet'],['Comp','Math','Sci']))

In [67]: headr = list(itertools.product(['Exams','Labs'],['I','II']))

In [68]: indx = pd.MultiIndex.from_tuples(index,names=['Student','Course'])

In [69]: cols = pd.MultiIndex.from_tuples(headr) #Notice these are un-named

In [70]: data = [(70+x+y+(x*y)%3 for x in range(4)) for y in range(9)]

In [71]: df = pd.DataFrame(data,indx,cols); df

Out[71]:

<table>
<thead>
<tr>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
</tr>
<tr>
<td>Student</td>
<td>Course</td>
</tr>
<tr>
<td>Ada</td>
<td>Comp</td>
</tr>
<tr>
<td></td>
<td>Math</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
</tr>
<tr>
<td>Quinn</td>
<td>Comp</td>
</tr>
<tr>
<td></td>
<td>Math</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
</tr>
<tr>
<td>Violet</td>
<td>Comp</td>
</tr>
<tr>
<td></td>
<td>Math</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
</tr>
</tbody>
</table>

In [72]: All = slice(None)

In [73]: df.loc['Violet']

Out[73]:

<table>
<thead>
<tr>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
</tr>
<tr>
<td>Course</td>
<td></td>
</tr>
<tr>
<td>Comp</td>
<td>76</td>
</tr>
<tr>
<td>Math</td>
<td>77</td>
</tr>
<tr>
<td>Sci</td>
<td>78</td>
</tr>
</tbody>
</table>

In [74]: df.loc[(All,'Math'),All]

In [75]: df.loc[(slice('Ada','Quinn'),'Math'),All]

In [76]: df.loc[(All,'Math'),('Exams')]

(continues on next page)
### 7.3.3 Sorting

Sort by specific column or an ordered list of columns, with a multi-index

```
In [78]: df.sort_values(by=('Labs', 'II'), ascending=False)
```

```
Out[78]:

<table>
<thead>
<tr>
<th>Student</th>
<th>Course</th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Violet</td>
<td>Sci</td>
<td>78</td>
<td>81</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>77</td>
<td>80</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>76</td>
<td>79</td>
</tr>
<tr>
<td>Quinn</td>
<td>Sci</td>
<td>75</td>
<td>78</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>74</td>
<td>78</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>73</td>
<td>76</td>
</tr>
<tr>
<td>Ada</td>
<td>Sci</td>
<td>72</td>
<td>75</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>71</td>
<td>74</td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>70</td>
<td>73</td>
</tr>
</tbody>
</table>
```

Partial Selection, the need for sortedness;

### 7.3.4 Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

### 7.4 Missing Data

The *missing data* docs.

Fill forward a reversed timeseries
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [79]: df = pd.DataFrame(np.random.randn(6,1), index=pd.date_range('2013-08-01',
                           periods=6, freq='B'), columns=list('A'))

In [80]: df.loc[df.index[3], 'A'] = np.nan

In [81]: df
Out[81]:
          A
2013-08-01 -1.054874
2013-08-02 -0.179642
2013-08-05  0.639589
2013-08-06   NaN
2013-08-07  1.906684
2013-08-08  0.104050

In [82]: df.reindex(df.index[::-1]).ffill()

A
2013-08-08  0.104050
2013-08-07  1.906684
2013-08-06  1.906684
2013-08-05  0.639589
2013-08-02 -0.179642
2013-08-01 -1.054874

cumsum reset at NaN values

7.4.1 Replace

Using replace with backrefs

7.5 Grouping

The grouping docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

In [83]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
                        ....:                      'size': list('SSMMMLL'),
                        ....:                      'weight': [8, 10, 11, 1, 20, 12, 12],
                        ....:                      'adult': [False] * 5 + [True] * 2}); df

Out[83]:
          animal size  weight  adult
0       cat    S      8   False
1       dog    S     10   False
2       cat    M     11   False
3       fish    M      1   False
4       dog    M     20   False
5       cat    L     12    True
6       cat    L     12    True

(continues on next page)
List the size of the animals with the highest weight.
In [84]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].idxmax()])

animal
cat   L
dog   M
fish  M
dtype: object

Using `get_group`

In [85]: gb = df.groupby(['animal'])
In [86]: gb.get_group('cat')
Out[86]:
animal size weight adult
0  cat   S   8  False
2  cat   M  11  False
5  cat   L  12   True
6  cat   L  12   True

Apply to different items in a group

In [87]: def GrowUp(x):
   .....:    avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
   .....:    avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
   .....:    avg_weight += sum(x[x['size'] == 'L'].weight)
   .....:    avg_weight /= len(x)
   .....:    return pd.Series(['L', avg_weight, True], index=['size', 'weight', 'adult'])
   .....:
In [88]: expected_df = gb.apply(GrowUp)
In [89]: expected_df
Out[89]:
size  weight  adult
animal
  cat   L  12.4375  True
  dog   L  20.0000  True
  fish  L  1.2500   True

Expanding Apply

In [90]: S = pd.Series([i / 100.0 for i in range(1,11)])
In [91]: def CumRet(x,y):
   .....:    return x * (1 + y)
   .....:
In [92]: def Red(x):
   .....:    return functools.reduce(CumRet,x,1.0)
   .....:
In [93]: S.expanding().apply(Red, raw=True)
Out[93]: (continues on next page)
Replacing some values with mean of the rest of a group

```
In [94]: df = pd.DataFrame({'A' : [1, 1, 2, 2], 'B' : [1, -1, 1, 2]})
In [95]: gb = df.groupby('A')
In [96]: def replace(g):
   ....:     mask = g < 0
   ....:     g.loc[mask] = g[~mask].mean()
   ....:     return g
   ....:
In [97]: gb.transform(replace)
Out[97]:
    B
0  1.0
1  1.0
2  1.0
3  2.0
```

Sort groups by aggregated data

```
In [98]: df = pd.DataFrame({'code': ['foo', 'bar', 'baz'] * 2,
   ....:                     'data': [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
   ....:                     'flag': [False, True] * 3})
In [99]: code_groups = df.groupby('code')
In [100]: agg_n_sort_order = code_groups[['data']].transform(sum).sort_values(by='data')
In [101]: sorted_df = df.loc[agg_n_sort_order.index]
In [102]: sorted_df
Out[102]:
      code   data  flag
    0    foo  0.16  False
    1    bar -0.21   True
    2    baz  0.33  False
    3    foo  0.45   True
    4    bar -0.59   False
    5    baz  0.62   True
```

Create multiple aggregated columns

### 7.5. Grouping
In [103]: rng = pd.date_range(start="2014-10-07", periods=10, freq='2min')

In [104]: ts = pd.Series(data = list(range(10)), index = rng)

In [105]: def MyCust(x):
   ....:     if len(x) > 2:
   ....:         return x[1] * 1.234
   ....:     return pd.NaT
   ....:

In [106]: mhc = {'Mean': np.mean, 'Max': np.max, 'Custom': MyCust}

In [107]: ts.resample("5min").apply(mhc)

Out[107]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Custom</td>
<td>2014-10-07 00:00:00</td>

</tbody>
</table>

In [108]: ts

In [109]: df = pd.DataFrame({'Color': 'Red Red Red Blue'.split(),
   ....:     'Value': [100, 150, 50, 50]})

In [110]: df['Counts'] = df.groupby(['Color']).transform(len)

Create a value counts column and reassign back to the DataFrame
Shift groups of the values in a column based on the index

```
In [112]: df = pd.DataFrame(
    ....:   {u'line_race': [10, 10, 8, 10, 10, 8],
    ....:    u'beyer': [99, 102, 103, 103, 88, 100],
    ....:    index=[u'Last Gunfighter', u'Last Gunfighter', u'Last Gunfighter',
    ....:    u'Paynter', u'Paynter', u'Paynter']}); df
```

```
Out[112]:
     line_race  beyer
Last Gunfighter    10   99
Last Gunfighter    10  102
Last Gunfighter     8  103
   Paynter        10  103
   Paynter        10   88
   Paynter         8  100
```

```
In [113]: df['beyer_shifted'] = df.groupby(level=0)['beyer'].shift(1)
```

```
In [114]: df
Out[114]:
     line_race  beyer  beyer_shifted
    Last Gunfighter   10     99          NaN
    Last Gunfighter   10  102      99.0
    Last Gunfighter     8  103    102.0
       Paynter      10  103         NaN
       Paynter      10   88    103.0
       Paynter       8  100     88.0
```

Select row with maximum value from each group

```
In [115]: df = pd.DataFrame({'host':['other','other','that','this','this'],
    ....:   'service':['mail','web','mail','mail','web'],
    ....:   'no':[1, 2, 1, 2, 1]}).set_index(['host', 'service'])
```

```
In [116]: mask = df.groupby(level=0).agg('idxmax')
```

```

7.6 Timeseries

Between times
Using indexer between time
Constructing a datetime range that excludes weekends and includes only certain times
Vectorized Lookup
Aggregation and plotting time series
Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series.
How to rearrange a Python pandas DataFrame?
Dealing with duplicates when reindexing a timeseries to a specified frequency
Calculate the first day of the month for each entry in a DatetimeIndex

```
In [147]: dates = pd.date_range('2000-01-01', periods=5)

In [148]: dates.to_period(freq='M').to_timestamp()
Out[148]:
       '2000-01-01'], dtype='datetime64[ns]', freq=None)
```

7.6.1 Resampling

The Resample docs.
Using Grouper instead of TimeGrouper for time grouping of values
Time grouping with some missing values
Valid frequency arguments to Grouper
Grouping using a MultiIndex
Using TimeGrouper and another grouping to create subgroups, then apply a custom function
Resampling with custom periods
Resample intraday frame without adding new days
Resample minute data
Resample with groupby
### 7.7 Merge

The *Concat* docs. The *Join* docs.

Append two dataframes with overlapping index (emulate R `rbind`)

```
In [149]: rng = pd.date_range('2000-01-01', periods=6)
In [150]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C'])
In [151]: df2 = df1.copy()
```

Depending on df construction, *ignore_index* may be needed

```
In [152]: df = df1.append(df2, ignore_index=True); df
```

**Self Join of a DataFrame**

```
In [153]: df = pd.DataFrame(data={'Area': ['A'] * 5 + ['C'] * 2, ...: 'Bins': [110] * 2 + [160] * 3 + [40] * 2, ...: 'Test_0': [0, 1, 0, 1, 2, 0, 1], ...: 'Data': np.random.randn(7)}); df
```

```
In [154]: df['Test_1'] = df['Test_0'] - 1
In [155]: pd.merge(df, df, left_on=['Bins', 'Area', 'Test_0'], right_on=['Bins', 'Area', 'Test_1'], suffixes=('_L', '_R'))
```

How to set the index and join
KDB like asof join
Join with a criteria based on the values
Using searchsorted to merge based on values inside a range

7.8 Plotting

The Plotting docs.
Make Matplotlib look like R
Setting x-axis major and minor labels
Plotting multiple charts in an ipython notebook
Creating a multi-line plot
Plotting a heatmap
Annotate a time-series plot
Annotate a time-series plot #2
Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter
Boxplot for each quartile of a stratifying variable

```
In [156]: df = pd.DataFrame(
    ......:    {u'stratifying_var': np.random.uniform(0, 100, 20),
    ......:        u'price': np.random.normal(100, 5, 20)})
    ......:

In [157]: df[u'quartiles'] = pd.qcut(
    ......:    df[u'stratifying_var'],
    ......:        4,
    ......:        labels=[u'0-25%', u'25-50%', u'50-75%', u'75-100%'])
    ......:

In [158]: df.boxplot(column=u'price', by=u'quartiles')
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x11f845470>
```
7.9 Data In/Out

Performance comparison of SQL vs HDF5

7.9.1 CSV

The CSV docs
read_csv in action
appending to a csv
Reading a csv chunk-by-chunk
Reading only certain rows of a csv chunk-by-chunk
Reading the first few lines of a frame
Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here
Inferring dtypes from a file
Dealing with bad lines
Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

### 7.9.1.1 Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```python
for i in range(3):
    data = pd.DataFrame(np.random.randn(10, 4))
    data.to_csv('file{}.csv'.format(i))
```

```python
files = ['file_0.csv', 'file_1.csv', 'file_2.csv']
result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```python
import glob
files = glob.glob('file*.csv')
result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*()` functions described in the `io docs`.

### 7.9.1.2 Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```python
i = pd.date_range('20000101', periods=10000)
df = pd.DataFrame(dict(year = i.year, month = i.month, day = i.day))
```

```python
%timeit pd.to_datetime(df.year*10000+df.month*100+df.day, format='%Y%m%d')
```

# simulate combining into a string, then parsing
```python
d = df.apply(lambda x: "%04d%02d%02d" % (x['year'],x['month'],x['day']), axis=1)
```

```python
d.head()
```

(continues on next page)
7.9.1.3 Skip row between header and data

In [165]: data = """";;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;
       .....;;;;;

7.9.2 SQL

The *SQL* docs
Reading from databases with SQL

7.9.3 Excel

The *Excel* docs
Reading from a filelike handle
Modifying formatting in XlsxWriter output

7.9.4 HTML

Reading HTML tables from a server that cannot handle the default request header

7.9.5 HDFStore

The *HDFStores* docs
Simple Queries with a Timestamp Index
Managing heterogeneous data using a linked multiple table hierarchy
Merging on-disk tables with millions of rows
Avoiding inconsistencies when writing to a store from multiple processes/threads
De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. See here
Creating a store chunk-by-chunk from a csv file
Appending to a store, while creating a unique index
Large Data work flows
Reading in a sequence of files, then providing a global unique index to a store while appending
Groupby on a HDFStore with low group density
Groupby on a HDFStore with high group density
Hierarchical queries on a HDFStore
Counting with a HDFStore
Troubleshoot HDFStore exceptions
Setting min_itemsize with strings
Using ptrepack to create a completely-sorted-index on a store
Storing Attributes to a group node

```
In [170]: df = pd.DataFrame(np.random.randn(8,3))
In [171]: store = pd.HDFStore('test.h5')
In [172]: store.put('df',df)

# you can store an arbitrary Python object via pickle
In [173]: store.get_storer('df').attrs.my_attribute = dict(A = 10)
In [174]: store.get_storer('df').attrs.my_attribute
Out[174]: {'A': 10}
```

### 7.9.6 Binary Files

Pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }
```

(continues on next page)
the following Python code will read the binary file ’binary.dat’ into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```python
def read_binary(data, names, offsets, formats):
    # Thesample code below is a simple, illustrative approach. In
    # practice it may be necessary to adapt the code based on
    # the specific details of the binary format.
    #
    # Import necessary libraries
    import numpy as np
    import pandas as pd

    # Define the data type
    dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
                   align=True)
    df = pd.DataFrame(np.fromfile(data, dt))
    return df

# Example

FILE *file = fopen("binary.dat", "wb");
fwrite(&d, sizeof(Data), n, file);
fclose(file);

    return 0;
}
```

Note: The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas’ IO facilities.

### 7.10 Computation

Numerical integration (sample-based) of a time series

### 7.11 Timedeltas

The Timedeltas docs.

Using timedeltas

```python
In [175]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
```

```python
In [176]: s - s.max()
```

```
Out[176]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]
```

```python
In [177]: s.max() - s
```

```
Out[177]:
0     2 days
1     1 days
2     0 days
dtype: timedelta64[ns]
```
In [178]: s = datetime.datetime(2011,1,1,3,5)

   → 0 364 days 20:55:00
   1 365 days 20:55:00
   2 366 days 20:55:00
   dtype: timedelta64[ns]

In [179]: s + datetime.timedelta(minutes=5)

   → 0 2012-01-01 00:05:00
   1 2012-01-02 00:05:00
   2 2012-01-03 00:05:00
   dtype: datetime64[ns]

In [180]: datetime.datetime(2011,1,1,3,5) - s

   → 0 -365 days +03:05:00
   1 -366 days +03:05:00
   2 -367 days +03:05:00
   dtype: timedelta64[ns]

In [181]: datetime.timedelta(minutes=5) + s

   → 0 2012-01-01 00:05:00
   1 2012-01-02 00:05:00
   2 2012-01-03 00:05:00
   dtype: datetime64[ns]

Adding and subtracting deltas and dates

In [182]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])

In [183]: df = pd.DataFrame(dict(A=s, B=deltas)); df

Out[183]:
             A          B
   0 2012-01-01  0 days
   1 2012-01-02  1 days
   2 2012-01-03  2 days

In [184]: df['New Dates'] = df['A'] + df['B']

In [185]: df['Delta'] = df['A'] - df['New Dates']; df

Out[185]:
             A          B  New Dates  Delta
   0 2012-01-01  0 days  2012-01-01  0 days
   1 2012-01-02  1 days  2012-01-03 -1 days
   2 2012-01-03  2 days  2012-01-05 -2 days

In [186]: df.dtypes

   → A   datetime64[ns]
Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [187]: y = s - s.shift(); y
Out[187]:
0    NaT
1    1 days
2    1 days
dtype: timedelta64[ns]

In [188]: y[1] = np.nan; y
Out[188]:
0    NaT
1    NaT
2    1 days
dtype: timedelta64[ns]
```

7.12 Aliasing Axis Names

To globally provide aliases for axis names, one can define these 2 functions:

```
In [189]: def set_axis_alias(cls, axis, alias):
    ....:     if axis not in cls._AXIS_NUMBERS:
    ....:         raise Exception("invalid axis \[\$s\] for alias \[\$s\]" % (axis, alias))
    ....:     cls._AXIS_ALIASES[alias] = axis
    ....:

In [190]: def clear_axis_alias(cls, axis, alias):
    ....:     if axis not in cls._AXIS_NUMBERS:
    ....:         raise Exception("invalid axis \[\$s\] for alias \[\$s\]" % (axis, alias))
    ....:     cls._AXIS_ALIASES.pop(alias, None)
    ....:

In [191]: set_axis_alias(pd.DataFrame,'columns', 'myaxis2')

In [192]: df2 = pd.DataFrame(np.random.randn(3,2),columns=['c1','c2'],index=['i1','i2','i3'])

In [193]: df2.sum(axis='myaxis2')
Out[193]:
   i1    0.745167
   i2   -0.176251
   i3    0.014354
dtype: float64

In [194]: clear_axis_alias(pd.DataFrame,'columns', 'myaxis2')
```
To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```python
In [195]: def expand_grid(data_dict):
    ...:     rows = itertools.product(*data_dict.values())
    ...:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())

In [196]: df = expand_grid(
    ...:     {'height': [60, 70],
    ...:     'weight': [100, 140, 180],
    ...:     'sex': ['Male', 'Female']})

In [197]: df
Out[197]:
       height  weight sex
0       60      100  Male
1       60      100  Female
2       60      140   Male
3       60      140  Female
4       60      180   Male
5       60      180  Female
6       70      100   Male
7       70      100  Female
8       70      140   Male
9       70      140  Female
10      70      180   Male
11      70      180  Female
We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```python
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic.** The link between labels and data will not be broken unless done so explicitly by you.

We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 8.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```python
>>> s = pd.Series(data, index=index)
```

Here, *data* can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what **data** is:

**From ndarray**

If *data* is an ndarray, **index** must be the same length as *data*. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```python
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [4]: s
Out[4]:
a    0.4691
b   -0.2829
```

(continues on next page)
c  -1.5091
d  -1.1356
e   1.2121
dtype: float64

In [5]: s.index
Out[5]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
0  -0.1732
1   0.1192
2  -1.0442
3  -0.8618
4  -2.1046
dtype: float64

Note: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

From dict

Series can be instantiated from dicts:

In [7]: d = {'b' : 1, 'a' : 0, 'c' : 2}

In [8]: pd.Series(d)
Out[8]:
b  1
a  0
c  2
dtype: int64

Note: When the data is a dict, and an index is not passed, the Series index will be ordered by the dict’s insertion order, if you’re using Python version >= 3.6 and Pandas version >= 0.23.

If you’re using Python < 3.6 or Pandas < 0.23, and an index is not passed, the Series index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the Series would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

In [9]: d = {'a' : 0., 'b' : 1., 'c' : 2.}

In [10]: pd.Series(d)
Out[10]:
a  0.0
b  1.0
c  2.0
### 8.1. Series is ndarray-like

Series acts very similarly to ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```python
In [13]: s[0]
Out[13]: 0.46911229990718628

In [14]: s[:3]
Out[14]: a 0.4691
c -0.2829
d -1.5091
dtype: float64

In [15]: s[s > s.median()]
Out[15]: a 0.4691
e 1.2121
dtype: float64

In [16]: s[[4, 3, 1]]
Out[16]: e 1.2121
d -1.1356
b -0.2829
```

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

From scalar value

If `data` is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```python
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
    a  5.0
    b  5.0
    c  5.0
    d  5.0
    e  5.0
dtype: float64
```

```python
In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out[11]:
    b  1.0
    c  2.0
    d  NaN
    a  0.0
dtype: float64
```
We will address array-based indexing in a separate section

8.1.2 Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```
In [18]: s['a']
Out[18]: 0.46911229990718628
```

```
In [19]: s['e'] = 12.
```

```
In [20]: s
Out[20]:
a 0.4691
b -0.2829
c -1.5091
d -1.1356
e 12.0000
dtype: float64
```

```
In [21]: 'e' in s
Out[21]: True
```

```
In [22]: 'f' in s
Out[22]: False
```

If a label is not contained, an exception is raised:

```
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [23]: s.get('f')
```

```
In [24]: s.get('f', np.nan)
Out[24]: nan
```

See also the section on attribute access.
8.1.3 Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [25]: s + s
Out[25]:
  a    0.9382
  b   -0.5657
  c   -3.0181
  d   -2.2713
  e    24.0000
       dtype: float64

In [26]: s * 2
Out[26]:
  a    0.9382
  b   -0.5657
  c   -3.0181
  d   -2.2713
  e    24.0000
       dtype: float64

In [27]: np.exp(s)
Out[27]:
  a    1.5986
  b    0.7536
  c    0.2211
  d    0.3212
  e  162754.7914
       dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [28]: s[1:] + s[:-1]
Out[28]:
  a     NaN
  b   -0.5657
  c   -3.0181
  d   -2.2713
  e     NaN
       dtype: float64
```

The result of an operation between unaligned Series will have the union of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

Note: In general, we chose to make the default result of operations between differently indexed objects yield the union of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with
missing data via the **dropna** function.

### 8.1.4 Name attribute

Series can also have a *name* attribute:

```python
In [29]: s = pd.Series(np.random.randn(5), name='something')
In [30]: s
Out[30]:
            0   -0.4949
           1    1.0718
           2    0.7216
           3   -0.7068
           4   -1.0396
Name: something, dtype: float64
In [31]: s.name
Out[31]: 'something'
```

The Series *name* will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

New in version 0.18.0.

You can rename a Series with the **pandas.Series.rename()** method.

```python
In [32]: s2 = s.rename("different")
In [33]: s2.name
Out[33]: 'different'
```

Note that *s* and *s2* refer to different objects.

### 8.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object.

Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- Structured or record ndarray
- A Series
- Another DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.
Note: When the data is a dict, and columns is not specified, the DataFrame columns will be ordered by the dict's insertion order, if you are using Python version >= 3.6 and Pandas >= 0.23.

If you are using Python < 3.6 or Pandas < 0.23, and columns is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

### 8.2.1 From dict of Series or dicts

The resulting index will be the union of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [34]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
       'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}

In [35]: df = pd.DataFrame(d)

In [36]: df
Out[36]:
   one  two
  a 1.0  1.0  
b 2.0  2.0  
c 3.0  3.0  
d  NaN  4.0

In [37]: pd.DataFrame(d, index=['d', 'b', 'a'])
Out[37]:
   one  two
  d  NaN  4.0
  b  2.0  NaN
  a  1.0  NaN

In [38]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
   two  three
  d   NaN     4.0
  b  2.0     NaN
  a  1.0     NaN
```

The row and column labels can be accessed respectively by accessing the index and columns attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [39]: df.index
Out[39]: Index(['a', 'b', 'c', 'd'], dtype='object')

In [40]: df.columns
Out[40]: Index(['one', 'two'], dtype='object')
```
8.2.2 From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be range(n), where n is the array length.

```
In [41]: d = {'one': [1., 2., 3., 4.],
       ...:       'two': [4., 3., 2., 1.],
       ...: }

In [42]: pd.DataFrame(d)
Out[42]:
       one  two
0   1.0  4.0
1   2.0  3.0
2   3.0  2.0
3   4.0  1.0

In [43]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
Out[43]:
       one  two
a   1.0  4.0
b   2.0  3.0
c   3.0  2.0
d   4.0  1.0

In [44]: data = np.zeros((2,), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])

In [45]: data[:] = [(1, 2., 'Hello'), (2, 3., 'World')]

In [46]: pd.DataFrame(data)
Out[46]:
      A    B        C
0  1.00  2.00  b'Hello'
1  2.00  3.00  b'World'

In [47]: pd.DataFrame(data, index=['first', 'second'])
Out[47]:
         A    B        C
first   1.00  2.00  b'Hello'
second  2.00  3.00  b'World'

In [48]: pd.DataFrame(data, columns=['C', 'A', 'B'])
      C    A    B
0  b'Hello'  1.00  2.00
1  b'World'  2.00  3.00
```

8.2.3 From structured or record array

This case is handled identically to a dict of arrays.

```
in [44]: data = np.zeros((2,), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])

in [45]: data[:] = [(1, 2., 'Hello'), (2, 3., 'World')]

in [46]: pd.DataFrame(data)
out[46]:
       A    B        C
0  1.00  2.00  b'Hello'
1  2.00  3.00  b'World'

in [47]: pd.DataFrame(data, index=['first', 'second'])
out[47]:
         A    B        C
first   1.00  2.00  b'Hello'
second  2.00  3.00  b'World'

in [48]: pd.DataFrame(data, columns=['C', 'A', 'B'])
→
      C    A    B
0  b'Hello'  1.00  2.00
1  b'World'  2.00  3.00
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.
8.2.4 From a list of dicts

```python
In [49]: data2 = [('a': 1, 'b': 2), ('a': 5, 'b': 10, 'c': 20)]

In [50]: pd.DataFrame(data2)
Out[50]:
       a  b   c
0     1  2  NaN
1     5 10 20.0

In [51]: pd.DataFrame(data2, index=['first', 'second'])
Out[51]:
       a  b   c
first 1  2  NaN
second 5 10 20.0

In [52]: pd.DataFrame(data2, columns=['a', 'b'])
```

8.2.5 From a dict of tuples

You can automatically create a multi-indexed frame by passing a tuples dictionary.

```python
In [53]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
                   ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
                   ('b', 'a'): {('A', 'C'): 5, ('A', 'B'): 6},
                   ('b', 'b'): {('A', 'D'): 9, ('A', 'B'): 10}})
Out[53]:
        a   b
    b A  B  1.0 4.0 5.0 8.0 10.0
    C  2.0 3.0 6.0 7.0 NaN
    D NaN NaN NaN NaN  9.0
```

8.2.6 From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

Missing Data

Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use np.nan to represent missing values. Alternatively, you may pass a numpy.MaskedArray as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

8.2.7 Alternate Constructors

DataFrame.from_dict
DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

In [54]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[54]:
    A  B
0  1  4
1  2  5
2  3  6

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

In [55]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),  
                           orient='index', columns=['one', 'two', 'three'])
Out[55]:
     one  two  three
   A   1   2   3
   B   4   5   6

DataFrame.from_records takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

In [56]: data
Out[56]:
    array([(1, 2., b'Hello'), (2, 3., b'World')],  
           dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [57]: pd.DataFrame.from_records(data, index='C')
   A   B
C  b'Hello' 1  2.0
    b'World' 2  3.0

8.2.8 Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

In [58]: df['one']
Out[58]:
   a  1.0
   b  2.0
   c  3.0
d  NaN
Name: one, dtype: float64

In [59]: df['three'] = df['one'] * df['two']
In [60]: df['flag'] = df['one'] > 2

In [61]: df
Out[61]:
   one  two  three  flag
  a    1.0  1.0  1.0  False
  b    2.0  2.0  4.0  False
  c    3.0  3.0  9.0   True
  d  NaN  4.0  NaN  False

Columns can be deleted or popped like with a dict:

In [62]: del df['two']

In [63]: three = df.pop('three')

In [64]: df
Out[64]:
   one  flag
  a  1.0  False
  b  2.0  False
  c  3.0   True
  d  NaN  False

When inserting a scalar value, it will naturally be propagated to fill the column:

In [65]: df['foo'] = 'bar'

In [66]: df
Out[66]:
   one  flag  foo
  a  1.0  False   bar
  b  2.0  False  bar
  c  3.0   True  bar
  d  NaN  False  bar

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame’s index:

In [67]: df['one_trunc'] = df['one'][:2]

In [68]: df
Out[68]:
   one  flag  foo  one_trunc
  a  1.0  False   bar  1.0
  b  2.0  False   bar  2.0
  c  3.0   True   bar  NaN
  d  NaN  False   bar  NaN

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The insert function is available to insert at a particular location in the columns:

In [69]: df.insert(1, 'bar', df['one'][:2])

In [70]: df
8.2.9 Assigning New Columns in Method Chains

Inspired by dplyr's `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

In [71]: iris = pd.read_csv('data/iris.data')

In [72]: iris.head()

Out[72]:

<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
</tbody>
</table>

In [73]: (iris.assign(sepal_ratio = iris['SepalWidth'] / iris['SepalLength'])).head()

→

<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6863</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6122</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6809</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6739</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.7200</td>
</tr>
</tbody>
</table>

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

In [74]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] / x['SepalLength'])).head()

→

<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6863</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6122</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6809</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6739</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.7200</td>
</tr>
</tbody>
</table>

`assign` always returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:
Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a Series or NumPy array), or a function of one argument to be called on the DataFrame. A copy of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for dependent assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```
In [75]: (iris.query('SepalLength > 5')
    .....: .assign(SepalRatio = lambda x: x.SepalWidth / x.SepalLength,
    .....:     PetalRatio = lambda x: x.PetalWidth / x.PetalLength)
    .....: .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
Out[75]: <matplotlib.axes._subplots.AxesSubplot at 0x1c259fd7b8>
```

```
8.2. DataFrame
```

(continues on next page)
In the second expression, \( x['C'] \) will refer to the newly created column, that’s equal to \( dfa['A'] + dfa['B'] \).

To write code compatible with all versions of Python, split the assignment in two.

```python
In [78]: dependent = pd.DataFrame({"A": [1, 1, 1]})
In [79]: (dependent.assign(A=lambda x: x['A'] + 1)  
       .assign(B=lambda x: x['A'] + 2))
```

```
Out[79]:
    A  B  
0  2  4
1  2  4
2  2  4
```

**Warning:** Dependent assignment maybe subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish write code that supports versions of python before and after 3.6, you’ll need to take care when passing `assign` expressions that

- Updating an existing column
- Referring to the newly updated column in the same `assign`

For example, we’ll update column “A” and then refer to it when creating “B”.

```python
>>> dependent = pd.DataFrame({"A": [1, 1, 1]})
>>> dependent.assign(A=lambda x: x["A"] + 1,  
                   B=lambda x: x["A"] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the “old” value of A, [1, 1, 1]. The output is then

```
    A  B  
0  2  3
1  2  3
2  2  3
```

For Python 3.6 and later, the expression creating A refers to the “new” value of A, [2, 2, 2], which results in

```
    A  B  
0  2  4
1  2  4
2  2  4
```

### 8.2.10 Indexing / Selection

The basics of indexing are as follows:
### Operation

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select column</td>
<td><code>df[col]</code></td>
<td>Series</td>
</tr>
<tr>
<td>Select row by label</td>
<td><code>df.loc[label]</code></td>
<td>Series</td>
</tr>
<tr>
<td>Select row by integer location</td>
<td><code>df.iloc[loc]</code></td>
<td>Series</td>
</tr>
<tr>
<td>Slice rows</td>
<td><code>df[5:10]</code></td>
<td>DataFrame</td>
</tr>
<tr>
<td>Select rows by boolean vector</td>
<td><code>df[bool_vec]</code></td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

Row selection, for example, returns a Series whose index is the columns of the DataFrame:

```python
In [80]: df.loc['b']
Out[80]:
one 2
bar 2
flag False
foo bar
one_trunc 2
Name: b, dtype: object
```

```python
In [81]: df.iloc[2]
Out[81]:
one 3
bar 3
flag True
foo bar
one_trunc NaN
Name: c, dtype: object
```

For a more exhaustive treatment of sophisticated label-based indexing and slicing, see the [section on indexing](#). We will address the fundamentals of reindexing / conforming to new sets of labels in the [section on reindexing](#).

#### 8.2.11 Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```python
In [82]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [83]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [84]: df + df2
Out[84]:
         A    B       C    D
0   0.0457 -0.0141   1.3809 NaN
1  -0.9554 -1.5010   0.0372 NaN
2   0.6627   1.5348  -0.8597 NaN
3  -2.4529   1.2373  -0.1337 NaN
4   1.4145   1.9517  -2.3204 NaN
5  -0.4949  -1.6497  -1.0846 NaN
6   1.0476   0.7486  -0.8055 NaN
7   NaN     NaN     NaN     NaN
8   NaN     NaN     NaN     NaN
9   NaN     NaN     NaN     NaN
```

8.2. DataFrame
When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [85]: df - df.iloc[0]
Out[85]:
       A    B    C    D
0  0.0000 0.0000 0.0000 0.0000
1 -1.3593 -0.2487 -0.4534 -1.7547
2  0.2531 0.8297 0.0100 -1.9912
3 -1.3111 0.0543 -1.7249 -1.6205
4  0.5730 1.5007 -0.6761 1.3673
5 -1.7412 0.7820 -1.2416 -2.0531
6 -1.2408 -0.8696 -0.1533 0.0004
7 -0.7439 0.4110 -0.9296 -0.2824
8 -1.1949 1.3207 0.2382 -1.4826
9  2.2938 1.8562 0.7733 -1.4465
```

In the special case of working with time series data, and the DataFrame index also contains dates, the broadcasting will be column-wise:

```
In [86]: index = pd.date_range('1/1/2000', periods=8)
In [87]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
In [88]: df
Out[88]:
       A    B    C
2000-01-01 -1.2268 0.7698 -1.2812
2000-01-02 -0.7277 -0.1213 -0.0979
2000-01-03  0.6958  0.3417  0.9597
2000-01-04 -1.1103 -0.6200  0.1497
2000-01-05 -0.7323  0.6877  0.1764
2000-01-06  0.4033 -0.1550  0.3016
2000-01-07 -2.1799 -1.3698 -0.9542
2000-01-08  1.4627 -1.7432 -0.8266
```

```
In [89]: type(df['A'])
→ pandas.core.series.Series
In [90]: df - df['A']
```

(continues on next page)
Warning:

def - df['A']

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is

df.sub(df['A'], axis=0)

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations.

Operations with scalars are just as you would expect:

```
In [91]: df * 5 + 2
Out[91]:
      A   B   C
2000-01-01 -4.1341  5.8490 -4.4062
2000-01-02 -1.6385  1.3935  1.5106
2000-01-03  5.4789  3.7087  6.7986
2000-01-04 -3.5517 -1.0999  2.7487
2000-01-05 -1.6617  5.4387  2.8822
2000-01-06  4.0165  1.2252  3.5081
2000-01-07 -8.8993 -4.8492 -2.7710
2000-01-08  9.3135 -6.7158 -2.1330

In [92]: 1 / df

Out[92]:
     A   B   C
2000-01-01  0.8151  1.2990  0.7805
2000-01-02  1.3742 -8.2436 -10.2163
2000-01-03  0.4372  2.9262  1.0420
2000-01-04  0.9006 -1.6130  6.6779
2000-01-05  1.3655  1.4540  5.6675
2000-01-06  2.4795 -6.4537  3.3154
2000-01-07  0.4587  0.7300 -1.0480
2000-01-08  0.6837  0.5737  1.2098

In [93]: df ** 4

Out[93]:
     A       B       C
2000-01-01  2.2653  0.3512  2.6948e+00
2000-01-02  0.2804  0.0002  9.1796e-05
2000-01-03  0.2344  0.0136  8.4838e-01
2000-01-04  1.5199  0.1477  5.0286e-04
2000-01-05  0.2876  0.2237  9.6924e-04
2000-01-06  0.0265  0.0006  8.2769e-03
2000-01-07  22.5795  3.5212  8.2903e-01
2000-01-08  4.5774  9.2332  4.6683e-01
```
Boolean operators work as well:

```python
In [94]: df1 = pd.DataFrame({'a' : [1, 0, 1], 'b' : [0, 1, 1] }, dtype=bool)
In [95]: df2 = pd.DataFrame({'a' : [0, 1, 1], 'b' : [1, 1, 0] }, dtype=bool)
In [96]: df1 & df2
Out[96]:
    a  b
0  False  False
1  False   True
2   True  False
In [97]: df1 | df2
Out[97]:
    a  b
0  True  True
1  True  True
2  True  True
In [98]: df1 ^ df2
    a  b
0  True  True
1  True  False
2  False  True
In [99]: -df1
    a  b
0  False  True
1   True  False
2  False  False
```

### 8.2.12 Transposing

To transpose, access the `.T` attribute (also the `transpose` function), similar to an ndarray:

```python
# only show the first 5 rows
In [100]: df[:5].T
Out[100]:
A     -1.2268   -0.7277    0.6958  -1.1103   -0.7323
B      0.7698   -0.1213    0.3417  -0.6200    0.6877
C    -1.2812   -0.0979    0.9597   0.1497    0.1764
```

### 8.2.13 DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on DataFrame, assuming the data within are numeric:

```python
In [101]: np.exp(df)
Out[101]: (continues on next page)
```
The dot method on DataFrame implements matrix multiplication:

```python
In [103]: df.T.dot(df)
Out[103]:
   A   B   C
A 11.3419 -0.0598 3.0080
B -0.0598 6.5206 2.0833
C  3.0080  2.0833 4.3105
```

Similarly, the dot method on Series implements dot product:

```python
In [104]: s1 = pd.Series(np.arange(5,10))
In [105]: s1.dot(s1)
Out[105]: 255
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics are quite different in places from a matrix.

### 8.2.14 Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the baseball dataset from the plyr R package):

```python
In [106]: baseball = pd.read_csv('data/baseball.csv')
In [107]: print(baseball)
```

<table>
<thead>
<tr>
<th>id</th>
<th>player</th>
<th>year</th>
<th>stint</th>
<th>...</th>
<th>hbp</th>
<th>sh</th>
<th>sf</th>
<th>gidp</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>womacto01</td>
<td>2006</td>
<td>2</td>
<td></td>
<td>0.0</td>
<td>3.0</td>
<td>0.0</td>
<td>0.0</td>
</tr>
<tr>
<td>1</td>
<td>schilcu01</td>
<td>2006</td>

(continues on next page)
Wide DataFrames will be printed across multiple rows by default:

```python
In [110]: pd.DataFrame(np.random.randn(3, 12))
Out[110]:
   0   1   2  3   4  ...   7   8
  --- --- --- --- ---  ...   --- ---
    0 -0.345352 1.314232 0.690579 0.995761 2.396780 ... -0.317441 -1.236269 0.0281461 0.030711 0.109121
    1 -2.182937 0.380396 0.084844 0.432390 1.519970 ... 0.274230 0.132885 -0.744471
    2  0.206053 -0.251905 -2.213588 1.063327 1.266143 ... 0.408204 -1.048089 -0.964980 -0.845696 -1.340896 ... 1.682706 -1.717693 0.0281461 0.030711 0.109121

[3 rows x 12 columns]
```

You can change how much to print on a single row by setting the `display.width` option:

```python
In [111]: pd.set_option('display.width', 40) # default is 80
In [112]: pd.DataFrame(np.random.randn(3, 12))
Out[112]:
   0   1   2  3   4  ...   7   8
  --- --- --- --- ---  ...   --- ---
    0  1.262731 1.289997 0.082423 -0.055758 0.536580 ... -0.034571 -2.484478 -0.744471
    1  1.126203 -0.977349 1.474071 -0.064034 -1.282782 ... 0.441153 2.353925 0.0281461 0.030711 0.109121
    2  0.758527 1.729689 -0.964980 -0.845696 -1.340896 ... 1.682706 -1.717693 0.0281461 0.030711 0.109121

[3 rows x 12 columns]
```

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```python
In [113]: datafile={'filename': ['filename_01', 'filename_02'],
     ...:               'path': ['media/user_name/storage/folder_01/filename_01",
     ...:                        "media/user_name/storage/folder_02/filename_02"]}
     ...
In [114]: pd.set_option('display.max_colwidth',30)
In [115]: pd.DataFrame(datafile)
Out[115]:

<table>
<thead>
<tr>
<th>filename</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename_01</td>
<td>media/user_name/storage/folder_01/filename_01</td>
</tr>
<tr>
<td>filename_02</td>
<td>media/user_name/storage/folder_02/filename_02</td>
</tr>
</tbody>
</table>
```

```python
In [116]: pd.set_option('display.max_colwidth',100)
In [117]: pd.DataFrame(datafile)
Out[117]:

<table>
<thead>
<tr>
<th>filename</th>
<th>path</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename_01</td>
<td>media/user_name/storage/folder_01/filename_01</td>
</tr>
<tr>
<td>filename_02</td>
<td>media/user_name/storage/folder_02/filename_02</td>
</tr>
</tbody>
</table>
```

(continues on next page)
8.2.15 DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [118]: df = pd.DataFrame({'foo1' : np.random.randn(5),
                      'foo2' : np.random.randn(5)})

In [119]: df
Out[119]:
  foo1    foo2
0  1.171216 -0.858447
1  0.520260  0.306996
2 -1.197071 -0.028665
3 -1.066969  0.384316
4 -0.303421  1.574159
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```
In [5]: df.fo<TAB>
df.foo1 df.foo2
```

8.3 Panel

**Warning:** In 0.20.0, Panel is deprecated and will be removed in a future version. See the section Deprecate Panel.

Panel is a somewhat less-used, but still important container for 3-dimensional data. The term panel data is derived from econometrics and is partially responsible for the name pandas: pan(el)-da(ta)-s. The names for the 3 axes are intended to give some semantic meaning to describing operations involving panel data and, in particular, econometric analysis of panel data. However, for the strict purposes of slicing and dicing a collection of DataFrame objects, you may find the axis names slightly arbitrary:

- **items:** axis 0, each item corresponds to a DataFrame contained inside
- **major_axis:** axis 1, it is the index (rows) of each of the DataFrames
• **minor_axis**: axis 2, it is the **columns** of each of the DataFrames

Construction of Panels works about like you would expect:

### 8.3.1 From 3D ndarray with optional axis labels

```python
In [121]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
                   major_axis=pd.date_range('1/1/2000', periods=5),
                   minor_axis=['A', 'B', 'C', 'D'])

In [122]: wp
Out[122]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

### 8.3.2 From dict of DataFrame objects

```python
In [123]: data = {'Item1' : pd.DataFrame(np.random.randn(4, 3)),
          'Item2' : pd.DataFrame(np.random.randn(4, 2))}

In [124]: pd.Panel(data)
Out[124]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 3
Minor_axis axis: 0 to 2
```

Note that the values in the dict need only be **convertible to DataFrame**. Thus, they can be any of the other valid inputs to DataFrame as per above.

One helpful factory method is `Panel.from_dict`, which takes a dictionary of DataFrames as above, and the following named parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>intersect</td>
<td>False</td>
<td>drops elements whose indices do not align</td>
</tr>
<tr>
<td>orient</td>
<td>items</td>
<td>use minor to use DataFrames' columns as panel items</td>
</tr>
</tbody>
</table>

For example, compare to the construction above:

```python
In [125]: pd.Panel.from_dict(data, orient='minor')
Out[125]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 2
Minor_axis axis: Item1 to Item2
```

Orient is especially useful for mixed-type DataFrames. If you pass a dict of DataFrame objects with mixed-type columns, all of the data will get upcasted to `dtype=object` unless you pass `orient='minor'`:

---

8.3. Panel 581
In [126]: df = pd.DataFrame({'a': ['foo', 'bar', 'baz'],
                      'b': np.random.randn(3)})

In [127]: df
Out[127]:
    a     b
0  foo -0.308853
1  bar -0.681087
2  baz  0.377953

In [128]: data = {'item1': df, 'item2': df}

In [129]: panel = pd.Panel.from_dict(data, orient='minor')

In [130]: panel['a']
Out[130]:
    item1  item2
0    foo    foo
1    bar    bar
2    baz    baz

In [131]: panel['b']
Out[131]:
    item1  item2
0 -0.308853 -0.308853
1 -0.681087 -0.681087
2  0.377953  0.377953

In [132]: panel['b'].dtypes
Out[132]:
item1  float64
item2  float64
dtype: object

Note: Panel, being less commonly used than Series and DataFrame, has been slightly neglected feature-wise. A number of methods and options available in DataFrame are not available in Panel.

8.3.3 From DataFrame using to_panel method

to_panel converts a DataFrame with a two-level index to a Panel.

In [133]: midx = pd.MultiIndex(levels=[['one', 'two'], ['x', 'y']],
                        labels=[[1, 1, 0, 0],
                                [1, 0, 1, 0]])

In [134]: df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [5, 6, 7, 8]}, index=midx)

In [135]: df.to_panel()
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: A to B

(continues on next page)
Major_axis axis: one to two
Minor_axis axis: x to y

8.3.4 Item selection / addition / deletion

Similar to DataFrame functioning as a dict of Series, Panel is like a dict of DataFrames:

```
In [136]: wp['Item1']
Out[136]:
          A         B         C         D
2000-01-01 1.588931 0.476720 0.473424 -0.242861
2000-01-02 -0.014805 -0.284319 0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921 1.613616
2000-01-04  0.464000  0.227371 -0.696922  1.613616
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838
```

```
In [137]: wp['Item3'] = wp['Item1'] / wp['Item2']
```

The API for insertion and deletion is the same as for DataFrame. And as with DataFrame, if the item is a valid Python identifier, you can access it as an attribute and tab-complete it in IPython.

8.3.5 Transposing

A Panel can be rearranged using its `transpose` method (which does not make a copy by default unless the data are heterogeneous):

```
In [138]: wp.transpose(2, 0, 1)
Out[138]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 5 (minor_axis)
Items axis: A to D
Major_axis axis: Item1 to Item3
Minor_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
```

8.3.6 Indexing / Selection

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select item</td>
<td>wp[item]</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Get slice at major_axis label</td>
<td>wp.major_xs(val)</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Get slice at minor_axis label</td>
<td>wp.minor_xs(val)</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

For example, using the earlier example data, we could do:

```
In [139]: wp['Item1']
Out[139]:
          A         B         C         D
2000-01-01 1.588931 0.476720 0.473424 -0.242861
2000-01-02 -0.014805 -0.284319 0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921 1.613616
2000-01-04  0.464000  0.227371 -0.696922  1.613616
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838
```

(continues on next page)
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838

```python
In [140]: wp.major_xs(wp.major_axis[2])

→ Item1 Item2 Item3
A 1.137707 0.800193 1.421791
B -0.891060 0.782098 1.139320
C -0.693921 -1.069094 0.649074
D 1.613616 -1.099248 1.467927
```

```python
Out[140]:
```

```
In [141]: wp.minor_axis

→ Index(['A', 'B', 'C', 'D'], dtype='object')
```

```python
In [142]: wp.minor_xs('C')

→ Item1 Item2 Item3
2000-01-01 0.473424 -0.902937 -0.524316
2000-01-02 0.650776 -1.144073 -0.568824
2000-01-03 -0.693921 -1.069094 0.649074
2000-01-04 -0.496922 0.661084 -0.751678
2000-01-05 -1.561819 -1.056652 1.478083
```

8.3.7 Squeezing

Another way to change the dimensionality of an object is to squeeze a 1-len object, similar to `wp['Item1']`.

```python
In [143]: wp.reindex(items=['Item1']).squeeze()
```

```
Out[143]:
```

```python
In [144]: wp.reindex(items=['Item1'], minor=['B']).squeeze()

→
2000-01-01 0.476720
2000-01-02 -0.284319
2000-01-03 -0.891060
2000-01-04 0.227371
2000-01-05 -1.134623
Freq: D, Name: B, dtype: float64
```

8.3.8 Conversion to DataFrame

A Panel can be represented in 2D form as a hierarchically indexed DataFrame. See the section `hierarchical indexing` for more on this. To convert a Panel to a DataFrame, use the `to_frame` method:
In [145]: panel = pd.Panel(np.random.randn(3, 5, 4), items=['one', 'two', 'three'],
                   major_axis=pd.date_range('1/1/2000', periods=5),
                   minor_axis=['a', 'b', 'c', 'd'])

In [146]: panel.to_frame()
Out[146]:

<table>
<thead>
<tr>
<th>major</th>
<th>minor</th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>a</td>
<td>0.493672</td>
<td>1.219492</td>
<td>-1.290493</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>-2.461467</td>
<td>0.062297</td>
<td>0.787872</td>
</tr>
<tr>
<td></td>
<td>c</td>
<td>-1.553902</td>
<td>-0.110388</td>
<td>1.515707</td>
</tr>
<tr>
<td></td>
<td>d</td>
<td>2.015523</td>
<td>-1.184357</td>
<td>-0.276487</td>

8.4 Deprecate Panel

Over the last few years, pandas has increased in both breadth and depth, with new features, datatype support, and manipulation routines. As a result, supporting efficient indexing and functional routines for Series, DataFrame and Panel has contributed to an increasingly fragmented and difficult-to-understand codebase.

The 3-D structure of a Panel is much less common for many types of data analysis, than the 1-D of the Series or the 2-D of the DataFrame. Going forward it makes sense for pandas to focus on these areas exclusively.

Oftentimes, one can simply use a MultiIndex DataFrame for easily working with higher dimensional data.

In addition, the xarray package was built from the ground up, specifically in order to support the multi-dimensional analysis that is one of Panel’s main usecases. Here is a link to the xarray panel-transition documentation.

In [147]: p = tm.makePanel()

In [148]: p
Out[148]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 30 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-02-11 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame.
In [149]: p.to_frame()
Out[149]:

</table>
Alternatively, one can convert to an xarray `DataArray`.

```python
In [150]: p.to_xarray()
Out[150]:
<xarray.DataArray (items: 3, major_axis: 30, minor_axis: 4)>
array([[[-0.390201, 1.562443, -1.085663, 0.136235],
       [1.207122, 0.763264, -1.114738, 0.886313],
       ...
       [1.592673, -0.571329, 1.998044, 0.303638],
       [1.559318, -0.026671, -0.244548, -0.917368]],
      [[-1.624062, 0.483103, 0.768159, -0.021763],
       [-0.758514, 0.061495, 0.225441, -0.047152],
       ...
       [2.137827, -1.761442, 0.292058, 0.388254],
       [0.452429, -0.899454, -2.019610, 0.479630]],
      [[-0.605044, 0.583129, -0.273458, -0.700648],
       [0.878404, -0.876690, -0.335117, -1.166607],
       ...
       [-1.828749, -0.826439, -0.280343, -0.500569],
       [-1.716981, 0.124808, 0.931536, 0.870690]]])
Coordinates:
* items (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05 ...
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

You can see the full-documentation for the `xarray` package.
Here we discuss a lot of the essential functionality common to the pandas data structures. Here’s how to create some of the objects used in the examples from the previous section:

In [1]: index = pd.date_range('1/1/2000', periods=8)
In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
\                      columns=['A', 'B', 'C'])
\                      ...
In [4]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
\                      major_axis=pd.date_range('1/1/2000', periods=5),
\                      minor_axis=['A', 'B', 'C', 'D'])
\                      ...

9.1 Head and Tail

To view a small sample of a Series or DataFrame object, use the head() and tail() methods. The default number of elements to display is five, but you may pass a custom number.

In [5]: long_series = pd.Series(np.random.randn(1000))
In [6]: long_series.head()
Out[6]:
0   0.229453
1   0.304418
2   0.736135
3  -0.859631
4  -0.424100
dtype: float64

In [7]: long_series.tail(3)
Out[7]:
997  -0.351587
998   1.136249
999  -0.448789
dtype: float64
9.2 Attributes and the raw ndarray(s)

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray

- Axis labels
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*
  - **Panel**: *items*, *major_axis*, and *minor_axis*

Note, these attributes can be safely assigned to!

```python
In [8]: df[:2]
Out[8]:
         A         B         C
2000-01-01 0.048869 -1.360687 -0.479010
2000-01-02 -0.859661 -0.231595 -0.527750

In [9]: df.columns = [x.lower() for x in df.columns]

In [10]: df
Out[10]:
         a         b         c
2000-01-01 0.048869 -1.360687 -0.479010
2000-01-02 -0.859661 -0.231595 -0.527750
2000-01-03 1.296337  0.150680  0.123836
2000-01-04 0.571764  1.555563 -0.823761
2000-01-05 0.535420  1.032853  1.469725
2000-01-06 1.304124  1.449735  0.203109
2000-01-07 1.032011  0.969818  0.962723
2000-01-08 1.382083  0.938794  0.669142
```

To get the actual data inside a data structure, one need only access the **values** property:

```python
In [11]: s.values
Out[11]: array([-1.9339,  0.3773,  0.7341,  2.1416, -0.0112])

In [12]: df.values
Out[12]:
array([[ 0.0489, -1.3607, -0.479 ],
       [-0.8597, -0.2316, -0.5278],
       [-1.2963,  0.1507,  0.1238],
       [ 0.5718,  1.5556, -0.8238],
       [ 0.5354, -1.0329,  1.4697],
       [ 1.3041,  1.4497,  0.2031],
       [-1.032 ,  0.9698, -0.9627],
       [ 1.3821, -0.9388,  0.6691]])

In [13]: wp.values
array([[-0.4336, -0.2736,  0.6804, -0.3084],
       [-0.2761,  1.8212, -1.9936, -1.9274],
       [-2.0279,  1.625 ,  0.5511,  3.0593],
       [ 0.4553, -0.0307,  0.9357,  1.0612],
       ...])
```

(continues on next page)
If a DataFrame or Panel contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

### 9.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have `nans`.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 * df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section *Recommended Dependencies* for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```python
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

### 9.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.
9.4.1 Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

In [14]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c →']),
                     'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c →', 'd']),
                     'three' : pd.Series(np.random.randn(3), index=['b', 'c', →'d'])))

In [15]: df
Out[15]:
   one  two  three
a -1.101558 1.124472 NaN
b -0.177289 2.487104 -0.634293
c  0.462215 -0.486066 1.931194
d   NaN -0.456288 -1.222918

In [16]: row = df.iloc[1]

In [17]: column = df['two']

In [18]: df.sub(row, axis='columns')
Out[18]:
   one  two  three
a  -0.924269 -1.362632 NaN
b   0.000000  0.000000  0.000000
c  0.639504  2.973170  2.565487
d  -2.943392  0.000000  0.588625

In [19]: df.sub(row, axis=1)

In [20]: df.sub(column, axis='index')

In [21]: df.sub(column, axis=0)
Furthermore you can align a level of a multi-indexed DataFrame with a Series.

```python
In [22]: dfmi = df.copy()
In [23]: dfmi.index = pd.MultiIndex.from_tuples([(1,'a'),(1,'b'),(1,'c'),(2,'a')],
                                            names=['first','second'])
In [24]: dfmi.sub(column, axis=0, level='second')
Out[24]:
   one    two    three
first  
   second
  1 a  -2.226031  0.00000      NaN
  b  -2.664393  0.00000  -3.121397
  c   0.948280  0.00000   2.417260
  2 a      NaN  -1.58076  -2.347391
```

With Panel, describing the matching behavior is a bit more difficult, so the arithmetic methods instead (and perhaps confusingly?) give you the option to specify the broadcast axis. For example, suppose we wished to demean the data over a particular axis. This can be accomplished by taking the mean over an axis and broadcasting over the same axis:

```python
In [25]: major_mean = wp.mean(axis='major')
In [26]: major_mean
Out[26]:
   Item1    Item2
A -0.878036 -0.092218
B -0.060128  0.529811
C  0.099453 -0.715139
D  0.248599 -0.186535
In [27]: wp.sub(major_mean, axis='major')
```

And similarly for axis="items" and axis="minor".

**Note:** I could be convinced to make the axis argument in the DataFrame methods match the broadcasting behavior of Panel. Though it would require a transition period so users can change their code.

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```python
In [28]: s = pd.Series(np.arange(10))
In [29]: s
Out[29]:
```

9.4. Flexible binary operations
In [30]: div, rem = divmod(s, 3)

In [31]: div
Out[31]:
0 0
1 0
2 0
3 1
4 1
5 1
6 2
7 2
8 2
9 3
dtype: int64

In [32]: rem
Out[32]:
0 0
1 1
2 2
3 0
4 1
5 2
6 0
7 1
8 2
9 0
dtype: int64

In [33]: idx = pd.Index(np.arange(10))

In [34]: idx
Out[34]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [35]: div, rem = divmod(idx, 3)

In [36]: div
Out[36]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [37]: rem
Out[37]: Int64Index([0, 1, 2, 0, 1, 2, 0, 1, 2, 0], dtype='int64')
We can also do elementwise `divmod()`:

```python
In [38]: div, rem = divmod(s, [2, 2, 3, 4, 4, 5, 5, 6, 6])
In [39]: div
Out[39]:
        0  1  2  3  4  5  6  7  8  9
0     0  0  0  0  0  0  0  0  0  0
1     1  1  1  1  1  1  1  1  1  1
2     2  2  2  2  2  2  2  2  2  2
dtype: int64
In [40]: rem
Out[40]:
        0  1  2  3  4  5  6  7  8  9
0     0  0  0  0  0  0  0  0  0  0
1     1  1  1  1  1  1  1  1  1  1
2     2  2  2  2  2  2  2  2  2  2
dtype: int64
```

### 9.4.2 Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a `fill_value`, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```python
In [41]: df
Out[41]:
     one  two  three
a -1.101558  1.124472  NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d    NaN -0.456288 -1.222918
In [42]: df2
Out[42]:
     one  two  three
a -1.101558  1.124472  1.000000
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d    NaN -0.456288 -1.222918
```

(continues on next page)
9.4.3 Flexible Comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```python
In [45]: df.gt(df2)
Out[45]:
   one  two  three
a  False False False
b  False False False
c  False False False
d  False False False

In [46]: df2.ne(df)
   →  
   one  two  three
   a  False False True
   b  False False False
   c  False False False
   d  True  False False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These `boolean` objects can be used in indexing operations, see the section on `Boolean indexing`.

9.4.4 Boolean Reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```python
In [47]: (df > 0).all()
Out[47]:
   one  False
   two  False
   three False
```
You can reduce to a final boolean value.

```
In [49]: (df > 0).any().any()
Out[49]: True
```

You can test if a pandas object is empty, via the `empty` property.

```
In [50]: df.empty
Out[50]: False
```

```
In [51]: pd.DataFrame(columns=list('ABC')).empty
Out[51]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```
In [52]: pd.Series([True]).bool()
Out[52]: True
```

```
In [53]: pd.Series([False]).bool()
Out[53]: False
```

```
In [54]: pd.DataFrame([True]).bool()
Out[54]: True
```

```
In [55]: pd.DataFrame([False]).bool()
Out[55]: False
```

**Warning:** You might be tempted to do the following:

```
>>> if df:
...    ...
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.

*ValueError:* The truth value of an array *is* ambiguous. Use `a.empty`, `a.any()` or `a.
all()`.

See *gotchas* for a more detailed discussion.
9.4.5 Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider \( df + df \) and \( df \times 2 \). To test that these two computations produce the same result, given the tools shown above, you might imagine using \((df + df == df \times 2).all()\). But in fact, this expression is False:

```
In [56]: df + df == df * 2
Out[56]:
    one  two  three
   a    True  True  False
   b    True  True   True
   c    True  True   True
   d   False  True   True
```

Notice that the boolean DataFrame \( df + df == df \times 2 \) contains some False values! This is because NaNs do not compare as equals:

```
In [58]: np.nan == np.nan
Out[58]: False
```

So, NDFrames (such as Series, DataFrames, and Panels) have an \( \text{equals()} \) method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [59]: (df + df).equals(df * 2)
Out[59]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [60]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
In [61]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [62]: df1.equals(df2)
Out[62]: False
In [63]: df1.equals(df2.sort_index())
Out[63]: True
```

9.4.6 Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [64]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[64]:
0   True
1  False
2  False
dtype: bool
```
In [65]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[65]: array([ True, False, False], dtype=bool)

Pandas also handles element-wise comparisons between different array-like objects of the same length:

In [66]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[66]:
0   True
1   True
2  False
dtype: bool

In [67]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[67]:
0   True
1   True
2  False
dtype: bool

Trying to compare Index or Series objects of different lengths will raise a ValueError:

In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare

Note that this is different from the NumPy behavior where a comparison can be broadcast:

In [68]: np.array([1, 2, 3]) == np.array([2])
Out[68]: array([False, True, False], dtype=bool)

or it can return False if broadcasting can not be done:

In [69]: np.array([1, 2, 3]) == np.array([1, 2])
Out[69]: False

9.4.7 Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

In [70]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
                    'B': [np.nan, 2., 3., np.nan, 6.]})

In [71]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
                    'B': [np.nan, np.nan, 3., 4., 6., 8.]})
9.4.8 General DataFrame Combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:
9.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on :class:`Series`, :class:`DataFrame`, and :class:`Panel`. Most of these are aggregations (hence producing a lower-dimensional result) like :meth:`sum()`, :meth:`mean()`, and :meth:`quantile()`, but some of them, like :meth:`cumsum()` and :meth:`cumprod()`, produce an object of the same size. Generally speaking, these methods take an axis argument, just like :py:class:`ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)
- **Panel**: “items” (axis=0), “major” (axis=1, default), “minor” (axis=2)

For example:

```
In [77]: df
Out[77]:
    one     two     three
  a -1.101558  1.124472    NaN
  b -0.177289  2.487104 -0.634293
  c  0.462215 -0.486066  1.931194
  d    NaN    -0.456288 -1.222918

In [78]: df.mean(0)
Out[78]:
\n→
  one  -0.272211
  two   0.667306
  three  0.024661
dtype: float64

In [79]: df.mean(1)
Out[79]:
\n→
  a   0.011457
  b   0.558507
  c   0.635781
  d  -0.839603
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

```
In [80]: df.sum(0, skipna=False)
Out[80]:
  one  NaN
  two  2.669223
  three NaN

dtype: float64

In [81]: df.sum(axis=1, skipna=True)
Out[81]:
\n→
  a  0.022914
  b  1.675522
  c  1.907343
  d -1.679206
dtype: float64
```

9.5. Descriptive statistics
Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```python
In [82]: ts_stand = (df - df.mean()) / df.std()
In [83]: ts_stand.std()
Out[83]:
   one  1.0
   two  1.0
   three 1.0
dtype: float64
In [84]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)
In [85]: xs_stand.std(1)
Out[85]:
a  1.0
b  1.0
c  1.0
d  1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see this note.

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a *hierarchical index*.

```python
In [86]: df.cumsum()
Out[86]:
     one    two    three
   a -1.101558 1.124472   NaN
   b -1.278848 3.611576 -0.634293
   c -0.816633 3.125511  1.296901
   d  NaN  2.669223  0.073983
```
### 9.5. Descriptive statistics

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>Number of non-NA observations</td>
</tr>
<tr>
<td>sum</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean</td>

</tr>
<tr>
<td>cumprod</td>
<td>Cumulative product</td>
</tr>
<tr>
<td>cummax</td>
<td>Cumulative maximum</td>
</tr>
<tr>
<td>cummin</td>
<td>Cumulative minimum</td>
</tr>
</tbody>
</table>

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```python
In [87]: np.mean(df['one'])
Out[87]: -0.27221094480450114

In [88]: np.mean(df['one'].values)
Out[88]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```python
In [89]: series = pd.Series(np.random.randn(500))
In [90]: series[20:500] = np.nan
In [91]: series[10:20] = 5
In [92]: series.nunique()
Out[92]: 11
```

#### 9.5.1 Summarizing data: `describe`

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```python
In [93]: series = pd.Series(np.random.randn(1000))
In [94]: series[:2] = np.nan
In [95]: series.describe()
```

(continues on next page)
count 500.000000
mean -0.032127
std 1.067484
min -3.463789
25% -0.725523
50% -0.053230
75% 0.679790
max 3.120271
dtype: float64

In [96]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])

In [97]: frame.iloc[::2] = np.nan

In [98]: frame.describe()

Out[98]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>500.000000</td>

<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

dtype: float64

By default, the median is always included.

For a non-numerical Series object, describe() will give a simple summary of the number of unique values and most frequently occurring values:

In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])

In [101]: s.describe()

Out[101]:

<table>
<thead>
<tr>
<th></th>
<th>count</th>
<th>unique</th>
<th>top</th>
<th>freq</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>9</td>
<td>4</td>
<td>a</td>
<td>5</td>
</tr>
</tbody>
</table>

dtype: object
Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})

In [103]: frame.describe()
Out[103]:
   b
count 4.000000
mean 1.500000
std  1.290994
min  0.000000
25%  0.750000
50%  1.500000
75%  2.250000
max  3.000000
```

This behaviour can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [104]: frame.describe(include=['object'])
Out[104]:
   a
count 4
unique 2
top Yes
freq 2

In [105]: frame.describe(include=['number'])
Out[105]:
   b
count 4.000000
mean 1.500000
std  1.290994
min  0.000000
25%  0.750000
50%  1.500000
75%  2.250000
max  3.000000

In [106]: frame.describe(include='all')
Out[106]:
   →
   a   b
count 4  4.000000
unique 2  NaN
top Yes  NaN
freq 2  NaN
mean  NaN  1.500000
std  NaN  1.290994
min  NaN  0.000000
25%  NaN  0.750000
50%  NaN  1.500000
75%  NaN  2.250000
max  NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

9.5. Descriptive statistics 605
9.5.2 Index of Min/Max Values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```python
In [107]: s1 = pd.Series(np.random.randn(5))
In [108]: s1
Out[108]:
0   -1.649461
1    0.169660
2    1.246181
3    0.131682
4    -2.001988
dtype: float64
In [109]: s1.idxmin(), s1.idxmax()
Out[109]:
(4, 2)
```

```python
In [110]: df1 = pd.DataFrame(np.random.randn(5,3), columns=['A','B','C'])
In [111]: df1
Out[111]:
   A          B          C
0 -1.273023  0.870502  0.214583
1  0.088452 -0.173364  1.207466
2  0.546121  0.409515 -0.310515
3  0.585014 -0.490528 -0.054639
4 -0.239226  0.701089  0.228656
In [112]: df1.idxmin(axis=0)
Out[112]:
   A   B   C
0  0   3   2
dtype: int64
In [113]: df1.idxmax(axis=1)
Out[113]:
   0  1  2
A  B  A
C  B
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```python
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))
In [115]: df3
Out[115]:
   A
---
e  2.0
```

(continues on next page)
9.5.3 Value counts (histogramming) / Mode

The `value_counts()` Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

```python
In [117]: data = np.random.randint(0, 7, size=50)

In [118]: data
Out[118]:
array([3, 3, 0, 2, 1, 0, 5, 5, 3, 6, 1, 5, 6, 2, 0, 0, 6, 3, 3, 5, 0, 4, 3,
      3, 3, 0, 6, 1, 3, 5, 5, 0, 4, 0, 6, 3, 6, 5, 4, 3, 2, 1, 5, 0, 1, 1,
      6, 4, 1, 4])

In [119]: s = pd.Series(data)

In [120]: s.value_counts()
Out[120]:
3   11
0    9
5    8
6    7
1    7
4    5
2    3
dtype: int64

In [121]: pd.value_counts(data)
Out[121]:
3   11
0    9
5    8
6    7
1    7
4    5
2    3
dtype: int64
```

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

```python
In [122]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])

In [123]: s5.mode()
```
9.5.4 Discretization and quantiling

Continuous values can be discretized using the \texttt{cut()} (bins based on values) and \texttt{qcut()} (bins based on sample quantiles) functions:

\begin{verbatim}
In [126]: arr = np.random.randn(20)
In [127]: factor = pd.cut(arr, 4)
\end{verbatim}

\begin{verbatim}
Out[128]:
[(-2.611, -1.58], (0.473, 1.499], (-2.611, -1.58], (-1.58, -0.554], (-0.554, 0.473], ...
          , (0.473, 1.499], (0.473, 1.499], (-0.554, 0.473], (-0.554, 0.473]
Length: 20
Categories (4, interval[float64]): 
[(-2.611, -1.58] < (-1.58, -0.554] < (-0.554, 0.473] < (0.473, 1.499]]
\end{verbatim}

\begin{verbatim}
In [129]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])
\end{verbatim}

\begin{verbatim}
In [130]: factor
Out[130]:
[(-5, -1], (0, 1], (-5, -1], (-1, 0], (-1, 0], ..., (1, 5], (1, 5], (-1, 0], (-1, 0], ...
          , (-1, 0], (1, 5]
Length: 20
Categories (4, interval[int64]): 
[(-5, -1] < (-1, 0] < (0, 1] < (1, 5]
\end{verbatim}

\texttt{qcut()} computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

\begin{verbatim}
In [131]: arr = np.random.randn(30)
In [132]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])
\end{verbatim}

\begin{verbatim}
In [133]: factor
Out[133]:
[(0.544, 1.976], (0.544, 1.976], (-1.255, -0.375], (0.544, 1.976], (-0.103, 0.544], ...
          , (-0.103, 0.544], (0.544, 1.976], (-0.103, 0.544], (-1.255, -0.375], (-0.375, -0.
          103]]
Length: 30
\end{verbatim}
Categories (4, interval[float64]): [(-1.255, -0.375) < (-0.375, -0.103) < (-0.103, 0.544) < (0.544, 1.976)]

In [134]: pd.value_counts(factor)

\[...
Out[134]:

\[
\begin{align*}
0.544, 1.976] & 8 \\
(-1.255, -0.375] & 8 \\
(-0.103, 0.544] & 7 \\
(-0.375, -0.103] & 7 \\
dtype: int64
\end{align*}
\]

We can also pass infinite values to define the bins:

In [135]: arr = np.random.randn(20)

In [136]: factor = pd.cut(arr, [-np.inf, 0, np.inf])

In [137]: factor

Out[137]:

\[
\begin{align*}
(0.0, \inf], (0.0, \inf], (0.0, \inf], (0.0, \inf], (-\inf, 0.0], ..., (-\inf, 0.0], (-\inf, 0.0], (0.0, \inf] \\
\end{align*}
\]

Length: 20
Categories (2, interval[float64]): [(-inf, 0.0] < (0.0, inf]

9.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application**: pipe()  
2. **Row or Column-wise Function Application**: apply()  
3. **Aggregation API**: agg() and transform()  
4. **Applying Elementwise Functions**: applymap()

9.6.1 Tablewise Function Application

DataFrames and Series can of course just be passed into functions. However, if the function needs to be called in a chain, consider using the pipe() method. Compare the following

```python
# f, g, and h are functions taking and returning "DataFrames"
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```python
>>> (df.pipe(h)
   .pipe(g, arg1=1)
   .pipe(f, arg2=2, arg3=3)
)
```
Pandas encourages the second style, which is known as method chaining. pipe makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions f, g, and h each expected the DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide pipe with a tuple of (callable, data_keyword). pipe will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, data. We pass in the function, keyword pair (sm.ols, 'data') to pipe:

```python
In [138]: import statsmodels.formula.api as sm
In [139]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [140]: (bb.query('h > 0')
.....: .assign(ln_h = lambda df: np.log(df.h))
.....: .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
.....: .fit()
.....: .summary()
.....: )
```

```
Out[140]:
<class 'statsmodels.iolib.summary.Summary'>

    strong multicollinearity or other numerical problems.

```
We encourage you to view the source code of pipe().

### 9.6.2 Row or Column-wise Function Application

Arbitrary functions can be applied along the axes of a DataFrame using the apply() method, which, like the descriptive statistics methods, takes an optional axis argument:

```python
In [141]: df.apply(np.mean)
Out[141]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-0.272211</td>
<td>0.667306</td>
<td>0.024661</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [142]: df.apply(np.mean, axis=1)
Out[142]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0.011457</td>
<td>0.558507</td>
<td>0.635781</td>
<td>-0.839603</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [143]: df.apply(lambda x: x.max() - x.min())
Out[143]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>1.563773</td>
<td>2.973170</td>
<td>3.154112</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [144]: df.apply(np.cumsum)
Out[144]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-1.101558</td>
<td>1.124472</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>-1.278848</td>
<td>3.611576</td>
<td>-0.634293</td>
</tr>
<tr>
<td></td>
<td>-0.816633</td>
<td>3.125511</td>
<td>1.296901</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>2.669223</td>
<td>0.073983</td>
</tr>
</tbody>
</table>
```

The apply() method will also dispatch on a string method name:

```python
In [145]: df.apply('mean')
Out[145]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>-0.272211</td>
<td>0.667306</td>
<td>0.024661</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

(continues on next page)
The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-likes return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```python
In [148]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
                       index=pd.date_range('1/1/2000', periods=1000))
In [149]: tsdf.apply(lambda x: x.idxmax())
```

```
Out[149]:
A  2001-04-25
B  2002-05-31
C  2002-09-25
dtype: datetime64[ns]
```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

```python
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass `Series` methods to carry out some `Series` operation on each column or row:

```python
In [150]: tsdf
```

```
Out[150]:
     A        B        C
2000-01-01 -0.720299  0.546303 -0.082042
2000-01-02  0.200295 -0.577554 -0.908402
2000-01-03  0.102533  1.653614  0.303319
2000-01-04  NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN
```

(continues on next page)
Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

### 9.6.3 Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see `groupby API`, the `window functions API`, and the `resample API`. The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [152]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                           index=pd.date_range('1/1/2000', periods=10))

In [153]: tsdf.iloc[3:7] = np.nan

In [154]: tsdf
```

```
Out[154]:
              A         B         C
2000-01-01  0.170247 -0.916844  0.835024
2000-01-02  1.259919  0.801111  0.445614
2000-01-03  1.453046  2.430373  0.653093
2000-01-04   NaN        NaN        NaN
2000-01-05   NaN        NaN        NaN
2000-01-06   NaN        NaN        NaN
2000-01-07   NaN        NaN        NaN
2000-01-08 -1.874526  0.569822 -0.609644
2000-01-09  0.812462  0.565894 -1.461363
2000-01-10 -0.985475  1.388154 -0.078747
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```python
In [151]: tsdf.apply(pd.Series.interpolate)
```

```
Out[151]:
             A         B         C
2000-01-01 -0.720299  0.546303 -0.082042
2000-01-02  0.200295 -0.577554 -0.908402
2000-01-03  0.102533  1.653614  0.303319
2000-01-04  0.188539  1.391201  0.272754
2000-01-05  0.274546  1.128788  0.242189
2000-01-06  0.360553  0.866374  0.211624
2000-01-07  0.446559  0.603961  0.181059
2000-01-08  0.532566  0.341548  0.150493
2000-01-09  0.624468  0.604838  0.181059
2000-01-10  0.716369  0.866374  0.211624
```

```
In [151]: tsdf.apply(pd.Series.interpolate, raw=True)
```

```
Out[151]:
             A         B         C
2000-01-01 -0.720299  0.546303 -0.082042
2000-01-02  0.200295 -0.577554 -0.908402
2000-01-03  0.102533  1.653614  0.303319
2000-01-04  0.188539  1.391201  0.272754
2000-01-05  0.274546  1.128788  0.242189
2000-01-06  0.360553  0.866374  0.211624
2000-01-07  0.446559  0.603961  0.181059
2000-01-08  0.532566  0.341548  0.150493
2000-01-09  0.624468  0.604838  0.181059
2000-01-10  0.716369  0.866374  0.211624
```
In [155]: tsdf.agg(np.sum)
Out[155]:
A  0.835673
B  4.838510
C -0.216025
dtype: float64

In [156]: tsdf.agg('sum')
Out[156]:
A  0.835673
B  4.838510
C -0.216025
dtype: float64

# these are equivalent to a `.sum()` because we are aggregating on a single function
In [157]: tsdf.sum()
Out[157]:
A  0.835673  
B  4.838510  
C -0.216025  
dtype: float64

Single aggregations on a Series this will return a scalar value:

In [158]: tsdf.A.agg('sum')
Out[158]: 0.83567297915820504

9.6.3.1 Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

In [159]: tsdf.agg(['sum'])
Out[159]:
   A     B      C
sum 0.835673  4.838510 -0.216025

Multiple functions yield multiple rows:

In [160]: tsdf.agg(['sum', 'mean'])
Out[160]:
   A     B      C
sum 0.835673  4.838510 -0.216025
mean 0.139279  0.806418 -0.036004

On a Series, multiple functions return a Series, indexed by the function names:

In [161]: tsdf.A.agg(['sum', 'mean'])
Out[161]:
   sum     mean
Name: A, dtype: float64

Passing a lambda function will yield a `<lambda>` named row:
In [162]: tsdf.A.agg(['sum', lambda x: x.mean()])
Out[162]:
    sum 0.835673
    <lambda> 0.139279
Name: A, dtype: float64

Passing a named function will yield that name for the row:

In [163]: def mymean(x):
    .....:     return x.mean()
    .....:

In [164]: tsdf.A.agg(['sum', mymean])
Out[164]:
    sum 0.835673
    mymean 0.139279
Name: A, dtype: float64

### 9.6.3.2 Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to DataFrame.agg allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an OrderedDict instead to guarantee ordering.

In [165]: tsdf.agg(dict('A': 'mean', 'B': 'sum'))
Out[165]:
    A 0.139279
    B 4.838510
dtype: float64

Passing a list-like will generate a DataFrame output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be NaN:

In [166]: tsdf.agg(dict('A': ['mean', 'min'], 'B': 'sum'))
Out[166]:
    A     B
    mean 0.139279 NaN
    min -1.874526 NaN
    sum NaN 4.83851

### 9.6.3.3 Mixed Dtypes

When presented with mixed dtypes that cannot aggregate, .agg will only take the valid aggregations. This is similar to how groupby .agg works.

In [167]: mdf = pd.DataFrame({'A': [1, 2, 3],
                   'B': [1., 2., 3.],
                   'C': ['foo', 'bar', 'baz'],
                   'D': pd.date_range('20130101', periods=3))

In [168]: mdf.dtypes
Out[168]:
          A  int64

(continues on next page)
B      float64  
C     object     
D    datetime64[ns]  
dtype: object

In [169]: mdf.agg(['min', 'sum'])
Out[169]:
   A    B     C     D
min 1.0  1.0  bar  2013-01-01
sum 6.0  6.0  foobarbaz       NaT

9.6.3.4 Custom describe

With `.agg()` is it possible to easily create a custom describe function, similar to the built in `describe` function.

In [170]: from functools import partial
In [171]: q_25 = partial(pd.Series.quantile, q=0.25)
In [172]: q_25.__name__ = '25%'
In [173]: q_75 = partial(pd.Series.quantile, q=0.75)
In [174]: q_75.__name__ = '75%'
In [175]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
Out[175]:
   A       B       C
count  6.000000  6.000000  6.000000
mean   0.139279  0.806418 -0.036004
std    1.323362  1.100830  0.874990
min   -1.874526 -0.916844 -1.461363
25%   -0.696544  0.566876 -0.476920
median 0.491354  0.685467  0.183433
75%   1.148055  1.241393  0.601223
max   1.453046  2.430373  0.835024

9.6.4 Transform API

New in version 0.20.0.

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

In [176]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                         index=pd.date_range('1/1/2000', periods=10))
In [177]: tsdf.iloc[3:7] = np.nan
In [178]: tsdf
Out[178]:
   A       B       C
0  0.046130 -0.431515  0.830173
1  0.732372  0.367200  0.084369
2 -0.186271  0.429106 -0.292791
3  1.069902  0.466821 -0.316469
4  0.232460  0.092117 -0.626224
5 -1.177275 -0.081943  0.987846
6 -0.177268  0.072035 -0.032987
7  1.149230 -0.162028  0.591057
8 -0.733425 -0.888261  0.001652
9 -2.224104 -1.563507  0.168814

(continues on next page)
Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

In [179]: tsdf.transform(np.abs)

Out[179]:

<p>| | | |</p>

In [180]: tsdf.transform('abs')

In [181]: tsdf.transform(lambda x: x.abs())

9.6. Function application
Here `transform()` received a single function; this is equivalent to a ufunc application.

```python
In [182]: np.abs(tsdf)
Out[182]:
         A         B         C
2000-01-01  0.578465  0.503335  0.987140
2000-01-02  0.767147  0.266046  1.083797
2000-01-03  0.195348  0.722247  0.894537
2000-01-04  NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN
2000-01-08  0.556397  0.542165  0.308675
2000-01-09  1.010924  0.672504  1.139222
2000-01-10  0.354653  0.563622  0.365106
Freq: D, Name: A, dtype: float64
```

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.

```python
In [183]: tsdf.A.transform(np.abs)
Out[183]:
         A
2000-01-01  0.578465
2000-01-02  0.767147
2000-01-03  0.195348
2000-01-04  NaN
2000-01-05  NaN
2000-01-06  NaN
2000-01-07  NaN
2000-01-08  0.556397
2000-01-09  1.010924
2000-01-10  0.354653
Freq: D, Name: A, dtype: float64
```

### 9.6.4.1 Transform with multiple functions

Passing multiple functions will yield a column multi-indexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```python
In [184]: tsdf.transform([np.abs, lambda x: x+1])
Out[184]:
            A          B          C
        absolute <lambda> absolute <lambda> absolute <lambda>
2000-01-01  0.578465  0.421535  0.503335  0.496665  0.987140  0.012860
2000-01-02  0.767147  0.232853  0.266046  0.733954  1.083797  2.083797
2000-01-03  0.195348  1.195348  0.722247  1.722247  0.894537  0.105463
2000-01-04  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-05  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-06  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-07  NaN      NaN      NaN      NaN      NaN      NaN
2000-01-08  0.556397  0.443603  0.542165  1.542165  0.308675  0.691325
2000-01-09  1.010924  1.010924  0.672504  0.327496  1.139222  2.139222
2000-01-10  0.354653  1.354653  0.563622  1.563622  0.365106  0.634894
```
Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```python
In [185]: tsdf.A.transform([np.abs, lambda x: x+1])
Out[185]:
          absolute <lambda>
2000-01-01  0.578465  0.421535
2000-01-02  0.767147  0.232853
2000-01-03  0.195348  1.195348
2000-01-04  NaN         NaN
2000-01-05  NaN         NaN
2000-01-06  NaN         NaN
2000-01-07  NaN         NaN
2000-01-08  0.556397  0.443603
2000-01-09  1.010924 -0.010924
2000-01-10  0.354653  1.354653
```

### 9.6.4.2 Transferring with a dict

Passing a dict of functions will allow selective transforming per column.

```python
In [186]: tsdf.transform({'A': np.abs, 'B': lambda x: x+1})
Out[186]:
     A  B
2000-01-01  0.578465  0.496665
2000-01-02  0.767147  0.733954
2000-01-03  0.195348  1.722247
2000-01-04  NaN       NaN
2000-01-05  NaN       NaN
2000-01-06  NaN       NaN
2000-01-07  NaN       NaN
2000-01-08  0.556397  1.542165
2000-01-09  1.010924  0.327496
2000-01-10  0.354653  1.563622
```

Passing a dict of lists will generate a multi-indexed DataFrame with these selective transforms.

```python
In [187]: tsdf.transform({'A': np.abs, 'B': [lambda x: x+1, 'sqrt']})
Out[187]:
     A  B
2000-01-01  0.578465  0.496665   NaN
2000-01-02  0.767147  0.733954   NaN
2000-01-03  0.195348  1.722247  0.849851
2000-01-04  NaN       NaN       NaN
2000-01-05  NaN       NaN       NaN
2000-01-06  NaN       NaN       NaN
2000-01-07  NaN       NaN       NaN
2000-01-08  0.556397  1.542165  0.750748
2000-01-09  1.010924  0.327496   NaN
2000-01-10  0.354653  1.563622  0.750748
```

### 9.6.5 Applying Elementwise Functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and...
returning a single value. For example:

```python
In [188]: df4
Out[188]:
    one     two     three
   a -1.101558  1.124472  NaN
   b -0.177289  2.487104 -0.634293
   c  0.462215 -0.486066  1.931194
   d  NaN -0.456288 -1.222918
```

```python
In [189]: f = lambda x: len(str(x))
In [190]: df4['one'].map(f)
Out[190]:
   a    19
   b    20
   c    18
   d     3
Name: one, dtype: int64
```

```python
In [191]: df4.applymap(f)
Out[191]:
     one     two     three
   a    19    18      3
   b    20    18     19
   c    18    20    18
   d     3    19     19
```

*Series.map()* has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```python
In [192]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
                   index=['a', 'b', 'c', 'd', 'e'])
In [193]: t = pd.Series({'six' : 6., 'seven' : 7.})
In [194]: s
Out[194]:
   a  six
   b  seven
   c  six
   d  seven
   e  six
   dtype: object
In [195]: s.map(t)
Out[195]:
   a    6.0
   b    7.0
   c    6.0
   d    7.0
   e    6.0
   dtype: float64
```
9.6.6 Applying with a Panel

Applying with a Panel will pass a Series to the applied function. If the applied function returns a Series, the result of the application will be a Panel. If the applied function reduces to a scalar, the result of the application will be a DataFrame.

In [196]: import pandas.util.testing as tm

In [197]: panel = tm.makePanel(5)

In [198]: panel
Out[198]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [199]: panel['ItemA']

A transformational apply.

In [200]: result = panel.apply(lambda x: x*2, axis='items')

In [201]: result
Out[201]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [202]: result['ItemA']

A reduction operation.

In [203]: panel.apply(lambda x: x.dtype, axis='items')
Out[203]:
   A        B        C        D
2000-01-03 float64  float64  float64  float64
2000-01-04 float64  float64  float64  float64
2000-01-05 float64  float64  float64  float64

(continues on next page)
A similar reduction type operation.

```
In [204]: panel.apply(lambda x: x.sum(), axis='major_axis')
```

```
Out[204]:
    ItemA  ItemB  ItemC
A    1.841893  0.918017 -1.160547
B    3.488158 -2.629773  0.603397
C   -3.164692  0.805970  0.806501
D    0.653349 -0.152299  0.252577
```

This last reduction is equivalent to:

```
In [205]: panel.sum('major_axis')
```

```
Out[205]:
    ItemA  ItemB  ItemC
A    1.841893  0.918017 -1.160547
B    3.488158 -2.629773  0.603397
C   -3.164692  0.805970  0.806501
D    0.653349 -0.152299  0.252577
```

A transformation operation that returns a Panel, but is computing the z-score across the major_axis.

```
In [206]: result = panel.apply(
.....:     lambda x: (x-x.mean())/x.std(),
.....:     axis='major_axis')
```

```
In [207]: result
```

```
Out[207]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
```

```
In [208]: result['ItemA']
```

```
    A  B  C  D
2000-01-03  0.585813 -0.102070 -1.394063  0.201263
2000-01-04 -1.496089 -1.295066  0.434343  1.318766
2000-01-05  1.142642  1.413112  0.661833 -0.431942
2000-01-06 -0.323445 -0.405085 -0.683386  0.305017
2000-01-07  0.091079  0.389108  0.981273 -1.393105
```

Apply can also accept multiple axes in the axis argument. This will pass a DataFrame of the cross-section to the applied function.

```
In [209]: f = lambda x: ((x.T-x.mean(1))/x.std(1)).T
```

```
In [210]: result = panel.apply(f, axis = ['items','major_axis'])
```

```
In [211]: result
```

```
(continues on next page)
```
9.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To `reindex` means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, fill data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:
Here, the \textit{f} label was not contained in the Series and hence appears as \textit{NaN} in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

You may also use \texttt{reindex} with an \textit{axis} keyword:

Note that the \texttt{Index} objects containing the actual axis labels can be \texttt{shared} between objects. So if we have a Series and a DataFrame, the following can be done:

\begin{Verbatim}
In [222]: rs = s.reindex(df.index)
In [223]: rs
Out[223]:
\end{Verbatim}
This means that the reindexed Series’s index is the same Python object as the DataFrame’s index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

```
In [225]: df.reindex(['c', 'f', 'b'], axis='index')
Out[225]:
   one  two  three
c 0.462215 -0.486066 1.931194
f NaN    NaN   NaN
b -0.177289 2.487104 -0.634293
```

```
In [226]: df.reindex(['three', 'two', 'one'], axis='columns')
```

See also:

*MultiIndex / Advanced Indexing* is an even more concise way of doing reindexing.

---

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: *many operations are faster on pre-aligned data*. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

### 9.7.1 Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [227]: df2
Out[227]:
   one  two
a -1.101558 1.124472
b -0.634293 2.487104
```

```
In [228]: df3
```

(continues on next page)
9.7.2 Aligning objects with each other with align

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to joining and merging):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object’s index
- `join='right'`: use the passed object’s index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```python
In [230]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [231]: s1 = s[:4]
In [232]: s2 = s[1:]
In [233]: s1.align(s2)
```

```
Out[233]:
(a 0.505453
 b 1.788110
 c -0.405908
d -0.801912
 e NaN          
           dtype: float64, a NaN
           b 1.788110
           c -0.405908
d -0.801912
e 0.768460      
           dtype: float64)
```

```python
In [234]: s1.align(s2, join='inner')
```

```
Out[234]:
(b 1.788110
 c -0.405908
d -0.801912
           dtype: float64, b 1.788110
           c -0.405908
           d -0.801912
```
In [235]: s1.align(s2, join='left')

\n\n
Out[235]:
\n\n
( a  0.505453
 b  1.788110
c -0.405908
d -0.801912
dtype: float64)

For DataFrames, the join method will be applied to both the index and the columns by default:

In [236]: df.align(df2, join='inner')

Out[236]:

( one two
 a -1.101558  1.124472
 b -0.177289  2.487104
c  0.462215 -0.486066, one two
 a -1.101558  1.124472
 b -0.177289  2.487104
c  0.462215 -0.486066)

You can also pass an axis option to only align on the specified axis:

In [237]: df.align(df2, join='inner', axis=0)

Out[237]:

( one two three
 a -1.101558 NaN  1.124472
 b -0.177289 -0.634293  2.487104
c  0.462215  1.931194 NaN, one two
 a -1.101558  1.124472
 b -0.177289  2.487104
c  0.462215 -0.486066)

If you pass a Series to DataFrame.align(), you can choose to align both objects either on the DataFrame’s index or columns using the axis argument:

In [238]: df.align(df2.iloc[0], axis=1)

Out[238]:

( one three two
 a -1.101558 NaN  1.124472
 b -0.177289 -0.634293  2.487104
c  0.462215  1.931194 -0.456288, one two
 a -1.101558  1.124472
 b -0.177289  2.487104
c  0.462215 -0.486066)

9.7. Reindexing and altering labels

627
9.7.3 Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```
In [239]: rng = pd.date_range('1/3/2000', periods=8)
In [240]: ts = pd.Series(np.random.randn(8), index=rng)
In [241]: ts2 = ts[[0, 3, 6]]
In [242]: ts
Out[242]:
2000-01-03  0.466284
2000-01-04  0.457411
2000-01-05 -0.364060
2000-01-06  0.785367
2000-01-07 -1.463093
2000-01-08  1.187315
2000-01-09 -0.493153
2000-01-10 -1.323445
Freq: D, dtype: float64
```

```
In [243]: ts2
→
2000-01-03  0.466284
2000-01-06  0.785367
2000-01-09 -0.493153
dtype: float64
```

```
In [244]: ts2.reindex(ts.index)
→
2000-01-03  0.466284
2000-01-04  NaN
2000-01-05  NaN
2000-01-06  0.785367
2000-01-07  NaN
2000-01-08  NaN
2000-01-09 -0.493153
2000-01-10  NaN
Freq: D, dtype: float64
```

```
In [245]: ts2.reindex(ts.index, method='ffill')
→
2000-01-03  0.466284
2000-01-04  0.466284
2000-01-05  0.466284
2000-01-06  0.785367
```

(continues on next page)
2000-01-07  0.785367
2000-01-08  0.785367
2000-01-09  -0.493153
2000-01-10  -0.493153
Freq: D, dtype: float64

In [246]: ts2.reindex(ts.index, method='bfill')

    2000-01-03  0.466284
    2000-01-04  0.466284
    2000-01-05  0.785367
    2000-01-06  0.785367
    2000-01-07  -0.493153
    2000-01-08  -0.493153
    2000-01-09  NaN
    2000-01-10  NaN
Freq: D, dtype: float64

In [247]: ts2.reindex(ts.index, method='nearest')

    2000-01-03  0.466284
    2000-01-04  0.466284
    2000-01-05  0.466284
    2000-01-06  0.785367
    2000-01-07  0.785367
    2000-01-08  -0.493153
    2000-01-09  -0.493153
    2000-01-10  -0.493153
Freq: D, dtype: float64

These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using `fillna` (except for method='nearest') or `interpolate`:

In [248]: ts2.reindex(ts.index).fillna(method='ffill')

Out[248]:
    2000-01-03  0.466284
    2000-01-04  0.466284
    2000-01-05  0.466284
    2000-01-06  0.785367
    2000-01-07  0.785367
    2000-01-08  -0.493153
    2000-01-09  -0.493153
    2000-01-10  -0.493153
Freq: D, dtype: float64

`reindex()` will raise a ValueError if the index is not monotonically increasing or decreasing. `fillna()` and `interpolate()` will not perform any checks on the order of the index.

### 9.7.4 Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:
In [249]: ts2.reindex(ts.index, method='ffill', limit=1)
Out[249]:
2000-01-03 0.466284
2000-01-04 0.466284
2000-01-05 NaN
2000-01-06 0.785367
2000-01-07 0.785367
2000-01-08 NaN
2000-01-09 -0.493153
2000-01-10 -0.493153
Freq: D, dtype: float64

In contrast, tolerance specifies the maximum distance between the index and indexer values:

In [250]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out[250]:
2000-01-03 0.466284
2000-01-04 0.466284
2000-01-05 NaN
2000-01-06 0.785367
2000-01-07 0.785367
2000-01-08 NaN
2000-01-09 -0.493153
2000-01-10 -0.493153
Freq: D, dtype: float64

Notice that when used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with appropriate strings.

### 9.7.5 Dropping labels from an axis

A method closely related to reindex is the drop() function. It removes a set of labels from an axis:

In [251]: df
Out[251]:
   one   two   three
a -1.101558 1.124472 NaN
b -0.177289 2.487104 -0.634293
c 0.462215 -0.486066 1.931194
d NaN -0.456288 -1.222918

In [252]: df.drop(['a', 'd'], axis=0)
Out[252]:
   one   two   three
b -0.177289 2.487104 -0.634293
c 0.462215 -0.486066 1.931194

In [253]: df.drop(['one'], axis=1)
Out[253]:
   two   three
a 1.124472 NaN
b 2.487104 -0.634293
c -0.486066 1.931194
d -0.456288 -1.222918

Chapter 9. Essential Basic Functionality
Note that the following also works, but is a bit less obvious / clean:

```python
In [254]: df.reindex(df.index.difference(['a', 'd']))
Out[254]:
         one    two    three
b  -0.177289  2.487104 -0.634293
c   0.462215 -0.486066  1.931194
```

### 9.7.6 Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```python
In [255]: s
Out[255]:
a    0.505453
b    1.788110
c   -0.405908
d   -0.801912
e    0.768460
dtype: float64
In [256]: s.rename(str.upper)
    →
       A   0.505453  
       B    1.788110
       C   -0.405908
       D   -0.801912
       E    0.768460
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```python
In [257]: df.rename(columns={'one': 'foo', 'two': 'bar'},
       index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
Out[257]:
         foo    bar    three
apple -1.101558  1.124472   NaN
banana -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
durian   NaN   -0.456288  1.222918
```

If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single `mapper` and the `axis` to apply that mapping to.

```python
In [258]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[258]:
         foo    bar    three
a -1.101558  1.124472   NaN
b -0.177289  2.487104 -0.634293
```

(continues on next page)
The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

New in version 0.18.0.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```
In [260]: s.rename("scalar-name")
Out[260]:
a  0.505453  
b  1.788110  
c -0.405908  
d -0.801912  
e  0.768460  
Name: scalar-name, dtype: float64
```

The Panel class has a related `rename_axis()` class which can rename any of its three axes.

### 9.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. Other data structures, like DataFrame and Panel, follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series**: values
- **DataFrame**: column labels
- **Panel**: item labels

Thus, for example, iterating over a DataFrame gives you the column names:

```
In [261]: df = pd.DataFrame({'col1': np.random.randn(3), 'col2': np.random.randn(3)})
     ....:
     .....:
     .....:
     index=['a', 'b', 'c'])
     ....:
     .....:
In [262]: for col in df:
     .....:
     .....:
     print(col)
     .....:
     >>> col1
     >>> col2
```
Pandas objects also have the dict-like `iteritems()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- **iterrows():** Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- **itertuples():** Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally slow. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a vectorized solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on [function application](#).
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the [enhancing performance](#) section for some examples of this approach.

**Warning:** You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```python
In [263]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [264]: for index, row in df.iterrows():
   ...:     row['a'] = 10
   ...:

In [265]: df
Out[265]:
   a  b
0  1  a
1  2  b
2  3  c
```

### 9.8.1 `iteritems`

Consistent with the dict-like interface, `iteritems()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs
- **Panel:** (item, DataFrame) pairs

For example:

```python
In [266]: for item, frame in wp.iteritems():
   ...:     print(item)
   ...:     print(frame)
   ...:
(continues on next page)
```
9.8.2 iterrows

iterrows() allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [267]: for row_index, row in df.iterrows():
    ..:      print('%s
    ..:      %s' % (row_index, row))
    ..:      
0
  a  1
  b  a
Name: 0, dtype: object
1
  a  2
  b  b
Name: 1, dtype: object
2
  a  3
  b  c
Name: 2, dtype: object
```

Note: Because iterrows() returns a Series for each row, it does not preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [268]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [269]: df_orig.dtypes
Out[269]:
int       int64
float     float64
dtype: object

In [270]: row = next(df_orig.iterrows())[1]

In [271]: row
Out[271]:
int   1.0
float 1.5
Name: 0, dtype: float64
```
All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column `x`:

```
In [272]: row['int'].dtype
Out[272]: dtype('float64')

In [273]: df_orig['int'].dtype
Out[273]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [274]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})

In [275]: print(df2)
   x  y
0 1 4
1 2 5
2 3 6

In [276]: print(df2.T)

In [277]: df2_t = pd.DataFrame([{idx: values} for idx, values in df2.iterrows()])

In [278]: print(df2_t)
   0 1
x 1 2
y 4 5
```

### 9.8.3 `itertuples`

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```
In [279]: for row in df.itertuples():
   ....:     print(row)
   ....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note**: The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.
9.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the values of the Series, if it is a date-
time/period like Series. This will return a Series, indexed like the existing Series.

```python
# datetime
In [280]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [281]: s
Out[281]:
  0  2013-01-01 09:10:12
  1  2013-01-02 09:10:12
  2  2013-01-03 09:10:12
  3  2013-01-04 09:10:12
dtype: datetime64[ns]

In [282]: s.dt.hour
→
  0  9
  1  9
  2  9
  3  9
dtype: int64

In [283]: s.dt.second
→
  0  12
  1  12
  2  12
  3  12
dtype: int64

In [284]: s.dt.day
→
  0  1
  1  2
  2  3
  3  4
dtype: int64
```

This enables nice expressions like this:

```python
In [285]: s[s.dt.day==2]
Out[285]:
  1  2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produces tz aware transformations:

```python
In [286]: stz = s.dt.tz_localize('US/Eastern')

In [287]: stz
Out[287]:
  0  2013-01-01 09:10:12-05:00
```

(continues on next page)
You can also chain these types of operations:

```python
In [289]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

```
Out[289]:
0  2013-01-01 04:10:12-05:00
1  2013-01-02 04:10:12-05:00
2  2013-01-03 04:10:12-05:00
3  2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```python
# DatetimeIndex
In [290]: s = pd.Series(pd.date_range('20130101', periods=4))

In [291]: s
```

```
Out[291]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]
```

```python
In [292]: s.dt.strftime('%Y/%m/%d')
```

```
Out[292]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
```

```python
# PeriodIndex
In [293]: s = pd.Series(pd.period_range('20130101', periods=4))

In [294]: s
```

```
Out[294]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
```

```python
In [295]: s.dt.strftime('%Y/%m/%d')
```

```
Out[295]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
```

(continues on next page)
The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [296]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [297]: s
Out[297]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: object

In [298]: s.dt.year
Out[298]:
0 2013
1 2013
2 2013
3 2013
dtype: int64

In [299]: s.dt.day
Out[299]:
0 1
1 2
2 3
3 4
dtype: int64
```

```python
# timedelta
In [300]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [301]: s
Out[301]:
0 1 days 00:00:05
1 1 days 00:00:06
2 1 days 00:00:07
3 1 days 00:00:08
dtype: timedelta64[ns]

In [302]: s.dt.days
Out[302]:
0 1
1 1
2 1
3 1
dtype: int64
```

(continues on next page)
In [303]: s.dt.seconds

Out[303]:
0   5
1   6
2   7
3   8
dtype: int64

In [304]: s.dt.components

Out[304]:
days hours minutes seconds milliseconds microseconds nanoseconds
0   1   0   0    5    0    0    0
1   1   0   0    6    0    0    0
2   1   0   0    7    0    0    0
3   1   0   0    8    0    0    0

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.

9.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's str attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

In [305]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog ➾', 'cat'])

In [306]: s.str.lower()
Out[306]:
0   a
1   b
2   c
3  aaba
4   baca
5   NaN
6   caba
7    dog
8    cat
dtype: object

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

Please see Vectorized String Methods for a complete description.
9.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

9.11.1 By Index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```python
In [307]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c
˓→']),
                   'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c
˓→', 'd']),
                   'three' : pd.Series(np.random.randn(3), index=['b', 'c',
˓→', 'd']))
.....:
In [308]: unsorted_df = df.reindex(index=['a', 'd', 'c', 'b'],
                         columns=['three', 'two', 'one'])
.....:
In [309]: unsorted_df
Out[309]:
    three  two  one
   a  NaN  0.708543  0.036274
   d -0.540166  0.586626  NaN
   c  0.410238  1.121731  1.044630
   b -0.282532 -2.038777 -0.490032

# DataFrame
In [310]: unsorted_df.sort_index()

Out[310]:
    three  two  one
   a  NaN  0.708543  0.036274
   d -0.540166  0.586626  NaN
   c  0.410238  1.121731  1.044630
   b -0.282532 -2.038777 -0.490032

In [311]: unsorted_df.sort_index(ascending=False)

Out[311]:
    three  two  one
   d -0.540166  0.586626  NaN
   c  0.410238  1.121731  1.044630
   b -0.282532 -2.038777 -0.490032
   a  NaN  0.708543  0.036274

In [312]: unsorted_df.sort_index(axis=1)

Out[312]:
    one  three  two
   a  0.036274  NaN  0.708543
   d  NaN -0.540166  0.586626
   c  1.044630  0.410238  1.121731
```
# Series

In [313]: unsorted_df['three'].sort_index()

Out[313]:
   a    NaN
   b -0.282532
   c  0.410238
   d -0.540166
Name: three, dtype: float64

## 9.11.2 By Values

The `Series.sort_values()` method is used to sort a `Series` by its values. The `DataFrame.sort_values()` method is used to sort a `DataFrame` by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may used to specify one or more columns to use to determine the sorted order.

In [314]: df1 = pd.DataFrame({'one':[2,1,1,1],'two':[1,3,2,4],'three':[5,4,3,2]})

In [315]: df1.sort_values(by='two')
Out[315]:
   one two three
0  2  1   5
2  1  2   3
1  1  3   4
3  1  4   2

The `by` parameter can take a list of column names, e.g.:

In [316]: df1[['one', 'two', 'three']].sort_values(by=['one','two'])
Out[316]:
   one two three
2  1  2   3
1  1  3   4
3  1  4   2
0  2  1   5

These methods have special treatment of NA values via the `na_position` argument:

In [317]: s[2] = np.nan

In [318]: s.sort_values()
Out[318]:
0     A
3   Aaba
1      B
4    Baca
6     CABA
8      cat
7      dog
2   NaN
5     NaN
dtype: object
9.11.3 By Indexes and Values

New in version 0.23.0.

Strings passed as the by parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```python
# Build MultiIndex
In [320]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                                        ('b', 2), ('b', 1), ('b', 1)],
                                        names=['first', 'second'])

# Build DataFrame
In [321]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
                                        index=idx)

In [322]: df_multi
Out[322]:
   A
first second
a  1   6
  2   5
  2   4
b  2   3
  1   2
  1   1

Sort by ‘second’ (index) and ‘A’ (column)

In [323]: df_multi.sort_values(by=['second', 'A'])
Out[323]:
   A
first second
b  1   1
  1   2
a  1   6
b  2   3
a  2   4
  2   5
```
**Note:** If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### 9.11.4 searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```python
In [325]: ser = pd.Series([1, 2, 3])
In [326]: ser.searchsorted([0, 3])
Out[326]: array([0, 2])
In [327]: ser.searchsorted([0, 4])
Out[327]: array([0, 3])
In [328]: ser.searchsorted([1, 3], side='right')
Out[328]: array([1, 3])
In [329]: ser.searchsorted([1, 3], side='left')
Out[329]: array([0, 2])
In [330]: ser = pd.Series([3, 1, 2])
In [331]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[331]: array([0, 2])
```

### 9.11.5 smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest $n$ values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```python
In [332]: s = pd.Series(np.random.permutation(10))
In [333]: s
Out[333]:
0     8
1     2
2     9
3     5
4     6
5     0
6     1
7     7
8     4
9     3
dtype: int64
In [334]: s.sort_values()
Out[334]:
5     0
6     1
```

(continues on next page)
In [335]: s.nsmallest(3)
Out[335]:
\n→
5 0
6 1
1 2
dtype: int64

In [336]: s.nlargest(3)
Out[336]:
\n→
2 9
0 8
7 7
dtype: int64

Dataframe also has the `nlargest` and `nsmallest` methods.

In [337]: df = pd.DataFrame({
'a': [-2, -1, 1, 10, 8, 11, -1],
.....:
'b': list('abdceff'),
.....:
'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})

In [338]: df.nlargest(3, 'a')
Out[338]:
       a  b  c
5  11  f  3.0
3  10  c  3.2
4   8  e  NaN

In [339]: df.nlargest(5, ['a', 'c'])
Out[339]:
       a  b  c
6 -1  f  4.0
5  11  f  3.0
3  10  c  3.2
4   8  e  NaN
2   1  d  4.0

In [340]: df.nsmallest(3, 'a')
\n→
      a  b  c
0  -2  a  1.0
1  -1  b  2.0
6  -1  f  4.0
In [341]: df.nsmallest(5, ['a', 'c'])

→  

Out[341]:

→  

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a</td>

</tr>
</tbody>
</table>

9.11.6 Sorting by a multi-index column

You must be explicit about sorting when the column is a multi-index, and fully specify all levels to by.

\begin{verbatim}
In [342]: df1.columns = pd.MultiIndex.from_tuples([('a','one'), ('a','two'), ('b','three')])

In [343]: df1.sort_values(by=('a','two'))
\end{verbatim}

Out[343]:

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>one</td>
<td>two</td>
<td>three</td>
</tr>
<tr>
<td>0</td>
<td>2</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>4</td>
</tr>
</tbody>
</table>

9.12 Copying

The copy() method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame in-place:

- Inserting, deleting, or modifying a column.
- Assigning to the index or columns attributes.
- For homogeneous data, directly modifying the values via the values attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

9.13 dtypes

The main types stored in pandas objects are float, int, bool, datetime64[ns] and datetime64[ns, tz], timedelta[ns], category and object. In addition these dtypes have item sizes, e.g. int64 and int32. See Series with TZ for more detail on datetime64[ns, tz] dtypes.

A convenient dtypes attribute for DataFrame returns a Series with the data type of each column.
C = 'foo',
D = pd.Timestamp('20010102'),
E = pd.Series([1.0]*3).astype('float32'),
F = False,
G = pd.Series([1]*3,dtype='int8'))

In [345]: dft
Out[345]:
   A     B    C     D   E    F    G
0  0.809 1 foo 2001-01-02 1.0 False 1
1  0.128 1 foo 2001-01-02 1.0 False 1
2  0.776 1 foo 2001-01-02 1.0 False 1

In [346]: dft.dtypes
Out[346]:
A float64
B int64
C object
D datetime64[ns]
E float32
F bool
G int8
dtype: object

On a Series object, use the dtype attribute.

In [347]: dft['A'].dtype
Out[347]: dtype('float64')

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

# these ints are coerced to floats
In [348]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[348]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an object dtype
In [349]: pd.Series([1, 2, 3, 6., 'foo'])
Out[349]:
0    1
1    2
2    3
3    6
4    foo
dtype: object

The number of columns of each type in a DataFrame can be found by calling get_dtype_counts().
In [350]: dft.get_dtype_counts()
Out[350]:
float64 1
float32 1
int64 1
int8 1
datetime64[ns] 1
bool 1
object 1
dtype: int64

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the dtype keyword, a passed ndarray, or a passed Series), then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

In [351]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')
In [352]: df1
Out[352]:
     A
0  0.890400
1  0.283331
2 -0.303613
3 -1.192210
4  0.065420
5  0.455918
6  2.008328
7  0.188942

In [353]: df1.dtypes
A float32
dtype: object

In [354]: df2 = pd.DataFrame(dict( A = pd.Series(np.random.randn(8), dtype='float16'),
                          B = pd.Series(np.random.randn(8)),
                          C = pd.Series(np.array(np.random.randn(8), dtype='uint8')) ))

In [355]: df2
Out[355]:
     A       B     C
0 -0.454346  0.200071 255
1 -0.916504 -0.557756 255
2 -0.303613  1.492210 255
3 -0.149118  0.654200 255
4 -1.255918  0.455918 255
5  0.106098  0.188942 255
6  0.849045  0.916868 255
7 -0.021000 -0.949458 255

In [356]: df2.dtypes
A float16
(continues on next page)
### 9.13.1 defaults

By default integer types are `int64` and float types are `float64`, regardless of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```python
In [357]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[357]:
da  int64
dtype: object

In [358]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[358]:
a  int64
dtype: object

In [359]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
Out[359]:
a  int64
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```python
In [360]: frame = pd.DataFrame(np.array([1, 2]))
```

### 9.13.2 upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```python
In [361]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [362]: df3
Out[362]:
   A          B          C
0  0.436054  0.200071  255.0
1 -0.633173 -0.557756  255.0
2  0.337012 -0.141988   0.0
3  1.483571 -0.174060   0.0
4  0.057555  0.258626   0.0
5  0.251695  0.941688   0.0
6  1.908231 -1.849045   0.0
7 -0.213158 -0.949458   0.0

In [363]: df3.dtypes
```

(continues on next page)
The `values` attribute on a DataFrame return the *lower-common-denominator* of the dtypes, meaning the dtype that can accommodate **ALL** of the types in the resulting homogeneous dtyped NumPy array. This can force some upcasting.

```
In [364]: df3.values.dtype
Out[364]: dtype('float64')
```

### 9.13.3 astype

You can use the `astype()` method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass `copy=False` to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the `numpy` rules. If two different dtypes are involved in an operation, then the more general one will be used as the result of the operation.

```
In [365]: df3
Out[365]:
    A      B      C
0  0.436054  0.200071  255.0
1 -0.633173 -0.557756  255.0
2  0.337012 -0.141988   0.0
3  1.483571 -0.174060   0.0
4  0.057555  0.258626   0.0
5  0.251695  0.941688   0.0
6  1.908231 -1.849045   0.0
7 -0.213158 -0.949458   0.0
```

```
In [366]: df3.dtypes
Out[366]:
A    float32
B    float64
C    float64
dtype: object
```

# conversion of dtypes
```
In [367]: df3.astype('float32').dtypes
```

```
In [368]: dft = pd.DataFrame({'a': [1,2,3], 'b': [4,5,6], 'c': [7, 8, 9]})

In [369]: dft[['a','b']] = dft[['a','b']].astype(np.uint8)

In [370]: dft
```

(continues on next page)
New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```python
In [372]: dft1 = pd.DataFrame({'a': [1,0,1], 'b': [4,5,6], 'c': [7, 8, 9]})
In [373]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})
```

```
Out[374]:
   a  b  c
0   True  4  7.0
1   False  5  8.0
2   True  6  9.0
```

```python
In [375]: dft1.dtypes
```

```
˓→
a  bool
b  int64
c  float64
dtype: object
```

**Note:** When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```python
In [376]: dft = pd.DataFrame({'a': [1,2,3], 'b': [4,5,6], 'c': [7, 8, 9]})
In [377]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
```

```
Out[377]:
a  uint8
b  uint8
dtype: object
```

```python
In [378]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)
In [379]: dft.dtypes
```

```
Out[379]:
a  int64
b  int64
c  int64
```

(continues on next page)
9.13.4 object conversion

pandas offers various functions to try to force conversion of types from the object dtype to other types. In cases where the data is already of the correct type, but stored in an object array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

```
In [380]: import datetime

In [381]: df = pd.DataFrame([[1, 2],
                     ['a', 'b'],
                     [datetime.datetime(2016, 3, 2), datetime.datetime(2016, 3, 2)]])

In [382]: df = df.T

In [383]: df
Out[383]:
     0    1
0  1 a  2016-03-02
1  2 b  2016-03-02

In [384]: df.dtypes
Out[384]:
0  object
1  object
2  object
dtype: object
```

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```
In [385]: df.infer_objects().dtypes
Out[385]:
0  int64
1  object
2  datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)
  - `In [386]: m = ['1.1', 2, 3]
  - `In [387]: pd.to_numeric(m)
  - `Out [387]: array([1.1, 2.0, 3.0])`

- `to_datetime()` (conversion to datetime objects)
To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```python
In [400]: import datetime
In [401]: m = ['apple', datetime.datetime(2016, 3, 2)]
In [402]: pd.to_datetime(m, errors='ignore')
Out[402]: array([  'apple', datetime.datetime(2016, 3, 2, 0, 0)], dtype=object)
In [403]: m = ['apple', 2, 3]
In [404]: pd.to_numeric(m, errors='ignore')
Out[404]: array(['apple', 2, 3], dtype=object)
In [405]: m = ['apple', pd.Timedelta('1day')]
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:
In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of
downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```
In [407]: m = ['1', 2, 3]
In [408]: pd.to_numeric(m, downcast='integer')  # smallest signed int dtype
Out[408]: array([1, 2, 3], dtype=int8)
In [409]: pd.to_numeric(m, downcast='signed')  # same as 'integer'
Out[409]: array([1, 2, 3], dtype=int8)
In [410]: pd.to_numeric(m, downcast='unsigned')  # smallest unsigned int dtype
Out[410]: array([1, 2, 3], dtype=uint8)
In [411]: pd.to_numeric(m, downcast='float')  # smallest float dtype
Out[411]: array([ 1., 2., 3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-
dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column
efficiently:

```
In [412]: import datetime
In [413]: df = pd.DataFrame([['2016-07-09', datetime.datetime(2016, 3, 2)]] * 2, dtype='O')
In [414]: df
Out[414]:
   0     1
0 2016-07-09 2016-03-02 00:00:00
1 2016-07-09 2016-03-02 00:00:00
In [415]: df.apply(pd.to_datetime)
Out[415]:
   0     1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02
In [416]: df = pd.DataFrame([['1.1', 2, 3]] * 2, dtype='O')
In [417]: df
Out[417]:
   0     1     2
0   1.1   2.0   3.0
1   1.1   2.0   3.0
In [418]: df.apply(pd.to_numeric)
Out[418]:
   0     1     2
0   1.0   2.0   3.0
1   1.0   2.0   3.0
```

(continues on next page)
1 1.1 2 3

In [419]: df = pd.DataFrame([['5us', pd.Timedelta('1day')]] * 2, dtype='O')

In [420]: df
Out[420]:
     0         1
0  5us 1 days 00:00:00  
1  5us 1 days 00:00:00

In [421]: df.apply(pd.to_timedelta)
Out[421]:
     0         1
0 00:00:00.000005 1 days  
1 00:00:00.000005 1 days

9.13.5 gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

In [422]: dfi = df.astype('int32')

In [423]: dfi['E'] = 1

In [424]: dfi
Out[424]:
     A   B   C   E
0  0  0  255   1
1  0  0  255   1
2  2  0  0   1
3  3  1  0   1
4  0  0  0   1
5  0  0  0   1
6  1 -1  0   1
7  0  0  0   1

In [425]: dfi.dtypes
Out[425]:
     A   B   C   E
int32 int32 int32 int64
dtype: object

In [426]: casted = dfi[dfi>0]

In [427]: casted
Out[427]:
     A     B     C   E
0 NaN NaN 255.0   1
1 NaN NaN 255.0   1
2 NaN NaN  NaN   1
3 1.0 NaN NaN 1
4 NaN NaN NaN 1
5 NaN NaN NaN 1
6 1.0 NaN NaN 1
7 NaN NaN NaN 1

In [428]: casted.dtypes

Out[428]:
A float64
B float64
C float64
E int64
dtype: object

While float dtypes are unchanged.

In [429]: dfa = df3.copy()
In [430]: dfa['A'] = dfa['A'].astype('float32')
In [431]: dfa.dtypes
Out[431]:
A float32
B float64
C float64
dtype: object
In [432]: casted = dfa[df2>0]
In [433]: casted
Out[433]:
   A       B       C
0 NaN  0.200071  255.0
1 NaN   NaN  255.0
2 0.337012  NaN   NaN
3 1.483571  NaN   NaN
4 NaN  0.258626   NaN
5 NaN  0.941688   NaN
6 NaN   NaN   NaN
7 NaN   NaN   NaN
In [434]: casted.dtypes

Out[434]:
A float32
B float64
C float64
dtype: object

9.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their `dtype`. First, let's create a `DataFrame` with a slew of different dtypes:

In [435]: df = pd.DataFrame({'string': list('abc'),
                       'int64': list(range(1, 4)),
                       'uint8': np.arange(3, 6).astype('u1'),
                       'float64': np.arange(4.0, 7.0),
                       'bool1': [True, False, True],
                       'bool2': [False, True, False],
                       'dates': pd.date_range('now', periods=3).values,
                       'category': pd.Series(list('ABC')).astype('category'))

In [436]: df['tdeltas'] = df.dates.diff()

In [437]: df['uint64'] = np.arange(3, 6).astype('u8')

In [438]: df['other_dates'] = pd.date_range('20130101', periods=3).values

In [439]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [440]: df
Out[440]:
   string  int64  uint8  float64  ...  tdeltas  uint64  other_dates
   dates    tz_aware_dates
0  a       1       3       4.0  ...  NaT        3  2013-01-01
1  b       2       4       5.0  ...   1 days    4  2013-01-02
2  c       3       5       6.0  ...   1 days    5  2013-01-03

[3 rows x 12 columns]

And the dtypes:

In [441]: df.dtypes
Out[441]:
string     object
int64      int64
uint8      uint8
float64    float64
bool1      bool
bool2      bool
dates      datetime64[ns]
category   category
tdeltas    timedelta64[ns]
tz_aware_dates  datetime64[ns, US/Eastern]
int64      uint64
others     datetime64[ns]
dtype: object

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (include) and/or “give the columns without these dtypes” (exclude).

For example, to select bool columns:

In [442]: df.select_dtypes(include=[bool])
Out[442]:
   bool1  bool2
0   True  False
You can also pass the name of a dtype in the NumPy dtype hierarchy:

```python
In [443]: df.select_dtypes(include=['bool'])
Out[443]:
   bool1  bool2
0   True  False
1  False   True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```python
In [444]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[444]:
     int64  float64   bool1   bool2       tdeltas
0  1.0      4.0   True   False         NaT
1  2.0      5.0  False   True       1 days
2  3.0      6.0   True   False       1 days
```

To select string columns you must use the `object` dtype:

```python
In [445]: df.select_dtypes(include=['object'])
Out[445]:
    string
0    a
1    b
2    c
```

To see all the child dtypes of a generic `dtype` like `numpy.number` you can define a function that returns a tree of child dtypes:

```python
In [446]: def subdtypes(dtype):
       ....:     subs = dtype.__subclasses__()
       ....:     if not subs:
       ....:         return dtype
       ....:     return [dtype, [subdtypes(dt) for dt in subs]]
```

All NumPy dtypes are subclasses of `numpy.generic`:

```python
In [447]: subdtypes(np.generic)
Out[447]:
[numpy.generic,
 [[numpy.number,
   [[numpy.integer,
     [[numpy.signedinteger,
       [numpy.int8,
         numpy.int16,
         numpy.int32,
         numpy.int64,
         numpy.int64,
         numpy.timedelta64]],
     [numpy.unsignedinteger,
      [numpy.timedelta64]]]]]]
```
[numpy.uint8,  
numpy.uint16,  
numpy.uint32,  
numpy.uint64,  
numpy.uint64]],  
[numpy.inexact,  
[[numpy.float32, numpy.float64, numpy.float128]],  
[numpy.complex64, numpy.complex128, numpy.complex256]],  
numpy.flexible,  
[[numpy.character, [numpy.bytes_, numpy.str_]],  
[numpy.bool_]],  
numpy.datetime64,  
numpy.object_]]

Note: Pandas also defines the types category and datetime64[ns, tz], which are not integrated into the normal NumPy hierarchy and won’t show up with the above function.
Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])

In [2]: s.str.lower()
Out[2]:
0    a
1    b
2    c
3   aaba
4   baca
5   NaN
6    caba
7    dog
8    cat
dtype: object

In [3]: s.str.upper()
Out[3]:
0    A
1    B
2    C
3   AABA
4   BACA
5   NaN
6    CABA
7    DOG
8    CAT
dtype: object

In [4]: s.str.len()
Out[4]:
0    1.0
1    1.0
2    1.0
3    4.0
4    4.0
5    NaN
6    4.0
7    3.0
```
The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(randn(3, 2), columns=[' Column A ', ' Column B '],
                      index=range(3))
In [10]: df
```

```
     Column A     Column B
   0 -1.425575 -1.336299
   1  0.740933  1.032121
   2 -1.585660  0.913812
```

Since `df.columns` is an Index object, we can use the `.str` accessor

```
In [11]: df.columns.str.strip()
Out[11]: Index([' Column A ', ' Column B '], dtype='object')
In [12]: df.columns.str.lower()
```

```
     column_a     column_b
   0 -1.425575 -1.336299
   1  0.740933  1.032121
   2 -1.585660  0.913812
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lowercasing all names, and replacing any remaining whitespaces with underscores:

```
In [13]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')
In [14]: df
```

```
   column_a     column_b
   0 -1.425575 -1.336299
   1  0.740933  1.032121
   2 -1.585660  0.913812
```

Note: If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the .categories and not on
each element of the Series.

Please note that a Series of type category with string .categories has some limitations in comparison of Series of type string (e.g. you can’t add strings to each other: s + " " + s won’t work if s is a Series of type category). Also, .str methods which operate on elements of type list are not available on such a Series.

## 10.1 Splitting and Replacing Strings

Methods like split return a Series of lists:

```
In [15]: s2 = pd.Series(["a_b_c", 'c_d_e', np.nan, 'f_g_h'])

In [16]: s2.str.split('_')
Out[16]:
          0        1
0        a    b    c
1        c    d    e
2         NaN
3        f    g    h
```

Elements in the split lists can be accessed using get or [] notation:

```
In [17]: s2.str.split('_').str.get(1)
Out[17]:
0    b
1    d
2   NaN
3    g
```

```
In [18]: s2.str.split('_')[1]
Out[18]:
0    b
1    d
2   NaN
3    g
```

It is easy to expand this to return a DataFrame using expand.

```
In [19]: s2.str.split('_', expand=True)
Out[19]:
     0  1  2
0  a  b  c
1  c  d  e
2   NaN NaN NaN
3  f  g  h
```

It is also possible to limit the number of splits:

```
In [20]: s2.str.split('_', expand=True, n=1)
Out[20]:
     0  1
0  a  b_c
1  c  d_e
```

(continues on next page)
rsplit is similar to split except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```python
In [21]: s2.str.rsplit('_', expand=True, n=1)
Out[21]:
   0  1
0  a_b  c
1  c_d  e
2  NaN NaN
3  f_g  h
```

replace by default replaces regular expressions:

```python
In [22]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
                     '', np.nan, 'CABA', 'dog', 'cat'])
In [23]: s3
Out[23]:
0    A
1    B
2    C
3  Aaba
4  Baca
5    
6  NaN
7  CABA
8    dog
9    cat
dtype: object
In [24]: s3.str.replace('^\.|dog', 'XX-XX ', case=False)
```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of $:

```python
# Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])
# This does what you'd naively expect:
```
In [26]: dollars.str.replace('$', '')
Out[26]:
0  12
1 -10
2 10,000
dtype: object

# But this doesn't:
In [27]: dollars.str.replace('-$', '-')
Out[27]:
0  12
1 -$10
2 $10,000
dtype: object

# We need to escape the special character (for >1 len patterns)
In [28]: dollars.str.replace(r'-$', '-')
Out[28]:
0  12
1 -10
2 $10,000
dtype: object

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

# These lines are equivalent
In [29]: dollars.str.replace(r'-\$', '-')
Out[29]:
0  12
1 -10
2 $10,000
dtype: object
In [30]: dollars.str.replace('-\$', '-', regex=False)
Out[30]:
0  12
1 -10
2 $10,000
dtype: object

New in version 0.20.0.

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

# Reverse every lowercase alphabetic word
In [31]: pat = r'[a-z]+'
In [32]: repl = lambda m: m.group(0)[::-1]
In [33]: pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(pat, repl)
Out[33]:
0  oof 123

(continues on next page)
# Using regex groups

```
In [34]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [35]: repl = lambda m: m.group('two').swapcase()

In [36]: pd.Series(['Foo Bar Baz', np.nan]).str.replace(pat, repl)
Out[36]:
0  bAR
1  NaN
```

New in version 0.20.0.

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```
In [37]: import re

In [38]: regex_pat = re.compile(r'^.a|dog', flags=re.IGNORECASE)

In [39]: s3.str.replace(regex_pat, 'XX-XX ')
Out[39]:
0  A
1  B
2  C
3  XX-XX ba
4  XX-XX ca
5  NaN
6  XX-XX BA
7  XX-XX
8  XX-XX t
```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```
In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
---------------------------------------------------------------------------
ValueError: case and flags cannot be set when pat is a compiled regex
```

## 10.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

### 10.2.1 Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])

In [42]: s.str.cat(sep=',')
Out[42]: 'a,b,c,d'

If not specified, the keyword sep for the separator defaults to the empty string, sep='':

In [43]: s.str.cat()
Out[43]: 'abcd'

By default, missing values are ignored. Using na_rep, they can be given a representation:

In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])

In [45]: t.str.cat(sep=',')
Out[45]: 'a,b,d'

In [46]: t.str.cat(sep=',', na_rep='-')
Out[46]: 'a,b,-,d'

10.2.2 Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling Series (or Index).

In [47]: s.str.cat(['A', 'B', 'C', 'D'])
Out[47]:
0  aA
1  bB
2  cC
3  dD
dtype: object

Missing values on either side will result in missing values in the result as well, unless na_rep is specified:

In [48]: s.str.cat(t)
Out[48]:
0  aa
1  bb
2  NaN
3  dd
dtype: object

In [49]: s.str.cat(t, na_rep='-')
Out[49]:
0  aa
1  bb
2  c-
3  dd
dtype: object

10.2.3 Concatenating a Series and something array-like into a Series

New in version 0.23.0.
The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling `Series` (or `Index`).

```python
In [50]: d = pd.concat([t, s], axis=1)
In [51]: s
Out[51]:
0  a
1  b
2  c
3  d
dtype: object
In [52]: d
Out[52]:
     0 1
0  a a
1  b b
2  NaN c
3  d d
```

In [53]: s.str.cat(d, na_rep='--')

```
0  a a
1  b b
2  -- c
3  d d
```

### 10.2.4 Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a `Series` or `DataFrame`, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```python
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])
In [55]: s
Out[55]:
0  a
1  b
2  c
3  d
dtype: object
In [56]: u
Out[56]:
1  b
3  d
0  a
2  c
dtype: object
In [57]: s.str.cat(u)

```

(continues on next page)
Warning: If the join keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [59]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4])

In [60]: s
Out[60]:
 0  a
 1  b
 2  c
 3  d
dtype: object

In [61]: v
Out[61]:
   -1  z
    0  a
    1  b
    3  d
    4  e
dtype: object

In [62]: s.str.cat(v, join='left', na_rep='-')
   →
    0  aa
    1  bb
    2  c-
    3  dd
dtype: object

In [63]: s.str.cat(v, join='outer', na_rep='-')
   →
     -1  -z
```
The same alignment can be used when `others` is a DataFrame:

```python
In [64]: f = d.loc[[3, 2, 1, 0], :]
In [65]: s
Out[65]:
   0  a
   1  b
   2  c
   3  d
   dtype: object
In [66]: f
Out[66]:
   0  1
   3  NaN
   2  c
   1  b
   0  a
   dtype: object
In [67]: s.str.cat(f, join='left', na_rep='-')
   →
   0  aaa
   1  bbb
   2  c-c
   3  ddd
   dtype: object
```

### 10.2.5 Concatenating a Series and many objects into a Series

All one-dimensional list-likes can be arbitrarily combined in a list-like container (including iterators, dict-views, etc.):

```python
In [68]: s
Out[68]:
   0  a
   1  b
   2  c
   3  d
   dtype: object
In [69]: u
Out[69]:
   1  b
   3  d
   0  a
   2  c
   dtype: object
```
All elements must match in length to the calling Series (or Index), except those having an index if join is not None:

```python
In [71]: v
Out[71]:
-1  z
  0  a
  1  b
  3  d
  4  e
dtype: object
```

```
In [72]: s.str.cat([u, v, ['A', 'B', 'C', 'D']], join='outer', na_rep='--')
```

```plaintext
-1 --z--
 0 aaaA
 1 bbbB
 2 cc-C
 3 dddD
 4 --e--
dtype: object
```

If using join='right' on a list of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:

```python
In [73]: u.loc[[3]]
Out[73]:
3  d
dtype: object
```

```python
In [74]: v.loc[[-1, 0]]
Out[74]:
-1  z
 0  a
dtype: object
```

```
In [75]: s.str.cat([u.loc[[3]], v.loc[[-1, 0]], join='right', na_rep='--')
```

```plaintext
-1 --z--
 0 a-a
 3 d- d
dtype: object
```

10.3 Indexing with .str

You can use [ ] notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
.....:   
In [77]: s.str[0]
Out[77]:
0   A
1   B
2   C
3   A
4   B
5   NaN
6   C
7   d
8   c
dtype: object

In [78]: s.str[1]
Out[78]:
0   NaN
1   NaN
2   NaN
3   a
4   a
5   NaN
6   A
7   o
8   a
dtype: object

10.4 Extracting Substrings

10.4.1 Extract first match in each subject (extract)

Warning: In version 0.18.0, extract gained the expand argument. When expand=False it returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When expand=True it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user. expand=True is the default since version 0.23.0.

The extract method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a DataFrame with one column per group.

In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract('([^ab])', expand=False)
Out[79]:
0   1
(continues on next page)
Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract('(?P<letter>[ab])(?P<digit>\d)', expand=False)
```

```
Out[80]:
   letter  digit
0     a     1
1     b     2
2    NaN    NaN
```

and optional groups like

```
In [81]: pd.Series(['a1', 'b2', '3']).str.extract('(?P<letter>[ab])?(?P<digit>\d)', expand=False)
```

```
Out[81]:
      0   1
0     a     1
1     b     2
2  NaN     3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if `expand=True`.

```
In [82]: pd.Series(['a1', 'b2', 'c3']).str.extract('(?P<letter>[ab])(?P<digit>\d)', expand=True)
```

```
Out[82]:
      0
0     1
1     2
2    NaN
```

It returns a Series if `expand=False`.

```
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract('(?P<letter>[ab])(?P<digit>\d)', expand=False)
```

```
Out[83]:
      0
0     1
1     2
2    NaN
dtype: object
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if `expand=True`.

```
In [84]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'])
In [85]: s
Out[85]:
     A11
0    a1
```

(continues on next page)
B22  b2
C33  c3
dtype: object

In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[86]:

<table>
<thead>
<tr>
<th>letter</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
</tbody>
</table>

It returns an Index if expand=False.

In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[87]: Index(['A', 'B', 'C'], dtype='object', name='letter')

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.

In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[88]:

<table>
<thead>
<tr>
<th>letter</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A 11</td>
</tr>
<tr>
<td>1</td>
<td>B 22</td>
</tr>
<tr>
<td>2</td>
<td>C 33</td>
</tr>
</tbody>
</table>

It raises ValueError if expand=False.

```python
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

The table below summarizes the behavior of extract (expand=False) (input subject in first column, number of groups in regex in first row)

<table>
<thead>
<tr>
<th></th>
<th>1 group</th>
<th>&gt;1 group</th>
</tr>
</thead>
<tbody>
<tr>
<td>Index</td>
<td>Index</td>
<td>ValueError</td>
</tr>
<tr>
<td>Series</td>
<td>Series</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

### 10.4.2 Extract all matches in each subject (extractall)

New in version 0.18.0.

Unlike extract (which returns only the first match),

```python
In [89]: s = pd.Series(["ala2", "b1", "c1"], index=["A", "B", "C"])
In [90]: s
Out[90]:
A  ala2
B  b1
C  c1
dtype: object
```

```python
In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'
```
the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```
In [93]: s.str.extractall(two_groups)
Out[93]:
    letter digit  match
  A    a 1       0
  1    a 2       1
  B    b 1       0
  C    c 1       0
```

When each subject string in the Series has exactly one match,

```
In [94]: s = pd.Series(['a3', 'b3', 'c2'])
In [95]: s
Out[95]:
0    a3
1    b3
2    c2
dtype: object
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [96]: extract_result = s.str.extract(two_groups, expand=True)
In [97]: extract_result
Out[97]:
    letter digit
  0    a  3
  1    b  3
  2    c  2
In [98]: extractall_result = s.str.extractall(two_groups)
In [99]: extractall_result
Out[99]:
    letter digit  match
  0    a  3       0
  1    b  3       0
  2    c  2       0
```

```
In [100]: extractall_result.xs(0, level="match")
    letter digit
```

(continues on next page)
Index also supports `.str.extractall`. It returns a DataFrame which has the same result as a Series.str.extractall with a default index (starts from 0).

New in version 0.19.0.

```
In [101]: pd.Index(['a1a2', 'b1', 'c1']).str.extractall(two_groups)
Out[101]:
   letter digit
0    a    1
1    a    2
1    b    1
2    c    1
```

```
In [102]: pd.Series(['a1a2', 'b1', 'c1']).str.extractall(two_groups)
```

```
   letter digit
0    a    1
1    a    2
1    b    1
2    c    1
```

## 10.5 Testing for Strings that Match or Contain a Pattern

You can check whether elements contain a pattern:

```
In [103]: pattern = r'[0-9][a-z]'

In [104]: pd.Series(['1', '2', '3a', '3b', '03c']).str.contains(pattern)
Out[104]:
0   False
1   False
2    True
3    True
4    True
dtype: bool
```

Or whether elements match a pattern:

```
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
Out[105]:
0   False
1   False
2    True
3    True
4   False
dtype: bool
```
The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered True or False:

```python
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [107]: s4.str.contains('A', na=False)
Out[107]:
0   True
1  False
2  False
3   True
4  False
5   True
6  False
7  False
8  False
dtype: bool
```

### 10.6 Creating Indicator Variables

You can extract dummy variables from string columns. For example if they are separated by a ' | ':

```python
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])
In [109]: s.str.get_dummies(sep='|')
```

String Index also supports `get_dummies` which returns a MultiIndex.

New in version 0.18.1.

```python
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])
In [111]: idx.str.get_dummies(sep='|')
```

See also `get_dummies()`.

### 10.7 Method Summary
<table>

11.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. display.max_rows). You can get/set options directly as attributes of the top-level options attribute:

```python
In [1]: import pandas as pd
In [2]: pd.options.display.max_rows
Out[2]: 15
In [3]: pd.options.display.max_rows = 999
In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the pandas namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

Note: Developers can check out pandas/core/config.py for more information.

All of the functions above accept a regexp pattern (re.search style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```python
In [5]: pd.get_option("display.max_rows")
Out[5]: 999
In [6]: pd.set_option("display.max_rows",101)
In [7]: pd.get_option("display.max_rows")
Out[7]: 101
In [8]: pd.set_option("max_r",102)
In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```
The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```python
In [10]: try:
   ....:     pd.get_option("column")
   ....:     except KeyError as e:
   ....:         print(e)
   ....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

### 11.2 Getting and Setting Options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```python
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

**Note:** The option ‘mode.sim_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```python
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It’s also possible to reset multiple options at once (using a regex):

```python
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the `with` block:

```python
In [20]: with pd.option_context("display.max_rows", 10,"display.max_columns", 5):
   ....:     print(pd.get_option("display.max_rows"))
   ....:     print(pd.get_option("display.max_columns"))
```

(continues on next page)
11.3 Setting Startup Options in python/ipython Environment

Using startup scripts for the python/ipython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the ipython documentation. An example startup script for pandas is displayed below:

```python
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

11.4 Frequently Used Options

The following is a walkthrough of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7,2))
In [24]: pd.set_option('max_rows', 7)
In [25]: df
Out[25]:
     0   1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771
In [26]: pd.set_option('max_rows', 5)
In [27]: df
```

(continues on next page)
0 1
0 0.469112 -0.282863
1 -1.509059 -1.135632
... ...
5 -0.494929 1.071804
6 0.721555 -0.706771
[7 rows x 2 columns]

In [28]: pd.reset_option('max_rows')

display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

In [29]: df = pd.DataFrame(np.random.randn(5,10))

In [30]: pd.set_option('expand_frame_repr', True)

In [31]: df

In [54]: pd.reset_option('max_info_columns')

display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller dimensions then specified. Note that you can specify the option df.info(null_counts=True) to override on showing a particular frame.

11.5 Available Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Default</th>
<th>Function</th>
</tr>
</thead>
</table>
| display.chop_threshold  | None    | If set to a float value, all float values smaller then the given threshold will be displayed as exactly 0.
| display.colheader_justify | right  | Controls the justification of column headers. used by DataFrameFormatter.  |
| display.column_space    | 12      | No description available.                                                |
| display.date_dayfirst   | False   | When True, prints and parses dates with the day first, eg 20/01/2005     |
| display.date_yearfirst  | False   | When True, prints and parses dates with the year first, eg 2005/01/20    |
| display.encoding        | UTF-8   | Defaults to the detected encoding of the console. Specifies the encoding to be used. |
| display.expand_frame_repr | True   | Whether to print out the full DataFrame repr for wide DataFrames across multiple lines. |
| display.float_format    | None    | The callable should accept a floating point number and return a string with the desired format.
| display.large_repr      | truncate| For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can become very wide. |
| display.latex.repr      | False   | Whether to produce a latex DataFrame representation for jupyter frontends that support it. |
| display.latex.escape    | True    | Escapes special characters in DataFrames, when using the to_latex method. |
| display.latex.longtable | False   | Specifies if the to_latex method of a DataFrame uses the longtable format. |
| display.latex.multicolumn | True  | Combines columns when using a MultiIndex. |
| display.latex.multicolumn_format | 'l'   | Alignment of multicoloumn labels. |
| display.latex.multirow  | False   | Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by a line. |
| display.max_columns     | 0 or 20 | max_rows and max_columns are used in __repr__() methods to decide if to_string() or info() is used to render an object to a string. |
| display.max_colwidth    | 50      | The maximum width in characters of a column in the repr of a pandas data structure. |
pandas: powerful Python data analysis toolkit, Release 0.23.2

<td>Use the numexpr library to accelerate computation if it is installed.</td>
</tr>
<tr>
<td><code>plotting.matplotlib.register_converters</code></td>
<td>True</td>
<td>Register custom converters with matplotlib. Set to False to de-register.</td>
</tr>
</tbody>
</table>

11.6 Number Formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```python
In [79]: import numpy as np

In [80]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [81]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [82]: s/1.e3
Out[82]:
   a   -236.866u
   b    846.974u
   c   -685.597u
   d    609.099u
   e   -303.961u
dtype: float64
```

(continues on next page)
To round floats on a case-by-case basis, you can also use `round()` and `round()`.  

### 11.7 Unicode Formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```
In [84]: df = pd.DataFrame({u'': ['UK', u''], u'': ['Alice', u'']})
```

```
In [85]: df;
```

```
Out[85]

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'名前'</td>
<td>'国籍'</td>
</tr>
<tr>
<td>Alice</td>
<td>UK</td>
</tr>
<tr>
<td>1</td>
<td>しのぶ</td>
</tr>
</tbody>
</table>
```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [86]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [87]: df;
```

```
Out[87]

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>'名前'</td>
<td>'国籍'</td>
</tr>
<tr>
<td>Alice</td>
<td>UK</td>
</tr>
<tr>
<td>1</td>
<td>しのぶ</td>
</tr>
</tbody>
</table>
```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.
By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```python
In [88]: df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
In [89]: df;
```

```python
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
In [91]: df;
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.) However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```python
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
In [91]: df;
```

11.8 Table Schema Display

New in version 0.20.0.

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```python
In [92]: pd.set_option('display.html.table_schema', True)
```

Only ‘display.max_rows’ are serialized and published.
INDEXING AND SELECTING DATA

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides metadata) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

**Note:** The Python and NumPy indexing operators [] and attribute operator . provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see here.

See the MultiIndex / Advanced Indexing for MultiIndex and more advanced indexing documentation.

See the cookbook for some advanced strategies.

### 12.1 Different Choices for Indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- .loc is primarily label based, but may also be used with a boolean array. .loc will raise KeyError when the items are not found. Allowed inputs are:
A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).

- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See Slicing with labels.).
- A boolean array
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at Selection by Label.

• .iloc is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. .iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy slice semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array.
  - A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at Selection by Position, Advanced Indexing and Advanced Hierarchical.

• .loc, .iloc, and also [] indexing can accept a callable as indexer. See more at Selection By Callable.

Getting values from an object with multi-axes selection uses the following notation (using .loc as an example, but the following applies to .iloc as well). Any of the axes accessors may be the null slice :. Axes left out of the specification are assumed to be :.e.g. p.loc['a'] is equivalent to p.loc['a', :, :].

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Indexers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>s.loc[indexer]</td>
</tr>
<tr>
<td>DataFrame</td>
<td>df.loc[row_indexer, column_indexer]</td>
</tr>
<tr>
<td>Panel</td>
<td>p.loc[item_indexer, major_indexer, minor_indexer]</td>
</tr>
</tbody>
</table>

### 12.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. __getitem__ for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>series[label]</td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td>frame[colname]</td>
<td>Series corresponding to colname</td>
</tr>
<tr>
<td>Panel</td>
<td>panel[itemname]</td>
<td>DataFrame corresponding to the itemname</td>
</tr>
</tbody>
</table>
Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4), index=dates, columns=['A', 'B', 'C', 'D'])
In [3]: df
Out[3]:
        A          B          C          D
2000-01-01  0.469112  -0.282863  -1.509059  -1.135632
2000-01-02  1.212112   0.173215   0.119209  -1.044236
2000-01-03  -0.861849  -2.104569  -0.494929   1.071804
2000-01-04   0.721555  -0.706771  -1.039575   0.271860
2000-01-05  -0.424972   0.567020   0.276232  -1.087401
2000-01-06  -0.673690   0.113648  -1.478427   0.524988
2000-01-07   0.404705   0.577046   1.715002  -1.039268
2000-01-08  -0.370647  -1.157892  -1.344312   0.844885
```

```python
In [4]: panel = pd.Panel({'one' : df, 'two' : df - df.mean()})
In [5]: panel
Out[5]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 8 (major_axis) x 4 (minor_axis)
Items axis: one to two
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-08 00:00:00
Minor_axis axis: A to D
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```python
In [6]: s = df['A']
In [7]: s[dates[5]]
Out[7]: -0.67368970808837059
```

```python
In [8]: panel['two']
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```python
In [9]: df
Out[9]:
        A          B          C          D
2000-01-01  0.409571   0.113086  -0.610826  -0.936507
2000-01-02   1.152571   0.227235   0.107442  -0.845111
2000-01-03  -0.921390  -1.708620   0.403304   1.270929
2000-01-04   0.662014  -0.310822  -0.141342   0.470985
2000-01-05  -0.484513   0.962970   1.174465  -0.888276
2000-01-06  -0.733231   0.509598  -0.580194   0.724113
2000-01-07   0.345164   0.972995  -0.816769  -0.840143
2000-01-08  -0.430188  -0.761943  -0.446079   1.044010
```

(continues on next page)
In [10]: df[['B', 'A']] = df[['A', 'B']]  

In [11]: df
Out[11]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.282863</td>
<td>0.469112</td>
<td>-1.509059</td>
<td>-1.135632</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.173215</td>
<td>1.212112</td>
<td>0.119209</td>
<td>-1.044236</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-2.104569</td>
<td>-0.861849</td>
<td>-0.494929</td>
<td>1.071804</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.706771</td>
<td>0.721555</td>
<td>0.271860</td>
<td>-1.087401</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.567020</td>
<td>-0.424972</td>
<td>0.276232</td>
<td>-1.478427</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.113648</td>
<td>-0.673690</td>
<td>-0.706771</td>
<td>0.524988</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.577046</td>
<td>-0.370647</td>
<td>-1.715002</td>
<td>-1.344312</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>-1.157892</td>
<td>0.404705</td>
<td>-1.344312</td>
<td>0.844885</td>
</tr>
</tbody>
</table>

You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting Series and DataFrame from .loc, and .iloc.  
This will **not** modify df because the column alignment is before value assignment.

In [12]: df[['A', 'B']]  

Out[12]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.282863</td>
<td>0.469112</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.173215</td>
<td>1.212112</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-2.104569</td>

<td>-0.706771</td>
<td>0.721555</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.567020</td>
<td>-0.424972</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.113648</td>
<td>-0.673690</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.577046</td>
<td>-0.370647</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>-1.157892</td>
<td>0.404705</td>
</tr>
</tbody>
</table>

In [13]: df.loc[:,['B', 'A']] = df[['A', 'B']]  

In [14]: df[['A', 'B']]  

Out[14]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.282863</td>
<td>0.469112</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.173215</td>
<td>1.212112</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-2.104569</td>
<td>-0.861849</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.706771</td>
<td>0.721555</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.567020</td>
<td>-0.424972</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.113648</td>
<td>-0.673690</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.577046</td>
<td>-0.370647</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>-1.157892</td>
<td>0.404705</td>
</tr>
</tbody>
</table>

The correct way to swap column values is by using raw values:
In [15]: df.loc[:,['B', 'A']] = df[['A', 'B']].values

In [16]: df[['A', 'B']]
Out[16]:
          A          B
2000-01-01  0.469112 -0.282863
2000-01-02  1.212112 -0.173215
2000-01-03 -0.861849 -2.104569
2000-01-04  0.721555 -0.706771
2000-01-05 -0.424972  0.567020
2000-01-06 -0.673690  0.113648
2000-01-07  0.404705  0.577046
2000-01-08 -0.370647 -1.157892

12.3 Attribute Access

You may access an index on a Series, column on a DataFrame, and an item on a Panel directly as an attribute:

In [17]: sa = pd.Series([1,2,3],index=list('abc'))

In [18]: dfa = df.copy()

In [19]: sa.b
Out[19]:
2

In [20]: dfa.A
Out[20]:
          A
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03 -0.861849
2000-01-04  0.721555
2000-01-05 -0.424972
2000-01-06 -0.673690
2000-01-07  0.404705
2000-01-08 -0.370647
Freq: D, Name: A, dtype: float64

In [21]: panel.one

In [22]: sa.a = 5

In [23]: sa
Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. s.1 is not allowed. See here for an explanation of valid identifiers.
- The attribute will not be available if it conflicts with an existing method name, e.g. s.min is not allowed.
- Similarly, the attribute will not be available if it conflicts with any of the following list: index, major_axis, minor_axis, items.
- In any of these cases, standard indexing will still work, e.g. s['1'], s['min'], and s['index'] will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

```
In [28]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})
In [29]: x.iloc[1] = dict(x=9, y=99)
```
You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```python
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In[2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In[3]: df
Out[3]:
one
0 1.0
1 2.0
2 3.0
```

## 12.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the *Selection by Position* section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an ndarray, returning a slice of the values and the corresponding labels:

```python
In[31]: s[:5]
Out[31]:
2000-01-01 0.469112
2000-01-02 1.212112
2000-01-03 -0.861849
2000-01-04 0.721555
2000-01-05 -0.424972
Freq: D, Name: A, dtype: float64
```

```python
In[32]: s[::2]
   →
2000-01-01 0.469112
2000-01-03 -0.861849
2000-01-05 -0.424972
Freq: 2D, Name: A, dtype: float64
```

```python
In[33]: s[::-1]
   →
2000-01-08 -0.370647
2000-01-07 0.404705
2000-01-06 -0.673690
2000-01-05 -0.424972
```

(continues on next page)
Note that setting works as well:

```
In [34]: s2 = s.copy()
In [35]: s2[:5] = 0
In [36]: s2
Out[36]:
2000-01-01 0.000000
2000-01-02 0.000000
2000-01-03 0.000000
2000-01-04 0.000000
2000-01-05 0.000000
2000-01-06 -0.673690
2000-01-07 0.404705
2000-01-08 -0.370647
Freq: D, Name: A, dtype: float64
```

With DataFrame, slicing inside of [] slices the rows. This is provided largely as a convenience since it is such a common operation.

```
In [37]: df[:3]
Out[37]:
   A      B      C      D
2000-01-01 0.469112 -0.282863 -1.509059 -1.135632
2000-01-02 1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [38]: df[::-1]
```

```
   A      B      C      D
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
```

### 12.5 Selection By Label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy.*
pandas: powerful Python data analysis toolkit, Release 0.23.2

Warning:
.loc is strict when you present slicers that are not compatible (or convertible) with the index type.
For example using integers in a DatetimeIndex. These will raise a TypeError.

```
In [39]: df1 = pd.DataFrame(np.random.randn(5,4), columns=list('ABCD'), index=pd.date_range('20130101',periods=5))
In [40]: df1.loc[2:3]
```

TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with these indexers [2] of <type 'int'>

String likes in slicing can be convertible to the type of the index and lead to natural slicing.

```
In [41]: df1.loc['20130102':'20130104']
```

```
A   B   C   D
2013-01-02 0.357021 -0.674600 -1.776904 -0.968914
2013-01-03 -1.294524  0.413738  0.276662 -0.472035
2013-01-04 -0.013960 -0.362543 -0.006154 -0.923061
```

Warning: Starting in 0.21.0, pandas will show a FutureWarning if indexing with a list with missing labels. In the future this will raise a KeyError. See list-like Using loc with missing keys in a list is Deprecated.

pandas provides a suite of methods in order to have purely label based indexing. This is a strict inclusion based protocol. Every label asked for must be in the index, or a KeyError will be raised. When slicing, both the start bound AND the stop bound are included, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The .loc attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See Slicing with labels.).
- A boolean array.
- A callable, see Selection By Callable.

```
In [42]: s1 = pd.Series(np.random.randn(6),index=list('abcdef'))
In [43]: s1
```

```
a  1.431256
```

(continues on next page)
b 1.340309
c -1.170299
d -0.226169
e 0.410835
f 0.813850
dtype: float64

In [44]: s1.loc['c':]
   →
c -1.170299
d -0.226169
e 0.410835
f 0.813850
dtype: float64

In [45]: s1.loc['b']
   →
1.3403088497993827

Note that setting works as well:

In [46]: s1.loc['c'] = 0

In [47]: s1
Out[47]:
a 1.431256
b 1.340309
c 0.000000
d 0.000000
e 0.000000
f 0.000000
dtype: float64

With a DataFrame:

In [48]: df1 = pd.DataFrame(np.random.randn(6,4),
                         index=list('abcdef'),
                         columns=list('ABCD'))

In [49]: df1
Out[49]:
   A      B      C      D
a 0.132003 -0.827317 -0.076467 -1.187678
b 1.130127 -1.436737 -1.413681  1.607920
c 1.024180  0.569605  0.875906 -2.211372
d 0.974466 -2.006747 -0.410001  0.078638
e 0.545952 -1.219217 -1.226825  0.769804
f -1.281247 -0.727707 -0.121306 -0.097883

In [50]: df1.loc[['a', 'b', 'd'], :]
   →
      A      B      C      D
a 0.132003 -0.827317 -0.076467 -1.187678
b 1.130127 -1.436737 -1.413681  1.607920

Accessing via label slices:

```
In [51]: df1.loc['d':, 'A':'C']
Out[51]:
A   B   C
d  0.974466 -2.006747 -0.410001
e  0.545952 -1.219217 -1.226825
f -1.281247 -0.727707  0.121306
```

For getting a cross section using a label (equivalent to `df.xs('a')`):

```
In [52]: df1.loc['a']
Out[52]:
A   0.132003
B  -0.827317
C  -0.076467
D  -1.187678
Name: a, dtype: float64
```

For getting values with a boolean array:

```
In [53]: df1.loc['a'] > 0
Out[53]:
A   True
B   False
C   False
D   False
Name: a, dtype: bool
```

```
In [54]: df1.loc[:, df1.loc['a'] > 0]
```

For getting a value explicitly (equivalent to deprecated `df.get_value('a','A')`):

```
# this is also equivalent to ```df1.at['a','A']```
In [55]: df1.loc['a', 'A']
Out[55]: 0.13200317033032932
```

### 12.5.1 Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [56]: s = pd.Series(list('abcde'), index=[0,3,2,5,4])
In [57]: s.loc[3:5]
```

---

**12.5. Selection By Label**

---
If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which rank between the two:

```
In [58]: s.sort_index()
Out[58]:
0  a
1  c
2  b
3  e
4  d
dtype: object
```

```
In [59]: s.sort_index().loc[1:6]
Out[59]:
2  c
3  b
4  e
5  d
dtype: object
```

However, if at least one of the two is absent and the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

### 12.6 Selection By Position

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called *chained assignment* and should be avoided. See *Returning a View versus Copy*.

Pandas provides a suite of methods in order to get purely integer based indexing. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bounds is included, while the upper bound is excluded. Trying to use a non-integer, even a valid label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers `[4, 3, 0]`.
- A slice object with ints `1:7`.
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [60]: s1 = pd.Series(np.random.randn(5), index=list(range(0,10,2)))
In [61]: s1
```
Out[61]:
0   0.695775
2   0.341734
4   0.959726
6  -1.110336
8  -0.619976
dtype: float64

In [62]: s1.iloc[:3]
Out[62]:
0   0.695775
2   0.341734
4   0.959726
dtype: float64

In [63]: s1.iloc[3]
→ -1.1103361028911669

Note that setting works as well:

In [64]: s1.iloc[3] = 0

In [65]: s1
Out[65]:
0   0.000000
2   0.000000
4   0.000000
6  -1.110336
8  -0.619976
dtype: float64

With a DataFrame:

In [66]: df1 = pd.DataFrame(np.random.randn(6,4),
    index=list(range(0,12,2)),
    columns=list(range(0,8,2)))

In [67]: df1
Out[67]:
     0   2   4   6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
6 -0.826591 -0.345352  1.314232  0.690579
8  0.995761  2.396780  0.014871  3.357427
10 -0.317441 -1.236269  0.896171 -0.487602

Select via integer slicing:

In [68]: df1.iloc[:3]
Out[68]:
     0   2   4   6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161

(continues on next page)
4 -1.369849 -0.954208 1.462696 -1.743161

**In [69]:** df1.iloc[1:5, 2:4]

<table>
<thead>
<tr>
<th></th>

</tr>
<tr>
<td>8</td>
<td>2.396780</td>
<td>0.014871</td>
</tr>
<tr>
<td>10</td>
<td>-1.236269</td>
<td>0.896171</td>
</tr>
</tbody>
</table>

# this is also equivalent to `df1.iat[1,1]`

**In [73]:** df1.iloc[1, 1]

<table>
<thead>
<tr>
<th></th>
<th>2</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.732339</td>
<td>0.687738</td>
</tr>
<tr>
<td>2</td>
<td>-0.154951</td>
<td>0.301624</td>
</tr>
<tr>
<td>4</td>
<td>-0.954208</td>
<td>1.462696</td>
</tr>
<tr>
<td>6</td>
<td>-0.345352</td>
<td>1.314232</td>
</tr>
<tr>
<td>8</td>
<td>2.396780</td>
<td>0.014871</td>
</tr>
<tr>
<td>10</td>
<td>-1.236269</td>
<td>0.896171</td>
</tr>
</tbody>
</table>

For getting a cross section using an integer position (equiv to df.xs(1)):

**In [74]:** df1.iloc[1]

<table>
<thead>
<tr>
<th></th>
<th>2</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.403310</td>
<td>0.687738</td>
</tr>
<tr>
<td>2</td>
<td>-0.154951</td>
<td>0.301624</td>
</tr>
<tr>
<td>4</td>
<td>0.301624</td>
<td>1.462696</td>
</tr>
<tr>
<td>6</td>
<td>2.179861</td>
<td>0.014871</td>
</tr>
</tbody>
</table>

Out of range slice indexes are handled gracefully just as in Python/Numpy.

# these are allowed in python/numpy.

**In [75]:** x = list('abcdef')
```python
In [76]: x
Out[76]: ['a', 'b', 'c', 'd', 'e', 'f']

In [77]: x[4:10]
Out[77]: ['e', 'f']

In [78]: x[8:10]
Out[78]: []

In [79]: s = pd.Series(x)

In [80]: s
Out[80]:
   0 a
   1 b
   2 c
   3 d
   4 e
   5 f
dtype: object

In [81]: s.iloc[4:10]
Out[81]:
   e
   f
dtype: object

In [82]: s.iloc[8:10]
→Series([], dtype: object)
```

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

```python
In [83]: dfl = pd.DataFrame(np.random.randn(5,2), columns=list('AB'))

In [84]: dfl
Out[84]:
   A   B
0 -0.082240 -2.182937
1  0.380396  0.084844
2  0.432390  1.519970
3 -0.493662  0.600178
4  0.274230  0.132885

In [85]: dfl.iloc[:, 2:3]
→Empty DataFrame
   Columns: []
   Index: [0, 1, 2, 3, 4]

In [86]: dfl.iloc[:, 1:3]
→    B
    0 -2.182937
    1  0.084844
```

12.6. Selection By Position 705
In [87]: df.iloc[4:6]

   A  B
4 0.27423 0.132885

A single indexer that is out of bounds will raise an IndexError. A list of indexers where any element is out of bounds will raise an IndexError.

dfl.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds
dfl.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds

### 12.7 Selection By Callable

New in version 0.18.1.

.loc, .iloc, and also [] indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing.

In [88]: df1 = pd.DataFrame(np.random.randn(6, 4),
                   index=list('abcdef'),
                   columns=list('ABCD'))

In [89]: df1

Out[89]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>-0.023688</td>
<td>2.410179</td>
<td>1.450520</td>
<td>0.206053</td>
</tr>
<tr>
<td>b</td>
<td>-0.251905</td>
<td>-2.213588</td>
<td>1.063327</td>
<td>1.266143</td>
</tr>
<tr>
<td>c</td>
<td>0.299368</td>
<td>-0.863838</td>
<td>0.408204</td>
<td>-1.048089</td>
</tr>
<tr>
<td>d</td>
<td>-0.025747</td>
<td>-0.988387</td>
<td>0.094055</td>
<td>1.262731</td>
</tr>
<tr>
<td>e</td>
<td>1.289997</td>
<td>0.082423</td>
<td>-0.055758</td>
<td>0.536580</td>
</tr>
<tr>
<td>f</td>
<td>-0.489682</td>
<td>0.369374</td>
<td>-0.034571</td>
<td>-2.484478</td>
</tr>
</tbody>
</table>

In [90]: df1.loc[lambda df: df.A > 0, :]

   A  B
|   |     |     |  |     |
| c | 0.299368 | -0.863838 | 0.408204 | -1.048089 |
| e | 1.289997 | 0.082423  | -0.055758 | 0.536580 |

In [91]: df1.loc[:, lambda df: ['A', 'B']]

   A  B
|   |     |     |
| a | -0.023688 | 2.410179 |
| b | -0.251905 | -2.213588 |
You can use callable indexing in Series.

```python
In [94]: df1.A.loc[lambda s: s > 0]
```

```
Out[94]:
     c  0.299368
     e  1.289997
```

Using these methods/indexers, you can chain data selection operations without using temporary variable.

```python
In [95]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [96]: (bb.groupby(['year', 'team']).sum()
          .loc[lambda df: df.r > 100])
```

```
Out[96]:
     stint g  ab  r  h  X2b  X3b  hr  rbi  sb  cs  bb  so
  year team
  2007 CIN  6  379  745 101 203  35  2 36 125.0  10.0  105 127.0  14.

12.8 IX Indexer is Deprecated

**Warning:** Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```python
In [97]: dfd = pd.DataFrame({
                      'A': [1, 2, 3],
                      'B': [4, 5, 6]},
                      index=list('abc'))
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```python
In [3]: dfd.ix[[0, 2], 'A']
Out[3]:
    A
a 1
b 2
c 3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```python
In [99]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[99]:
    A
a 1
b 2
c 3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```python
In [100]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[100]:
```

(continues on next page)
For getting *multiple* indexers, using `.get_indexer`:

```python
In [101]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[101]:
   A   B
a  1  4
c  3  6
```

## 12.9 Indexing with list with missing labels is Deprecated

**Warning:** Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as at least 1 of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```python
In [102]: s = pd.Series([1, 2, 3])
In [103]: s
Out[103]:
0  1
1  2
2  3
dtype: int64
```

Selection with all keys found is unchanged.

```python
In [104]: s.loc[[1, 2]]
Out[104]:
1  2
2  3
dtype: int64
```

### Previous Behavior

```python
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1  2.0
2  3.0
3  NaN
dtype: float64
```

### Current Behavior

12.9. Indexing with list with missing labels is Deprecated
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
˓listlike

Out[4]:
1 2.0
2 3.0
3 NaN
dtype: float64

12.9.1 Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via .reindex(). See also the section on
reindexing.

In [105]: s.reindex([1, 2, 3])
Out[105]:
1 2.0
2 3.0
3 NaN
dtype: float64

Alternatively, if you want to select only valid keys, the following is idiomatic and efficient; it is guaranteed to preserve
the dtype of the selection.

In [106]: labels = [1, 2, 3]
In [107]: s.loc[s.index.intersection(labels)]
Out[107]:
1 2
2 3
dtype: int64

Having a duplicated index will raise for a .reindex():

In [108]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [109]: labels = ['c', 'd']

In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis

Generally, you can intersect the desired labels with the current axis, and then reindex.

In [110]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[110]:
c 3.0
d NaN
dtype: float64

However, this would still raise if your resulting index is duplicated.
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis

12.10 Selecting Random Samples

A random selection of rows or columns from a Series, DataFrame, or Panel with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

In [111]: s = pd.Series([0,1,2,3,4,5])

# When no arguments are passed, returns 1 row.
In [112]: s.sample()
Out[112]:
   0
   4
dtype: int64

# One may specify either a number of rows:
In [113]: s.sample(n=3)
Out[113]:
   0
   4
   1
dtype: int64

# Or a fraction of the rows:
In [114]: s.sample(frac=0.5)
Out[114]:
   5
   3
   1
dtype: int64

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

In [115]: s = pd.Series([0,1,2,3,4,5])

# Without replacement (default):
In [116]: s.sample(n=6, replace=False)
Out[116]:
   0
   4
   5
   3
   2
   4
   dtype: int64

# With replacement:
In [117]: s.sample(n=6, replace=True)
Out[117]:
   0
   4
(continues on next page)
By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```
In [118]: s = pd.Series([0,1,2,3,4,5])
In [119]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]
In [120]: s.sample(n=3, weights=example_weights)
Out[120]:
3 3
2 2
4 4
dtype: int64
```

```
# Weights will be re-normalized automatically
In [121]: example_weights2 = [0.5, 0, 0, 0, 0, 0]
In [122]: s.sample(n=1, weights=example_weights2)
Out[122]:
0 0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```
In [123]: df2 = pd.DataFrame({'col1':[9,8,7,6], 'weight_column':[0.5, 0.4, 0.1, 0]})
In [124]: df2.sample(n = 3, weights = 'weight_column')
Out[124]:
   col1  weight_column
0     9             0.4
1     8             0.4
2     7             0.1
```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [125]: df3 = pd.DataFrame({'col1':[1,2,3], 'col2':[2,3,4]})
In [126]: df3.sample(n=1, axis=1)
Out[126]:
   col1
0     1
1     2
2     3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.
12.11 Setting With Enlargement

The .loc[] operations can perform enlargement when setting a non-existent key for that axis. In the Series case this is effectively an appending operation.

A DataFrame can be enlarged on either axis via .loc.
This is like an *append* operation on the DataFrame.

```
In [138]: dfi.loc[3] = 5
```

```
In [139]: dfi
Out[139]:
     A  B  C
0   0  1  0
1   2  3  2
2   4  5  4
3   5  5  5
```

### 12.12 Fast scalar value getting and setting

Since indexing with `[]` must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you’re asking for. If you only want to access a scalar value, the fastest way is to use the *at* and *iat* methods, which are implemented on all of the data structures.

Similarly to *loc*, *at* provides *label* based scalar lookups, while, *iat* provides *integer* based lookups analogously to *iloc*

```
In [140]: s.iat[5]
Out[140]: 5
```

```
In [141]: df.at[dates[5], 'A']
Out[141]: -0.67368970808837059
```

```
In [142]: df.iat[3, 0]
Out[142]: 0.72155516224436689
```

You can also set using these same indexers.

```
In [143]: df.at[dates[5], 'E'] = 7
```

```
In [144]: df.iat[3, 0] = 7
```

*at* may enlarge the object in-place as above if the indexer is missing.

```
In [145]: df.at[dates[-1]+1, 0] = 7
```

```
In [146]: df
Out[146]:
     A   B   C   D   E   0
0 2000-01-01 0.469112 -0.282863 -1.509059 -1.135632 NaN NaN
1 2000-01-02 1.212112 -0.173215 0.119209 -1.044236 NaN NaN
2 2000-01-03 -0.861849 -2.104569 -0.494929 1.071804 NaN NaN
3 2000-01-04 7.000000 -0.706771 -1.039575 0.271860 NaN NaN
```

(continues on next page)
Another common operation is the use of boolean vectors to filter the data. The operators are: \( \lor \) for or, \& for and, and \( \neg \) for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as \( \text{df.A} > 2 \ \& \ \text{df.B} < 3 \) as \( \text{df.A} > (2 \ \& \ \text{df.B}) < 3 \), while the desired evaluation order is \((\text{df.A} > 2) \ \& \ (\text{df.B} < 3)\).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

In [147]: s = pd.Series(range(-3, 4))

In [148]: s
Out[148]:
0   -3
1   -2
2   -1
3    0
4    1
5    2
6    3
dtype: int64

In [149]: s[s > 0]
Out[149]:
4    1
5    2
6    3
dtype: int64

In [150]: s[(s < -1) | (s > 0.5)]
→
0   -3
1   -2
4    1
5    2
6    3
dtype: int64

In [151]: s[~(s < 0)]
→
3    0
4    1
5    2
6    3
dtype: int64

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example,
something derived from one of the columns of the DataFrame):

```
In [152]: df[df['A'] > 0]
Out[152]:
   A      B      C      D      E
0 0.469112 -0.282863 -1.509059 -1.135632 NaN
1 1.212112 -0.173215  0.119209 -1.044236 NaN
2 7.000000 -0.706771 -1.039575  0.271860 NaN
3 0.404705  0.577046 -1.715002 -1.039268 NaN

List comprehensions and map method of Series can also be used to produce more complex criteria:

```
In [153]: df2 = pd.DataFrame({'a' : ['one', 'one', 'two', 'three', 'two', 'one', 'six
˓→'],
   .....
   'b' : ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
   .....
   'c' : np.random.randn(7))
   .....

# only want 'two' or 'three'
In [154]: criterion = df2['a'].map(lambda x: x.startswith('t'))
In [155]: df2[criterion]
Out[155]:
   a  b  c
2 two y  0.041290
3 three x  0.361719
4 two y -0.238075

# equivalent but slower
In [156]: df2[[x.startswith('t') for x in df2['a']]]
Out[156]:
   a  b  c
2 two y  0.041290
3 three x  0.361719
4 two y -0.238075

# Multiple criteria
In [157]: df2[criterion & (df2['b'] == 'x')]
Out[157]:
   a  b  c
2 two y  0.041290
3 three x  0.361719

With the choice methods Selection by Label, Selection by Position, and Advanced Indexing you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [158]: df2.loc[criterion & (df2['b'] == 'x'),'b':'c']
Out[158]:
   b  c
2 y 0.041290
3 x 0.361719

12.14 Indexing with isin

Consider the isin() method of Series, which returns a boolean vector that is true wherever the Series elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [159]: df2.isin([0, 'x'])
Out[159]:
   a  b  c
2 False True
3   True False
4   True False

In [160]: df2.loc[df2['b'].isin(['x', 'y'])]
Out[160]:
   a  b  c
2 two y  0.041290
3 three x  0.361719
4 two y -0.238075
```
The same method is available for Index objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

```
In [163]: s[s.index.isin([2, 4, 6])]
Out[163]:
4  0
2  2
dtype: int64
```

# compare it to the following
```
In [164]: s.reindex([2, 4, 6])
Out[164]:
2  2.0
4  0.0
6  NaN
dtype: float64
```

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

```
In [159]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
In [160]: s
Out[160]:
4  0
3  1
2  2
1  3
0  4
dtype: int64
In [161]: s.isin([2, 4, 6])
Out[161]:
4  False
3  False
2  True
1  False
0  True
dtype: bool
In [162]: s[s.isin([2, 4, 6])]
```

(continues on next page)
DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```python
df.isin(values)
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a `dict` where the key is the column, and the value is a list of items you want to check for.

```python
df.isin(values)
```

Combine DataFrame’s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```python
df.isin(values)
```

(continues on next page)
In [175]: row_mask = df.isin(values).all(1)

In [176]: df[row_mask]
Out[176]:
   vals ids ids2
0    1   a   a
1  12.15 The

where() Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

In [177]: s[s > 0]
Out[177]:
   3  1
   2  2
   1  3
   0  4

dtype: int64

To return a Series of the same shape as the original:

In [178]: s.where(s > 0)
Out[178]:
   4  NaN
   3  1.0
   2  2.0
   1  3.0
   0  4.0

dtype: float64

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df.where(df < 0)`.

In [179]: df[df < 0]
Out[179]:
   A   B    C   D
2000-01-01 -2.104139 -1.309525 NaN NaN
2000-01-02 -0.352480 NaN -1.192319 NaN
2000-01-03 -0.864883 NaN -0.227870 NaN
2000-01-04 NaN -1.222082 NaN -1.233203
2000-01-05 NaN -0.605656 -1.169184 NaN
2000-01-06 NaN -0.948458 NaN -0.684718
2000-01-07 -2.670153 -0.114722 NaN -0.048048
2000-01-08 NaN NaN -0.048788 -0.808838

In addition, `where` takes an optional `other` argument for replacement of values where the condition is False, in the returned copy.

In [180]: df.where(df < 0, -df)
Out[180]:
   A   B    C   D
2000-01-01 -2.104139 -1.309525 NaN NaN
2000-01-02 -0.352480 NaN -1.192319 NaN
2000-01-03 -0.864883 NaN -0.227870 NaN
2000-01-04 NaN -1.222082 NaN -1.233203
2000-01-05 NaN -0.605656 -1.169184 NaN
2000-01-06 NaN -0.948458 NaN -0.684718
2000-01-07 -2.670153 -0.114722 NaN -0.048048
2000-01-08 NaN NaN -0.048788 -0.808838

(continues on next page)
You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [181]: s2 = s.copy()
In [182]: s2[s2 < 0] = 0
In [183]: s2
Out[183]:
        0  1  2  3
0  0  0  0  0
1  0  0  0  0
dtype: int64
```

```
In [184]: df2 = df.copy()
In [185]: df2[df2 < 0] = 0
In [186]: df2
Out[186]:
   A     B      C      D
0 0.000000 0.000000 0.485855 0.245166
1 0.000000 0.390389 0.000000 1.655824
2 0.000000 0.299674 0.000000 0.281059
3 0.846958 0.000000 0.600705 0.000000
4 0.669692 0.000000 0.000000 0.342416
5 0.868584 0.948458 2.297780 0.684718
6 0.000000 0.000000 0.168904 0.000000
7 0.801196 1.392071 0.000000 0.000000
```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```
In [187]: df_orig = df.copy()
In [188]: df_orig.where(df > 0, -df, inplace=True);
In [189]: df_orig
Out[189]:
   A     B      C      D
0 2.104139 1.309525 0.485855 0.245166
1 0.352480 0.390389 1.192319 1.655824
2 0.864883 0.299674 0.227870 0.281059
3 0.846958 1.220822 0.600705 1.233203
4 0.669692 0.605656 1.169184 0.342416
5 0.868584 0.948458 2.297780 0.684718
6 0.000000 0.000000 0.168904 0.000000
7 0.801196 1.392071 0.000000 0.000000
```

(continues on next page)
2000-01-07  2.670153  0.114722  0.168904  0.048048
2000-01-08  0.801196  1.392071  0.048788  0.808838

Note: The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2).

```python
In [190]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[190]:
     A      B      C      D
2000-01-01   True   True   True   True
2000-01-02   True   True   True   True
2000-01-03   True   True   True   True
2000-01-04   True   True   True   True
2000-01-05   True   True   True   True
2000-01-06   True   True   True   True
2000-01-07   True   True   True   True
2000-01-08   True   True   True   True
```

alignment
Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```python
In [191]: df2 = df.copy()
In [192]: df2[df2[1:4] > 0] = 3
In [193]: df2
Out[193]:
     A      B      C      D
2000-01-01 -2.104139 -2.104139  0.485855  0.245166
2000-01-02 -0.352480  0.390389 -0.352480  1.655824
2000-01-03 -0.864883  0.299674 -0.864883  0.281059
2000-01-04  0.846958  0.846958  0.600705  0.846958
2000-01-05  0.669692  0.669692  0.669692  0.342416
2000-01-06  0.868584  0.948458  2.297780 -0.684718
2000-01-07 -2.670153 -0.114722  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196
```

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```python
In [194]: df2 = df.copy()
In [195]: df2.where(df2>0,df2['A'],axis='index')
Out[195]:
     A      B      C      D
2000-01-01 -2.104139 -2.104139  0.485855  0.245166
2000-01-02 -0.352480  0.390389 -0.352480  1.655824
2000-01-03 -0.864883  0.299674 -0.864883  0.281059
2000-01-04  0.846958  0.846958  0.600705  0.846958
2000-01-05  0.669692  0.669692  0.669692  0.342416
2000-01-06  0.868584  0.868584  2.297780 -0.684718
2000-01-07 -2.670153 -0.114722  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196
```

12.15. The `where()` Method and Masking
This is equivalent to (but faster than) the following.

```
In [196]: df2 = df.copy()

In [197]: df.apply(lambda x, y: x.where(x>0,y), y=df['A'])
Out[197]:
         A          B          C          D
2000-01-01 -2.104139 -2.104139  0.485855  0.245166
2000-01-02 -0.352480  0.390389 -0.352480  1.655824
2000-01-03 -0.864883  0.299674 -0.864883  0.281059
2000-01-04  0.846958  0.846958  0.600705  0.846958
2000-01-05  0.669692  0.669692  0.669692  0.342416
2000-01-06  0.868584  0.868584  2.297780  0.868584
2000-01-07 -2.670153 -2.670153  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196
```

New in version 0.18.1.

Where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

```
In [198]: df3 = pd.DataFrame({'A': [1, 2, 3],
                      'B': [4, 5, 6],
                      'C': [7, 8, 9]})

In [199]: df3.where(lamda x: x > 4, lamda x: x + 10)
```

```
In [200]: s.mask(s >= 0)
Out[200]:
   0  11  14  7
   1  12  5  8
   2  13  6  9

12.15.1 Mask

mask() is the inverse boolean operation of where.

```
In [201]: df.mask(df >= 0)
Out[201]:
   2000-01-01 -2.104139 -1.309525   NaN   NaN
   2000-01-02 -0.352480   NaN -1.192319   NaN
   2000-01-03 -0.864883   NaN  -0.227870   NaN
   2000-01-04   NaN -1.222082   NaN -1.233203
   2000-01-05   NaN  -0.605656 -1.169184   NaN
   2000-01-06   NaN -0.948458   NaN -0.684718
   2000-01-07 -2.670153  -0.114722   NaN -0.048788
   2000-01-08   NaN  -0.048788 -0.808838
```
DataFrame objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```python
In [202]: n = 10
In [203]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [204]: df
Out[204]:
    a   b    c
0  0.438921  0.118680  0.863670
1  0.138138  0.577363  0.686602
2  0.595307  0.564592  0.520630
3  0.913052  0.926075  0.616184
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
6  0.792342  0.216974  0.564056
7  0.397890  0.454131  0.915716
8  0.074315  0.437913  0.019794
9  0.559209  0.502065  0.026437

# pure python
In [205]: df[(df.a < df.b) & (df.b < df.c)]
  ...:
   a   b    c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

# query
In [206]: df.query('(a < b) & (b < c)')
  ...:
   a   b    c
1  0.138138  0.577363  0.686602
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716

Do the same thing but fall back on a named index if there is no column with the name `a`.

```
In [207]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [208]: df.index.name = 'a'

In [209]: df
Out[209]:
    b    c
a 0 0 4
1 0 1
2 3 4
```

(continues on next page)
In [210]: df.query('a < b and b < c')

Out[210]:
    b  c
2  3  4

If instead you don’t want to or cannot name your index, you can use the name `index` in your query expression:

In [211]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))

In [212]: df
Out[212]:
    b  c
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9

In [213]: df.query('index < b < c')

Out[213]:
    b  c
2  5  6

**Note:** If the name of your index overlaps with a column name, the column name is given precedence. For example,

In [214]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})

In [215]: df.index.name = 'a'

In [216]: df.query('a > 2')  # uses the column 'a', not the index
Out[216]:
    a
0  3
1  3

You can still use the index in a query expression by using the special identifier `index`:

In [217]: df.query('index > 2')

(continues on next page)
If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

### 12.16.1 MultiIndex `query()` Syntax

You can also use the levels of a `DataFrame` with a `MultiIndex` as if they were columns in the frame:

```python
In [218]: n = 10
In [219]: colors = np.random.choice(['red', 'green'], size=n)
In [220]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [221]: colors
Out[221]: array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'], dtype='<U5')
In [222]: foods
Out[222]: array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'], dtype='<U4')
In [223]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
In [224]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
In [225]: df
Out[225]:     0     1
color food
red  ham  0.194889 -0.381994
   ham  0.318587  2.089075
   eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
          eggs -2.029766  0.792652
          ham  0.461007 -0.542749
          ham -0.305384 -0.479195
          eggs  0.095031 -0.270099
          eggs -0.707140 -0.773882
          eggs  0.229453  0.304418
In [226]: df.query('color == "red"')
```

(continues on next page)
If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```
In [227]: df.index.names = [None, None]

In [228]: df
Out[228]:
\n                   0       1
  red   ham  0.194889 -0.381994
  ham    0.318587  2.089075
  eggs  -0.728293 -0.090255
  green eggs -0.748199  1.318931
  eggs    2.029766  0.792652
  ham    0.461007 -0.542749
  ham   -0.305384 -0.479195
  eggs   0.095031 -0.270099
  eggs  -0.707140 -0.773882
  eggs   0.229453  0.304418

In [229]: df.query('ilevel_0 == "red"')
```

The convention is ilevel_0, which means “index level 0” for the 0th level of the index.

### 12.16.2 query() Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you’re interested in querying.

```
In [230]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [231]: df
Out[231]:
\n                   a       b       c
  0  0.224283  0.736107  0.139168
  1  0.302827  0.657803  0.713897
  2  0.611185  0.136624  0.984960
  3  0.195246  0.123436  0.627712
  4  0.618673  0.371660  0.047902
  5  0.480088  0.062993  0.185760
  6  0.568018  0.483467  0.445289
  7  0.309040  0.274580  0.587101
  8  0.258993  0.477769  0.370255
  9  0.550459  0.840870  0.304611
```

(continues on next page)
In [232]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
In [233]: df2
Out[233]:
   a      b      c
0  0.357579  0.229800  0.596001
1  0.309059  0.957923  0.965663
2  0.123102  0.336914  0.318616
3  0.526506  0.323321  0.860813
4  0.518736  0.486514  0.384724
5  0.190804  0.505723  0.614533
6  0.891939  0.623977  0.676639
7  0.480559  0.378528  0.460858
8  0.420223  0.136404  0.141295
9  0.732206  0.419540  0.604675
10 0.604466  0.848974  0.896165
11 0.589168  0.920046  0.732716

In [234]: expr = '0.0 <= a <= c <= 0.5'

In [235]: map(lambda frame: frame.query(expr), [df, df2])
Out[235]: <map at 0x1c2b11f5f8>

12.16.3 query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

In [236]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
In [237]: df
Out[237]:
   a  b  c
0  7  8  9
1  1  0  7
2  2  7  2
3  6  2  2
4  2  6  3
5  3  8  2
6  1  7  2
7  5  1  5
8  9  8  0
9  1  5  0

In [238]: df.query('(a < b) & (b < c)')
→   a  b  c
0  7  8  9

In [239]: df[(df.a < df.b) & (df.b < df.c)]
→   a  b  c
0  7  8  9

12.16. The query() Method
Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than & and |).

In [240]: df.query('a < b & b < c')
Out[240]:
    a  b  c
0  7  8  9

Use English instead of symbols:

In [241]: df.query('a < b and b < c')
Out[241]:
    a  b  c
0  7  8  9

Pretty close to how you might write it on paper:

In [242]: df.query('a < b < c')
Out[242]:
    a  b  c
0  7  8  9

12.16.4 The in and not in operators

query() also supports special use of Python’s in and not in comparison operators, providing a succinct syntax for calling the isin method of a Series or DataFrame.

# get all rows where columns "a" and "b" have overlapping values
In [243]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbcccc'),
                      ....:             'c': np.random.randint(5, size=12),
                      ....:             'd': np.random.randint(9, size=12)})

In [244]: df
Out[244]:
    a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

In [245]: df.query('a in b')
Out[245]:
    a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1

(continues on next page)
# How you'd do it in pure Python

```python
In [246]: df[df.a.isin(df.b)]
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>a</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
<td>a</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>b</td>
<td>a</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>c</td>
<td>b</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
<td>b</td>
<td>0</td>
</tr>
</tbody>
</table>
```

```python
Out[246]:
```

```python
In [247]: df.query('a not in b')
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>d</td>
<td>b</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>d</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>e</td>
<td>c</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>e</td>
<td>c</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>f</td>
<td>c</td>
<td>0</td>
</tr>
<tr>
<td>11</td>
<td>f</td>
<td>c</td>
<td>1</td>
</tr>
</tbody>
</table>
```

# pure Python

```python
In [248]: df[~df.a.isin(df.b)]
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>d</td>
<td>b</td>
<td>3</td>
</tr>
<tr>
<td>7</td>
<td>d</td>
<td>b</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>e</td>
<td>c</td>
<td>4</td>
</tr>
<tr>
<td>9</td>
<td>e</td>
<td>c</td>
<td>2</td>
</tr>
<tr>
<td>10</td>
<td>f</td>
<td>c</td>
<td>0</td>
</tr>
<tr>
<td>11</td>
<td>f</td>
<td>c</td>
<td>1</td>
</tr>
</tbody>
</table>
```

You can combine this with other expressions for very succinct queries:

```python
# rows where cols a and b have overlapping values and col c's values are less than col d's
```

```python
In [249]: df.query('a in b and c < d')
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>a</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>a</td>
<td>a</td>
<td>4</td>
</tr>
<tr>
<td>2</td>
<td>b</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td>4</td>
<td>c</td>
<td>b</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>c</td>
<td>b</td>
<td>0</td>
</tr>
</tbody>
</table>
```

# pure Python

```python
In [250]: df[df.b.isin(df.a) & (df.c < df.d)]
```

```
<table>
<thead>
<tr>
<th>a</th>
<th>b</th>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>a</td>
<td>2</td>
</tr>
</tbody>
</table>
| 12.16. The query() Method
Note: Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, only the `in/not in` expression itself is evaluated in vanilla Python. For example, in the expression

```python
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and then the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

### 12.16.5 Special use of the `==` operator with `list` objects

Comparing a list of values to a column using `==`/`!=` works similarly to `in/not in`.

```python
In [251]: df.query('b == ["a", "b", "c"]')
Out[251]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2
```

# pure Python

```python
In [252]: df[df.b.isin(["a", "b", "c")]
```

(continues on next page)
In [253]: df.query('c == [1, 2]

\rightarrow
da
0 a a 2 6
2 b a 1 6
3 b a 2 1
7 d b 2 1
9 e c 2 0
11 f c 1 2

In [254]: df.query('c != [1, 2]

\rightarrow
da
1 a a 4 7
4 c b 3 6
5 c b 0 2
6 d b 3 3
8 e c 4 3
10 f c 0 6

# using in/not in
In [255]: df.query('[1, 2] in c

\rightarrow
da
0 a a 2 6
2 b a 1 6
3 b a 2 1
7 d b 2 1
9 e c 2 0
11 f c 1 2

In [256]: df.query('[1, 2] not in c

\rightarrow
da
1 a a 4 7
4 c b 3 6
5 c b 0 2
6 d b 3 3
8 e c 4 3
10 f c 0 6

# pure Python
In [257]: df[df.c.isin([1, 2])]

\rightarrow
da
0 a a 2 6
2 b a 1 6
3 b a 2 1
7 d b 2 1
9 e c 2 0
11 f c 1 2

12.16. The `query()` Method
12.16.6 Boolean Operators

You can negate boolean expressions with the word `not` or the ~ operator.

```
In [258]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [259]: df['bools'] = np.random.rand(len(df)) > 0.5
In [260]: df.query('~bools')
Out[260]:
   a    b    c  bools
2  0.697753  0.212799  0.329209    False
7  0.275396  0.691034  0.826619    False
8  0.190649  0.558748  0.262467    False
```

```
In [261]: df.query('not bools')
Out[261]:
   a    b    c  bools
2  0.697753  0.212799  0.329209    False
7  0.275396  0.691034  0.826619    False
8  0.190649  0.558748  0.262467    False
```

Of course, expressions can be arbitrarily complex too:

```
# short query syntax
In [263]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [264]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]

In [265]: shorter
Out[265]:
   a    b    c  bools
2  0.697753  0.212799  0.329209    False
7  0.275396  0.691034  0.826619    False
8  0.190649  0.558748  0.262467    False

In [266]: longer
Out[266]:
   a    b    c  bools
2  0.697753  0.212799  0.329209    False
7  0.275396  0.691034  0.826619    False
8  0.190649  0.558748  0.262467    False
```

```
In [267]: shorter == longer
Out[267]:
   a    b    c  bools
2  True  True  True  True
7  True  True  True  True
8  True  True  True  True
```
12.16.7 Performance of `query()`

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

![Graph showing performance comparison between `python` and `numexpr` for `DataFrame.query()`](image)

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

12.17 Duplicate Data

If you want to identify and remove duplicate rows in a `DataFrame`, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.
• duplicated returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
• drop_duplicates removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a keep parameter to specify targets to be kept.

• keep='first' (default): mark / drop duplicates except for the first occurrence.
• keep='last': mark / drop duplicates except for the last occurrence.
• keep=False: mark / drop all duplicates.

```
In[268]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
                        'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
                        'c': np.random.randn(7))

In[269]: df2
Out[269]:
   a    b         c
0  one  x -1.067137
1  one  y  0.309500
2  two  x -0.211056
3  two  y -1.842023
4  two  x -0.390820
5  three  x -1.964475
6   four  x  1.298329

In[270]: df2.duplicated('a')
Out[270]:
0  False
1   True
2  False
3   True
4   True
5  False
6  False
dtype: bool

In[271]: df2.duplicated('a', keep='last')
Out[271]:
0   True
1  False
2   True
3   True
4  False
5  False
6  False
dtype: bool

In[272]: df2.duplicated('a', keep=False)
Out[272]:
0   True
1   True
```

(continues on next page)
In [273]: df2.drop_duplicates('a')

\[\rightarrow\]

\[
\begin{array}{ccc}
 0 & one & x -1.067137 \\
 2 & two & x -0.211056 \\
 5 & three & x -1.964475 \\
 6 & four & x 1.298329 \\
\end{array}
\]

In [274]: df2.drop_duplicates('a', keep='last')

\[\rightarrow\]

\[
\begin{array}{ccc}
 1 & one & y 0.309500 \\
 4 & two & x -0.390820 \\
 5 & three & x -1.964475 \\
 6 & four & x 1.298329 \\
\end{array}
\]

In [275]: df2.drop_duplicates('a', keep=False)

\[\rightarrow\]

\[
\begin{array}{ccc}
 5 & three & x -1.964475 \\
 6 & four & x 1.298329 \\
\end{array}
\]

Also, you can pass a list of columns to identify duplications.

In [276]: df2.duplicated(['a', 'b'])

Out[276]:

\[
\begin{array}{cccc}
 0 & False \\
 1 & False \\
 2 & False \\
 3 & False \\
 4 & True \\
 5 & False \\
 6 & False \\
\end{array}
\]

dtype: bool

In [277]: df2.drop_duplicates(['a', 'b'])

\[\rightarrow\]

\[
\begin{array}{ccc}
 0 & one & x -1.067137 \\
 1 & one & y 0.309500 \\
 2 & two & x -0.211056 \\
 3 & two & y -1.842023 \\
 5 & three & x -1.964475 \\
 6 & four & x 1.298329 \\
\end{array}
\]

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are
available for the `keep` parameter.

```python
In [278]: df3 = pd.DataFrame(
               {'a': np.arange(6),
               'b': np.random.randn(6)},
               index=['a', 'a', 'b', 'c', 'b', 'a'])

In [279]: df3
Out[279]:
      a   b
a 0  1.4405
a 1  2.45609
b 2  1.0384
b 3  0.6835
b 4  3.0828
a 5  3.0828

In [280]: df3.index.duplicated()
\[\rightarrow\]
array([False, True, False, False, True, True], dtype=bool)

In [281]: df3[~df3.index.duplicated()]
\[\rightarrow\]
      a   b
a 0  1.4405
b 2  1.0384
b 3  0.6835
a 5  3.0828

In [282]: df3[~df3.index.duplicated(keep='last')]
\[\rightarrow\]
      a   b
b 3  0.6835
b 4  0.6835
a 5  3.0828

In [283]: df3[~df3.index.duplicated(keep=False)]
\[\rightarrow\]
      a   b
b 3  0.6835
```

### 12.18 Dictionary-like `get()` method

Each of Series, DataFrame, and Panel have a `get` method which can return a default value.

```python
In [284]: s = pd.Series([1,2,3], index=['a','b','c'])

In [285]: s.get('a')                      # equivalent to s['a']
Out[285]: 1

In [286]: s.get('x', default=-1)
\[\rightarrow\]
Out[286]: -1
```
12.19 The `lookup()` Method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```python
In [287]: dflookup = pd.DataFrame(np.random.rand(20,4), columns=['A','B','C','D'])
In [288]: dflookup.lookup(list(range(0,10,2)), ['B','C','A','B','D'])
```

Out[288]:
```
array([ 0.3506, 0.4779, 0.4825, 0.9197, 0.5019])
```

12.20 Index objects

The pandas `Index` class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an `Index` object with duplicate entries into a `set`, an exception will be raised.

`Index` also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an `Index` directly is to pass a list or other sequence to `Index`:

```python
In [289]: index = pd.Index(['e', 'd', 'a', 'b'])
In [290]: index
```

Out[290]:
```
Index(['e', 'd', 'a', 'b'], dtype='object')
```

You can also pass a name to be stored in the index:

```python
In [292]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
In [293]: index.name
```

Out[293]:
```
'something'
```

The name, if set, will be shown in the console display:

```python
In [294]: index = pd.Index(list(range(5)), name='rows')
In [295]: columns = pd.Index(['A', 'B', 'C'], name='cols')
In [296]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
In [297]: df
```

Out[297]:
```
   A     B     C
rows  
0  1.295989  0.185778  0.436259
1  0.678101  0.311369 -0.528378
2 -0.674808 -1.103529 -0.656157
3  1.889957  2.076651 -1.102192
4 -1.211795 -0.791746  0.634724
```

(continues on next page)
12.20.1 Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index name (or, for MultiIndex, levels and labels).

You can use the rename, set_names, set_levels, and set_labels to set these attributes directly. They default to returning a copy; however, you can specify inplace=True to have the data change in place.

See Advanced Indexing for usage of MultiIndexes.

```python
In [299]: ind = pd.Index([1, 2, 3])
In [300]: ind.rename("apple")
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [301]: ind
Out[301]: Int64Index([1, 2, 3], dtype='int64')

In [302]: ind.set_names(['apple'], inplace=True)
In [303]: ind.name = "bob"
In [304]: ind
Out[304]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

set_names, set_levels, and set_labels also take an optional level' argument

```python
In [305]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])
In [306]: index
Out[306]: MultiIndex(levels=[[0, 1, 2], ['one', 'two']],
               labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
               names=['first', 'second'])

In [307]: index.levels[1]
Index(['one', 'two'], dtype='object', name='second')

In [308]: index.set_levels(['a', 'b'], level=1)
MultiIndex(levels=[[0, 1, 2], ['a', 'b']],
           labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
           names=['first', 'second'])
```
12.20.2 Set operations on Index objects

The two main operations are `union (|)` and `intersection (&)`. These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```python
In [309]: a = pd.Index(['c', 'b', 'a'])
In [310]: b = pd.Index(['c', 'e', 'd'])
In [311]: a | b
Out[311]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [312]: a & b
Out[312]: Index(['c'], dtype='object')

In [313]: a.difference(b)
Out[313]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference (^)` operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```python
In [314]: idx1 = pd.Index([1, 2, 3, 4])
In [315]: idx2 = pd.Index([2, 3, 4, 5])
In [316]: idx1.symmetric_difference(idx2)
Out[316]: Int64Index([1, 5], dtype='int64')

In [317]: idx1 ^ idx2
Out[317]: Int64Index([1, 5], dtype='int64')
```

**Note:** The resulting index from a set operation will be sorted in ascending order.

12.20.3 Missing values

**Important:** Even though `Index` can hold missing values (`NaN`), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```python
In [318]: idx1 = pd.Index([1, np.nan, 3, 4])
In [319]: idx1
Out[319]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [320]: idx1.fillna(2)
Out[320]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')
```

(continues on next page)

In [322]: idx2
Out[322]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]', freq=None)

In [323]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[323]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]', freq=None)

12.21 Set / Reset Index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you’ve already done so. There are a couple of different ways.

12.21.1 Set an index

DataFrame has a set_index() method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

In [324]: data
Out[324]:
   a   b   c   d
0  bar  one  z  1.0
1  bar  two  y  2.0
2  foo  one  x  3.0
3  foo  two  w  4.0

In [325]: indexed1 = data.set_index('c')

In [326]: indexed1
Out[326]:
   b   d
   c
  z  bar  one  1.0
  y  bar  two  2.0
  x  foo  one  3.0
  w  foo  two  4.0

In [327]: indexed2 = data.set_index(['a', 'b'])

In [328]: indexed2
Out[328]:
   c   d
   a
   bar  one  z  1.0
         two  y  2.0
         two  w  4.0
The `append` keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```python
In [329]: frame = data.set_index('c', drop=False)
In [330]: frame = frame.set_index(['a', 'b'], append=True)
In [331]: frame
Out[331]:
   c  d
   a b
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0
```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```python
In [332]: data.set_index('c', drop=False)
Out[332]:
   a  b  c  d
   c
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0
In [333]: data.set_index(['a', 'b'], inplace=True)
In [334]: data
Out[334]:
   c  d
   a b
   bar one z 1.0
   two y 2.0
   foo one x 3.0
   two w 4.0
```

### 12.21.2 Reset the index

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```python
In [335]: data
Out[335]:
   c  d
   a b
   bar one z 1.0
   two y 2.0
   foo one x 3.0
   two w 4.0
In [336]: data.reset_index()
```

(continues on next page)
The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the names attribute.

You can use the level keyword to remove only a portion of the index:

```python
In [337]: frame
Out[337]:
   c  d
   a  b
z bar one  z  1.0
y bar two  y  2.0
x foo one   x  3.0
w foo two   w  4.0
```

```
In [338]: frame.reset_index(level=1)
```

reset_index takes an optional parameter drop which if true simply discards the index, instead of putting index values in the DataFrame’s columns.

### 12.21.3 Adding an ad hoc index

If you create an index yourself, you can just assign it to the index field:

```python
data.index = index
```

### 12.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

```python
In [339]: dfmi = pd.DataFrame([[list('abcd'),
                        list('efgh'),
                        list('ijkl'),
                        list('mnop')],
                       columns=pd.MultiIndex.from_product([[ 'one','two'],
                                                ['first','second']],
                                              level=['one','two']))
```

```
In [340]: dfmi
```
Compare these two access methods:

```
In [341]: dfmi['one']['second']
Out[341]:
   0  b
   1  f
   2  j
   3  n
Name: second, dtype: object
```

```
In [342]: dfmi.loc[:,('one','second')]
Out[342]:
   0  b
   1  f
   2  j
   3  n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `.[]`).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to df.loc[:,('one','second')] which passes a nested tuple of (slice(None),('one','second')) to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations can be significantly faster, and allows one to index both axes if so desired.

### 12.22.1 Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What’s up with the `SettingWithCopy` warning? We don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:,('one','second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

### 12.22. Returning a view versus a copy
See that __getitem__ in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the __setitem__ will modify dfmi or a temporary object that gets thrown out immediately afterward. That’s what SettingWithCopy is warning you about!

**Note:** You may be wondering whether we should be concerned about the loc property in the first example. But dfmi.loc is guaranteed to be dfmi itself with modified indexing behavior, so dfmi.loc.__getitem__/dfmi.loc.__setitem__ operate on dfmi directly. Of course, dfmi.loc.__getitem__(idx) may be a view or a copy of dfmi.

Sometimes a SettingWithCopy warning will arise at times when there’s no obvious chained indexing going on. These are the bugs that SettingWithCopy is designed to catch! Pandas is probably trying to warn you that you’ve done this:

```python
def do_something(df):
    foo = df[['bar', 'baz']]
    # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    foo['quux'] = value
    # We don’t know whether this will modify df or not!
    return foo
```

Yikes!

### 12.22.2 Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the SettingWithCopyWarning because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the option mode.chained_assignment to one of these values:

- 'warn', the default, means a SettingWithCopyWarning is printed.
- 'raise' means pandas will raise a SettingWithCopyException you have to deal with.
- None will suppress the warnings entirely.

```python
In [343]: dfb = pd.DataFrame({'a' : ['one', 'one', 'two', 'three', 'two', 'one', 'six'],
                        'c' : np.arange(7)})
                        
# This will show the SettingWithCopyWarning
# but the frame values will be set
In [344]: dfb['c'][dfb.a.str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```python
>>> pd.set_option('mode.chained_assignment', 'warn')
>>> dfb[dfb.a.str.startswith('o')]['c'] = 42
Traceback (most recent call last)
... SettingWithCopyWarning:
```

(continues on next page)
A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc/.iloc`.

This is the correct access method:

```python
In [345]: dfc = pd.DataFrame({'A':['aaa','bbb','ccc'],'B':[1,2,3]})
In [346]: dfc.loc[0,'A'] = 11
In [347]: dfc
Out[347]:
   A  B
0  11  1
1  bbb  2
2   ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```python
In [348]: dfc = dfc.copy()
In [349]: dfc['A'][0] = 111
In [350]: dfc
Out[350]:
   A  B
0  111  1
1  bbb  2
2   ccc  3
```

This will **not** work at all, and so should be avoided:

```python
>>> pd.set_option('mode.chained_assignment','raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last)
  ... 
SettingWithCopyException:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.
This section covers indexing with a MultiIndex and more advanced indexing features.

See the Indexing and Selecting Data for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

See the cookbook for some advanced strategies.

### 13.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing group by and pivoting and reshaping data, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the cookbook for some advanced strategies.

#### 13.1.1 Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays), an array of tuples (using MultiIndex.from_tuples), or a crossed set of iterables (using MultiIndex.from_product). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

```python
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
               ...
               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
  ('bar', 'two'),
  ('baz', 'one'),
  ('baz', 'two'),
  ...]
```

(continues on next page)
In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first    second
bar one   0.469112
         two -0.282863
baz one   -1.509059
         two -1.135632
foo one   1.212112
         two -0.173215
qux one   0.119209
         two -1.044236

When you want every pairing of the elements in two iterables, it can be easier to use the MultiIndex.
from_product function:

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

In [10]: arrays = [np.array( ['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'] ),
             np.array( ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'] )]

In [11]: s = pd.Series(np.random.randn(8), index=arrays)

In [12]: s
Out[12]:
bar one   -0.861849
         two -2.104569
baz one   -0.494929

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.2

(continued from previous page)

two 1.071804
foo one 0.721555
two -0.706771
qux one -1.039575
two 0.271860
dtype: float64

In [13]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [14]: df
Out[14]:
     0   1   2   3
bar one -0.424972 0.567020 0.276232 -1.087401
two -0.673690 0.113648 -1.478427 0.524988
baz one 0.404705 0.577046 -1.715002 -1.039268
two -0.370647 -1.157892 -1.344312 0.844885
foo one 1.075770 -0.109050 1.643563 -1.469388
two 0.357021 -0.674600 -1.776904 -0.968914
qux one -1.294524 0.413738 0.276662 -0.472035
two -0.013960 -0.362543 -0.006154 -0.923061

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

In [15]: df.index.names
Out[15]: FrozenList([None, None])

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

In [16]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
                     columns=index)

In [17]: df
Out[17]:
   first  bar  baz  foo  qux
second one  two  one  two  one  two
A  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299 -0.226169
B  0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466 -2.006747

In [18]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the multi_sparse option in pandas.set_options():

13.1. Hierarchical indexing (MultiIndex)
In [19]: with pd.option_context('display.multi_sparse', False):
    ....:  df
    ....:

It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

In [20]: pd.Series(np.random.randn(8), index=tuples)
Out[20]:
(bar, one) -1.236269
(bar, two)  0.896171
(baz, one) -0.487602
(baz, two) -0.082240
(foo, one) -2.182937
(foo, two)  0.380396
(qux, one)  0.084844
(qux, two)  0.432390
dtype: float64

The reason that the MultiIndex matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a MultiIndex explicitly yourself. However, when loading data from a file, you may wish to generate your own MultiIndex when preparing the data set.

13.1.2 Reconstructing the level labels

The method `get_level_values` will return a vector of the labels for each location at a particular level:

In [21]: index.get_level_values(0)
Out[21]:
Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object',
      name='first')

In [22]: index.get_level_values('second')

In [23]: df['bar']
Out[23]:
second one two
A  0.895717  0.805244
B  0.410835  0.813850
C -1.413681  1.607920

In [24]: df['bar', 'one']

(continues on next page)
C  -1.413681
Name: (bar, one), dtype: float64

In [25]: df['bar']['one']

→
A  0.895717
B  0.410835
C  -1.413681
Name: one, dtype: float64

In [26]: s['qux']

→
one  -1.039575
two  0.271860
dtype: float64

See Cross-section with hierarchical index for how to select on a deeper level.

13.1.4 Defined Levels

The repr of a MultiIndex shows all the defined levels of an index, even if they are not actually used. When slicing an index, you may notice this. For example:

In [27]: df.columns  # original MultiIndex
Out[27]:
MultiIndex(levels=['bar', 'baz', 'foo', 'qux'], ['one', 'two'],
labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

In [28]: df[['foo', 'qux']].columns  # sliced

→
MultiIndex(levels=['bar', 'baz', 'foo', 'qux'], ['one', 'two'],
labels=[[2, 2, 3, 3], [0, 1, 0, 1]],
names=['first', 'second'])

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the MultiIndex.get_level_values() method.

In [29]: df[['foo', 'qux']].columns.values
Out[29]:
array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
dtype=object)

# for a specific level
In [30]: df[['foo', 'qux']].columns.get_level_values(0)

→
Index([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
dtype=object, name='first')

To reconstruct the MultiIndex with only the used levels, the remove_unused_levels method may be used. New in version 0.20.0.
13.1.5 Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```python
In [32]: s + s[:,-2]
Out[32]:
bar one  -1.723698
two   -4.209138
baz one  -0.989859
two   2.143608
foo one  1.443110
two  -1.413542
qux one   NaN
two   NaN
dtype: float64
```

```python
In [33]: s + s[::2]
```

```
bar one  -1.723698
two   NaN
baz one  -0.989859
two   NaN
foo one  1.443110
two   NaN
qux one  -2.079150
two   NaN
dtype: float64
```

`reindex` can be called with another `MultiIndex`, or even a list or array of tuples:

```python
In [34]: s.reindex(index[:3])
Out[34]:
first second
bar one   -0.861849
two  -2.104569
baz one   -0.494929
dtype: float64
```

```python
In [35]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
```

```
foo two  -0.706771
bar one  -0.861849
qux one  -1.039575
baz one  -0.494929
dtype: float64
```
13.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with .loc is a bit challenging, but we’ve made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [36]: df = df.T

In [37]: df
Out[37]:
   A    B    C
first second
   bar  one  0.895717  0.410835 -1.413681
        two  0.805244  0.813850  1.607920
   baz  one -1.206412  0.132003  1.024180
        two  2.565646 -0.827317  0.569605
   foo  one  1.431256 -0.076467  0.875906
        two  1.340309 -1.187678 -2.211372
   qux  one -1.170299  1.130127  0.974466
        two -0.226169 -1.436737 -2.006747

In [38]: df.loc[('bar', 'two'),]

A  0.805244
B  0.813850
C  1.607920
Name: (bar, two), dtype: float64
```

Note that df.loc['bar', 'two'] would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with .loc, you must use a tuple like this:

```
In [39]: df.loc[('bar', 'two'), 'A']
Out[39]: 0.80524402538637851
```

You don’t have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with bar in the first level as follows:

df.loc['bar']

This is a shortcut for the slightly more verbose notation df.loc[('bar',),] (equivalent to df.loc['bar',] in this example).

“Partial” slicing also works quite nicely.

```
In [40]: df.loc['baz':'foo']
Out[40]:
   A    B    C
first second
   baz  one -1.206412  0.132003  1.024180
        two  2.565646 -0.827317  0.569605
   foo  one  1.431256 -0.076467  0.875906
        two  1.340309 -1.187678 -2.211372
```

You can slice with a ‘range’ of values, by providing a slice of tuples.
In [41]: df.loc[('baz', 'two'):('qux', 'one')]
Out[41]:
   A     B    C
first second
baz two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
two      1.340309 -1.187678 -2.211372
qux one  -1.170299  1.130127  0.974466

In [42]: df.loc[('baz', 'two'):'foo']
   ...
   ...
Out[42]:
   A     B    C
first second
baz two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
two      1.340309 -1.187678 -2.211372

Passing a list of labels or tuples works similar to reindexing:

In [43]: df.loc[['bar', 'two'], ('qux', 'one')]
Out[43]:
   A     B    C
first second
bar two  0.805244  0.813850  1.607920
qux one  -1.170299  1.130127  0.974466

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

In [44]: s = pd.Series([1, 2, 3, 4, 5, 6],
   index=pd.MultiIndex.from_product([['A', 'B'], ['c', 'd', 'e']]))

In [45]: s.loc[('A', 'c'), ('B', 'd')]  # list of tuples
Out[45]:
A c  1
B d  5
dtype: int64

In [46]: s.loc[['A', 'B'], ['c', 'd']]  # tuple of lists
Out[46]:
A c  1
d  2
B c  4
d  5
dtype: int64
13.2.1 Using slicers

You can slice a `MultiIndex` by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of that level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, both sides of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the *index* and for the *columns*. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the `MultiIndex` for the rows.

You should do this:

```python
df.loc[(slice('A1','A3'),.....), :]
```

You should not do this:

```python
df.loc[(slice('A1','A3'),.....)]
```

```python
In [47]: def mklbl(prefix,n):
    ....:     return ["%s%s" % (prefix,i) for i in range(n)]
    ....:

In [48]: miindex = pd.MultiIndex.from_product([mklbl('A',4),
                                 mklbl('B',2),
                                 mklbl('C',4),
                                 mklbl('D',2)])

In [49]: micolumns = pd.MultiIndex.from_tuples([('a','foo'),('a','bar'),
                                         ('b','foo'),('b','bah')],
                                         names=['lvl0', 'lvl1'])

In [50]: dfmi = pd.DataFrame(np.arange(len(miindex)*len(micolumns)).reshape((len(miindex),len(micolumns))),
                         index=miindex,
                         columns=micolumns).sort_index().sort_index(axis=1)

In [51]: dfmi
Out[51]:
<table>

</tr>
</tbody>
</table>

[24 rows x 4 columns]
It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [55]: dfmi.loc['A1', (slice(None), 'foo')]
Out[55]:
   lvl0   a   b
B0   C0   D0   64   66
     D1   68   70
C1   D0   72   74
     D1   76   78
C2   D0   80   82
     D1   84   86
C3   D0   88   90
...     ... ...
B1   C0   D1  100  102
     D1  108  110
C1   D0  112  114
     D1  116  118
C2   D0  120  122
     D1  124  126
[16 rows x 2 columns]
```

```
In [56]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
lvl0   a   b
lvl1   foo  foo
A0   B0   C1   D0   8   10
     D1   12   14
     C3   D0  24   26
      D1   28   30
B1   C1   D0  40   42
     D1  44   46
     C3   D0  56   58
...     ... ...
A3   B0   C1   D1  204  206
     C3   D0  216  218
      D1  220  222
B1   C1   D0  232  234
     D1  236  238
     C3   D0  248  250
      D1  252  254
[32 rows x 2 columns]
```

Using a boolean indexer you can provide selection related to the values.

```
In [57]: mask = dfmi['a', 'foo'] > 200

In [58]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
Out[58]:
   lvl0   a   b
   lvl1   foo  foo
```

(continues on next page)
You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```
In [59]: dfmi.loc(axis=0)[:, :, ['C1', 'C3']]
Out[59]:
     a    b
   lvl0
lvl1 bar  foo  bah  foo
   A0  9    8  11    10
   D0 13   12  15    14
   C0 25   24  27    26
   D0 29   28  31    30
   B1 41   40  43    42
   D0 45   44  47    46
   C0 57   56  59    58
   D0 ...
```

Furthermore you can set the values using the following methods.

```
In [60]: df2 = dfmi.copy()

In [61]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [62]: df2
Out[62]:
     a    b
   lvl0
   A0  1    0  3    2
   D0  5    4  7     6
   C0-10   -10 -10  -10
   D0-10   -10 -10  -10
   B1 17    16  19    18
   D0 21    20  23    22
   C0-10   -10 -10  -10
   D0 ...
```

(continues on next page)
You can use a right-hand-side of an alignable object as well.

```python
In [63]: df2 = dfmi.copy()
In [64]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
In [65]: df2
Out[65]:
    lvl0    a    b
   lvl1
A0  B0  C0  D0  1  0  3  2
   D1  5  4  7  6
   C1  D0  9000  8000  11000  10000
   D1  13000  12000  15000  14000
   C2  D0  17  16  19  18
   D1  21  20  23  22
   C3  D0  25000  24000  27000  26000
   D1  253000  252000  255000  254000
... ... ... ... ...
   A3  B1  C0  D1  229  228  231  230
   C1  D0  233000  232000  235000  234000
   D1  237000  236000  239000  238000
   C2  D0  241  240  243  242
   D1  245  244  247  246
   C3  D0  249000  248000  251000  250000
   D1  253000  252000  255000  254000
[64 rows x 4 columns]
```

### 13.2.2 Cross-section

The **xs** method of **DataFrame** additionally takes a level argument to make selecting data at a particular level of a **MultiIndex** easier.

```python
In [66]: df
Out[66]:
     A  B  C
first  bar 0.895717 0.410835 -1.413681
     baz -1.206412 0.132003  1.024180
     foo  1.431256 -0.076467  0.875906
     qux -1.170299  1.130127  0.974466
     baz  1.340309 -1.187678 -2.211372
     foo -0.226169 -1.436737 -2.006747

In [67]: df.xs('one', level='second')
```

```\------------------------
   A  B  C
first  bar 0.895717 0.410835 -1.413681
\------------------------```
You can also select on the columns with `xs()`, by providing the axis argument.

```
In [69]: df = df.T

In [70]: df.xs('one', level='second', axis=1)
Out[70]:
    first   bar   baz   foo   qux
A       0.895717 -1.206412 1.431256 -1.170299
B       0.410835  0.132003 0.076467  0.875906
C      -1.413681  1.024180  1.130127  0.974466
```

`xs()` also allows selection with multiple keys.

```
In [72]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[72]:
    first   bar
second
A       0.895717
B       0.410835
C      -1.413681
```

You can pass `drop_level=False` to `xs()` to retain the level that was selected.
In [74]: df.xs('one', level='second', axis=1, drop_level=False)
Out[74]:
first  bar  baz  foo  qux
second one  one  one  one
A  0.895717 -1.206412  1.431256 -1.170299
B  0.410835  0.132003 -0.076467  1.130127
C -1.413681  1.024180  0.875906  0.974466

Compare the above with the result using drop_level=True (the default value).

In [75]: df.xs('one', level='second', axis=1, drop_level=True)
Out[75]:
first  bar  baz  foo  qux
A  0.895717 -1.206412  1.431256 -1.170299
B  0.410835  0.132003 -0.076467  1.130127
C -1.413681  1.024180  0.875906  0.974466

13.2.3 Advanced reindexing and alignment

The parameter level has been added to the reindex and align methods of pandas objects. This is useful to broadcast values across a level. For instance:

In [76]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x','y']],
                   labels=[[1,1,0,0],[1,0,1,0]])

In [77]: df = pd.DataFrame(np.random.randn(4,2), index=midx)

In [78]: df
Out[78]:
   0   1
one y  1.519970 -0.493662
   x   0.600178  0.274230
zero y  0.132885 -0.023688
   x   2.410179  1.450520

In [79]: df2 = df.mean(level=0)

In [80]: df2
Out[80]:
   0   1
one  1.060074 -0.109716
zero  1.271532  0.713416

In [81]: df2.reindex(df.index, level=0)

# aligning
In [82]: df_aligned, df2_aligned = df.align(df2, level=0)

(continues on next page)
In [83]: df_aligned
Out[83]:
   0  1
one y 1.519970 -0.493662
   x 0.600178  0.274230
zero y 0.132885 -0.023688
   x 2.410179  1.450520

In [84]: df2_aligned

In [85]: df[:5]
Out[85]:
   0  1
one y 1.519970 -0.493662
   x 0.600178  0.274230
zero y 0.132885 -0.023688
   x 2.410179  1.450520

In [86]: df[:5].swaplevel(0, 1, axis=0)

In [87]: df[:5].reorder_levels([1,0], axis=0)

13.2.4 Swapping levels with swaplevel()

The swaplevel function can switch the order of two levels:

In [88]: df[:5]
Out[88]:
   0  1
one y 1.519970 -0.493662
   x 0.600178  0.274230
zero y 0.132885 -0.023688
   x 2.410179  1.450520

In [89]: df[:5].swaplevel(0, 1, axis=0)

13.2.5 Reordering levels with reorder_levels()

The reorder_levels function generalizes the swaplevel function, allowing you to permute the hierarchical index levels in one step:

In [90]: df[:5].reorder_levels([1,0], axis=0)
Out[90]:
   0  1
y one 1.519970 -0.493662
x one 0.600178  0.274230
y zero 0.132885 -0.023688
x zero 2.410179  1.450520
13.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index`.

```
In [88]: import random; random.shuffle(tuples)

In [89]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [90]: s
Out[90]:
foo one 0.206053
qux one -0.251905
baz two -2.213588
bar two 1.063327
qux two 1.266143
foo two 0.299368
baz one -0.863838
bar one 0.408204
dtype: float64

In [91]: s.sort_index()
...
bar one 0.408204
two 1.063327
baz one -0.863838
two -2.213588
foo one 0.206053
two 0.299368
qux one -0.251905
two 1.266143
dtype: float64

In [92]: s.sort_index(level=0)
...
bar one 0.408204
two 1.063327
baz one -0.863838
two -2.213588
foo one 0.206053
two 0.299368
qux one -0.251905
two 1.266143
dtype: float64

In [93]: s.sort_index(level=1)
...
bar one 0.408204
baz one -0.863838
foo one 0.206053
qux one -0.251905
bar two 1.063327
baz two -2.213588
foo two 0.299368
```

(continues on next page)
You may also pass a level name to `sort_index` if the MultiIndex levels are named.

```
In [94]: s.index.set_names(['L1', 'L2'], inplace=True)

In [95]: s.sort_index(level='L1')
Out[95]:
   L1  L2
  bar one  0.408204
two  1.063327
  baz one -0.863838
two  2.213588
  foo one  0.206053
two  0.299368
  qux one -0.251905
two  1.266143
dtype: float64
```

```
In [96]: s.sort_index(level='L2')
   L1  L2
  bar one  0.408204
  baz one -0.863838
  foo one  0.206053
  qux one -0.251905
  bar two  1.063327
  baz two -2.213588
  foo two  0.299368
  qux two  1.266143
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

```
In [97]: df.T.sort_index(level=1, axis=1)
Out[97]:
     one  zero  one  zero
       x     x     y     y
    0  0.600178  2.410179  1.519970  0.132885
   1  0.274230  1.450520 -0.493662  0.023688
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
in [98]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
                        'joe': ['x', 'x', 'z', 'y'],
                        'jolie': np.random.rand(4)})

in [99]: dfm = dfm.set_index(['jim', 'joe'])
```

```
in [100]: dfm
Out[100]:
    jolie
```

(continues on next page)
In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:
    jolie
  jim joe
1   z  0.64094

Furthermore if you try to index something that is not fully lexsorted, this can raise:

In [5]: dfm.loc[(0,'y'):(1, 'z')]
UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'

The `is_lexsorted()` method on an Index show if the index is sorted, and the `lexsort_depth` property returns the sort depth:

In [101]: dfm.index.is_lexsorted()
Out[101]: False

In [102]: dfm.index.lexsort_depth
Out[102]: 1

In [103]: dfm = dfm.sort_index()

In [104]: dfm
Out[104]:
    jolie
  jim joe
0   x  0.490671
   x  0.120248
1   y  0.110968
   z  0.537020

In [105]: dfm.index.is_lexsorted()
Out[105]: True

In [106]: dfm.index.lexsort_depth
Out[106]: 2

And now selection works as expected.

In [107]: dfm.loc[(0,'y'):(1, 'z')]
Out[107]:
    jolie
  jim joe
1   y  0.110968
   z  0.537020
13.4 Take Methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [108]: index = pd.Index(np.random.randint(0, 1000, 10))
In [109]: index
Out[109]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')
In [110]: positions = [0, 9, 3]
In [111]: index[positions]
Out[111]: Int64Index([214, 329, 567], dtype='int64')
In [112]: index.take(positions)
Out[112]: Int64Index([214, 329, 567], dtype='int64')
```

```
In [113]: ser = pd.Series(np.random.randn(10))
In [114]: ser.iloc[positions]
Out[114]:
      0  -0.179666
      9   1.824375
      3   0.392149
      dtype: float64
In [115]: ser.take(positions)
Out[115]:
      0  -0.179666
      9   1.824375
      3   0.392149
      dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [116]: frm = pd.DataFrame(np.random.randn(5, 3))
In [117]: frm.take([1, 4, 3])
Out[117]:
     0       1       2
0 -1.237881  0.106854 -1.276829
1  0.629675 -1.425966  1.857704
2  0.979542 -1.633678  0.615855
In [118]: frm.take([0, 2], axis=1)
Out[118]:
     0       2
0  0.595974  0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```
It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [119]: arr = np.random.randn(10)
In [120]: arr.take([False, False, True, True])
Out[120]: array([-1.1935, -1.1935, 0.6775, 0.6775])
In [121]: arr[[0, 1]]
Out[121]: array([-1.1935, 0.6775])
In [122]: ser = pd.Series(np.random.randn(10))
In [123]: ser.take([False, False, True, True])
Out[123]:
   0   0.233141
   1  -0.223540
   dtype: float64
In [124]: ser.iloc[[0, 1]]
Out[124]:
   0   0.233141
   1  -0.223540
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

### 13.5 Index Types

We have discussed `MultiIndex` in the previous sections pretty extensively. `DatetimeIndex` and `PeriodIndex` are shown here, and information about `TimedeltaIndex` is found [here](#).

In the following sub-sections we will highlight some other index types.

#### 13.5.1 CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [125]: from pandas.api.types import CategoricalDtype

In [126]: df = pd.DataFrame({'A': np.arange(6),
                       'B': list('aabbca'))

In [127]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [128]: df
```

(continues on next page)
Setting the index will create a `CategoricalIndex`.

Indexing with `__getitem__/ .iloc/.loc` works similarly to an `Index` with duplicates. The indexers must be in the category or the operation will raise a `KeyError`.

The `CategoricalIndex` is preserved after indexing:

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is `cab`).
Groupby operations on the index will preserve the index nature as well.

```python
In [136]: df2.groupby(level=0).sum()
Out[136]:
   A  B
c  4
a  6
b  5
```

```
In [137]: df2.groupby(level=0).sum().index
Out[137]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the passed Categorical dtype. This allows one to arbitrarily index these even with values not in the categories, similarly to how you can reindex any pandas index.

```python
In [138]: df2.reindex(['a','e'])
Out[138]:
A   B
a  0.0
a  1.0
a  5.0
e  NaN
```

```python
In [139]: df2.reindex(['a','e']).index
Out[139]: Index(['a', 'a', 'a', 'e'], dtype='object', name='B')
```

```python
In [140]: df2.reindex(pd.Categorical(['a','e'],categories=list('abcde')))
```

```python
In [141]: df2.reindex(pd.Categorical(['a','e'],categories=list('abcde'))).index
```

**Warning:** Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

```python
In [9]: df3 = pd.DataFrame({'A' : np.arange(6),
       'B' : pd.Series(list('aabbca')).astype('category')})
In [11]: df3 = df3.set_index('B')
```

```python
In [11]: df3.index
Out[11]: CategoricalIndex([u'a', u'a', u'b', u'b', u'c', u'a'], categories=[u'a', u'b', u'c'], ordered=False, name=u'B', dtype='category')
```

```
In [10]: pd.concat([df2, df3])
```
13.5.2 Int64Index and RangeIndex

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see here.

Int64Index is a fundamental basic index in pandas. This is an Immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the Int64Index would provide the default index for all NDFrame objects.

RangeIndex is a sub-class of Int64Index added in version 0.18.0, now providing the default index for all NDFrame objects. RangeIndex is an optimized version of Int64Index that can represent a monotonic ordered set. These are analogous to Python range types.

13.5.3 Float64Index

By default a Float64Index will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [], ix, loc for scalar indexing and slicing work exactly the same.

```
In [142]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])
In [143]: indexf
Out[143]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [144]: sf = pd.Series(range(5), index=indexf)
In [145]: sf
Out[145]:
  1.5  0
  2.0  1
  3.0  2
  4.5  3
  5.0  4
dtype: int64
```

Scalar selection for [], loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [146]: sf[3]
Out[146]: 2
In [147]: sf[3.0]
Out[147]: 2
In [148]: sf.loc[3]
Out[148]: 2
In [149]: sf.loc[3.0]
Out[149]: 2
```

The only positional indexing is via iloc.
In [150]: sf.iloc[3]
Out[150]: 3

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using [], ix, loc, and always positional when using iloc. The exception is when the slice is boolean, in which case it will always be positional.

In [151]: sf[2:4]
Out[151]:
2.0  1
3.0  2
dtype: int64

In [152]: sf.loc[2:4]
2.0  1
3.0  2
dtype: int64

In [153]: sf.iloc[2:4]
3.0  2
4.5  3
dtype: int64

In float indexes, slicing using floats is allowed.

In [154]: sf[2.1:4.6]
Out[154]:
3.0  2
4.5  3
dtype: int64

In [155]: sf.loc[2.1:4.6]
3.0  2
4.5  3
dtype: int64

In non-float indexes, slicing using floats will raise a `TypeError`.

In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type

Warning: Using a scalar float indexer for .iloc has been removed in 0.18.0, so the following will raise a `TypeError`:

In [3]: pd.Series(range(5)).iloc[3.0]
TypeError: cannot do positional indexing on <class 'pandas.indexes.range.RangeIndex'> with these indexers [3.0] of <type 'float'>

13.5. Index Types
Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could for example be millisecond offsets.

```python
In [156]: dfir = pd.concat([pd.DataFrame(np.random.randn(5,2),
                        index=np.arange(5) * 250.0, columns=list('AB')),
                        pd.DataFrame(np.random.randn(6,2),
                        index=np.arange(4,10) * 250.1, columns=list('AB'))])

In [157]: dfir
Out[157]:
   A    B
0  0.997289 -1.693316
250.0 -0.179129 -1.598062
500.0  0.936914  0.912560
750.0 -1.003401  1.632781
1000.0 -0.724626  0.178219
1000.4  0.310610 -0.108002
...

Selection operations then will always work on a value basis, for all selection operators.

```python
In [158]: dfir[0:1000.4]
Out[158]:
   A    B
0  0.997289 -1.693316
250.0 -0.179129 -1.598062
500.0  0.936914  0.912560
750.0 -1.003401  1.632781
1000.0 -0.724626  0.178219
1000.4  0.310610 -0.108002
...

In [159]: dfir.loc[0:1001,'A']
Out[159]:
   A
0  0.997289
250.0 -0.179129
500.0  0.936914
750.0 -1.003401
1000.0 -0.724626
1000.4  0.310610
Name: A, dtype: float64

In [160]: dfir.loc[1000.4]
Out[160]:
   A    B
0  0.997289 -1.693316
250.0 -0.179129 -1.598062
500.0  0.936914  0.912560
750.0 -1.003401  1.632781
1000.0 -0.724626  0.178219
1000.4  0.310610 -0.108002
Name: 1000.4, dtype: float64

You could retrieve the first 1 second (1000 ms) of data as such:
If you need integer based selection, you should use `iloc`:

```python
In [162]: dfir.iloc[0:5]
Out[162]:
   A     B
0  0.0  0.997289 -1.693316
250.0 -0.179129 -1.598062
500.0  0.936914  0.912560
750.0 -1.003401  1.632781
1000.0 -0.724626  0.178219
```

### 13.5.4 `IntervalIndex`

New in version 0.20.0.

`IntervalIndex` together with its own `dtype`, `interval` as well as the `Interval` scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

**Warning:** These indexing behaviors are provisional and may change in a future version of pandas.

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```python
In [163]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
                    index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
In [164]: df
Out[164]:
          A
(0, 1]     1
(1, 2]     2
(2, 3]     3
(3, 4]     4
```

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```python
In [165]: df.loc[2]
Out[165]:
          A
0 (1, 2]  2
Name: (1, 2], dtype: int64
```
If you select a label *contained* within an interval, this will also select the interval.

```python
In [167]: df.loc[2.5]
Out[167]:
A
(2, 3] 3
```

```
In [168]: df.loc[[2.5, 3.5]]
Out[168]:
A
(2, 3] 3
(3, 4] 4
```

*Interval* and *IntervalIndex* are used by *cut* and *qcut*:

```python
In [169]: c = pd.cut(range(4), bins=2)
In [170]: c
Out[170]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

```python
In [171]: c.categories
Out[171]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]
closed='right',
dtype='interval[float64]')
```

Furthermore, *IntervalIndex* allows one to bin *other* data with these same bins, with *NaN* representing a missing value similar to other dtypes.

```python
In [172]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[172]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

### 13.5.4.1 Generating Ranges of Intervals

If we need intervals on a regular frequency, we can use the *interval_range()* function to create an *IntervalIndex* using various combinations of start, end, and periods. The default frequency for *interval_range* is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```python
In [173]: pd.interval_range(start=0, end=5)
Out[173]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4], (4, 5]]
closed='right',
dtype='interval[int64]')
```

(continues on next page)
In [174]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)

Out[174]:
IntervalIndex([(2017-01-01, 2017-01-02],
               (2017-01-02, 2017-01-03],
               (2017-01-03, 2017-01-04],
               (2017-01-04, 2017-01-05]],
               closed='right',
               dtype='interval[datetime64[ns]]')

In [175]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)

Out[175]:
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00],
               (1 days 00:00:00, 2 days 00:00:00],
               (2 days 00:00:00, 3 days 00:00:00]],
               closed='right',
               dtype='interval[timedelta64[ns]]')

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of *frequency aliases* with datetime-like intervals:

In [176]: pd.interval_range(start=0, periods=5, freq=1.5)

Out[176]:
IntervalIndex([(0.0, 1.5],
               (1.5, 3.0],
               (3.0, 4.5],
               (4.5, 6.0],
               (6.0, 7.5]],
               closed='right',
               dtype='interval[float64]')

In [177]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')

Out[177]:
IntervalIndex([(2017-01-01, 2017-01-08],
               (2017-01-08, 2017-01-15],
               (2017-01-15, 2017-01-22],
               (2017-01-22, 2017-01-29]],
               closed='right',
               dtype='interval[datetime64[ns]]')

In [178]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')

Out[178]:
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00],
               (0 days 09:00:00, 0 days 18:00:00],
               (0 days 18:00:00, 1 days 03:00:00]],
               closed='right',
               dtype='interval[timedelta64[ns]]')

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

In [179]: pd.interval_range(start=0, end=4, closed='both')

Out[179]:
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]],
               closed='both',
               dtype='interval[int64]')

In [180]: pd.interval_range(start=0, end=4, closed='neither')

Out[180]:
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]],
               closed='neither',
               dtype='interval[int64]')
New in version 0.23.0.

Specifying \texttt{start}, \texttt{end}, and \texttt{periods} will generate a range of evenly spaced intervals from \texttt{start} to \texttt{end} inclusively, with \texttt{periods} number of elements in the resulting \texttt{IntervalIndex}:

\begin{verbatim}
In [181]: pd.interval_range(start=0, end=6, periods=4)
Out[181]:
IntervalIndex([[(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]],
             closed='right',
             dtype='interval[float64]')
In [182]: pd.interval_range(pd.Timestamp('2018-01-01'), pd.Timestamp('2018-02-28'),
                          periods=3)
Out[182]:
IntervalIndex([[(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08 16:00:00],
               (2018-02-08 16:00:00, 2018-02-28]],
             closed='right',
             dtype='interval[datetime64[ns]]')
\end{verbatim}

13.6 Miscellaneous indexing FAQ

13.6.1 Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like \texttt{.loc}. The following code will generate exceptions:

\begin{verbatim}
s = pd.Series(range(5))
s[-1]
df = pd.DataFrame(np.random.randn(5, 4))
df
df.loc[-2:]
\end{verbatim}

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

13.6.2 Non-monotonic indexes require exact matches

If the index of a \texttt{Series} or \texttt{DataFrame} is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the \texttt{is_monotonic_increasing} and \texttt{is_monotonic_decreasing} attributes.

\begin{verbatim}
In [183]: df = pd.DataFrame(index=[2,3,3,4,5], columns=['data'], data=list(range(5)))
In [184]: df.index.is_monotonic_increasing
Out[184]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [185]: df.loc[0:4, :]
Out[185]:
   data
(continues on next page)
On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```python
In [187]: df = pd.DataFrame({'data': list(range(6))}, index=[2,3,1,4,3,5])
In [188]: df.index.is_monotonic_increasing
Out[188]: False

# OK because 2 and 4 are in the index
In [189]: df.loc[2:4, :]
```

```
   data
2    0
3    1
1    2
4    3
```

```
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'
```

`Index.is_monotonic_increasing()` and `Index.is_monotonic_decreasing()` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with `Index.is_unique()`

```python
In [190]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])

In [191]: weakly_monotonic
Out[191]: Index(['a', 'b', 'c', 'c'], dtype='object')

In [192]: weakly_monotonic.is_monotonic_increasing
Out[192]: True

In [193]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[193]: False
```
13.6.3 Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```
In [194]: s = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
Out[195]:
   a    0.112246
   b    0.871721
   c   -0.816064
   d   -0.784880
   e    1.030659
   f    0.187483
dtype: float64
```

Suppose we wished to slice from `c` to `e`, using integers this would be accomplished as such:

```
In [196]: s[2:5]
```

```
Out[196]:
   c   -0.816064
   d   -0.784880
   e    1.030659
```

However, if you only had `c` and `e`, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e'+1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design to make label-based slicing include both endpoints:

```
In [197]: s.loc['c':'e']
```

```
Out[197]:
   c   -0.816064
   d   -0.784880
   e    1.030659
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

13.6.4 Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [198]: series1 = pd.Series([1, 2, 3])
```

```
In [199]: series1.dtype
Out[199]: dtype('int64')
```

```
In [200]: res = series1.reindex([0, 4])
```
In [201]: res.dtype
Out[201]: dtype('float64')

In [202]: res

Out[202]:
0   1.0
4   NaN
dtype: float64

In [203]: series2 = pd.Series([True])

In [204]: series2.dtype
Out[204]: dtype('bool')

In [205]: res = series2.reindex_like(series1)

In [206]: res.dtype
Out[206]: dtype('O')

In [207]: res

Out[207]:
0    True
1   NaN
2   NaN
dtype: object

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as numpy.logical_and.

See the this old issue for a more detailed discussion.
14.1 Statistical Functions

14.1.1 Percent Change

Series, DataFrame, and Panel all have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values before computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
In [2]: ser.pct_change()
Out[2]:
   0     NaN
   1  -1.60298
   2   4.33494
   3  -0.24746
   4  -2.06735
   5  -1.14290
   6  -1.68821
   7  -9.75973
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))
In [4]: df.pct_change(periods=3)
Out[4]:
     0     1      2      3
0  NaN  NaN  NaN  NaN
1  NaN  NaN  NaN  NaN
2  NaN  NaN  NaN  NaN
3  NaN  NaN  NaN  NaN
4  NaN  NaN  NaN  NaN
5  NaN  NaN  NaN  NaN
6  NaN  NaN  NaN  NaN
7  NaN  NaN  NaN  NaN
8  NaN  NaN  NaN  NaN
9  NaN  NaN  NaN  NaN
```

14.1.2 Covariance

Series.cov() can be used to compute covariance between series (excluding missing values).
Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.
14.1.3 Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

**Note:** Please see the caveats associated with this method of calculating correlation matrices in the covariance section.

In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])

In [16]: frame.iloc[::2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: 0.013479040400098794

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.0072898851595406371

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:

```
a           b          c            d           e
a  1.000000  0.013479 -0.049269 -0.042239 -0.028525
b  0.013479  1.000000 -0.020433 -0.011139  0.005654
c -0.049269 -0.020433  1.000000  0.018587 -0.054269
d -0.042239 -0.011139  0.018587  1.000000 -0.017060
e -0.028525  0.005654 -0.054269 -0.017060  1.000000
```

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov, corr` also supports the optional `min_periods` keyword:

In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [21]: frame.loc[frame.index[:5], 'a'] = np.nan

In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```python
In [25]: index = ['a', 'b', 'c', 'd', 'e']
In [26]: columns = ['one', 'two', 'three', 'four']
In [27]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
In [28]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
In [29]: df1.corrwith(df2)
Out[29]:
one   -0.125501
two   -0.493244
three  0.344056
four   0.004183
dtype: float64
```

14.1.4 Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```python
In [31]: s = pd.Series(np.random.randn(5), index=list('abcde'))
In [32]: s['d'] = s['b']  # so there's a tie
In [33]: s.rank()
Out[33]:
a    5.0
b    2.5
c    1.0
d    2.5
```

(continues on next page)
rank() is also a DataFrame method and can rank either the rows (axis=0) or the columns (axis=1). NaN values are excluded from the ranking.

```python
In [34]: df = pd.DataFrame(np.random.randn(10, 6))
In [36]: df
Out[36]:
   0    1    2    3    4    5
0 -0.904948 -1.163537 -1.457187 0.135463 -1.457187 0.294650
1 -0.976288 -0.244652 -0.748406 -0.999601 -0.748406 -0.800809
2  0.401965  1.460840  1.256057  1.308127  1.256057  0.876004
3  0.205954  0.369552 -0.669304  0.383788 -0.669304  1.140296
4 -0.477586 -0.730705 -1.129149 -0.601463 -1.129149 -0.211196
5 -1.092970 -0.689246  0.908114  0.204848 NaN  0.463347
6  0.376892  0.959292  0.095572 -0.593740 NaN -0.069180
7 -1.002601  1.957794 -0.120708  0.094214 NaN -1.467422
8 -0.547231  0.664402 -0.519424 -0.073254 NaN -1.263544
9 -0.250277 -0.237428 -1.056443  0.419477 NaN  1.375064
In [37]: df.rank(1)
   0    1    2    3    4    5
0  4.0  3.0  1.5  5.0  1.5  6.0
1  2.0  6.0  4.5  1.0  4.5  3.0
2  1.0  6.0  3.5  5.0  3.5  2.0
3  4.0  5.0  1.5  3.0  1.5  6.0
4  5.0  3.0  1.5  4.0  1.5  6.0
5  1.0  2.0  5.0  3.0 NaN  4.0
6  4.0  5.0  3.0  1.0 NaN  2.0
7  2.0  5.0  3.0  4.0 NaN  1.0
8  2.0  5.0  3.0  4.0 NaN  1.0
9  2.0  3.0  1.0  4.0 NaN  5.0
```

rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- **average**: average rank of tied group
- **min**: lowest rank in the group
- **max**: highest rank in the group
- **first**: ranks assigned in the order they appear in the array

### 14.2 Window Functions

For working with data, a number of window functions are provided for computing common window or rolling statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and
kurtosis.

The `rolling()` and `expanding()` functions can be used directly from DataFrameGroupBy objects, see the `groupby docs`.

**Note:** The API for window statistics is quite similar to the way one works with GroupBy objects, see the documentation here.

We work with `rolling`, `expanding` and `exponentially weighted` data through the corresponding objects, `Rolling`, `Expanding` and `EWM`.

```python
In [38]: s = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', period=1000))
In [39]: s = s.cumsum()
In [40]: r = s.rolling(window=60)
```

These are created from methods on `Series` and `DataFrame`.

```python
In [41]: r = s.rolling(window=60)
```

These object provide tab-completion of the available methods and properties.

```python
In [14]: r.
```

Generally these methods all have the same interface. They all accept the following arguments:

- `window`: size of moving window
- `min_periods`: threshold of non-null data points to require (otherwise result is NA)
- `center`: boolean, whether to set the labels at the center (default is False)

We can then call methods on these `rolling` objects. These return like-indexed objects:
In [43]: r.mean()
Out[43]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05    NaN
2000-01-06    NaN
2000-01-07    NaN
...
2002-09-20   -62.694135
2002-09-21   -62.812190
2002-09-22   -62.914971
2002-09-23   -63.061867
2002-09-24   -63.213876
2002-09-25   -63.375074
2002-09-26   -63.539734
Freq: D, Length: 1000, dtype: float64

In [44]: s.plot(style='k--')
Out[44]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24661e80>

In [45]: r.mean().plot(style='k')
Out[45]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24661e80>
They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame’s columns:

```python
In [46]: df = pd.DataFrame(np.random.randn(1000, 4),
                      index=pd.date_range('1/1/2000', periods=1000),
                      columns=['A', 'B', 'C', 'D'])

In [47]: df = df.cumsum()

In [48]: df.rolling(window=60).sum().plot(subplots=True)
```

14.2.1 Method Summary

We provide a number of common statistical functions:
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count()</code></td>
<td>Number of non-null observations</td>
</tr>
<tr>
<td><code>sum()</code></td>
<td>Sum of values</td>
</tr>
<tr>
<td><code>mean()</code></td>
<td>Mean of values</td>
</tr>
<tr>
<td><code>median()</code></td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td><code>min()</code></td>
<td>Minimum</td>
</tr>
<tr>
<td><code>max()</code></td>
<td>Maximum</td>
</tr>
<tr>
<td><code>std()</code></td>
<td>Bessel-corrected sample standard deviation</td>
</tr>
<tr>
<td><code>var()</code></td>
<td>Unbiased variance</td>
</tr>
<tr>
<td><code>skew()</code></td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td><code>kurt()</code></td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td><code>quantile()</code></td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td><code>apply()</code></td>
<td>Generic apply</td>
</tr>
<tr>
<td><code>cov()</code></td>
<td>Unbiased covariance (binary)</td>
</tr>
<tr>
<td><code>corr()</code></td>
<td>Correlation (binary)</td>
</tr>
</tbody>
</table>

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argument should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```python
In [49]: mad = lambda x: np.fabs(x - x.mean()).mean()

In [50]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[50]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24b21630>
```
14.2.2 Rolling Windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according the `win_type`. The following methods are available:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sum()</code></td>
<td>Sum of values</td>
</tr>
<tr>
<td><code>mean()</code></td>
<td>Mean of values</td>
</tr>
</tbody>
</table>

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- boxcar
- triang
- blackman
- hamming
- bartlett
- parzen
- bohman
- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general_gaussian (needs power, width)
- slepian (needs width).

```python
In [51]: ser = pd.Series(np.random.randn(10), index=pd.date_range('1/1/2000', periods=10))
In [52]: ser.rolling(window=5, win_type='triang').mean()
Out[52]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -1.037870
2000-01-06  -0.767705
2000-01-07  -0.383197
2000-01-08  -0.395513
2000-01-09  -0.558440
2000-01-10  -0.672416
Freq: D, dtype: float64
```

Note that the boxcar window is equivalent to `mean()`.

```python
In [53]: ser.rolling(window=5, win_type='boxcar').mean()
Out[53]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -0.841164
2000-01-06  -0.779948
2000-01-07  -0.565487
2000-01-08  -0.502815
2000-01-09  -0.553755
2000-01-10  -0.472211
Freq: D, dtype: float64
```

```python
In [54]: ser.rolling(window=5).mean()
```

14.2. Window Functions
For some windowing functions, additional parameters must be specified:

```
In [55]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out[55]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -1.309989
2000-01-06  -1.153000
2000-01-07   0.606382
2000-01-08  -0.681101
2000-01-09  -0.289724
2000-01-10  -0.996632
Freq: D, dtype: float64
```

Note: For .sum() with a win_type, there is no normalization done to the weights for the window. Passing custom weights of [1, 1, 1] will yield a different result than passing weights of [2, 2, 2], for example. When passing a win_type instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the .mean() calculation is such that the weights are normalized with respect to each other. Weights of [1, 1, 1] and [2, 2, 2] yield the same result.

### 14.2.3 Time-aware Rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a .rolling() method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```
In [56]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                       index=pd.date_range('20130101 09:00:00', periods=5, freq='s'))
```

```
In [57]: dft
Out[57]:
            B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  4.0
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [58]: dft.rolling(2).sum()
Out[58]:
            B
2013-01-01 09:00:00  NaN
2013-01-01 09:00:01  1.0
```

(continues on next page)
Specifying an offset allows a more intuitive specification of the rolling frequency.

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.
Using the time-specification generates variable windows for this sparse data.

```python
In [64]: dft.rolling('2s').sum()
Out[64]:
     B
foo  
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```python
In [65]: dft = dft.reset_index()
In [66]: dft
Out[66]:
     foo  B
0 2013-01-01 09:00:00 0.0
1 2013-01-01 09:00:02 1.0
2 2013-01-01 09:00:03 2.0
3 2013-01-01 09:00:05 NaN
4 2013-01-01 09:00:06 4.0
In [67]: dft.rolling('2s', on='foo').sum()
```

### 14.2.4 Rolling Window Endpoints

New in version 0.20.0.

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th><code>closed</code></th>
<th>Description</th>
<th>Default for</th>
</tr>
</thead>
<tbody>
<tr>
<td>right</td>
<td>close right endpoint</td>
<td>time-based windows</td>
</tr>
<tr>
<td>left</td>
<td>close left endpoint</td>
<td></td>
</tr>
<tr>
<td>both</td>
<td>close both endpoints</td>
<td>fixed windows</td>
</tr>
<tr>
<td>neither</td>
<td>open endpoints</td>
<td></td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```python
In [68]: df = pd.DataFrame({'x': 1},
                      index = [pd.Timestamp('20130101 09:00:01'),
                      pd.Timestamp('20130101 09:00:02'))
```

(continues on next page)
In [69]: df["right"] = df.rolling('2s', closed='right').x.sum()  # default

In [70]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [71]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [72]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [73]: df

Out[73]:
<table>
<thead>
<tr>
<th>x</th>
<th>right</th>
<th>both</th>
<th>left</th>
<th>neither</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01 09:00:01</td>
<td>1.0</td>
<td>1.0</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-01 09:00:02</td>
<td>2.0</td>
<td>2.0</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-01 09:00:03</td>
<td>2.0</td>
<td>3.0</td>
<td>2.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-01 09:00:04</td>
<td>2.0</td>
<td>3.0</td>
<td>2.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-01 09:00:06</td>
<td>1.0</td>
<td>2.0</td>
<td>1.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

### 14.2.5 Time-aware Rolling vs. Resampling

Using `rolling()` with a time-based index is quite similar to `resampling`. They both operate and perform reductive operations on time-indexed pandas objects.

When using `rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

### 14.2.6 Centering Windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

In [74]: ser.rolling(window=5).mean()

Out[74]:
<table>
<thead>
<tr>
<th>x</th>
<th>NaN</th>
<th>NaN</th>
<th>NaN</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-02</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
### 14.2.7 Binary Window Functions

`cov()` and `corr()` can compute moving window statistics about two `Series` or any combination of `DataFrame/Series` or `DataFrame/DataFrame`. Here is the behavior in each case:

- **two `Series`**: compute the statistic for the pairing.
- **`DataFrame/Series`**: compute the statistics for each column of the `DataFrame` with the passed `Series`, thus returning a `DataFrame`.
- **`DataFrame/DataFrame`**: by default compute the statistic for matching column names, returning a `DataFrame`. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a MultiIndexed `DataFrame` whose index are the dates in question (see the next section).

For example:

```py
In [76]: df = pd.DataFrame(np.random.randn(1000, 4),
...:                    index=pd.date_range('1/1/2000', periods=1000),
...:                    columns=['A', 'B', 'C', 'D'])
...
...
In [77]: df = df.cumsum()
In [78]: df2 = df[:20]
In [79]: df2.rolling(window=5).corr(df2['B'])
Out[79]:
       A       B       C       D
2000-01-01 NaN  NaN  NaN  NaN
2000-01-02 NaN  NaN  NaN  NaN
2000-01-03 NaN  NaN  NaN  NaN
2000-01-04 NaN  NaN  NaN  NaN
...
```
In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a MultiIndexed `DataFrame` whose index are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

**Note:** Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.

```python
In [80]: covs = df[['B','C','D']].rolling(window=50).cov(df[['A','B','C']], pairwise=True)
```

```python
In [81]: covs.loc['2002-09-22':]
```

<table>

[20 rows x 4 columns]

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

In [84]: correls.unstack(1)[('A', 'C')].plot()

Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c25247630>
### 14.3 Aggregation

Once the `Rolling`, `Expanding` or `EWM` objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the *aggregating API*, *groupby API*, and *resample API*.

In [85]:
   : dfa = pd.DataFrame(np.random.randn(1000, 3),
   ....:                   index=pd.date_range('1/1/2000', periods=1000),
   ....:                   columns=['A', 'B', 'C'])
   ....:

In [86]:
   r = dfa.rolling(window=60, min_periods=1)

In [87]:
   r
   Out[87]: Rolling [window=60, min_periods=1, center=False, axis=0]

We can aggregate by passing a function to the entire DataFrame, or select a Series (or multiple Series) via standard `__getitem__`.

In [88]:
   r.aggregate(np.sum)
   Out[88]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>

    2002-09-21  0.844497 -9.280944
    2002-09-22  2.860036 -9.270337
    2002-09-23  3.510163 -8.151439
    2002-09-24  6.524983 -10.168078
    2002-09-25  6.409626 -9.956226
    2002-09-26  5.093787 -7.074515
[1000 rows x 2 columns]
As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

### 14.3.1 Applying multiple functions

With windowed `Series` you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```python
In [91]: r['A'].agg([np.sum, np.mean, np.std])
```

```plaintext
Out[91]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.289838</td>
<td>-0.289838</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.216612</td>
<td>-0.108306</td>
<td>0.256725</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.154661</td>
<td>0.384887</td>
<td>0.873311</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>2.969393</td>
<td>0.742348</td>
<td>1.009734</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>4.690630</td>
<td>0.938126</td>
<td>0.977914</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>3.880630</td>
<td>0.646772</td>
<td>1.128883</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>4.001957</td>
<td>0.571708</td>
<td>1.049487</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2002-09-20</td>
<td>2.652493</td>
<td>0.044208</td>
<td>1.164919</td>
</tr>
<tr>
<td>2002-09-21</td>
<td>0.844497</td>
<td>0.014075</td>
<td>1.148231</td>
</tr>
<tr>
<td>2002-09-22</td>
<td>2.860036</td>
<td>0.047667</td>
<td>1.132051</td>
</tr>
<tr>
<td>2002-09-23</td>
<td>3.510163</td>
<td>0.058503</td>
<td>1.134296</td>
</tr>
<tr>
<td>2002-09-24</td>
<td>6.524983</td>
<td>0.108750</td>
<td>1.144204</td>
</tr>
<tr>
<td>2002-09-25</td>
<td>6.409626</td>
<td>0.106827</td>
<td>1.142913</td>
</tr>
<tr>
<td>2002-09-26</td>
<td>5.093787</td>
<td>0.084896</td>
<td>1.151416</td>
</tr>
</tbody>
</table>

[1000 rows x 3 columns]
```

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [92]: r.agg([np.sum, np.mean])
```

```plaintext
Out[92]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>mean</td>
<td>sum</td>
</tr>
<tr>
<td>2000-01-01</td>
<td>-0.289838</td>
<td>-0.289838</td>
<td>-0.370545</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.216612</td>
<td>-0.108306</td>
<td>-1.675528</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.154661</td>
<td>0.384887</td>
<td>-1.634017</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>2.969393</td>
<td>0.742348</td>
<td>-4.003274</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>4.690630</td>
<td>0.938126</td>
<td>-4.682017</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>3.880630</td>
<td>0.646772</td>
<td>-4.447700</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>4.001957</td>
<td>0.571708</td>
<td>-2.884072</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2002-09-20</td>
<td>2.652493</td>
<td>0.044208</td>
<td>-10.528875</td>
</tr>
<tr>
<td>2002-09-21</td>
<td>0.844497</td>
<td>0.014075</td>
<td>-9.280944</td>
</tr>
<tr>
<td>2002-09-22</td>
<td>2.860036</td>
<td>0.047667</td>
<td>-9.270337</td>
</tr>
<tr>
<td>2002-09-23</td>
<td>3.510163</td>
<td>0.058503</td>
<td>-8.151439</td>
</tr>
<tr>
<td>2002-09-24</td>
<td>6.524983</td>
<td>0.108750</td>
<td>-10.168078</td>
</tr>
<tr>
<td>2002-09-25</td>
<td>6.409626</td>
<td>0.106827</td>
<td>-9.956226</td>
</tr>
<tr>
<td>2002-09-26</td>
<td>5.093787</td>
<td>0.084896</td>
<td>-7.074515</td>
</tr>
</tbody>
</table>

[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.
14.3.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [93]: r.agg({'A' : np.sum,
         ....:      'B' : lambda x: np.std(x, ddof=1)})
```

```
Out[93]:
    A       B
2000-01-01 -0.289838 NaN
2000-01-02 -0.216612 0.660747
2000-01-03  1.154661 0.689929
2000-01-04  2.969393 1.072199
2000-01-05  4.690630 0.939657
2000-01-06  3.880630 0.966848
2000-01-07  4.001957 1.240137
...       ...
2002-09-20 2.652493 1.114814
2002-09-21 0.844497 1.113220
2002-09-22 2.860036 1.113208
2002-09-23 3.510163 1.132381
2002-09-24 6.524983 1.080963
2002-09-25 6.409626 1.082911
2002-09-26 5.093787 1.136199
```

[1000 rows x 2 columns]

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object:

```
In [94]: r.agg({'A' : 'sum', 'B' : 'std'})
```

```
Out[94]:
    A       B
2000-01-01 -0.289838 NaN
2000-01-02 -0.216612 0.660747
2000-01-03  1.154661 0.689929
2000-01-04  2.969393 1.072199
2000-01-05  4.690630 0.939657
2000-01-06  3.880630 0.966848
2000-01-07  4.001957 1.240137
...       ...
2002-09-20 2.652493 1.114814
2002-09-21 0.844497 1.113220
2002-09-22 2.860036 1.113208
2002-09-23 3.510163 1.132381
2002-09-24 6.524983 1.080963
2002-09-25 6.409626 1.082911
2002-09-26 5.093787 1.136199
```

[1000 rows x 2 columns]

Furthermore you can pass a nested dict to indicate different aggregations on different columns.

```
In [95]: r.agg({'A' : ['sum','std'], 'B' : ['mean','std']})
```

```
Out[95]:
     A             B
     sum           std   mean       std
2000-01-01 -0.289838  NaN  -0.370545  NaN
```

(continues on next page)
14.4 Expanding Windows

A common alternative to rolling statistics is to use an expanding window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to .rolling, with the .expanding method returning an Expanding object. As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```
In [96]: df.rolling(window=len(df), min_periods=1).mean()[:5]
Out[96]:
   A         B         C         D
2000-01-01 0.314226 -0.001675 0.071823 0.892566
2000-01-02 0.654522 -0.171495 0.179278 0.853361
2000-01-03 0.708733 -0.064489 -0.238271 1.371111
2000-01-04 0.987613 0.163472 -0.919693 1.566485
2000-01-05 1.426971 0.288267 -1.358877 1.808650
```

```
In [97]: df.expanding(min_periods=1).mean()[:5]
```

These have a similar set of methods to .rolling methods.
14.4.1 Method Summary

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>count()</td>
<td>Number of non-null observations</td>
</tr>
<tr>
<td>sum()</td>
<td>Sum of values</td>
</tr>
<tr>
<td>mean()</td>
<td>Mean of values</td>
</tr>
<tr>

</tr>
<tr>
<td>var()</td>
<td>Unbiased variance</td>
</tr>
<tr>
<td>skew()</td>
<td>Unbiased skewness (3rd moment)</td>
</tr>
<tr>
<td>kurt()</td>
<td>Unbiased kurtosis (4th moment)</td>
</tr>
<tr>
<td>quantile()</td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td>apply()</td>
<td>Generic apply</td>
</tr>
<tr>
<td>cov()</td>
<td>Unbiased covariance (binary)</td>
</tr>
<tr>
<td>corr()</td>
<td>Correlation (binary)</td>
</tr>
</tbody>
</table>

Aside from not having a `window` parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- **min_periods**: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- **center**: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```python
In [98]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [99]: sn
Out[99]:
0    1.0
1    2.0
2     NaN
3    3.0
4     NaN
5    4.0
dtype: float64

In [100]: sn.rolling(2).max()
Out[100]:
0     NaN
1    2.0
2     NaN
3     NaN
4     NaN
5     NaN
dtype: float64

In [101]: sn.rolling(2, min_periods=1).max()
```
(continues on next page)
In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with expanding, use `fillna()`:

```
In [102]: sn.expanding().sum()
Out[102]:
   0   1.0
   1   3.0
   2   3.0
   3   6.0
   4   6.0
   5  10.0
dtype: float64
```

```
In [103]: sn.cumsum()
Out[103]:
   0   1.0
   1  NaN
   2   3.0
   3   6.0
   4  NaN
   5  10.0
dtype: float64
```

```
In [104]: sn.cumsum().fillna(method='ffill')
```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the `mean()` output for the previous time series dataset:

```
In [105]: s.plot(style='k--')
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x1c254345f8>
```

```
In [106]: s.expanding().mean().plot(style='k')
```

14.4. Expanding Windows
14.5 Exponentially Weighted Windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an `EWM` object. A number of expanding EW (exponentially weighted) methods are provided:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mean()</code></td>
<td>EW moving average</td>
</tr>
<tr>
<td><code>var()</code></td>
<td>EW moving variance</td>
</tr>
<tr>
<td><code>std()</code></td>
<td>EW moving standard deviation</td>
</tr>
<tr>
<td><code>corr()</code></td>
<td>EW moving correlation</td>
</tr>
<tr>
<td><code>cov()</code></td>
<td>EW moving covariance</td>
</tr>
</tbody>
</table>

In general, a weighted moving average is calculated as

\[
y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i},
\]

where \( x_t \) is the input, \( y_t \) is the result and the \( w_i \) are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights \( w_i = \)

\[\text{in general, a weighted moving average is calculated as}\]

\[
y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i},
\]

\[\text{where } x_t \text{ is the input, } y_t \text{ is the result and the } w_i \text{ are the weights.}\]

\[\text{The EW functions support two variants of exponential weights. The default, adjust=True, uses the weights } w_i =\]
When \( \text{adjust=False} \) is specified, moving averages are calculated as
\[
y_0 = x_0
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]
which is equivalent to using weights
\[
w_i = \begin{cases} 
\alpha(1-\alpha)^i & \text{if } i < t \\
(1-\alpha)^i & \text{if } i = t.
\end{cases}
\]

**Note:** These equations are sometimes written in terms of \( \alpha' = 1 - \alpha \), e.g.
\[
y_t = \alpha' y_{t-1} + (1 - \alpha')x_t.
\]

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history:
\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \cdots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \cdots}
\]
Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of \( 1 - \alpha \) we have
\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \cdots}{1 - (1 - \alpha)}
\]
\[= \frac{[x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \cdots] \alpha}{\alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \cdots] \alpha}
\]
\[= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \cdots] \alpha
\]
\[= \alpha x_t + (1 - \alpha)y_{t-1}
\]
which shows the equivalence of the above two variants for infinite series. When \( \text{adjust=True} \) we have \( y_0 = x_0 \) and from the last representation above we have \( y_t = \alpha x_t + (1 - \alpha)y_{t-1} \), therefore there is an assumption that \( x_0 \) is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have \( 0 < \alpha \leq 1 \), and while since version 0.18.0 it has been possible to pass \( \alpha \) directly, it’s often easier to think about either the span, center of mass (com) or half-life of an EW moment:
\[
\alpha = \begin{cases} 
\frac{s+1}{s}, & \text{for span } s \geq 1 \\
\frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\
1 - \exp \frac{\log 0.5}{h}, & \text{for half-life } h > 0
\end{cases}
\]
One must specify precisely one of span, center of mass, half-life and alpha to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: \( c = (s - 1)/2 \).
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:
EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

\[
\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.
\]

Whereas if `ignore_na=True`, the weighted average would be calculated as

\[
\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.
\]

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) =

\[
\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.
\]
ewma(x**2) - ewma(x)**2; whereas if bias=False (the default), the biased variance statistics are scaled by debiasing factors

\[ \frac{\left( \sum_{i=0}^{t} w_i \right)^2}{\left( \sum_{i=0}^{t} w_i \right)^2 - \sum_{i=0}^{t} w_i^2} \]

(For \( w_i = 1 \), this reduces to the usual \( N/(N - 1) \) factor, with \( N = t + 1 \).) See Weighted Sample Variance on Wikipedia for further details.
CHAPTER
FIFTEEN

WORKING WITH MISSING DATA

In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. It differs from the MaskedArray approach of, for example, scikits.timeseries. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

See the cookbook for some advanced strategies.

15.1 Missing data basics

15.1.1 When / why does data become missing?

Some might quibble over our usage of missing. By “missing” we simply mean NA (“not available”) or “not present for whatever reason”. Many data sets simply arrive with missing data, either because it exists and was not collected or it never existed. For example, in a collection of financial time series, some of the time series might start on different dates. Thus, values prior to the start date would generally be marked as missing.

In pandas, one of the most common ways that missing data is introduced into a data set is by reindexing. For example:

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
                       columns=['one', 'two', 'three'])

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:

   one   two   three  five
a -0.166778 0.501113 -0.355322 bar False
b  0.337890 0.580967  0.983801 bar False
c  0.057802 0.761948 -0.712964 bar True
d -0.443160 -0.974602  1.047704 bar False
f -0.717852 -1.053898 -0.019369 bar False

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
Out[6]:
```
15.1.2 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While \texttt{NaN} is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python \texttt{None} will arise and we wish to also consider that “missing” or “not available” or “NA”.

\textbf{Note:} If you want to consider \texttt{inf} and \texttt{-inf} to be “NA” in computations, you can set \texttt{pandas.options.mode.use_inf_as_na = True}.

To make detecting missing values easier (and across different array dtypes), pandas provides the \texttt{isna()} and \texttt{notna()} functions, which are also methods on Series and DataFrame objects:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
<th>four</th>
<th>five</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>

</tr>
</tbody>
</table>
c  True
d  False
e  True
f  True
g  False
h  True
Name: four, dtype: bool

In [10]: df2.isna()

```
   one   two   three   four   five
a  False  False  False  False  False
b   True   True   True   True   True
c  False  False  False  False  False
d   True   True   True   True   True
e  False  False  False  False  False
f  False  False  False  False  False
g   True   True   True   True   True
h  False  False  False  False  False
```

Warning: One has to be mindful that in Python (and NumPy), the nan's don't compare equal, but None's do. Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

In [11]: None == None
Out[11]: True

In [12]: np.nan == np.nan
\n\n\n\nOut[12]: False

So as compared to above, a scalar equality comparison versus a None(np.nan doesn’t provide useful information.

In [13]: df2['one'] == np.nan
Out[13]:
a  False
b  False
c  False
d  False
e  False
f  False
g  False
h  False
Name: one, dtype: bool

15.2 Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide intercompatibility between NaT and NaN.

In [14]: df2 = df.copy()

In [15]: df2['timestamp'] = pd.Timestamp('20120101')

(continues on next page)
15.3 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtypes.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [20]: s = pd.Series([1, 2, 3])

In [21]: s.loc[0] = None

In [22]: s
Out[22]:
0    NaN
1    2.0
2    3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [23]: s = pd.Series(["a", "b", "c"])

In [24]: s.loc[0] = None
```

(continues on next page)
In [25]: s.loc[1] = np.nan

In [26]: s
Out[26]:
0   None
1   NaN
2    c
 dtype: object

15.4 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

In [27]: a
Out[27]:
   one   two
a  NaN  0.501113
b  NaN  0.580967
c  NaN  0.761948
d -0.443160 -0.974602
e  0.057802  0.761948
f  1.053898  0.057802
g -0.443160 -0.974602
h -1.053898 -0.057802

In [28]: b
   →
   one   two   three
a  NaN  0.501113 -0.355322
b  NaN  0.580967  0.983801
c  NaN  0.761948  0.712964
d -0.443160 -0.974602  1.047704
e  0.057802  0.761948 -0.712964
f  1.053898  0.057802 -1.047704
g -0.443160 -0.974602  1.047704
h  NaN  0.761948 -0.712964

In [29]: a + b
   →
   one   three   two
a  NaN          NaN  1.002226
b  NaN          NaN  0.983801
c  NaN          NaN  1.523896
d -0.886321     NaN -1.849205
e  0.057802     NaN  0.206935
f  1.053898     NaN  0.019369
g -0.443160     NaN -0.846433
h -1.053898     NaN -2.063263

The descriptive statistics and computational methods discussed in the data structure overview (and listed here and here) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like cumsum() and cumprod() ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use skipna=False.
pandas: powerful Python data analysis toolkit, Release 0.23.2

15.4.1 Sum/Prod of Empties/Nans

**Warning**: This behavior is now standard as of v0.22.0 and is consistent with the default in numpy; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See v0.22.0 whatsnw for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

In [35]: pd.Series([np.nan]).sum()
Out[35]: 0.0

In [36]: pd.Series([]).sum()
Out[36]: 0.0
The product of an empty or all-NA Series or column of a DataFrame is 1.

```python
In [37]: pd.Series([np.nan]).prod()
Out[37]: 1.0

In [38]: pd.Series([]).prod()
```

### 15.4.2 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```python
In [39]: df
Out[39]:
\begin{tabular}{ccc}
\hline
one & two & three \\
\hline
a & NaN & 0.501113 -0.355322 \\
c & NaN & 0.580967 0.983801 \\
e & 0.057802 & 0.761948 -0.712964 \\
f & -0.443160 & -0.974602 1.047704 \\
h & NaN & -1.053898 -0.019369 \\
\hline
\end{tabular}

In [40]: df.groupby('one').mean()
```

See the groupby section [here](#) for more information.

### 15.5 Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

#### 15.5.1 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

**Replace NA with a scalar value**

```python
In [41]: df2
Out[41]:
\begin{tabular}{cccccc}
\hline
one & two & three & four & five & timestamp \\
\hline
a & NaN & 0.501113 -0.355322 & bar & False & NaT \\
c & NaN & 0.580967 0.983801 & bar & False & NaT \\
e & 0.057802 & 0.761948 -0.712964 & bar & True & 2012-01-01 \\
f & -0.443160 & -0.974602 1.047704 & bar & False & 2012-01-01 \\
h & NaN & -1.053898 -0.019369 & bar & False & NaT \\
\hline
\end{tabular}

In [42]: df2.fillna(0)
```
In [43]: df2['one'].fillna('missing')

→

a missing
b missing
c missing
e 0.057802
  
f -0.44316
  
h missing
Name: one, dtype: object

Fill gaps forward or backward

Using the same filling arguments as *reindexing*, we can propagate non-NA values forward or backward:

In [44]: df

Out[44]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>0.057802</td>
<td>0.761948</td>
<td>-0.712964</td>
</tr>
<tr>
<td>-0.443160</td>
<td>-0.974602</td>
<td>1.047704</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

In [45]: df.fillna(method='pad')

→

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>0.057802</td>
<td>0.761948</td>
<td>-0.712964</td>
</tr>
<tr>
<td>-0.443160</td>
<td>-0.974602</td>
<td>1.047704</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the *limit* keyword:

In [46]: df

Out[46]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

In [47]: df.fillna(method='pad', limit=1)

→

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>
To remind you, these are the available filling methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
</tbody>
</table>

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 15.5.2 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```python
In [48]: dff = pd.DataFrame(np.random.randn(10,3), columns=list('ABC'))
In [49]: dff.iloc[3:5,0] = np.nan
In [50]: dff.iloc[4:6,1] = np.nan
In [51]: dff.iloc[5:8,2] = np.nan
In [52]: dff
Out[52]:
       A         B         C
0  0.758887  2.340598  0.219039
1 -1.235583  0.031785  0.701683
2 -1.557016 -0.636986 -1.238610
3  NaN  1.002278  0.654052
4  NaN     NaN   1.053999
5  0.651981     NaN     NaN
6  0.109001 -0.533294     NaN
7 -1.037831 -1.150016     NaN
8 -1.037831 -1.150016     NaN
9 -0.258742 -0.706329  0.402547
```

```python
In [53]: dff.fillna(dff.mean())
```
In [54]: dff.fillna(dff.mean()['B':'C'])

    A       B       C
 0  0.758887  2.340598  0.219039
 1 -1.235583  0.031785  0.701683
 2 -1.557016 -0.636986 -1.238610
 3  NaN       -1.002278  0.654052
 4  NaN       0.033067  1.053999
 5  0.651981  0.033067  0.238800
 6  0.109001 -0.533294  0.238800
 7 -1.037831 -1.150016  0.238800
 8 -0.687693  1.921056 -0.121113
 9 -0.258742 -0.706329  0.402547

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

In [55]: dff.where(pd.notna(dff), dff.mean(), axis='columns')

    A       B       C
 0  0.758887  2.340598  0.219039
 1 -1.235583  0.031785  0.701683
 2 -1.557016 -0.636986 -1.238610
 3 -0.407125 -1.002278  0.654052
 4 -0.407125  0.033067  1.053999
 5  0.651981  0.033067  0.238800
 6  0.109001 -0.533294  0.238800
 7 -1.037831 -1.150016  0.238800
 8 -0.687693  1.921056 -0.121113
 9 -0.258742 -0.706329  0.402547

### 15.5.3 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

In [56]: df
Out[56]:

    one  two  three
  a  NaN  0.501113 -0.355322
  c  NaN  0.580967  0.983801
  e  NaN  0.000000  0.000000
  f  NaN  0.000000  0.000000
  h  NaN -1.053898  0.019369

In [57]: df.dropna(axis=0)

Empty DataFrame
Columns: [one, two, three]
Index: []

In [58]: df.dropna(axis=1)

   two     three
  a  0.501113 -0.355322
  c  0.580967  0.983801
  e  0.000000  0.000000
  f  0.000000  0.000000
  h -1.053898 -0.019369

In [59]: df['one'].dropna()

Series([], Name: one, dtype: float64)

An equivalent dropna() is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined in the API.

15.5.4 Interpolation

New in version 0.21.0: The limit_area keyword argument was added.

Both Series and DataFrame objects have interpolate() that, by default, performs linear interpolation at missing datapoints.

In [60]: ts
Out[60]:
2000-01-31 0.469112
2000-02-29 NaN
2000-03-31 NaN
2000-04-28 NaN
2000-05-31 NaN
2000-06-30 NaN
2000-07-31 NaN
... 2007-10-31 -3.305259
2007-11-30 -5.485119
2007-12-31 -6.854968
2008-01-31 -7.809176
2008-02-29 -6.346480
2008-03-31 -8.089641
2008-04-30 -8.916232
Freq: BM, Length: 100, dtype: float64

In [61]: ts.count()

In [62]: ts.interpolate().count()

In [63]: ts.interpolate().plot()
Index aware interpolation is available via the method keyword:

```python
In [64]: ts2
Out[64]:
2000-01-31   0.469112
2000-02-29     NaN
2002-07-31  -5.689738
2005-01-31     NaN
2008-04-30  -8.916232
dtype: float64
```

```python
In [65]: ts2.interpolate()
```

```
→
2000-01-31   0.469112
2000-02-29   -2.610313
2002-07-31  -5.689738
2005-01-31   -7.302985
2008-04-30  -8.916232
```

```python
In [66]: ts2.interpolate(method='time')
```

```
→
2000-01-31   0.469112
2000-02-29   -2.610313
2002-07-31  -5.689738
2005-01-31   -7.302985
2008-04-30  -8.916232
```

(continues on next page)
For a floating-point index, use method='values':

```python
In [67]: ser
Out[67]:
0.0 0.0
1.0 NaN
10.0 10.0
dtype: float64
```

```python
In [68]: ser.interpolate()
Out[68]:
0.0 0.0
1.0 1.0
10.0 10.0
dtype: float64
```

```python
In [69]: ser.interpolate(method='values')
Out[69]:
0.0 0.0
1.0 1.0
10.0 10.0
dtype: float64
```

You can also interpolate with a DataFrame:

```python
In [70]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
```

```python
In [71]: df
Out[71]:
       A   B
0  1.0  0.25
1  2.1   NaN
2   NaN   NaN
3  4.7   4.00
4  5.6  12.20
5  6.8  14.40
```

```python
In [72]: df.interpolate()
Out[72]:
       A   B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6  12.20
5  6.8  14.40
```

The method argument gives access to fancier interpolation methods. If you have scipy installed, you can pass the...
name of a 1-d interpolation routine to method. You’ll want to consult the full scipy interpolation documentation and reference guide for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, method='quadratic' may be appropriate.
- If you have values approximating a cumulative distribution function, then method='pchip' should work well.
- To fill missing values with goal of smooth plotting, consider method='akima'.

**Warning:** These methods require scipy.

```
In [73]: df.interpolate(method='barycentric')
Out[73]:
   A   B
0  1.00  0.250
1  2.10 -7.660
2  3.53 -4.515
3  4.70  4.000
4  5.60 12.200
5  6.80 14.400

In [74]: df.interpolate(method='pchip')

In [75]: df.interpolate(method='akima')
```

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [76]: df.interpolate(method='spline', order=2)
Out[76]:
   A   B
0  1.000000  0.250000
1  2.100000  0.672808
2  3.434545  1.928950
3  4.700000  4.000000
4  5.600000 12.200000
5  6.800000 14.400000
```

(continues on next page)
In [77]: df.interpolate(method='polynomial', order=2)

\[
\begin{array}{cc}
0 & 1.000000 \\
1 & 2.100000 \\
2 & 3.451351 \\
3 & 4.700000 \\
4 & 5.600000 \\
5 & 6.800000 \\
\end{array}
\]

Compare several methods:

```
In [78]: np.random.seed(2)

In [79]: ser = pd.Series(np.arange(1, 10.1, .25)**2 + np.random.randn(37))

In [80]: bad = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])

In [81]: ser[bad] = np.nan

In [82]: methods = ['linear', 'quadratic', 'cubic']

In [83]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})

In [84]: df.plot()
```

Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3702e518>
Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```python
In [85]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [86]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [87]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [88]: interp_s[49:51]
Out[88]:
        49.00  0.471410
        49.25  0.476841
        49.50  0.481780
        49.75  0.485998
        50.00  0.489266
        50.25  0.491814
        50.50  0.493995
        50.75  0.495763
        51.00  0.497074
dtype: float64
```
15.5.4.1 Interpolation Limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```python
In [89]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
# fill all consecutive values in a forward direction
In [90]: ser.interpolate()
Out[90]:
   0   NaN
   1   NaN
   2   5.0
   3   7.0
   4   9.0
   5  11.0
   6  13.0
   7  13.0
   8  13.0
dtype: float64
# fill one consecutive value in a forward direction
In [91]: ser.interpolate(limit=1)
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```python
# fill one consecutive value backwards
In [92]: ser.interpolate(limit=1, limit_direction='backward')
Out[92]:
   0   NaN
   1   NaN
   2   5.0
   3   7.0
   4  13.0
   5  13.0
   6   NaN
   7   NaN
   8   NaN
dtype: float64
# fill one consecutive value in both directions
In [93]: ser.interpolate(limit=1, limit_direction='both')
```

(continues on next page)
### pandas: powerful Python data analysis toolkit, Release 0.23.2

<table>
<thead>
<tr>
<th>#</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>5.0</td>
</tr>
<tr>
<td>2</td>
<td>5.0</td>
</tr>
<tr>
<td>3</td>
<td>7.0</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>11.0</td>
</tr>
<tr>
<td>6</td>
<td>13.0</td>
</tr>
<tr>
<td>7</td>
<td>13.0</td>
</tr>
<tr>
<td>8</td>
<td>NaN</td>
</tr>
</tbody>
</table>

dtype: float64

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the limit_area parameter restricts filling to either inside or outside values.

### # fill all consecutive values in both directions
In [94]: ser.interpolate(limit_direction='both')

dtype: float64

(continues on next page)
15.5.5 Replacing Generic Values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```python
In [98]: ser = pd.Series([0., 1., 2., 3., 4.])
In [99]: ser.replace(0, 5)
```

```
Out[99]:
0   5.0
1   1.0
2   2.0
3   3.0
4   4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```python
In [100]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
```

```
Out[100]:
0   4.0
1   3.0
2   2.0
3   1.0
4   0.0
dtype: float64
```

You can also specify a mapping dict:

```python
In [101]: ser.replace({0: 10, 1: 100})
```

```
Out[101]:
0  10.0
1 100.0
2   2.0
```
For a DataFrame, you can specify individual values by column:

```
In [102]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})
In [103]: df.replace({'a': 0, 'b': 5}, 100)
Out[103]:
   a  b
0 100 100
1  1  6
2  2  7
3  3  8
4  4  9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [104]: ser.replace([1, 2, 3], method='pad')
Out[104]:
0 0.0
1 0.0
2 0.0
3 0.0
4 4.0
```

**15.5.6 String/Regular Expression Replacement**

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '\\'. You should read about them if this is unclear.

Replace the `.` with NaN (str -> str):

```
In [105]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}
In [106]: df = pd.DataFrame(d)
In [107]: df.replace('.', np.nan)
Out[107]:
   a  b  c
0  a  a  a
1  b  b  b
2  NaN NaN NaN
3  NaN NaN NaN
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [108]: df.replace(r'\s*\.', np.nan, regex=True)
Out[108]:
   a  b  c
0  a  a  a
1  b  b  b
2  NaN NaN NaN
3  NaN NaN NaN
```
Replace a few different values (list -> list):

```python
In [109]: df.replace(['a', 'b'], ['b', np.nan])
Out[109]:
   a  b  c
0  0  0  b
1  1  1  b
2  NaN NaN
3  NaN  d
```

list of regex -> list of regex:

```python
In [110]: df.replace([r'.', r'(a)'], ['dot', '{\1}stuff'], regex=True)
Out[110]:
   a  {stuff  c
0  0  {stuff
1  1  b  b
2  dot NaN
3  dot  d
```

Only search in column 'b' (dict -> dict):

```python
In [111]: df.replace({'b': '.'}, {'b': np.nan})
Out[111]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```python
In [112]: df.replace({'b': r'\s*\s*'}, {'b': np.nan}, regex=True)
Out[112]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

You can pass nested dictionaries of regular expressions that use regex=True:

```python
In [113]: df.replace({'b': {'b': r'\s*\s*'}}, regex=True)
Out[113]:
   a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

Alternatively, you can pass the nested dictionary like so:

```
15.5. Cleaning / filling missing data 831
```
In [114]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[114]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>a</td>
<td>a</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>b</td>
<td>b</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>NaN</td>
<td>d</td>
</tr>
</tbody>
</table>

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

In [115]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\1ty'}, regex=True)
Out[115]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>a</td>
<td>a</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>b</td>
<td>b</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>.ty</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>.ty</td>
<td>d</td>
</tr>
</tbody>
</table>

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

In [116]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out[116]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>NaN</td>
<td>d</td>
</tr>
</tbody>
</table>

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [117]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out[117]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>NaN</td>
<td>d</td>
</tr>
</tbody>
</table>
```

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

### 15.5.7 Numeric Replacement

`replace()` is similar to `fillna()`.

```
In [118]: df = pd.DataFrame(np.random.randn(10, 2))
In [119]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
```

(continues on next page)
In [120]: df.replace(1.5, np.nan)
Out[120]:
    0  1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4  NaN    NaN
5  NaN    NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9  NaN    NaN

Replacing more than one value is possible by passing a list.

In [121]: df00 = df.values[0, 0]
In [122]: df.replace([1.5, df00], [np.nan, 'a'])
Out[122]:
    0  1
0  a  -1.02141
1  0.432396 -0.32358
2  0.423825  0.79918
3  1.26261  0.751965
4  NaN  NaN
5  NaN  NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.01985  -1.48247
9  NaN  NaN

In [123]: df[1].dtype
   ...
   -> dtype('float64')

You can also operate on the DataFrame in place:

In [124]: df.replace(1.5, np.nan, inplace=True)

Warning: When replacing multiple bool or datetime64 objects, the first argument to replace (to_replace) must match the type of the value being replaced. For example,

s = pd.Series([True, False, True])
s.replace({'a string': 'new value', True: False})  # raises

TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

will raise a TypeError because one of the dict keys is not of the correct type for replacement.

However, when replacing a single object such as,
15.6 Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

In [127]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [128]: s > 0
Out[128]:
0   True
2   True
4   True
6   True
7   True
dtype: bool

In [129]: (s > 0).dtype
Out[129]: dtype('bool')

In [130]: crit = (s > 0).reindex(list(range(8)))

In [131]: crit
Out[131]:
0   True
1   NaN
2   True
3   NaN
4   True
5   NaN
6   True

(continues on next page)
Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```python
In [133]: reindexed = s.reindex(list(range(8))).fillna(0)
```
```
In [134]: reindexed[crit]
```
```
---------------------------------------------------------------------------
ValueError                      Traceback (most recent call last)

GROUP BY: SPLIT-APPLY-COMBINE

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to one of the following:

- **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.

- **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.

- **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.

- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or itertools), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.
16.1 Splitting an object into groups

Pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```python
# default is axis=0
>>> grouped = obj.groupby(key)
>>> grouped = obj.groupby(key, axis=1)
>>> grouped = obj.groupby([key1, key2])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course df.groupby('A') is just syntactic sugar for df.groupby(df['A']), but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the keys. For example, consider the following DataFrame:

```python
In [1]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
                   'foo', 'bar', 'foo', 'foo'],
                   'B': ['one', 'one', 'two', 'three',
                   'two', 'two', 'one', 'three'],
                   'C': np.random.randn(8),
                   'D': np.random.randn(8))
```

```
In [2]: df
Out[2]:
     A  B         C         D
0  foo  one  0.469112 -0.861849
1  bar  one  0.282863 -2.104569
2  foo  two  1.509059  0.494929
3  bar  three  1.35632  1.071804
4  foo  two  1.212112  0.721555
5  bar  two  0.173215  0.706771
6  foo  one  0.119209  0.271860
7  foo  three -1.044236  0.271860
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:
These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [5]: def get_letter_type(letter):
    ...:     if letter.lower() in 'aeiou':
    ...:         return 'vowel'
    ...:     else:
    ...:         return 'consonant'
    ...

In [6]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a `groupby` operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```python
In [7]: lst = [1, 2, 3, 1, 2, 3]

In [8]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)

In [9]: grouped = s.groupby(level=0)

In [10]: grouped.first()
Out[10]:
   1  1
   2  2
   3  3
   dtype: int64

In [11]: grouped.last()
Out[11]:
   1 10
   2 20
   3 30
   dtype: int64

In [12]: grouped.sum()
Out[12]:
   1 11
   2 22
   3 33
   dtype: int64
```

Note that no splitting occurs until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.
16.1.1 GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```python
In [13]: df2 = pd.DataFrame({'X' : ['B', 'B', 'A', 'A'], 'Y' : [1, 2, 3, 4]})
In [14]: df2.groupby(['X']).sum()
Out[14]:
     Y
X    
A    7
B    3
In [15]: df2.groupby(['X'], sort=False).sum()
Out[15]:
     Y
X    
B    3
A    7
```

Note that `groupby` will preserve the order in which `observations` are sorted within each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```python
In [16]: df3 = pd.DataFrame({'X' : ['A', 'B', 'A', 'B'], 'Y' : [1, 4, 3, 2]})
In [17]: df3.groupby(['X']).get_group('A')
Out[17]:
     X  Y
0    A  1
2    A  3
In [18]: df3.groupby(['X']).get_group('B')
Out[18]:
     X  Y
1    B  4
3    B  2
```

16.1.2 GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```python
In [19]: df.groupby('A').groups
Out[19]:
{'bar': Int64Index([1, 3, 5], dtype='int64'),
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}
In [20]: df.groupby(get_letter_type, axis=1).groups
Out[20]:
{'consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')}
```

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:
```python
In [21]: grouped = df.groupby(['A', 'B'])

In [22]: grouped.groups
Out[22]:
{('bar', 'one'): Int64Index([1], dtype='int64'),
 ('bar', 'three'): Int64Index([3], dtype='int64'),
 ('bar', 'two'): Int64Index([5], dtype='int64'),
 ('foo', 'one'): Int64Index([0, 6], dtype='int64'),
 ('foo', 'three'): Int64Index([7], dtype='int64'),
 ('foo', 'two'): Int64Index([2, 4], dtype='int64')}

In [23]: len(grouped)
Out[23]:
6
```

GroupBy will tab complete column names (and other attributes):

```python
In [24]: df
Out[24]:
height  weight  gender
2000-01-01 42.849980 157.500553  male
2000-01-02 49.607315 177.340407  male
2000-01-03 56.293531 171.524640  male
2000-01-04 48.421077 144.251986  female
2000-01-05 46.556882 152.526206  male
2000-01-06 68.448851 168.272968  female
2000-01-07 70.757698 136.431469  male
2000-01-08 58.909500 176.499753  female
2000-01-09 76.435631 174.094104  female
2000-01-10 45.306120 177.540920  male

In [25]: gb = df.groupby('gender')

In [26]: gb.
```

16.1.3 GroupBy with MultiIndex

With **hierarchically-indexed data**, it’s quite natural to group by one of the levels of the hierarchy.

Let’s create a Series with a two-level MultiIndex.

```python
In [27]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]

In [28]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

(continues on next page)
We can then group by one of the levels in `s`.

```
In [31]: grouped = s.groupby(level=0)
```

```
In [32]: grouped.sum()
```

```
Out[32]:
   first
bar  one   -0.962232
     two   0.962232
baz  one    1.237723
     two  -0.067723
foo  one   0.785980
     two  -0.945867
qux  one   1.911055
     two  0.136294

dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [33]: s.groupby(level='second').sum()
```

```
Out[33]:
   second
one  0.980950
two  1.991575

dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```
In [34]: s.sum(level='second')
```

```
Out[34]:
   second
one  0.980950
two  1.991575

dtype: float64
```

Grouping with multiple levels is supported.

```
In [35]: s
```

```
Out[35]:
   first   second   third
bar  doo one -1.131345
     two  0.089329
baz  bee one  0.337863
     two -0.945867
```

(continues on next page)
foo  bop  one  -0.932132
     two  1.956030
qux  bop  one  0.017587
     two -0.016692
dtype: float64

In [36]: s.groupby(level=['first', 'second']).sum()

         first second
bar     doo  -1.220674
baz     bee  -0.608004
foo     bop   1.023898
qux     bop   0.000895
dtype: float64

New in version 0.20.

Index level names may be supplied as keys.

In [37]: s.groupby(['first', 'second']).sum()

Out[37]:
first second
bar     doo  -1.220674
baz     bee  -0.608004
foo     bop   1.023898
qux     bop   0.000895
dtype: float64

More on the sum function and aggregation later.

16.1.4 Grouping DataFrame with Index Levels and Columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as pd.Grouper objects.

In [38]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
In [39]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])

In [40]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
                   'B': np.arange(8)},
                   index=index)

In [41]: df
Out[41]:
    A  B
first second
bar one  1  0
     two  1  1
baz one  1  2
     two  1  3

(continues on next page)
The following example groups `df` by the `second` index level and the `A` column.

```python
In [42]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[42]:
         B
second A
  one  1  2
        2  4
        3  6
  two  1  4
        2  5
        3  7
```

Index levels may also be specified by name.

```python
In [43]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[43]:
         B
second A
  one  1  2
        2  4
        3  6
  two  1  4
        2  5
        3  7
```

New in version 0.20.

Index level names may be specified as keys directly to `groupby`.

```python
In [44]: df.groupby(['second', 'A']).sum()
Out[44]:
         B
second A
  one  1  2
        2  4
        3  6
  two  1  4
        2  5
        3  7
```

### 16.1.5 DataFrame column selection in GroupBy

Once you have created the `GroupBy` object from a DataFrame, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a DataFrame, you can do:

```python
In [45]: grouped = df.groupby(['A'])
In [46]: grouped_C = grouped['C']
In [47]: grouped_D = grouped['D']
```
This is mainly syntactic sugar for the alternative and much more verbose:

```python
In [48]: df['C'].groupby(df['A'])
Out[48]: <pandas.core.groupby.groupby.SeriesGroupBy object at 0x1c2adc8390>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

### 16.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```python
In [49]: grouped = df.groupby('A')
In [50]: for name, group in grouped:
    ....:     print(name)
    ....:     print(group)
    ....:
bar
   A  B   C    D
  1 bar one 0.254161 1.511763
  3 bar three 0.215897 -0.990582
  5 bar two -0.077118 1.211526
foo
   A  B   C    D
  0 foo one -0.575247 1.346061
  2 foo two -1.143704 1.627081
  4 foo two 1.193555 -0.441652
  6 foo one -0.408530 0.268520
  7 foo three -0.862495 0.024580
```

In the case of grouping by multiple keys, the group name will be a tuple:

```python
In [51]: for name, group in df.groupby(['A', 'B']):
    ....:     print(name)
    ....:     print(group)
    ....:
('bar', 'one')
   A  B   C    D
  1 bar one 0.254161 1.511763
('bar', 'three')
   A  B   C    D
  3 bar three 0.215897 -0.990582
('bar', 'two')
   A  B   C    D
  5 bar two -0.077118 1.211526
('foo', 'one')
   A  B   C    D
  0 foo one -0.575247 1.346061
('foo', 'three')
   A  B   C    D
  6 foo one -0.408530 0.268520
('foo', 'two')
   A  B   C    D
  7 foo three -0.862495 0.024580
```

(continues on next page)
It’s standard Python-fu but remember you can unpack the tuple in the for loop statement if you wish: for (k1, k2), group in grouped:

### 16.3 Selecting a group

A single group can be selected using `get_group()`:

```python
In [52]: grouped.get_group('bar')
Out[52]:
    A     B      C      D
   --- ---- ---- ----
  1 bar one  0.254  1.511763
  3 bar three 0.215897  0.990582
  5 bar two -0.077118  1.211526
```

Or for an object grouped on multiple columns:

```python
In [53]: df.groupby([A, B]).get_group(('bar', 'one'))
Out[53]:
    A     B      C      D
   --- ---- ---- ----
  1 bar one  0.254  1.511763
```

### 16.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the aggregating API, window functions API, and resample API.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```python
In [54]: grouped = df.groupby('A')
In [55]: grouped.aggregate(np.sum)
Out[55]:
   C      D
  --- ----
  bar 0.392940 1.732707
  foo -1.796421 2.824590
```

```python
In [56]: grouped = df.groupby([A, B])
In [57]: grouped.aggregate(np.sum)
Out[57]:
    A     B      C      D
   --- ---- ---- ----
  bar one 0.254161 1.511763
  three 0.215897  0.990582
  two  -0.077118  1.211526
  foo one -0.983776  1.614581
  three -0.862495   0.024580
  two   0.049851  1.185429
```
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index` option:

```python
In [58]: grouped = df.groupby(['A', 'B'], as_index=False)

In [59]: grouped.aggregate(np.sum)
Out[59]:
   A   B    C      D
0  bar  one  0.254161  1.511763
1  bar  three  0.215897  0.990582
2  bar  two  -0.077118  1.211526
3  foo  one  -0.983776  1.614581
4  foo  three  -0.862495  0.024580
5  foo  two   0.049851  1.185429
```

```python
In [60]: df.groupby('A', as_index=False).sum()

Out[60]:
   A   C      D
0  bar  0.392940  1.732707
1  foo -1.796421  2.824590
```

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting `MultiIndex`:

```python
In [61]: df.groupby(['A', 'B']).sum().reset_index()
Out[61]:
    A   B    C      D
0  bar  one  0.254161  1.511763
1  bar  three  0.215897  0.990582
2  bar  two  -0.077118  1.211526
3  foo  one  -0.983776  1.614581
4  foo  three  -0.862495  0.024580
5  foo  two   0.049851  1.185429
```

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```python
In [62]: grouped.size()
Out[62]:
    A   B
   bar one 1
    three 1
    two  1
   foo one 2
    three 1
    two  2
dtype: int64
```

```python
In [63]: grouped.describe()
Out[63]:
     C     ...      D
   ...   ...     ...
   count  mean     std    min  25% ...    min  25%  50%  ...  75%  max
   ...  75%    max
   0  1.0  0.254161  NaN  0.254161  0.254161 ...  1.511763  1.511763  1.511763  1.511763
```

(continues on next page)
Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean of groups</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive statistics</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset if n is a list</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a `Series` to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda x: x)` Note that `nth()` can act as a reducer or a filter, see [here](#).

### 16.4.1 Applying multiple functions at once

With grouped `Series` you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [64]: grouped = df.groupby('A')

In [65]: grouped['C'].agg([np.sum, np.mean, np.std])
Out[65]:
          sum   mean   std
A
```

(continues on next page)
On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [66]: grouped.agg([np.sum, np.mean, np.std])
Out[66]:
          C          D
    sum  mean  std   sum  mean  std
   A  
    bar  0.392940  0.130980  0.181231  1.732707  0.577569  1.366330
    foo -1.796421 -0.359284  0.912265  2.824590  0.564918  0.884785
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```python
In [67]: (grouped['C'].agg([np.sum, np.mean, np.std])
       .rename(columns={'sum': 'foo',
                        'mean': 'bar',
                        'std': 'baz'}))
Out[67]:
          foo  bar  baz
   A  
    bar  0.392940  0.130980  0.181231
    foo -1.796421 -0.359284  0.912265
```

For a grouped DataFrame, you can rename in a similar manner:

```python
In [68]: (grouped.agg({np.sum, np.mean, np.std})
       .rename(columns={'sum': 'foo',
                        'mean': 'bar',
                        'std': 'baz'}))
Out[68]:
          C          D
    foo  bar  baz   foo  bar  baz
   A  
    bar  0.392940  0.130980  0.181231  1.732707  0.577569  1.366330
    foo -1.796421 -0.359284  0.912265  2.824590  0.564918  0.884785
```

### 16.4.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```python
In [69]: grouped.agg({'C': np.sum, 'D': lambda x: np.std(x, ddof=1)})
Out[69]:
          C          D
   A  
    bar  0.392940  0.130980  0.181231  1.732707  0.577569  1.366330
    foo -1.796421 -0.359284  0.912265  2.824590  0.564918  0.884785
```
The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via dispatching:

```python
In [70]: grouped.agg({'C' : 'sum', 'D' : 'std'})
Out[70]:
   C       D
   A  0.392940  1.366330
   bar  0.392940  1.366330
   foo -1.796421  0.884785
```

**Note:** If you pass a dict to `aggregate`, the ordering of the output columns is non-deterministic. If you want to be sure the output columns will be in a specific order, you can use an `OrderedDict`. Compare the output of the following two commands:

```python
In [71]: grouped.agg({'D': 'std', 'C': 'mean'})
Out[71]:
   D       C
   A  1.366330  0.130980
   bar  1.366330  0.130980
   foo  0.884785 -0.359284

In [72]: grouped.agg(OrderedDict([('D', 'std'), ('C', 'mean')]))
```

### 16.4.3 Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```python
In [73]: df.groupby('A').sum()
Out[73]:
   C       D
   A  0.392940  1.732707
   bar  0.392940  1.732707
   foo -1.796421  2.824590

In [74]: df.groupby(['A', 'B']).mean()
```

(continues on next page)
Of course `sum` and `mean` are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

## 16.5 Transformation

The `transform` method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, `grouped.transform(lambda x: x.iloc[-1])`).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using `chunk.apply`.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using `fillna`, `inplace` must be `False` (`grouped.transform(lambda x: x.fillna(inplace=False))`).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.

For example, suppose we wished to standardize the data within each group:

```python
In [75]: index = pd.date_range('10/1/1999', periods=1100)
In [76]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [77]: ts = ts.rolling(window=100,min_periods=100).mean().dropna()
In [78]: ts.head()
Out[78]:
2000-01-08  0.779333
2000-01-09  0.778852
2000-01-10  0.786476
2000-01-11  0.782797
2000-01-12  0.798110
Freq: D, dtype: float64
In [79]: ts.tail()
Out[79]:
2002-09-30  0.660294
2002-10-01  0.631095
2002-10-02  0.673601
2002-10-03  0.709213
2002-10-04  0.719369
Freq: D, dtype: float64
```

```python
In [80]: key = lambda x: x.year
In [81]: zscore = lambda x: (x - x.mean()) / x.std()
In [82]: transformed = ts.groupby(key).transform(zscore)
```
We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```python
# Original Data
In [83]: grouped = ts.groupby(key)

In [84]: grouped.mean()
Out[84]:
2000  0.442441
2001  0.526246
2002  0.459365
dtype: float64

In [85]: grouped.std()
Out[85]:
2000  0.131752
2001  0.210945
2002  0.128753
dtype: float64

# Transformed Data
In [86]: grouped_trans = transformed.groupby(key)

In [87]: grouped_trans.mean()
Out[87]:
2000  1.168208e-15
2001  1.454544e-15
2002  1.726657e-15
dtype: float64

In [88]: grouped_trans.std()
Out[88]:
2000  1.0
2001  1.0
2002  1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```python
In [89]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [90]: compare.plot()
Out[90]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2ad9db38>
```
Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [91]: data_range = lambda x: x.max() - x.min()

In [92]: ts.groupby(key).transform(data_range)
Out[92]:
       2000-01-08  0.623893
       2000-01-09  0.623893
       2000-01-10  0.623893
       2000-01-11  0.623893
       2000-01-12  0.623893
       2000-01-13  0.623893
       2000-01-14  0.623893
       ...
       2002-09-28  0.558275
       2002-09-29  0.558275
       2002-09-30  0.558275
       2002-10-01  0.558275
       2002-10-02  0.558275
       2002-10-03  0.558275
       2002-10-04  0.558275
Freq: D, Length: 1001, dtype: float64
```

Alternatively the built-in methods can be used to produce the same outputs.
Another common data transform is to replace missing data with the group mean.

In [94]: data_df
Out[94]:
   A      B      C
0  1.539708 -1.166480  0.533026
1  1.302092 -0.505754  NaN
2 -0.371983  1.104803 -0.651520
3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
5  0.815643  0.367816 -0.469478
6 -0.030651  1.376106 -0.645129
...       ...       ...

994  0.042312 -1.628835  1.013822
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572  NaN
997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148  NaN
999  0.234564  0.517098  0.393534

[1000 rows x 3 columns]

In [95]: countries = np.array(['US', 'UK', 'GR', 'JP'])

In [96]: key = countries[np.random.randint(0, 4, 1000)]

In [97]: grouped = data_df.groupby(key)

# Non-NA count in each group
In [98]: grouped.count()
Out[98]:
   A  B  C
GR 209 217 189
JP 240 255 217
UK 216 231 193
US 239 250 217

(continues on next page)
We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.

```python
In [101]: grouped_trans = transformed.groupby(key)

In [102]: grouped.mean()  # original group means
Out[102]:
   A      B      C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [103]: grouped_trans.mean()  # transformation did not change group means
    →
   A      B      C
GR -0.098371 -0.015420  0.068053
JP  0.069025  0.023100 -0.077324
UK  0.034069 -0.052580 -0.116525
US  0.058664 -0.020399  0.028603

In [104]: grouped.count()  # original has some missing data points
    →
   A    B    C
GR 209 217 189
JP 240 255 217
UK 216 231 193
US 239 250 217

In [105]: grouped_trans.count()  # counts after transformation
    →
   A    B    C
GR 228 228 228
JP 267 267 267
UK 247 247 247

In [106]: grouped_trans.size()  # Verify non-NA count equals group size
    →
   GR 228
   JP 267
   UK 247
   US 258
dtype: int64
```

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing `as_index=False` will not affect these transformation methods.
For example: `fillna, ffill, bfill, shift`.

```
In [107]: grouped.ffill()
Out[107]:
   NaN    A      B      C
0  NaN  1.54  -1.17   0.53

```

### 16.5.1 New syntax to window and resample operations

New in version 0.18.1.

Working with the resample, expanding or rolling operations on the groupby level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupby.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```
     ...:                     'B': np.arange(20)})
     ...
In [109]: df_re
Out[109]:
   A  B
0  1  0
1  1  1
2  2  2
3  3  3
4  4  4
5  5  5
6  6  6
... ...
13  5 13
14  5 14
15  5 15
16  5 16
17  5 17
18  5 18
19  5 19
```

(continues on next page)
In [110]: df_re.groupby('A').rolling(4).B.mean()

A
1  0   NaN
1  1   NaN
2  2   1.5
3  3   2.5
4  4   3.5
5  5   4.5
... ...
5 13 11.5
14 12.5
15 13.5
16 14.5
17 15.5
18 16.5
19 17.5
Name: B, Length: 20, dtype: float64

The `expanding()` method will accumulate a given operation (sum() in the example) for all the members of each particular group.

In [111]: df_re.groupby('A').expanding().sum()

Out[111]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>

| 16 | 35.0 91.0 |
| 17 | 40.0 108.0 |
| 18 | 45.0 126.0 |
| 19 | 50.0 145.0 |

[20 rows x 2 columns]

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

In [112]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
                          .....: period=4,
                          .....: freq='W'),
                          .....: 'group': [1, 1, 2, 2],
                          .....: 'group': [1, 1, 2, 2],
                          .....: })

...
......:
......:
'dval': [5, 6, 7, 8]).set_index('date')

In [113]: df_re
Out[113]:
group  val
date
2016-01-03 1 5
2016-01-10 1 6
2016-01-17 2 7
2016-01-24 2 8

In [114]: df_re.groupby('group').resample('1D').ffill()

16.6 Filtration

The filter method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

In [115]: sf = pd.Series([1, 1, 2, 3, 3, 3])

In [116]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[116]:
3 3
4 3
5 3
dtype: int64

The argument of filter must be a function that, applied to the group as a whole, returns True or False. Another useful operation is filtering out elements that belong to groups with only a couple members.
In [117]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc'))

In [118]: dff.groupby('B').filter(lambda x: len(x) > 2)

Out[118]:
   A  B
0  2 b
1  3 b
2  4 b
3  5 b

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

In [119]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)

Out[119]:
   A  B     
0 NaN NaN
1 NaN NaN
2  2.0 b
3  3.0 b
4  4.0 b
5  5.0 b
6 NaN NaN
7 NaN NaN

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

In [120]: dff['C'] = np.arange(8)

In [121]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)

Out[121]:
   A  B  C
0  0 a 0
1  1 a 1
2  2 b 2
3  3 b 3
4  4 b 4
5  5 b 5

**Note:** Some functions when applied to a groupby object will act as a filter on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: head, tail.

In [122]: dff.groupby('B').head(2)

Out[122]:
   A  B  C
0  0 a 0
1  1 a 1
2  2 b 2
3  3 b 3
4  4 b 4
5  5 b 5
16.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [123]: grouped = df.groupby('A')
```

```
In [124]: grouped.agg(lambda x: x.std())
Out[124]:
        C       D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```
In [125]: grouped.std()
Out[125]:
        C       D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [126]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
......:          index=pd.date_range('1/1/2000', periods=1000),
......:          columns=['A', 'B', 'C'])
```

```
In [127]: tsdf.iloc[::2] = np.nan
```

```
In [128]: grouped = tsdf.groupby(lambda x: x.year)
```

```
In [129]: grouped.fillna(method='pad')
Out[129]:
           A       B       C
2000-01-01 NaN     NaN     NaN
2000-01-02 0.353501 0.080957 0.876864
2000-01-03 0.353501 0.080957 0.876864
2000-01-04 0.050976 0.044273 0.559849
2000-01-05 0.050976 0.044273 0.559849
2000-01-06 0.030091 0.186460 0.680149
2000-01-07 0.030091 0.186460 0.680149
......       ......       ......
2002-09-20 2.310215 0.157482 0.064476
2002-09-21 2.310215 0.157482 0.064476
2002-09-22 0.005011 0.053897 1.026922
2002-09-23 0.005011 0.053897 1.026922
2002-09-24 -0.456542 1.849051 1.559856
2002-09-25 -0.456542 1.849051 1.559856
2002-09-26 1.123162 0.354660 1.128135
```

(continues on next page)
In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on `Series` style groupbys:

```
In [130]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
In [131]: g = pd.Series(list('abababab'))
In [132]: gb = s.groupby(g)
In [133]: gb.nlargest(3)
Out[133]:
   a  4  19.0
      0  9.0
      2  7.0
   b  1  8.0
      3  5.0
      7  3.3
dtype: float64
```

```
In [134]: gb.nsmallest(3)
Out[134]:
   ->
   a  6  4.2
      2  7.0
      0  9.0
   b  5  1.0
      7  3.3
      3  5.0
dtype: float64
```

### 16.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want `GroupBy` to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```
In [135]: df
Out[135]:
   A    B      C    D
  0 foo   one -0.575247 1.346061
  1 bar   one  0.254161 1.511763
  2 foo   two -1.143704 1.627081
  3 bar   three  0.215897 -0.990582
  4 foo   two  1.193555 -0.441652
  5 bar   two -0.077118 1.211526
  6 foo   one  -0.408530 0.268520
  7 foo   three -0.862495  0.024580
```
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [136]: grouped = df.groupby('A')

# could also just call .describe()
In [137]: grouped['C'].apply(lambda x: x.describe())

Out[137]:

<table>
<thead>
<tr>
<th></th>
<th>bar</th>
<th>count</th>
<th>mean</th>
<th>std</th>
<th>min</th>
<th>25%</th>
<th>50%</th>
<th>75%</th>
<th>max</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>3.000000</td>

<td>-1.143704</td>
<td>-0.862495</td>
<td>-0.575247</td>
<td>-0.408530</td>
<td>1.193555</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The dimension of the returned result can also change:

In [138]: grouped = df.groupby('A')['C']

In [139]: def f(group):
       .....:     return pd.DataFrame({'original': group,'demeaned': group - group.mean()})
       .....:

In [140]: grouped.apply(f)

Out[140]:

<table>
<thead>
<tr>
<th></th>
<th>original</th>
<th>demeaned</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>0 -0.575247</td>
<td>-0.215962</td>
</tr>
<tr>
<td></td>
<td>1 0.254161</td>
<td>0.123181</td>
</tr>
<tr>
<td></td>
<td>2 -1.143704</td>
<td>-0.784420</td>
</tr>
<tr>

<tr>
<td></td>
<td>7 -0.862495</td>
<td>-0.503211</td>
</tr>
</tbody>
</table>

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

In [141]: def f(x):
       .....:     return pd.Series([ x, x**2 ], index = ['x', 'x^2'])
       .....:

In [142]: s

Out[142]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>9.0</td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>8.0</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>7.0</td>
<td></td>
</tr>
</tbody>
</table>
3  5.0
4  19.0
5  1.0
6  4.2
7  3.3
dtype: float64

In [143]: s.apply(f)
\  
\  x  x^2
\  0  9.0  81.00
\  1  8.0  64.00
\  2  7.0  49.00
\  3  5.0  25.00
\  4  19.0  361.00
\  5  1.0  1.00
\  6  4.2  17.64
\  7  3.3  10.89

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Warning: In the current implementation apply calls func twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if func has side-effects, as they will take effect twice for the first group.

In [144]: d = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})

In [145]: def identity(df):
   .....:
   ......:  print(df)
   ......:  return df
   ......:

In [146]: d.groupby("a").apply(identity)
a b
0 x 1
  a b
0 x 1
  a b
1 y 2
Out[146]:
a b
0 x 1
1 y 2

16.8. Flexible apply
16.9 Other useful features

16.9.1 Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```python
In [147]: df
Out[147]:
   A  B    C     D
0  foo one -0.575247  1.346061
1  bar one  0.254161  1.511763
2  foo two -1.143704  1.627081
3  bar three 0.215897 -0.990582
4  foo two  1.193555 -0.441652
5  bar two -0.077118  1.211526
6  foo one -0.408530  0.268520
7  foo three -0.862495  0.024580
```

Suppose we wish to compute the standard deviation grouped by the `A` column. There is a slight problem, namely that we don’t care about the data in column `B`. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```python
In [148]: df.groupby('A').std()
Out[148]:
     C     D
A
bar 0.181231  1.366330
foo 0.912265  0.884785
```

Note that `df.groupby('A').colname.std().` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered `before` applying the aggregation function.

16.9.2 Handling of (un)observed Categorical values

When using a `Categorical` grouper (as a single grouper, or as part of multipler groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```python
In [149]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a →', 'b']), observed=False).count()
Out[149]:
a    3
b    0
dtype: int64
```

Show only the observed values:

```python
In [150]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a →', 'b']), observed=True).count()
Out[150]:
```

(continues on next page)
The returned dtype of the grouped will always include all of the categories that were grouped.

```
In [151]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
                                 categories=['a', 'b'], observed=False)).count()
In [152]: s.index.dtype
Out[152]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

### 16.9.3 NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

### 16.9.4 Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [153]: data = pd.Series(np.random.randn(100))
In [154]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])
In [155]: data.groupby(factor).mean()
Out[155]:

(continues on next page)
```

### 16.9.5 Grouping with a Grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [156]: import datetime
In [157]: df = pd.DataFrame(
   ....:     'Branch' : 'A A A A A A A B'.split(),
   ....:     'Buyer' : 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
   ....:     'Quantity': [1,3,5,1,8,1,9,3],
   ....:     'Date' : [
   ....:         datetime.datetime(2013,1,1,13,0),
   ....:         datetime.datetime(2013,1,1,13,5),
   ....:         datetime.datetime(2013,10,1,20,0),
   ....:         datetime.datetime(2013,10,2,10,0),
   ....:         datetime.datetime(2013,10,1,20,0),
   ....:     ]
   ....:
```

(continues on next page)
Groupby a specific column with the desired frequency. This is like resampling.

```python
In [159]: df.groupby([pd.Grouper(freq='1M', key='Date'), 'Buyer']).sum()
```

```
Quantity
Date  Buyer
2013-01-31 Carl 1
      Mark 3
2013-10-31 Carl 6
      Joe 9
```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```python
In [160]: df = df.set_index('Date')
In [161]: df['Date'] = df.index + pd.offsets.MonthEnd(2)
In [162]: df.groupby([pd.Grouper(freq='6M', key='Date'), 'Buyer']).sum()
```

```
Quantity
Date  Buyer
2013-02-28 Carl 1
      Mark 3
2014-02-28 Carl 9
      Joe 18
```

```python
In [163]: df.groupby([pd.Grouper(freq='6M', level='Date'), 'Buyer']).sum()
```

```
Quantity
Date  Buyer
2013-01-31 Carl 1
      Mark 3
2014-01-31 Carl 9
      Joe 18
```
16.9.6 Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```
In [164]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])

In [165]: df
Out[165]:
   A  B
0  1  2
1  1  4
2  5  6

In [166]: g = df.groupby('A')

In [167]: g.head(1)
Out[167]:
   A  B
0  1  2
2  5  6

In [168]: g.tail(1)
```

This shows the first or last n rows from each group.

16.9.7 Taking the nth row of each group

To select from a DataFrame or Series the nth item, use nth(). This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```
In [169]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [170]: g = df.groupby('A')

In [171]: g.nth(0)
Out[171]:
   B
A
1  NaN
5  6.0

In [172]: g.nth(-1)
Out[172]:
   B
A
1  4.0
5  6.0

In [173]: g.nth(1)
```

(continues on next page)
If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```python
# nth(0) is the same as g.first()
In [174]: g.nth(0, dropna='any')
Out[174]:
   B
A
  1  4.0
  5  6.0

In [175]: g.first()
Out[175]:
   B
A
  1  4.0
  5  6.0

# nth(-1) is the same as g.last()
In [176]: g.nth(-1, dropna='any')  # NaNs denote group exhausted when using dropna
Out[176]:
   B
A
  1  4.0
  5  6.0

In [177]: g.last()
Out[177]:
   B
A
  1  4.0
  5  6.0

In [178]: g.B.nth(0, dropna='all')
Out[178]:
   B
A
  1  4.0
  5  6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```python
In [179]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [180]: g = df.groupby('A', as_index=False)
In [181]: g.nth(0)
Out[181]:
   A   B
0  1  NaN
```
2 5 6.0

In [182]: g.nth(-1)
\nOut[182]:
<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4.0</td>
</tr>
<tr>
<td>2</td>
<td>6.0</td>
</tr>
</tbody>
</table>

You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

```
In [183]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')

In [184]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

# get the first, 4th, and last date index for each month
In [185]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[185]:
<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>2014</td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>4</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>5</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>6</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>6</td>
<td>1</td>
</tr>
</tbody>
</table>
```

### 16.9.8 Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [186]: dfg = pd.DataFrame(list('aabba'), columns=['A'])

In [187]: dfg
Out[187]:
    A
0   a
1   a
2   a
3   b
4   b
5   a

In [188]: dfg.groupby('A').cumcount()
Out[188]:
<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>3</td>
<td></td>
<td>3</td>
</tr>
</tbody>
</table>
```

```
In [189]: dfg.groupby('A').cumcount(ascending=False)
```

(continues on next page)
16.9.9 Enumerate groups

New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by cumcount) you can use ngroup().

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the groupby object, not the order they are first observed.

```python
In [190]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [191]: dfg
Out[191]:
     A
0   a
1   a
2   a
3   b
4   b
5   a

In [192]: dfg.groupby('A').ngroup()
Out[192]:
0  0
1  0
2  0
3  1
4  1
5  0
dtype: int64

In [193]: dfg.groupby('A').ngroup(ascending=False)
Out[193]:
         0  1
0         1  1
1         1  1
2         1  1
3         0  0
4         0  0
5         1  1
dtype: int64
```
16.9.10 Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```python
In [194]: np.random.seed(1234)
In [195]: df = pd.DataFrame(np.random.randn(50, 2))
In [196]: df['g'] = np.random.choice(['A', 'B'], size=50)
In [197]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```python
In [198]: df.groupby('g').boxplot()
Out[198]:
A    AxesSubplot(0.1,0.15;0.363636x0.75)
B    AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the visualization documentation for more.

16.9. Other useful features
Warning: For historical reasons, `df.groupby('g').boxplot()` is not equivalent to `df.boxplot(by='g')`. See [here](#) for an explanation.

### 16.9.11 Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a DataFrame with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [199]: import numpy as np
In [200]: n = 1000
In [201]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
                           'Product': np.random.choice(['Product_1', 'Product_2'], n),
                           'Revenue': (np.random.random(n)*50+10).round(2),
                           'Quantity': np.random.randint(1, 10, size=n)})
In [202]: df.head(2)
```

```
<table>
<thead>
<tr>
<th>Store</th>
<th>Product</th>
<th>Revenue</th>
<th>Quantity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store_2</td>
<td>Product_1</td>
<td>26.12</td>
<td>1</td>
</tr>
<tr>
<td>Store_2</td>
<td>Product_1</td>
<td>28.86</td>
<td>1</td>
</tr>
</tbody>
</table>
```

Now, to find prices per store/product, we can simply do:

```python
In [203]: (df.groupby(['Store', 'Product']).pipe(
   ...:     lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
   ...:     .unstack().round(2))
```

```
<table>
<thead>
<tr>
<th>Product</th>
<th>Product_1</th>
<th>Product_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Store</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Store_1</td>
<td>6.82</td>
<td>7.05</td>
</tr>
<tr>
<td>Store_2</td>
<td>6.30</td>
<td>6.64</td>
</tr>
</tbody>
</table>
```

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```python
(df.groupby(['Store', 'Product'])).pipe(report_func)
```

where `report_func` takes a `GroupBy` object and creates a report from that.
pandas: powerful Python data analysis toolkit, Release 0.23.2

16.10 Examples
16.10.1 Regrouping by factor
Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.
In [204]: df = pd.DataFrame({'a':[1,0,0], 'b':[0,1,0], 'c':[1,0,0], 'd':[2,3,4]})
In [205]: df
Out[205]:
a b c d
0 1 0 1 2
1 0 1 0 3
2 0 0 0 4
In [206]: df.groupby(df.sum(), axis=1).sum()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[206]:
1 9
0 2 2
1 1 3
2 0 4

16.10.2 Multi-column factorization
By using ngroup(), we can extract information about the groups in a way similar to factorize() (as described
further in the reshaping API) but which applies naturally to multiple columns of mixed type and different sources.
This can be useful as an intermediate categorical-like step in processing, when the relationships between the group
rows are more important than their content, or as input to an algorithm which only accepts the integer encoding.
(For more information about support in pandas for full categorical data, see the Categorical introduction and the API
documentation.)
In [207]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})
In [208]: dfg
Out[208]:
A B
0 1 a
1 1 a
2 2 a
3 3 b
4 2 a
In [209]: dfg.groupby(["A", "B"]).ngroup()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[209]:
0
0
1
0
2
1
3
2
4
1
dtype: int64

In [210]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\

16.10. Examples

873


16.10.3 Groupby by Indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [211]: df = pd.DataFrame(np.random.randn(10,2))
In [212]: df
Out[212]:
   0  1
0 -0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847 -1.405919
4 -0.810847 -1.405919
5 -0.810847 -1.405919
6 -0.810847 -1.405919
7 -0.810847 -1.405919
8 -0.810847 -1.405919

In [213]: df.index // 5
Int64Index([0, 0, 0, 0, 0, 1, 1, 1, 1, 1], dtype='int64')

In [214]: df.groupby(df.index // 5).std()
```

16.10.4 Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the
column index name will be used as the name of the inserted column:

```python
In [215]: df = pd.DataFrame({
    .....:     'a': [0, 0, 0, 1, 1, 1, 2, 2, 2, 2],
    .....:     'b': [0, 1, 0, 0, 1, 1, 0, 0, 1, 1],
    .....:     'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
    .....:     'd': [0, 0, 1, 0, 0, 1, 0, 0, 0, 1],
    .....:  })
```

```python
In [216]: def compute_metrics(x):
    .....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
    .....:     return pd.Series(result, name='metrics')
```

```python
In [217]: result = df.groupby('a').apply(compute_metrics)
```

```python
In [218]: result
```

```
Out[218]:
```
```
metrics  b_sum  c_mean
a
0  2.0  0.5
1  2.0  0.5
2  2.0  0.5
```

```python
In [219]: result.stack()
```

```
Out[219]:
```
```
metrics     a     b_sum  c_mean
0          a    2.0     0.5
1          a    2.0     0.5
2          a    2.0     0.5
dtype: float64
```

16.10. Examples 875
pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

### 17.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```python
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],     
                      'B': ['B0', 'B1', 'B2', 'B3'],     
                      'C': ['C0', 'C1', 'C2', 'C3'],     
                      'D': ['D0', 'D1', 'D2', 'D3'],     
                      index=[0, 1, 2, 3])
...

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],     
                      'B': ['B4', 'B5', 'B6', 'B7'],     
                      'C': ['C4', 'C5', 'C6', 'C7'],     
                      'D': ['D4', 'D5', 'D6', 'D7'],     
                      index=[4, 5, 6, 7])
...

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],    
                      'B': ['B8', 'B9', 'B10', 'B11'],   
                      'C': ['C8', 'C9', 'C10', 'C11'],  
                      'D': ['D8', 'D9', 'D10', 'D11'],  
                      index=[8, 9, 10, 11])
...

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```
Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', join_axes=None, keys=None, levels=None, names=None, verify_integrity=False, copy=True)
```

- **objs**: a sequence or mapping of Series, DataFrame, or Panel objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.

- **axis**: {0, 1, …}, default 0. The axis to concatenate along.

- **join**: {‘inner’, ‘outer’}, default ‘outer’. How to handle indexes on other axis(es). Outer for union and inner for intersection.

- **ignore_index**: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, …, n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.

- **join_axes**: list of Index objects. Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic.

- **keys**: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.

- **levels**: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.

- **names**: list, default None. Names for the levels in the resulting hierarchical index.

- **verify_integrity**: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
• **copy** : boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the **keys** argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a **hierarchical index**. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
Out[7]:
        A  B  C  D
0 A0  B0  C0  D0
1 A1  B1  C1  D1
2 A2  B2  C2  D2
3 A3  B3  C3  D3
```

It’s not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that **concat ()** (and therefore **append ()**) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(f)
```
17.1.1 Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following three ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.
- Use a specific index, as passed to the `join_axes` argument.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
                         'C': ['C2', 'C3', 'C6', 'C7'],
                         'D': ['D2', 'D3', 'D6', 'D7'],
                         'F': ['F2', 'F3', 'F6', 'F7']},
                      index=[2, 3, 6, 7])
In [9]: result = pd.concat([df1, df4], axis=1, sort=False)

Warning: Changed in version 0.23.0. The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```python
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

Lastly, suppose we just wanted to reuse the exact index from the original DataFrame:
In [11]: result = pd.concat([df1, df4], axis=1, join_axes=[df1.index])

17.1.2 Concatenating using \texttt{append}

A useful shortcut to \texttt{concat}() are the \texttt{append()} instance methods on \texttt{Series} and \texttt{DataFrame}. These methods actually predated \texttt{concat}. They concatenate along \texttt{axis}=0, namely the index:

In [12]: result = df1.append(df2)

In the case of \texttt{DataFrame}, the indexes must be disjoint but the columns do not need to be:

In [13]: result = df1.append(df4)
append may take multiple objects to concatenate:

```python
In [14]: result = df1.append([df2, df3])
```

Note: Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here does not modify `df1` and returns its copy with `df2` appended.
17.1.3 Ignoring indexes on the concatenation axis

For DataFrame s which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```
In [15]: result = pd.concat([df1, df4], ignore_index=True)
```

This is also a valid argument to `DataFrame.append()`:

```
In [16]: result = df1.append(df4, ignore_index=True)
```

17.1.4 Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame s. The Series will be transformed to DataFrame with the column name as the name of the Series.
In [17]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')

In [18]: result = pd.concat([df1, s1], axis=1)

Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with DataFrame.assign(). To concatenate an arbitrary number of pandas objects (DataFrame or Series), use concat.

If unnamed Series are passed they will be numbered consecutively.

In [19]: s2 = pd.Series(['_0', '_1', '_2', '_3'])

In [20]: result = pd.concat([df1, s2, s2, s2], axis=1)

Passing ignore_index=True will drop all name references.

In [21]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
17.1.5 More concatenating with group keys

A fairly common use of the keys argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series' name, when these existed.

```
In [22]: s3 = pd.Series([0, 1, 2, 3], name='foo')
In [23]: s4 = pd.Series([0, 1, 2, 3])
In [24]: s5 = pd.Series([0, 1, 4, 5])
In [25]: pd.concat([s3, s4, s5], axis=1)
```

```
Out[25]:
  foo 0 1
0 0 0 0
1 1 1 1
2 2 2 4
3 3 3 5
```

Through the keys argument we can override the existing column names.

```
In [26]: pd.concat([s3, s4, s5], axis=1, keys=['red','blue','yellow'])
```

```
Out[26]:
      red  blue  yellow
0       0     0       0
1       1     1       1
2       2     2       4
3       3     3       5
```

Let's consider a variation of the very first example presented:

```
In [27]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```
You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [28]: pieces = {'x': df1, 'y': df2, 'z': df3}
In [29]: result = pd.concat(pieces)
```
In [30]: result = pd.concat(pieces, keys=['z', 'y'])

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:
In [31]: result.index.levels
Out[31]: FrozenList([['z', 'y'], [4, 5, 6, 7, 8, 9, 10, 11]])

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```python
In [32]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
......:   levels=[['z', 'y', 'x', 'w']],
......:   names=['group_key'])
```

This is fairly esoteric, but it is actually necessary for implementing things like GroupBy where the order of a categorical variable is meaningful.

### 17.1.6 Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or dict to `append`, which returns a new `DataFrame` as above.

```python
In [34]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
In [35]: result = df1.append(s2, ignore_index=True)
```
You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```python
In [36]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
   {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
   ...

In [37]: result = df1.append(dicts, ignore_index=True)
```

17.2 Database-style DataFrame joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in DataFrame.

See the **cookingbook** for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a **comparison with SQL**.

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between DataFrame objects:
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
left_index=False, right_index=False, sort=True,
suffixes=('_x', '_y'), copy=True, indicator=False,
validate=None)

- **left**: A DataFrame object.
- **right**: Another DataFrame object.
- **on**: Column or index level names to join on. Must be found in both the left and right DataFrame objects. If not passed and left_index and right_index are False, the intersection of the columns in the DataFrames will be inferred to be the join keys.
- **left_on**: Columns or index levels from the left DataFrame to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame.
- **right_on**: Columns or index levels from the right DataFrame to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame.
- **left_index**: If True, use the index (row labels) from the left DataFrame as its join key(s). In the case of a DataFrame with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame.
- **right_index**: Same usage as left_index for the right DataFrame
- **how**: One of 'left', 'right', 'outer', 'inner'. Defaults to inner. See below for more detailed description of each method.
- **sort**: Sort the result DataFrame by the join keys in lexicographical order. Defaults to True, setting to False will improve performance substantially in many cases.
- **suffixes**: A tuple of string suffixes to apply to overlapping columns. Defaults to ('_x', '_y').
- **copy**: Always copy data (default True) from the passed DataFrame objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- **indicator**: Add a column to the output DataFrame called _merge with information on the source of each row. _merge is Categorical-type and takes on a value of left_only for observations whose merge key only appears in 'left' DataFrame, right_only for observations whose merge key only appears in 'right' DataFrame, and both if the observation’s merge key is found in both.
- **validate**: string, default None. If specified, checks if merge is of specified type.
  - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
  - “many_to_many” or “m:m”: allowed, but does not result in checks.

New in version 0.21.0.

**Note**: Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0.

The return type will be the same as left. If left is a DataFrame and right is a subclass of DataFrame, the return type will still be DataFrame.

merge is a function in the pandas namespace, and it is also available as a DataFrame instance method merge(), with the calling DataFrame being implicitly considered the left object in the join.
The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

### 17.2.1 Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects will be discarded.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```python
In [38]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
                        'A': ['A0', 'A1', 'A2', 'A3'],
                        'B': ['B0', 'B1', 'B2', 'B3']})

In [39]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
                        'C': ['C0', 'C1', 'C2', 'C3'],
                        'D': ['D0', 'D1', 'D2', 'D3']})

In [40]: result = pd.merge(left, right, on='key')
```

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```python
In [41]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
                        'key2': ['K0', 'K1', 'K0', 'K1'],
                        'A': ['A0', 'A1', 'A2', 'A3'],
                        'B': ['B0', 'B1', 'B2', 'B3']})
```

(continues on next page)
In [42]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
                        'key2': ['K0', 'K0', 'K0', 'K0'],
                        'C': ['C0', 'C1', 'C2', 'C3'],
                        'D': ['D0', 'D1', 'D2', 'D3']})

In [43]: result = pd.merge(left, right, on=['key1', 'key2'])

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination does not appear in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:

<table>
<thead>
<tr>
<th>Merge method</th>
<th>SQL Join Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>LEFT OUTER JOIN</td>
<td>Use keys from left frame only</td>
</tr>
<tr>
<td>right</td>
<td>RIGHT OUTER JOIN</td>
<td>Use keys from right frame only</td>
</tr>
<tr>
<td>outer</td>
<td>FULL OUTER JOIN</td>
<td>Use union of keys from both frames</td>
</tr>
<tr>
<td>inner</td>
<td>INNER JOIN</td>
<td>Use intersection of keys from both frames</td>
</tr>
</tbody>
</table>

In [44]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])

In [45]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
In [46]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])

In [47]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])

Here is another example with duplicate join keys in DataFrames:

In [48]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
In [49]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [50]: result = pd.merge(left, right, on='B', how='outer')
17.2.2 Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right DataFrame. As this is not a one-to-one merge— as specified in the `validate` argument—an exception will be raised.

```python
In [51]: left = pd.DataFrame({'A': [1, 2], 'B': [1, 2]})
In [52]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...:
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```python
In [53]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
Out[53]:
   A_x  B  A_y
0   1  1  NaN
1   2  2  4.0
2   2  2  5.0
3   2  2  6.0
```

17.2.3 The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

```
left  right  Result
A  B  A  B  A_x  B  A_y
0 1 2 0 4 1 2 4
1 2 2 1 2 2 5
2 3 2 2 2 2 6
3 2 2 3 2 2 4
4 2 2 4 2 2 5
5 2 2 5 2 2 6
```
### Observation Origin

<table>
<thead>
<tr>
<th>Merge key in both frames</th>
<th>right_only</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
</tbody>
</table>

#### In [54]:
```python
df1 = pd.DataFrame({'col1': [0, 1], 'col_left': ['a', 'b']})
```

#### In [55]:
```python
df2 = pd.DataFrame({'col1': [1, 2, 2], 'col_right': [2, 2, 2]})
```

#### In [56]:
```python
df.merge(df1, df2, on='col1', how='outer', indicator=True)
```

```python
Out[56]:
<table>
<thead>
<tr>
<th>col1</th>
<th>col_left</th>
<th>col_right</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>
```

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

#### In [57]:
```python
df.merge(df1, df2, on='col1', how='outer', indicator='indicator_column')
```

```python
Out[57]:
<table>
<thead>
<tr>
<th>coll</th>
<th>col_left</th>
<th>col_right</th>
<th>indicator_column</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>
```

### 17.2.4 Merge Dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

#### In [58]:
```python
left = pd.DataFrame({'key': [1], 'v1': [10]})
```

#### In [59]:
```python
left
```

```python
Out[59]:
<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>
```

#### In [60]:
```python
right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
```

#### In [61]:
```python
right
```

```python
Out[61]:
<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
</tr>
</tbody>
</table>
```

We are able to preserve the join keys:

#### In [62]:
```python
pd.merge(left, right, how='outer')
```

```python
Out[62]:
<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>10</td>
</tr>
</tbody>
</table>
```

(continues on next page)
In [63]: pd.merge(left, right, how='outer').dtypes
Out[63]

<table>
<thead>
<tr>
<th>key</th>
<th>int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>v1</td>
<td>int64</td>
</tr>
</tbody>
</table>

dtype: object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

In [64]: pd.merge(left, right, how='outer', on='key')
Out[64]

<table>
<thead>
<tr>
<th>key</th>
<th>v1_x</th>
<th>v1_y</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10.0</td>
<td>20</td>
</tr>
<tr>
<td>1</td>
<td>NaN</td>
<td>30</td>
</tr>
</tbody>
</table>

In [65]: pd.merge(left, right, how='outer', on='key').dtypes
Out[65]

<table>
<thead>
<tr>
<th>key</th>
<th>int64</th>
</tr>
</thead>
<tbody>
<tr>
<td>v1_x</td>
<td>float64</td>
</tr>
<tr>
<td>v1_y</td>
<td>int64</td>
</tr>
</tbody>
</table>

dtype: object

New in version 0.20.0.

Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

In [66]: from pandas.api.types import CategoricalDtype

In [67]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [68]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [69]: left = pd.DataFrame({'X': X,
                          'Y': np.random.choice(['one', 'two', 'three'], size=(10,))})

In [70]: left
Out[70]

<table>
<thead>
<tr>
<th>X</th>
<th>Y</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
</tr>
<tr>
<td>foo</td>
<td>three</td>
</tr>
<tr>
<td>bar</td>
<td>three</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
</tr>
<tr>
<td>bar</td>
<td>one</td>
</tr>
<tr>
<td>bar</td>
<td>three</td>
</tr>
<tr>
<td>bar</td>
<td>three</td>
</tr>
<tr>
<td>foo</td>
<td>three</td>
</tr>
</tbody>
</table>

In [71]: left.dtypes
(continues on next page)
The right frame.

```python
In [72]: right = pd.DataFrame({
       ...: 'X': pd.Series(['foo', 'bar'],
       ...: dtype=CategoricalDtype(['foo', 'bar'])),
       ...: 'Z': [1, 2]
       ...: })
       ...

In [73]: right
Out[73]:
   X  Z
0  foo  1
1  bar  2
```

The merged result:

```python
In [75]: result = pd.merge(left, right, how='outer')

In [76]: result
Out[76]:
   X  Y  Z
0  bar one  2
1  bar three  2
2  bar one  2
3  bar three  2
4  bar three  2
5  foo one  1
6  foo three  1
7  foo one  1
8  foo three  1
9  foo three  1
```

Note: The category dtypes must be exactly the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to object dtype.
Note: Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

17.2.5 Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```python
In [78]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
    ....:                   'B': ['B0', 'B1', 'B2'],
    ....:                   index=['K0', 'K1', 'K2'])
    ....:
In [79]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
    ....:                  'D': ['D0', 'D2', 'D3'],
    ....:                  index=['K0', 'K2', 'K3'])
    ....:
In [80]: result = left.join(right)
```

The same as above, but with `how='inner'`.

```python
In [81]: result = left.join(right, how='inner')
```

In [82]: result = left.join(right, how='outer')
The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```python
In [83]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')
```

17.2.6 Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```python
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True, how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```python
In [85]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                        'B': ['B0', 'B1', 'B2', 'B3'],
                        'key': ['K0', 'K1', 'K0', 'K1']})

In [86]: right = pd.DataFrame({'C': ['C0', 'C1'],
                           'D': ['D0', 'D1']},
                          index=['K0', 'K1'])

In [87]: result = left.join(right, on='key')
```
In [88]: result = pd.merge(left, right, left_on='key', right_index=True,
how='left', sort=False);

To join on multiple keys, the passed DataFrame must have a MultiIndex:

In [89]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
'B': ['B0', 'B1', 'B2', 'B3'],
'key1': ['K0', 'K0', 'K1', 'K2'],
'key2': ['K0', 'K1', 'K0', 'K1']})

In [90]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
('K2', 'K0'), ('K2', 'K1')])

In [91]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
'D': ['D0', 'D1', 'D2', 'D3']},
index=index)

Now this can be joined by passing the two key column names:

In [92]: result = left.join(right, on=['key1', 'key2'])

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which
uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

```
In [93]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

As you can see, this drops any rows where there was no match.

### 17.2.7 Joining a single Index to a Multi-index

You can join a singly-indexed DataFrame with a level of a multi-indexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the multi-indexed frame.

```
In [94]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                        'B': ['B0', 'B1', 'B2'],
                        index=pd.Index(['K0', 'K1', 'K2'], name='key'))

In [95]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'), ('K2', 'Y2'), ('K2', 'Y3')],
                                        names=['key', 'Y'])

In [96]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                          'D': ['D0', 'D1', 'D2', 'D3'],
                          index=index)

In [97]: result = left.join(right, how='inner')
```

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [98]: result = pd.merge(left.reset_index(), right.reset_index(),
                       on=['key'], how='inner').set_index(['key', 'Y'])
```

---

**17.2. Database-style DataFrame joining/merging**

901
17.2.8 Joining with two multi-indexes

This is not implemented via `join` at-the-moment, however it can be done using the following code.

```
In [99]: index = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
                                           ('K1', 'X2')],
                                          names=['key', 'X'])

In [100]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                          'B': ['B0', 'B1', 'B2'],
                          'key2': ['K0', 'K1', 'K0'],
                          index=left_index)

In [101]: result = pd.merge(left.reset_index(), right.reset_index(),
                        on=['key'], how='inner').set_index(['key', 'X', 'Y'])
```

17.2.9 Merging on a combination of columns and index levels

New in version 0.22.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```
In [102]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [103]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                          'B': ['B0', 'B1', 'B2', 'B3'],
                          'key2': ['K0', 'K1', 'K0', 'K1'],
                          index=left_index)
```

(continues on next page)
In [104]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [105]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                     'D': ['D0', 'D1', 'D2', 'D3'],
                     'key2': ['K0', 'K0', 'K0', 'K1'],
                     index=right_index)

In [106]: result = left.merge(right, on=['key1', 'key2'])

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

17.2.10 Overlapping value columns

The merge suffixes argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

In [107]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})

In [108]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})

In [109]: result = pd.merge(left, right, on='k')

17.2. Database-style DataFrame joining/merging
In [110]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])

DataFrame.join() has lsuffix and rsuffix arguments which behave similarly.

In [111]: left = left.set_index('k')
In [112]: right = right.set_index('k')
In [113]: result = left.join(right, lsuffix='_l', rsuffix='_r')

17.2.11 Joining multiple DataFrame or Panel objects

A list or tuple of DataFrames can also be passed to join() to join them together on their indexes.

In [114]: right2 = pd.DataFrame({'v': [7, 8, 9], index=['K1', 'K1', 'K2']})
In [115]: result = left.join([right, right2])

Chapter 17. Merge, join, and concatenate
### 17.2.12 Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [116]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
                        ...:                      [np.nan, 7., np.nan]])

In [117]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4.]],
                        ...:                      index=[1, 2])
```

For this, use the `combine_first()` method:

```
In [118]: result = df1.combine_first(df2)
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values inplace:

```
In [119]: df1.update(df2)
```

### 17.3 Timeseries friendly merging

#### 17.3.1 Merging Ordered Data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [120]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
                           ...:                        'lv': [1, 2, 3, 4],
                           ...:                        's': ['a', 'b', 'c', 'd']})

In [121]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
                           ...:                        ...
```

(continues on next page)
In [122]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[122]:
       k lv  s  rv
0    K0  1.0  a  NaN
1    K1  1.0  a   1.0
2    K2  1.0  a   2.0
3    K4  1.0  a   3.0
4    K1  2.0  b   1.0
5    K2  2.0  b   2.0
6    K4  2.0  b   3.0
7    K1  3.0  c   1.0
8    K2  3.0  c   2.0
9    K4  3.0  c   3.0
10  K1  NaN  d   1.0
11  K2   4.0  d   2.0
12  K4   4.0  d   3.0

17.3.2 Merging AsOf

New in version 0.19.0.

A merge_asof() is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the left DataFrame, we select the last row in the right DataFrame whose on key is less than the left’s key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the by key equally, in addition to the nearest match on the on key.

For example; we might have trades and quotes and we want to asof merge them.

In [123]: trades = pd.DataFrame({
       'time': pd.to_datetime(['20160525 13:30:00.023',
       '20160525 13:30:00.038',
       '20160525 13:30:00.048'],
       columns=['time', 'ticker', 'price', 'quantity'])

In [124]: quotes = pd.DataFrame({
       'time': pd.to_datetime(['20160525 13:30:00.023',
       '20160525 13:30:00.038',
       '20160525 13:30:00.048'],
       columns=['time', 'ticker', 'price', 'quantity'])

(continues on next page)
In [125]: trades
Out[125]:

<table>
<thead>
<tr>
<th>time</th>
<th>ticker</th>
<th>price</th>
<th>quantity</th>
</tr>
</thead>

18.1 Reshaping by pivoting DataFrame objects

Data is often stored in CSV files or databases in so-called “stacked” or “record” format:

```python
In [1]: df
Out[1]:
   date variable  value
0  2000-01-03      A    0.469112
1  2000-01-04      A   -0.282863
2  2000-01-05      A   -1.509059
3  2000-01-03      B   -1.135632
4  2000-01-04      B    1.212112
5  2000-01-05      B   -0.173215
6  2000-01-03      C    0.119209
7  2000-01-04      C   -1.044236
8  2000-01-05      C   -0.861849
9  2000-01-03      D   -2.104569
10 2000-01-04      D   -0.494929
11 2000-01-05      D    1.071804
```

For the curious here is how the above DataFrame was created:

```python
import pandas.util.testing as tm; tm.N = 3
def unpivot(frame):
    N, K = frame.shape
    data = {'value' : frame.values.ravel('F'),
            'variable' : np.asarray(frame.columns).repeat(N),
            'date' : np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])
df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

```python
In [2]: df[df['variable'] == 'A']
Out[2]:
   date variable  value
0  2000-01-03      A    0.469112
1  2000-01-04      A   -0.282863
2  2000-01-05      A   -1.509059
```
But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the DataFrame.pivot() method (also implemented as a top level function pivot()):

```
In [3]: df.pivot(index='date', columns='variable', values='value')
```

```
Out[3]:

<table>
<thead>
<tr>
<th>variable</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.469112</td>
<td>-1.135632</td>
<td>0.119209</td>
<td>-2.104569</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.282863</td>
<td>1.212112</td>
<td>-1.044236</td>
<td>-0.494929</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-1.509059</td>
<td>-0.173215</td>
<td>-0.861849</td>
<td>1.071804</td>
</tr>
</tbody>
</table>
```

If the values argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to pivot, then the resulting “pivoted” DataFrame will have hierarchical columns whose topmost level indicates the respective value column:

```
In [4]: df['value2'] = df['value'] * 2
In [5]: pivoted = df.pivot('date', 'variable')
In [6]: pivoted
```

```
Out[6]:

<table>
<thead>
<tr>
<th>variable</th>
<th>value</th>
<th>value2</th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.469112</td>
<td>0.938225</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.282863</td>
<td>-0.565727</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-1.509059</td>
<td>-3.018117</td>
</tr>
</tbody>
</table>
```

You can then select subsets from the pivoted DataFrame:
Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

### 18.2 Reshaping by stacking and unstacking

#### Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on `Series` and `DataFrame`. These methods are designed to work together with `MultiIndex` objects (see the section on `hierarchical indexing`). Here are essentially what these methods do:

- **stack**: “pivot” a level of the (possibly hierarchical) column labels, returning a `DataFrame` with an index with a new inner-most level of row labels.
- **unstack**: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped `DataFrame` with a new inner-most level of column labels.
The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:

```python
In [8]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
...:               'foo', 'foo', 'qux', 'qux'],
...:               ['one', 'two', 'one', 'two',
...:               'one', 'two', 'one', 'two']]))

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

In [12]: df2
Out[12]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>0.721555</td>
<td>-0.706771</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>-1.039575</td>
<td>0.271860</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>-0.424972</td>
<td>0.567020</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.276232</td>
<td>-1.087401</td>
</tr>
</tbody>
</table>
```

The `stack` function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:
With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the last level:

```python
In [15]: stacked.unstack()
Out[15]:
                        A         B
bar one 0.721555    -0.706771
   two -1.039575   -1.087401
baz one -0.424972    0.567020
   two  0.276232    -1.087401
```

```python
In [16]: stacked.unstack(1)
```

```python
In [17]: stacked.unstack(0)
```

18.2. Reshaping by stacking and unstacking
If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
        second   one    two
    first   
bar   A  0.721555 -1.039575
      B -0.706771  0.271860
baz   A -0.424972  0.276232
      B  0.567020 -1.087401
```

```
stacked.unstack(1)
```

```
stacked.unstack('second')
```

If the indexes have names, you can use the level names instead of specifying the level numbers:
Unstack(0)

stacked

<table>
<thead>
<tr>
<th></th>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>7</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8</td>
</tr>
</tbody>
</table>

or

stacked.unstack(0)

<table>
<thead>
<tr>
<th></th>
<th>first</th>
<th>second</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td></td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>2</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>4</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>5</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>A</td>
</tr>
<tr>
<td></td>
<td></td>
<td>7</td>
</tr>
<tr>
<td></td>
<td></td>
<td>B</td>
</tr>
<tr>
<td></td>
<td></td>
<td>8</td>
</tr>
</tbody>
</table>

Notice that the stack and unstack methods implicitly sort the index levels involved. Hence a call to stack and then unstack, or vice versa, will result in a sorted copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2,1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])
In [21]: df
Out[21]:
     A
2 a -0.370647
    b -1.157892
1 a -1.344312
    b  0.844885
In [22]: all(df.unstack().stack() == df.sort_index())
True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

18.2.1 Multiple Levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples([
         ('A', 'cat', 'long'), ('B', 'cat', 'long'),
         ('A', 'dog', 'short'), ('B', 'dog', 'short')
     ], names=['exp', 'animal', 'hair_length'])
```

(continues on next page)
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df
Out[25]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>animal</td>
<td>cat</td>
<td>cat</td>
<td>dog</td>
<td>dog</td>
</tr>
<tr>
<td>hair_length</td>
<td>long</td>
<td>long</td>
<td>short</td>
<td>short</td>
</tr>
<tr>
<td>0</td>
<td>1.075770</td>
<td>-0.109050</td>
<td>1.643563</td>
<td>-1.469388</td>
</tr>
<tr>
<td>1</td>
<td>0.357021</td>
<td>-0.674600</td>
<td>-1.776904</td>
<td>-0.968914</td>
</tr>
<tr>
<td>2</td>
<td>-1.294524</td>
<td>0.413738</td>
<td>0.276662</td>
<td>-0.472035</td>
</tr>
<tr>
<td>3</td>
<td>-0.013960</td>
<td>-0.362543</td>
<td>-0.006154</td>
<td>-0.923061</td>
</tr>
</tbody>
</table>

In [26]: df.stack(level=['animal', 'hair_length'])

 exp  A          B
animal hair_length
0 cat long 1.075770 -0.109050
  dog short 1.643563 -1.469388
1 cat long 0.357021 -0.674600
  dog short -1.776904 -0.968914
2 cat long -1.294524 0.413738
  dog short 0.276662 -0.472035
3 cat long -0.013960 -0.362543
  dog short -0.006154 -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:

In [27]: df.stack(level=[1, 2])
Out[27]:

 exp  A          B
animal hair_length
0 cat long 1.075770 -0.109050
  dog short 1.643563 -1.469388
1 cat long 0.357021 -0.674600
  dog short -1.776904 -0.968914
2 cat long -1.294524 0.413738
  dog short 0.276662 -0.472035
3 cat long -0.013960 -0.362543
  dog short -0.006154 -0.923061

18.2.2 Missing Data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling sort_index, of course). Here is a more complex example:

In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
                                           ('B', 'cat'), ('A', 'dog')],
                                          names=['exp', 'animal'])

(continues on next page)
As mentioned above, stack can be called with a level argument to select which level in the columns to stack:

```
In [33]: df2.stack('exp')
Out[33]:
        A         B
animal
first second
bar   one 0.895717  0.805244
      two 1.431256  1.340309
baz   one 0.410835  0.132003
      two 0.875906 -2.211372
foo   one 1.413681  1.607920
      two 0.875906 -2.006747
qux   two 0.769804  0.769804

In [34]: df2.stack('animal')
```

(continues on next page)
Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will be converted to float and missing values will be set to NaN.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]

In [36]: df3
Out[36]:
exp  
animal  B
first second
bar one 0.805244 -1.206412
  two 1.340309 -1.170299
foo one 1.607920 1.024180
  two 0.769804 -1.281247
qux two -1.226825 -1.281247

dog  

   0.727707 0.769804
```

New in version 0.18.0.

Alternatively, unstack takes an optional fill_value argument, for specifying the value of missing data.

```
In [37]: df3.unstack()

exp  
animal  B
animal dog cat
first second
bar one 0.805244 1.340309 -1.206412 
  two 1.340309 -1.170299 
foo one 1.607920 NaN 1.024180
  two 0.769804 NaN -1.281247
qux NaN NaN NaN NaN
```

```
In [38]: df3.unstack(fill_value=-1e9)

exp  
animal  B
animal dog cat
first second
bar one 8.052440e-01 1.340309e+00 -1.206412e+00
  two 1.340309e+00 -1.170299e+00
foo one 1.607920e+00 -1.000000e+09 1.024180e+00
  two -1.000000e+09 7.698036e-01 -1.281247e+00
qux -1.000000e+09 7.698036e-01 -1.000000e+09 -1.281247e+00
```

### 18.2.3 With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)

exp  
animal  B
animal cat dog cat dog
first second
bar one 0.895717 0.410835 0.805244 0.81385 -1.206412 0.132003 2.565646
  two 0.805244 -1.206412 -1.206412e+00 -1.206412e+00
foo one 0.805244 -1.206412 0.805244 0.81385 -1.206412 0.132003 2.565646
  two 0.805244 -1.206412 -1.206412e+00 -1.206412e+00
qux one 0.895717 0.410835 0.805244 0.81385 -1.206412 0.132003 2.565646
  two 0.805244 -1.206412 -1.206412e+00 -1.206412e+00
```
18.3 Reshaping by Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```python
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
                           'last': ['Doe', 'Bo'],
                           'height': [5.5, 6.0],
                           'weight': [130, 150]})
```

```
In [42]: cheese
Out[42]:
```

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```python
In [41]: cheese = pd.DataFrame({'first': ['John', 'Mary'],
                           'last': ['Doe', 'Bo'],
                           'height': [5.5, 6.0],
                           'weight': [130, 150]})
```

```
In [42]: cheese
Out[42]:
```
Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```python
In [45]: dft = pd.DataFrame({
    "A1970" : {0 : "a", 1 : "b", 2 : "c"},
    ....:    "A1980" : {0 : "d", 1 : "e", 2 : "f"},
    ....:    "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
    ....:    "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
    ....:    "X" : dict(zip(range(3), np.random.randn(3))
    ....:    })

In [46]: dft["id"] = dft.index

In [47]: dft
Out[47]:
0      a      d  2.5    3.2 -0.121306     0
1      b      e  1.2    1.3 -0.097883     1
2      c      f  0.7    0.1  0.695775     2

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
```

```output
   X  A   B
0 1970 -0.121306 a  2.5
1 1970 -0.097883 b  1.2
2 1970  0.695775 c  0.7
0 1980 -0.121306 d  3.2
1 1980 -0.097883 e  1.3
2 1980  0.695775 f  0.1
```
18.4 Combining with stats and GroupBy

It should be no shock that combining `pivot`/`stack`/`unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
Out[49]:
exp  A     B
    cat   dog cat   dog
animal first second

18.5 Pivot tables

While \texttt{pivot()} provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides \texttt{pivot_table()} for pivoting with aggregation of numeric data.

The function \texttt{pivot_table()} can be used to create spreadsheet-style pivot tables. See the \texttt{cookbook} for some advanced strategies.

It takes a number of arguments:

- **data**: a DataFrame object.
- **values**: a column or a list of columns to aggregate.
- **index**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- **columns**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- **aggfunc**: function to use for aggregation, defaulting to \texttt{numpy.mean}.

Consider a data set like this:

\begin{verbatim}
In [54]: import datetime
In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
                         'B': ['A', 'B', 'C'] * 8,
                         'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
                         'D': np.random.randn(24),
                         'E': np.random.randn(24),
                         'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)] +
                         [datetime.datetime(2013, i, 15) for i in range(1, 13)]})
In [56]: df
Out [56]:
\end{verbatim}
We can produce pivot tables from this data very easily:

```
In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
Out[57]:
                   C    bar    foo
   A          B
one A  1.120915 -0.514058
       B -0.338421  0.002759
       C -0.538846  0.699535
three A -1.181568    NaN
       B    NaN  0.433512
       C   0.588783    NaN
two A   NaN  1.000985
       B  0.158248    NaN
       C -0.176180    NaN
```

```
In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.sum)
Out[58]:
            A one       three       two
   C      B  bar foo   bar foo   bar foo
one
A   2.241830 -1.028115 -2.363137    NaN    NaN  2.001971
B -0.676843  0.005518    NaN  0.867024  0.316495    NaN
C -1.077692  1.399070  1.177566    NaN    NaN  0.352360
```

```
In [59]: pd.pivot_table(df, values=['D','E'], index=['B'], columns=['A', 'C'], aggfunc=np.sum)
Out[59]:
    D ...        E
         A one       three       two ... one       three
         B                   ...                   ...
   C       two
         B                   ...                   ...
         A  2.241830 -1.028115 -2.363137    NaN    NaN ... -0.043211  1.922577
         B -0.676843  0.005518    NaN  0.867024  0.316495 ... -1.103384    NaN -2.
         C -1.077692  1.399070  1.177566    NaN    NaN ...  1.495717 -0.263660
   B                   ...                   ...
         A   NaN    NaN  0.128491    NaN    NaN ... -0.194294    NaN -2.
         B   NaN    NaN -1.103384    NaN    NaN ... -1.103384    NaN -2.
         C   NaN    NaN  0.128491    NaN    NaN ...  1.495717 -0.263660
[3 rows x 12 columns]
```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values
column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
Out[60]:

<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th></th>
<th>E</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>bar</td>
<td>foo</td>
<td>bar</td>
<td>foo</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>A</td>
<td>-0.514058</td>
<td>1.393057</td>
<td>-0.021605</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>-0.338421</td>
<td>0.002759</td>
<td>0.684140</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>-0.538846</td>
<td>0.699535</td>
<td>-0.988442</td>
</tr>
<tr>
<td>three</td>
<td>A</td>
<td>-1.181568</td>
<td>NaN</td>
<td>0.961289</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>NaN</td>
<td>0.433512</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>0.588783</td>
<td>NaN</td>
<td>-0.131830</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
<td>NaN</td>
<td>1.000985</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.158248</td>
<td>NaN</td>
<td>-0.097147</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>NaN</td>
<td>0.176180</td>
<td>NaN</td>
</tr>
</tbody>
</table>
```

Also, you can use `Grouper` for `index` and `columns` keywords. For detail of `Grouper`, see *Grouping with a Grouper specification*.

```
In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'), columns=['C'])
Out[61]:

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>F</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-31</td>
<td>NaN</td>
<td>-0.514058</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-02-28</td>
<td>NaN</td>
<td>0.002759</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-03-31</td>
<td>NaN</td>
<td>0.176180</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-04-30</td>
<td>-1.181568</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-05-31</td>
<td>-0.338421</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-06-30</td>
<td>-0.538846</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-07-31</td>
<td>NaN</td>
<td>1.000985</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-08-31</td>
<td>NaN</td>
<td>0.433512</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-09-30</td>
<td>NaN</td>
<td>0.699535</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-10-31</td>
<td>1.120915</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-11-30</td>
<td>0.158248</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-12-31</td>
<td>0.588783</td>
<td>NaN</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
In [63]: print(table.to_string(na_rep=''))
```

```
<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>C</td>
<td></td>
<td>E</td>
<td></td>
</tr>
<tr>
<td>D</td>
<td>bar</td>
<td>foo</td>
<td>bar</td>
</tr>
<tr>
<td>A</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>A</td>
<td>-0.514058</td>
<td>1.393057</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>-0.338421</td>
<td>0.002759</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>-0.538846</td>
<td>0.699535</td>
</tr>
<tr>
<td>three</td>
<td>A</td>
<td>-1.181568</td>
<td>0.961289</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.433512</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>0.588783</td>
<td>-0.131830</td>
</tr>
<tr>
<td>two</td>
<td>A</td>
<td>1.000985</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>B</td>
<td>0.158248</td>
<td>-0.097147</td>
</tr>
<tr>
<td></td>
<td>C</td>
<td>0.176180</td>
<td>0.436241</td>
</tr>
</tbody>
</table>
```

Note that `pivot_table` is also available as an instance method on DataFrame, i.e. `DataFrame.pivot_table()`.

924 Chapter 18. Reshaping and Pivot Tables
18.5.1 Adding margins

If you pass `margins=True` to `pivot_table`, special `All` columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```python
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out[64]:
       D       E
   bar  foo  All  bar  foo  All
A
one  1.804346 1.210272 1.569879 0.179483 0.418374 0.858005
    0.690376 1.353355 0.898998 1.083825 0.968138 1.101401
    0.273641 0.418926 0.771139 1.689271 0.446140 1.422136
three  0.794212 NaN  2.049040  NaN  2.049040
      NaN  0.363548  0.363548  NaN  1.625237  1.625237
      3.915454 NaN  3.915454  1.035215  NaN  1.035215
two  0.442998  NaN  0.442998  NaN  0.447104  0.447104
     0.202765  NaN  0.202765  0.560757  NaN  0.560757
      NaN  1.819408  1.819408  NaN  0.650439  0.650439
All  1.556868  0.952552  1.246608  1.250924  0.899904  1.059389
    1.556868  0.952552  1.246608  1.250924  0.899904  1.059389
```

18.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, {‘all’, ‘index’, ‘columns’}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```python
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [67]: b = np.array([one, one, two, one, two, one], dtype=object)
In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```
Out[69]:

<table>
<thead>
<tr>
<th>b</th>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>dull</td>
<td>shiny</td>
</tr>
<tr>
<td>a</td>
<td>bar</td>
<td>1</td>
</tr>
<tr>
<td>foo</td>
<td>2</td>
<td>1</td>
</tr>
</tbody>
</table>

If `crosstab` receives only two Series, it will provide a frequency table.

In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
                      'C': [1, 1, np.nan, 1, 1]})

In [71]: df

Out[71]:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>3</td>
<td>2</td>
<td>4</td>
</tr>
<tr>
<td>4</td>
<td>2</td>
<td>4</td>
</tr>
</tbody>
</table>

In [72]: pd.crosstab(df.A, df.B)

Out[72]:

<table>
<thead>
<tr>
<th></th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

Any input passed containing `Categorical` data will have all of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])

In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])

In [75]: pd.crosstab(foo, bar)

Out[75]:

<table>
<thead>
<tr>
<th></th>
<th>d</th>
<th>e</th>
</tr>
</thead>
<tbody>
<tr>
<td>row_0</td>
<td>a</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>1</td>
</tr>
</tbody>
</table>

### 18.6.1 Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

In [76]: pd.crosstab(df.A, df.B, normalize=True)

Out[76]:

<table>
<thead>
<tr>
<th></th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.2</td>
<td>0.0</td>
</tr>
<tr>
<td>2</td>
<td>0.2</td>
<td>0.6</td>
</tr>
</tbody>
</table>
normalize can also normalize values within each row or within each column:

```python
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out[77]:
    B  3  4
   A
   1  0.5  0.0
   2  0.5  1.0
```

crosstab can also be passed a third Series and an aggregation function (aggfunc) that will be applied to the values of the third Series within each group defined by the first two Series:

```python
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out[78]:
    B  3  4
   A
   1  1.0  NaN
   2  1.0  2.0
```

### 18.6.2 Adding Margins

Finally, one can also add margins or normalize this output.

```python
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True, margins=True)
```

### 18.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```python
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out[81]:
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```python
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [83]: c
Out[83]:
```

(continues on next page)
(continued from previous page)

New in version 0.20.0.

If the bins keyword is an IntervalIndex, then these will be used to bin the passed data:

```python
pd.cut([25, 20, 50], bins=c.categories)
```

## 18.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has \( k \) distinct values, can derive a DataFrame containing \( k \) columns of 1s and 0s using `get_dummies()`:

```python
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})
In [85]: pd.get_dummies(df['key'])
Out[85]:
   a  b  c
0  0  1  0
1  0  1  0
2  1  0  0
3  0  0  1
4  1  0  0
5  0  1  0
```

Sometimes it’s useful to prefix the column names, for example when merging the result with the original DataFrame:

```python
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')
In [87]: dummies
Out[87]:
   key_a  key_b  key_c
0     0     1     0
1     0     1     0
2     1     0     0
3     0     0     1
4     1     0     0
5     0     1     0
```

```python
In [88]: df[['data1']].join(dummies)
```

This function is often used along with discretization functions like `cut`:
In [89]: values = np.random.randn(10)

In [90]: values
Out[90]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 
       ,  0.0824, -0.0558,  0.5366])

In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [92]: pd.get_dummies(pd.cut(values, bins))
Out[92]:
(0.0, 0.2] (0.2, 0.4] (0.4, 0.6] (0.6, 0.8] (0.8, 1.0]
0   0   0   1   0   0
1   0   0   0   0   0
2   0   0   0   0   0
3   0   0   0   0   0
4   1   0   0   0   0
5   0   0   0   0   0
6   0   0   0   0   0
7   1   0   0   0   0
8   0   0   0   0   0
9   0   0   1   0   0

See also Series.str.get_dummies.

get_dummies() also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with object or categorical dtype) are encoded as dummy variables.

In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
                   'C': [1, 2, 3]})

In [94]: pd.get_dummies(df)
Out[94]:
   C  A_a  A_b  B_b  B_c
0  1    1    0    0    1
1  2    0    1    0    1
2  3    1    0    1    0

All non-object columns are included untouched in the output. You can control the columns that are encoded with the columns keyword.

In [95]: pd.get_dummies(df, columns=['A'])
Out[95]:
   B  C  A_a  A_b
0  c  1    1    1
1  c  2    0    1
2  b  3    1    0

Notice that the B column is still included in the output, it just hasn’t been encoded. You can drop B before calling get_dummies if you don’t want to include it in the output.

As with the Series version, you can pass values for the prefix and prefix_sep. By default the column name is used as the prefix, and '_' as the prefix separator. You can specify prefix and prefix_sep in 3 ways:

- string: Use the same value for prefix or prefix_sep for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')

In [97]: simple
Out[97]:
   C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0  1          1           0           0           1
1  2           0           1           0           1
2  3           1           0           1           0

In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])

In [99]: from_list
Out[99]:
   C   from_A_a  from_A_b   from_B_b   from_B_c
0  1           1           0           0           1
1  2           0           1           0           1
2  3           1           0           1           0

In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})

In [101]: from_dict
Out[101]:
   C   from_A_a  from_A_b   from_B_b   from_B_c
0  1           1           0           0           1
1  2           0           1           0           1
2  3           1           0           1           0

New in version 0.18.0.
Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on drop_first.

In [102]: s = pd.Series(list('abcaa'))

In [103]: pd.get_dummies(s)
Out[103]:
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0

In [104]: pd.get_dummies(s, drop_first=True)

   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0

When a column contains only one level, it will be omitted in the result.

In [105]: df = pd.DataFrame({'A':list('aaaaa'),'B':list('ababc')})

In [106]: pd.get_dummies(df)
Out[106]:
   A_a  B_a  B_b  B_c
0   1    1    0    0
1   1    0    1    0
2   1    1    0    0
3   1    0    1    0
4   1    0    0    1

In [107]: pd.get_dummies(df, drop_first=True)

→
   B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1

By default new columns will have np.uint8 dtype. To choose another dtype, use the ‘dtype’ argument:

In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})

In [109]: pd.get_dummies(df, dtype=bool).dtypes
Out[109]:
   B    float64
  A_a   bool
  A_b   bool
  A_c   bool
dtype: object

New in version 0.23.0.

18.9 Factorizing values

To encode 1-d values as an enumerated type use factorize():

In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [111]: x
Out[111]:
   0    A
   1    A
   2  NaN
   3    B
   4    3.14
   5     inf
dtype: object

In [112]: labels, uniques = pd.factorize(x)

In [113]: labels
Out[113]: array([ 0,  0, -1,  1,  2,  3])

In [114]: uniques

(continues on next page)
Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

**Note:** The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also here.

```python
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2, 2, -1, 3,  0,  1]),
 Index([3.14, inf, u'A', u'B'], dtype='object'))
```

```python
In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

**Note:** If you just want to handle one column as a categorical variable (like R's factor), you can use `df['cat_col'] = pd.Categorical(df['col'])` or `df['cat_col'] = df['col'].astype('category')`. For full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`. 

pandas has proven very successful as a tool for working with time series data, especially in the financial data analysis space. Using the NumPy datetime64 and timedelta64 dtypes, we have consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

In working with time series data, we will frequently seek to:

- generate sequences of fixed-frequency dates and time spans
- conform or convert time series to a particular frequency
- compute “relative” dates based on various non-standard time increments (e.g. 5 business days before the last business day of the year), or “roll” dates forward or backward

pandas provides a relatively compact and self-contained set of tools for performing the above tasks.

Create a range of dates:

```python
# 72 hours starting with midnight Jan 1st, 2011
In [1]: rng = pd.date_range('1/1/2011', periods=72, freq='H')
In [2]: rng[:5]
Out[2]:
```

```python
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 01:00:00',
              '2011-01-01 02:00:00', '2011-01-01 03:00:00',
              '2011-01-01 04:00:00'],
             dtype='datetime64[ns]', freq='H')
```

Index pandas objects with dates:

```python
In [3]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [4]: ts.head()
Out[4]:
```

```python
2011-01-01 00:00:00 0.469112
2011-01-01 01:00:00 -0.282863
2011-01-01 02:00:00 -1.509059
2011-01-01 03:00:00 -1.135632
2011-01-01 04:00:00 1.212112
Freq: H, dtype: float64
```

Change frequency and fill gaps:

```python
# to 45 minute frequency and forward fill
In [5]: converted = ts.asfreq('45Min', method='pad')
```

(continues on next page)
In [6]: converted.head()
Out[6]:
2011-01-01 00:00:00 0.469112
2011-01-01 00:45:00 0.469112
2011-01-01 01:30:00 -0.282863
2011-01-01 02:15:00 -1.509059
2011-01-01 03:00:00 -1.135632
Freq: 45T, dtype: float64

Resample the series to a daily frequency:

# Daily means
In [7]: ts.resample('D').mean()
Out[7]:
2011-01-01 -0.319569
2011-01-02 -0.337703
2011-01-03 0.117258
Freq: D, dtype: float64

19.1 Overview

The following table shows the type of time-related classes pandas can handle and how to create them.

<table>
<thead>
<tr>
<th>Class</th>
<th>Remarks</th>
<th>How to create</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timestamp</td>
<td>Represents a single timestamp</td>
<td>to_datetime, Timestamp</td>
</tr>
<tr>
<td>DatetimeIndex</td>
<td>Index of Timestamp</td>
<td>to_datetime, date_range, bdate_range, DatetimeIndex</td>
</tr>
<tr>
<td>Period</td>
<td>Represents a single time span</td>
<td>Period</td>
</tr>
<tr>
<td>PeriodIndex</td>
<td>Index of Period</td>
<td>period_range, PeriodIndex</td>
</tr>
</tbody>
</table>

19.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

In [8]: pd.Timestamp(datetime(2012, 5, 1))
Out[8]: Timestamp('2012-05-01 00:00:00')

In [9]: pd.Timestamp('2012-05-01')
Out[9]: Timestamp('2012-05-01 00:00:00')

In [10]: pd.Timestamp(2012, 5, 1)
Out[10]: Timestamp('2012-05-01 00:00:00')

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by Period can be specified explicitly, or inferred from datetime string format.

For example:
In [11]: pd.Period('2011-01')
Out[11]: Period('2011-01', 'M')

In [12]: pd.Period('2012-05', freq='D')
Out[12]: Period('2012-05-01', 'D')

**Timestamp** and **Period** can serve as an index. Lists of Timestamp and Period are automatically coerced to **DatetimeIndex** and **PeriodIndex** respectively.

In [14]: ts = pd.Series(np.random.randn(3), dates)
In [15]: type(ts.index)
Out[15]: pandas.core.indexes.datetimes.DatetimeIndex

In [16]: ts.index
Out[16]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [17]: ts
Out[17]:
2012-05-01 -0.410001
2012-05-02 -0.078638
2012-05-03  0.545952
dtype: float64

In [18]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]
In [19]: ts = pd.Series(np.random.randn(3), periods)
In [20]: type(ts.index)
Out[20]: pandas.core.indexes.period.PeriodIndex

In [21]: ts.index
Out[21]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')

In [22]: ts
Out[22]:
2012-01  -1.219217
2012-02  -1.226825
2012-03   0.769804
Freq: M, dtype: float64

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of **Timestamp** and sequences of timestamps using instances of **DatetimeIndex**. For regular time spans, pandas uses **Period** objects for scalar values and **PeriodIndex** for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

19.2. Timestamps vs. Time Spans
19.3 Converting to Timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DatetimeIndex`:

```python
In [23]: pd.to_datetime(pd.Series(["Jul 31, 2009", '2010-01-10', None]))
Out[23]:
0  2009-07-31
1  2010-01-10
2  NaT
dtype: datetime64[ns]
```

```python
In [24]: pd.to_datetime(["2005/11/23", '2010.12.31'])
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```python
In [25]: pd.to_datetime(["04-01-2012 10:00"], dayfirst=True)
Out[25]:
 DatetimeIndex(["2012-01-04 10:00:00"], dtype='datetime64[ns]', freq=None)
```

```python
In [26]: pd.to_datetime(["14-01-2012", "01-14-2012"], dayfirst=True)
```

**Warning:** You see in the above example that `dayfirst` isn’t strict, so if a date can’t be parsed with the day being first it will be parsed as if `dayfirst` were False.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn’t accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```python
In [27]: pd.to_datetime('2010/11/12')
Out[27]: Timestamp('2010-11-12 00:00:00')
```

```python
In [28]: pd.Timestamp('2010/11/12')
```

19.3.1 Providing a Format Argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```python
In [29]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[29]:
 Timestamp('2010-11-12 00:00:00')
```

```python
In [30]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
```

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.
19.3.2 Assembling Datetime from Multiple DataFrame Columns

New in version 0.18.1.

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```
In [31]: df = pd.DataFrame({'year': [2015, 2016],
          ....:               'month': [2, 3],
          ....:               'day': [4, 5],
          ....:               'hour': [2, 3]})
```

```
In [32]: pd.to_datetime(df)
Out[32]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
Out[33]:
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- **required**: year, month, day
- **optional**: hour, minute, second, millisecond, microsecond, nanosecond

19.3.3 Invalid Data

The default behavior, `errors='raise'`, is to raise when unparsable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparsable:

```
In [34]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[34]: array(['2009/07/31', 'asd'], dtype=object)
```

Pass `errors='coerce'` to convert unparsable data to NaT (not a time):

```
In [35]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[35]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

19.3.4 Epoch Timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.
In [36]: pd.to_datetime([1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit='s')

Out[36]:
dtype='datetime64[ns]', freq=None)

In [37]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500], unit='ms')

Out[37]:
DateTimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000', '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000', '2012-10-08 18:15:05.500000'],
dtype='datetime64[ns]', freq=None)

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

In [38]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')

Out[38]:
DateTimeIndex(['2017-03-22 15:16:45.433000088', '2017-03-22 15:16:45.433502913'],
dtype='datetime64[ns]', freq=None)

In [39]: pd.to_datetime(1490195805433502912, unit='ns')

Out[39]:
Timestamp('2017-03-22 15:16:45.433502912')

See also:
Using the origin Parameter

19.3.5 From Timestamps to Epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

In [40]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [41]: stamps
Out[41]:
DateTimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
dtype='datetime64[ns]', freq='D')

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

In [42]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out[42]:
Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
19.3.6 Using the origin Parameter

New in version 0.20.0.

Using the origin parameter, one can specify an alternative starting point for creation of a DatetimeIndex. For example, to use 1960-01-01 as the starting date:

```
In [43]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[43]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

The default is set at origin='unix', which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [44]: pd.to_datetime([1, 2, 3], unit='D')
Out[44]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```

19.4 Generating Ranges of Timestamps

To generate an index with timestamps, you can use either the DatetimeIndex or Index constructor and pass in a list of datetime objects:

```
In [45]: dates = [datetime(2012, 5, 1), datetime(2012, 5, 2), datetime(2012, 5, 3)]
   # Note the frequency information
In [46]: index = pd.DatetimeIndex(dates)

In [47]: index
Out[47]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
   # Automatically converted to DatetimeIndex
In [48]: index = pd.Index(dates)

In [49]: index
Out[49]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the date_range() and bdate_range() functions to create a DatetimeIndex. The default frequency for date_range is a calendar day while the default for bdate_range is a business day:

```
In [50]: start = datetime(2011, 1, 1)
In [51]: end = datetime(2012, 1, 1)
In [52]: index = pd.date_range(start, end)
In [53]: index
   '2011-01-09', '2011-01-10'],
   (continues on next page)
```
... '2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
'2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
'2011-12-31', '2012-01-01'],
dtype='datetime64[ns]', length=366, freq='D')

In [54]: index = pd.bdate_range(start, end)

In [55]: index
Out[55]:
               '2011-01-13', '2011-01-14',
               ...
               '2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
               '2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
               '2011-12-29', '2011-12-30'],
dtype='datetime64[ns]', length=260, freq='B')

Convenience functions like `date_range` and `bdate_range` can utilize a variety of frequency aliases:

In [56]: pd.date_range(start, periods=1000, freq='M')
Out[56]:
               '2011-09-30', '2011-10-31',
               ...
               '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
               '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
               '2094-03-31', '2094-04-30'],
dtype='datetime64[ns]', length=1000, freq='M')

In [57]: pd.bdate_range(start, periods=250, freq='BQS')

               '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
               '2013-01-01', '2013-04-01',
               ...
               '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
               '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
               '2073-01-02', '2073-04-03'],
dtype='datetime64[ns]', length=250, freq='BQS-JAN')

date_range and bdate_range make it easy to generate a range of dates using various combinations of parameters like start, end, periods, and freq. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

In [58]: pd.date_range(start, end, freq='BM')
Out[58]:
               '2011-09-30', '2011-10-30',
               ...
               '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
               '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
               '2073-01-02', '2073-04-03'],
dtype='datetime64[ns]', freq='BM')

In [59]: pd.date_range(start, end, freq='W')

(continues on next page)
dtype='datetime64[ns]', freq='W-SUN')

In [60]: pd.bdate_range(end=end, periods=20)

dtype='datetime64[ns]', freq='B')

In [61]: pd.bdate_range(start=start, periods=20)

dtype='datetime64[ns]', freq='B')

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:

In [62]: pd.date_range('2018-01-01', '2018-01-05', periods=5)
Out[62]:
dtype='datetime64[ns]', freq=None)

In [63]: pd.date_range('2018-01-01', '2018-01-05', periods=10)

DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 01:00:00', '2018-01-01 02:00:00', '2018-01-01 03:00:00', '2018-01-01 04:00:00', '2018-01-01 05:00:00', '2018-01-01 06:00:00', '2018-01-01 07:00:00', '2018-01-01 08:00:00', '2018-01-01 09:00:00'],
dtype='datetime64[ns]', freq=None)
19.4.1 Custom Frequency Ranges

**Warning:** This functionality was originally exclusive to `cdate_range`, which is deprecated as of version 0.21.0 in favor of `bdate_range`. Note that `cdate_range` only utilizes the `weekmask` and `holidays` parameters when custom business day, ‘C’, is passed as the frequency string. Support has been expanded with `bdate_range` to work with any custom frequency string.

New in version 0.21.0.

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [64]: weekmask = 'Mon Wed Fri'
In [65]: holidays = [datetime(2011, 1, 5), datetime(2011, 3, 14)]
In [66]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out[66]:
              '2011-01-24', '2011-01-26',
              '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
              '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
              '2011-12-28', '2011-12-30'],
dtype='datetime64[ns]', length=154, freq='C')
```

```
In [67]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
    --->
DatetimeIndex(['2011-01-03', '2011-02-02', '2011-03-02', '2011-04-01',
                '2011-09-02', '2011-10-03', '2011-11-02', '2011-12-02'],
dtype='datetime64[ns]', freq='CBMS')
```

See also:

*Custom Business Days*

19.5 Timestamp Limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [68]: pd.Timestamp.min
Out[68]: Timestamp('1677-09-21 00:12:43.145225')
```

```
In [69]: pd.Timestamp.max
```
See also:
Representing Out-of-Bounds Spans

19.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

See also:
Reindexing methods

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [70]: rng = pd.date_range(start, end, freq='BM')
In [71]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [72]: ts.index
```

```
                       dtype='datetime64[ns]', freq='BM')
```

```
In [73]: ts[:5].index
```

```
                       '2011-05-31'],
                       dtype='datetime64[ns]', freq='BM')
```

```
In [74]: ts[::2].index
```

```
Out[74]: (continues on next page)
```

(continues on next page)
19.6.1 Partial String Indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

In [75]: ts['1/31/2011']
Out[75]: -1.2812473076599531

In [76]: ts[datetime(2011, 12, 25):]
Out[76]:
2011-12-30 0.687738
Freq: BM, dtype: float64

In [77]: ts['10/31/2011':'12/31/2011']
Out[77]:
2011-10-31 0.149748
2011-11-30 -0.732339
2011-12-30 0.687738
Freq: BM, dtype: float64

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

In [78]: ts['2011']
Out[78]:
2011-01-31 -1.281247
2011-02-28 -0.727707
2011-03-31 -0.121306
2011-04-29 -0.097883
2011-05-31 0.695775
2011-06-30 0.341734
2011-07-29 0.959726
2011-08-31 -1.110336
2011-09-30 -0.619976
2011-10-31 0.149748
2011-11-30 -0.732339
2011-12-30 0.687738
Freq: BM, dtype: float64

In [79]: ts['2011-6']
Out[79]:
2011-06-30 0.341734
Freq: BM, dtype: float64

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:

In [80]: dft = pd.DataFrame(randn(100000,1),
                   columns=['A'],
                   index=pd.date_range('20130101',periods=100000,freq='T'))
In [81]: dft
Out[81]:
\[
\begin{array}{c}
\text{A} \\
2013-01-01 00:00:00 0.176444 \\
2013-01-01 00:01:00 0.403310 \\
2013-01-01 00:02:00 -0.154951 \\
2013-01-01 00:03:00 0.301624 \\
2013-01-01 00:04:00 -2.179861 \\
2013-01-01 00:05:00 -1.369849 \\
2013-01-01 00:06:00 -0.954208 \\
\ldots \\
2013-03-11 10:33:00 -0.293083 \\
2013-03-11 10:34:00 -0.059881 \\
2013-03-11 10:35:00 1.252450 \\
2013-03-11 10:36:00 0.046611 \\
2013-03-11 10:37:00 0.059478 \\
2013-03-11 10:38:00 -0.286539 \\
2013-03-11 10:39:00 0.841669 \\
\end{array}
\]

[100000 rows x 1 columns]

In [82]: dft['2013']
\[
\begin{array}{c}
\text{A} \\
2013-01-01 00:00:00 0.176444 \\
2013-01-01 00:01:00 0.403310 \\
2013-01-01 00:02:00 -0.154951 \\
2013-01-01 00:03:00 0.301624 \\
2013-01-01 00:04:00 -2.179861 \\
2013-01-01 00:05:00 -1.369849 \\
2013-01-01 00:06:00 -0.954208 \\
\ldots \\
2013-03-11 10:33:00 -0.293083 \\
2013-03-11 10:34:00 -0.059881 \\
2013-03-11 10:35:00 1.252450 \\
2013-03-11 10:36:00 0.046611 \\
2013-03-11 10:37:00 0.059478 \\
2013-03-11 10:38:00 -0.286539 \\
2013-03-11 10:39:00 0.841669 \\
\end{array}
\]

[100000 rows x 1 columns]

This starts on the very first time of the month, and includes the last date and time for the month:

In [83]: dft['2013-1':'2013-2']
Out[83]:
\[
\begin{array}{c}
\text{A} \\
2013-01-01 00:00:00 0.176444 \\
2013-01-01 00:01:00 0.403310 \\
2013-01-01 00:02:00 -0.154951 \\
2013-01-01 00:03:00 0.301624 \\
2013-01-01 00:04:00 -2.179861 \\
2013-01-01 00:05:00 -1.369849 \\
2013-01-01 00:06:00 -0.954208 \\
\ldots \\
2013-03-11 10:33:00 -0.293083 \\
2013-03-11 10:34:00 -0.059881 \\
2013-03-11 10:35:00 1.252450 \\
2013-03-11 10:36:00 0.046611 \\
2013-03-11 10:37:00 0.059478 \\
2013-03-11 10:38:00 -0.286539 \\
2013-03-11 10:39:00 0.841669 \\
\end{array}
\]

[100000 rows x 1 columns]
This specifies a stop time that includes all of the times on the last day:

```
In [84]: dft['2013-1':'2013-2-28']
Out[84]:
                   A
2013-01-01 00:00:00  0.176444
2013-01-01 00:01:00  0.403310
2013-01-01 00:02:00  -0.154951
2013-01-01 00:03:00  0.301624
2013-01-01 00:04:00  -2.179861
2013-01-01 00:05:00  -1.369849
2013-01-01 00:06:00  -0.954208
...            ...
2013-02-28 23:53:00  0.103114
2013-02-28 23:54:00  -1.303422
2013-02-28 23:55:00  0.451943
2013-02-28 23:56:00  0.220534
2013-02-28 23:57:00  -1.624220
2013-02-28 23:58:00  0.093915
2013-02-28 23:59:00  -1.087454
```

[84960 rows x 1 columns]

This specifies an exact stop time (and is not the same as the above):

```
In [85]: dft['2013-1':'2013-2-28 00:00:00']
Out[85]:
                   A
2013-01-01 00:00:00  0.176444
2013-01-01 00:01:00  0.403310
2013-01-01 00:02:00  -0.154951
2013-01-01 00:03:00  0.301624
2013-01-01 00:04:00  -2.179861
2013-01-01 00:05:00  -1.369849
2013-01-01 00:06:00  -0.954208
...            ...
2013-02-27 23:54:00  0.897051
2013-02-27 23:55:00  -0.309230
2013-02-27 23:56:00  1.944713
2013-02-27 23:57:00  0.369265
2013-02-27 23:58:00  0.053071
2013-02-27 23:59:00  -0.019734
2013-02-28 00:00:00  1.388189
```

[83521 rows x 1 columns]

We are stopping on the included end-point as it is part of the index:
In [86]: dft['2013-1-15':'2013-1-15 12:30:00']
Out[86]:
      A
2013-01-15 00:00:00  0.501288
2013-01-15 00:01:00 -0.605198
2013-01-15 00:02:00  0.215146
2013-01-15 00:03:00  0.924732
2013-01-15 00:04:00 -2.228519
2013-01-15 00:05:00  1.517331
2013-01-15 00:06:00 -1.188774
... ...
2013-01-15 12:24:00  1.358314
2013-01-15 12:25:00 -0.737727
2013-01-15 12:26:00  1.838323
2013-01-15 12:27:00 -0.774090
2013-01-15 12:28:00  0.622261
2013-01-15 12:29:00 -0.631649
2013-01-15 12:30:00  0.193284
[751 rows x 1 columns]

New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

In [87]: dft2 = pd.DataFrame(np.random.randn(20, 1),
                   columns=['A'],
                   index=pd.MultiIndex.from_product([pd.date_range('20130101',
                                                      periods=10,
                                                      freq='12H'),
                                                      ['a', 'b']))

In [88]: dft2
Out[88]:
      A
2013-01-01 00:00:00 a  -0.659574
   b   1.494522
2013-01-01 12:00:00 a  -0.778425
   b  -0.253355
2013-01-02 00:00:00 a  -2.816159
   b  -1.210929

   b   0.149867
... ...
2013-01-04 00:00:00 b  -1.624463
2013-01-04 12:00:00 a   0.056912
   b   0.149867
2013-01-05 00:00:00 a  -1.256173
   b   2.324544
2013-01-05 12:00:00 a  -1.067396
   b  -0.660996
[20 rows x 1 columns]

In [89]: dft2.loc['2013-01-05'] (continues on next page)
A timestamp string less accurate than a minute gives a `Series` object.

```python
In [95]: series_minute['2011-12-31 23']
Out[95]:
2011-12-31 23:59:00    1
Name: 2011-12-31 23:59:00, dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```python
In [96]: series_minute['2011-12-31 23:59']
Out[96]: 1
```

```python
In [97]: series_minute['2011-12-31 23:59:00']
```

If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```python
In [98]: idx = pd.IndexSlice
```

```python
In [99]: dft2 = dft2.swaplevel(0, 1).sort_index()
```

```python
In [100]: dft2.loc[idx[:, '2013-01-05'], :]
```

19.6.2 Slice vs. Exact Match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```python
In [93]: series_minute = pd.Series([1, 2, 3],
       ...: index=datetime_index(['2011-12-31 23:59:00',
       ...: '2012-01-01 00:00:00',
       ...: '2012-01-01 00:02:00']))
```

A timestamp string less accurate than a minute gives a `Series` object.

```python
In [94]: series_minute.index.resolution
Out[94]: 'minute'
```

```python
In [95]: series_minute['2011-12-31 23']
Out[95]:
2011-12-31 23:59:00    1
Name: 2011-12-31 23:59:00, dtype: int64
```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```python
In [96]: series_minute['2011-12-31 23:59']
Out[96]: 1
```

If index resolution is second, then the minute-accurate timestamp gives a `Series`. 

```python
In [97]: series_minute['2011-12-31 23:59:00']
```
If the timestamp string is treated as a slice, it can be used to index DataFrame with [] as well.

```
In [101]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
                           index=series_minute.index)

In [102]: dft_minute['2011-12-31 23:59']
Out[102]:
   a   b
2011-12-31 23:59:00 1   4
```

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see *Indexing Basics*. For example `dft_minute['2011-12-31 23:59']` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

```
In [103]: dft_minute.loc['2011-12-31 23:59']
Out[103]:
a   1
b   4
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that `DateTimeIndex` resolution cannot be less precise than day.

```
In [104]: series_monthly = pd.Series([1, 2, 3],
                           pd.DatetimeIndex(['2011-12',
                                            '2012-01',
                                            '2012-02']))

In [105]: series_monthly.index.resolution
Out[105]: 'day'

In [106]: series_monthly['2011-12'] # returns Series
Out[106]:
2011-12-01 1
dtype: int64
```
19.6.3 Exact Indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of including both endpoints.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```python
dft[datetime(2013, 1, 1):datetime(2013, 2, 28)]
```

```
  A
2013-01-01  00:00:00  0.176444
2013-01-01  00:01:00  0.403310
2013-01-01  00:02:00 -0.154951
2013-01-01  00:03:00  0.301624
2013-01-01  00:04:00 -2.179861
2013-01-01  00:05:00 -1.369849

```
19.6.4 Truncating & Fancy Indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [109]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')

In [110]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)

In [111]: ts2.truncate(before='2011-11', after='2011-12')
Out[111]:
         2011-11-06   -0.773743
         2011-11-13    0.247216
         2011-11-20    0.591308
         2011-11-27    2.228500
Freq: W-SUN, dtype: float64

In [112]: ts2['2011-11':'2011-12']
Out[112]:
         2011-11-06   -0.773743
         2011-11-13    0.247216
         2011-11-20    0.591308
         2011-11-27    2.228500
         2011-12-04    0.838769
         2011-12-11    0.658538
         2011-12-18    0.567353
         2011-12-25  -1.076735
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [113]: ts2[[0, 2, 6]].index
Out[113]: DatetimeIndex([2011-01-02, 2011-01-16, 2011-02-13], dtype='datetime64[ns]', freq=None)
```

19.7 Time/Date Components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>year</td>
<td>The year of the datetime</td>
</tr>
<tr>
<td>month</td>
<td>The month of the datetime</td>
</tr>
<tr>
<td>day</td>
<td>The days of the datetime</td>
</tr>
<tr>
<td>hour</td>
<td>The hour of the datetime</td>
</tr>
<tr>
<td>minute</td>
<td>The minutes of the datetime</td>
</tr>
<tr>
<td>second</td>
<td>The seconds of the datetime</td>
</tr>
<tr>
<td>microsecond</td>
<td>The microseconds of the datetime</td>
</tr>
<tr>
<td>nanosecond</td>
<td>The nanoseconds of the datetime</td>
</tr>
<tr>
<td>date</td>
<td>Returns datetime.date (does not contain timezone information)</td>
</tr>
<tr>
<td>time</td>
<td>Returns datetime.time (does not contain timezone information)</td>
</tr>
<tr>
<td>dayofyear</td>
<td>The ordinal day of year</td>
</tr>
<tr>
<td>weekofyear</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>week</td>
<td>The week ordinal of the year</td>
</tr>
<tr>
<td>dayofweek</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>weekday</td>
<td>The number of the day of the week with Monday=0, Sunday=6</td>
</tr>
<tr>
<td>weekday_name</td>
<td>The name of the day in a week (ex: Friday)</td>
</tr>
<tr>
<td>quarter</td>
<td>Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.</td>
</tr>
<tr>
<td>days_in_month</td>
<td>The number of days in the month of the datetime</td>
</tr>
<tr>
<td>is_month_start</td>
<td>Logical indicating if first day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_month_end</td>
<td>Logical indicating if last day of month (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_start</td>
<td>Logical indicating if first day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_quarter_end</td>
<td>Logical indicating if last day of quarter (defined by frequency)</td>
</tr>
<tr>
<td>is_year_start</td>
<td>Logical indicating if first day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_year_end</td>
<td>Logical indicating if last day of year (defined by frequency)</td>
</tr>
<tr>
<td>is_leap_year</td>
<td>Logical indicating if the date belongs to a leap year</td>
</tr>
</tbody>
</table>

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the .dt accessor, as detailed in the section on .dt accessors.

### 19.8 DateOffset Objects

In the preceding examples, we created DatetimeIndex objects at various frequencies by passing in frequency strings like ‘M’, ‘W’, and ‘BM’ to the freq keyword. Under the hood, these frequency strings are being translated into an instance of DateOffset, which represents a regular frequency increment. Specific offset logic like “month”, “business day”, or “one hour” is represented in its various subclasses.

<table>
<thead>
<tr>
<th>Class name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DateOffset</td>
<td>Generic offset class, defaults to 1 calendar day</td>
</tr>
<tr>
<td>BDay</td>
<td>business day (weekday)</td>
</tr>
<tr>
<td>CDay</td>
<td>custom business day</td>
</tr>
<tr>
<td>Week</td>
<td>one week, optionally anchored on a day of the week</td>
</tr>
<tr>
<td>WeekOfMonth</td>
<td>the x-th day of the y-th week of each month</td>
</tr>
<tr>
<td>LastWeekOfMonth</td>
<td>the x-th day of the last week of each month</td>
</tr>
<tr>
<td>MonthEnd</td>
<td>calendar month end</td>
</tr>
<tr>
<td>MonthBegin</td>
<td>calendar month begin</td>
</tr>
<tr>
<td>BMonthEnd</td>
<td>business month end</td>
</tr>
<tr>
<td>BMonthBegin</td>
<td>business month begin</td>
</tr>
<tr>
<td>CBMonthEnd</td>
<td>custom business month end</td>
</tr>
</tbody>
</table>

Continued on next page
### Table 1 – continued from previous page

<table>
<thead>
<tr>
<th>Class name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBMonthBegin</td>
<td>custom business month begin</td>
</tr>
<tr>
<td>SemiMonthEnd</td>
<td>15th (or other day_of_month) and calendar month end</td>
</tr>
<tr>
<td>SemiMonthBegin</td>
<td>15th (or other day_of_month) and calendar month begin</td>
</tr>
<tr>
<td>QuarterEnd</td>
<td>calendar quarter end</td>
</tr>
<tr>
<td>QuarterBegin</td>
<td>calendar quarter begin</td>
</tr>
<tr>
<td>BQuarterEnd</td>
<td>business quarter end</td>
</tr>
<tr>
<td>BQuarterBegin</td>
<td>business quarter begin</td>
</tr>
<tr>
<td>FY5253Quarter</td>
<td>retail (aka 52-53 week) quarter</td>
</tr>
<tr>
<td>YearEnd</td>
<td>calendar year end</td>
</tr>
<tr>
<td>YearBegin</td>
<td>calendar year begin</td>
</tr>
<tr>
<td>BYearEnd</td>
<td>business year end</td>
</tr>
<tr>
<td>BYearBegin</td>
<td>business year begin</td>
</tr>
<tr>
<td>FY5253</td>
<td>retail (aka 52-53 week) year</td>
</tr>
<tr>
<td>BusinessHour</td>
<td>business hour</td>
</tr>
<tr>
<td>CustomBusinessHour</td>
<td>custom business hour</td>
</tr>
<tr>
<td>Hour</td>
<td>one hour</td>
</tr>
<tr>
<td>Minute</td>
<td>one minute</td>
</tr>
<tr>
<td>Second</td>
<td>one second</td>
</tr>
<tr>
<td>Milli</td>
<td>one millisecond</td>
</tr>
<tr>
<td>Micro</td>
<td>one microsecond</td>
</tr>
<tr>
<td>Nano</td>
<td>one nanosecond</td>
</tr>
</tbody>
</table>

The basic `DateOffset` takes the same arguments as `dateutil.relativedelta`, which works as follows:

```python
In [114]: d = datetime(2008, 8, 18, 9, 0)
In [115]: d + relativedelta(months=4, days=5)
Out[115]: datetime.datetime(2008, 12, 23, 9, 0)
```

We could have done the same thing with `DateOffset`:

```python
In [116]: from pandas.tseries.offsets import *
In [117]: d + DateOffset(months=4, days=5)
Out[117]: Timestamp('2008-12-23 09:00:00')
```

The key features of a `DateOffset` object are:

- It can be added / subtracted to/from a datetime object to obtain a shifted date.
- It can be multiplied by an integer (positive or negative) so that the increment will be applied multiple times.
- It has `rollforward()` and `rollback()` methods for moving a date forward or backward to the next or previous “offset date”.

Subclasses of `DateOffset` define the `apply` function which dictates custom date increment logic, such as adding business days:

```python
class BDay(DateOffset):
    """DateOffset increments between business days""
    def apply(self, other):
        ...
```

19.8. DateOffset Objects
The `rollforward` and `rollback` methods do exactly what you would expect:

```python
In [120]: d = datetime.datetime(2008, 8, 18, 9, 0)
In [121]: offset = BMonthEnd()
In [122]: offset.rollforward(d)
Out[122]: Timestamp('2008-08-29 09:00:00')
In [123]: offset.rollback(d)
Out[123]: Timestamp('2008-07-31 09:00:00')
```

It’s definitely worth exploring the `pandas.tseries.offsets` module and the various docstrings for the classes. These operations (`apply`, `rollforward` and `rollback`) preserve time (hour, minute, etc) information by default. To reset time, use `normalize=True` when creating the offset instance. If `normalize=True`, the result is normalized after the function is applied.

```python
In [124]: day = Day()
In [125]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[125]: Timestamp('2014-01-02 09:00:00')
In [126]: day = Day(normalize=True)
In [127]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[127]: Timestamp('2014-01-02 00:00:00')
In [128]: hour = Hour()
In [129]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[129]: Timestamp('2014-01-01 23:00:00')
In [130]: hour = Hour(normalize=True)
In [131]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[131]: Timestamp('2014-01-01 00:00:00')
In [132]: hour.apply(pd.Timestamp('2014-01-01 23:00'))
Out[132]: Timestamp('2014-01-01 00:00:00')
```

### 19.8.1 Parametric Offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```python
In [133]: d = datetime.datetime(2008, 8, 18, 9, 0)
```

(continues on next page)
In [134]: d + Week()
Out[134]: Timestamp('2008-08-25 09:00:00')

In [135]: d + Week(weekday=4)
Out[135]: Timestamp('2008-08-22 09:00:00')

In [136]: (d + Week(weekday=4)).weekday()
Out[136]: 4

In [137]: d - Week()
Out[137]: Timestamp('2008-08-11 09:00:00')

The normalize option will be effective for addition and subtraction.

In [138]: d + Week(normalize=True)
Out[138]: Timestamp('2008-08-25 00:00:00')

In [139]: d - Week(normalize=True)
Out[139]: Timestamp('2008-08-11 00:00:00')

Another example is parameterizing YearEnd with the specific ending month:

In [140]: d + YearEnd()
Out[140]: Timestamp('2008-12-31 09:00:00')

In [141]: d + YearEnd(month=6)
Out[141]: Timestamp('2009-06-30 09:00:00')

19.8.2 Using Offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

In [142]: rng = pd.date_range('2012-01-01', '2012-01-03')
In [143]: s = pd.Series(rng)
In [144]: rng
Out[144]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')
In [145]: rng + DateOffset(months=2)
Out[145]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq='D')
In [146]: s + DateOffset(months=2)
Out[146]:
0 2012-03-01
1 2012-03-02

(continues on next page)
If the offset class maps directly to a `Timedelta` (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a `Timedelta` - see the `Timedelta` section for more examples.

```
In [148]: s - Day(2)
Out[148]:
0  2011-12-30
1  2011-12-31
2  2012-01-01
dtype: datetime64[ns]
```

```
In [149]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))
In [150]: td
Out[150]:
0   3 days
1   3 days
2   3 days
dtype: timedelta64[ns]
```

```
In [151]: td + Minute(15)
Out[151]:
0 3 days 00:15:00
1 3 days 00:15:00
2 3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as `BQuarterEnd`) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```
In [152]: rng + BQuarterEnd()
Out[152]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype='datetime64[ns]', freq='D')
```

### 19.8.3 Custom Business Days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let’s look at Egypt where a Friday-Saturday weekend is observed.

```
In [153]: from pandas.tseries.offsets import CustomBusinessDay
In [154]: weekmask_egypt = 'Sun Mon Tue Wed Thu'
```

(continues on next page)
# They also observe International Workers' Day so let's
# add that for a couple of years
In [155]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01')]

In [156]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [157]: dt = datetime(2013, 4, 30)

In [158]: dt + 2 * bday_egypt
Out[158]: Timestamp('2013-05-05 00:00:00')

Let's map to the weekday names:

In [159]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [160]: pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat'.split()))
Out[160]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

In [161]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [162]: bday_us = CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [163]: dt = datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [164]: dt + bday_us
Out[164]: Timestamp('2014-01-21 00:00:00')

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

In [165]: from pandas.tseries.offsets import CustomBusinessMonthBegin

In [166]: bmth_us = CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [167]: dt = datetime(2013, 12, 17)

In [168]: dt + bmth_us
Out[168]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [169]: pd.DatetimeIndex(start='20100101',end='20120101',freq=bmth_us)

Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

19.8.4 Business Hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [170]: bh = BusinessHour()

In [171]: bh
Out[171]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [172]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[172]: 4

In [173]: pd.Timestamp('2014-08-01 10:00') + bh
Out[173]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [174]: pd.Timestamp('2014-08-01 08:00') + bh
Out[174]: Timestamp('2014-08-01 10:00:00')

# If the result is on the end time, move to the next business day
In [175]: pd.Timestamp('2014-08-01 16:00') + bh
Out[175]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [176]: pd.Timestamp('2014-08-01 16:30') + bh
Out[176]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [177]: pd.Timestamp('2014-08-01 10:00') + BusinessHour(2)
Out[177]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
```
You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start or previous day’s end. Different from other offsets, BusinessHour.rollforward may output different results from apply by definition.

This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 00:00.

19.8. DateOffset Objects

959
09:00.

```python
# This adjusts a Timestamp to business hour edge
In [190]: BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[190]: Timestamp('2014-08-01 17:00:00')

In [191]: BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[191]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [192]: BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
→ Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [193]: BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
→ Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollforwrd because BusinessDay never overlap.
In [194]: BusinessHour().apply(pd.Timestamp('2014-08-02'))
→ Timestamp('2014-08-04 10:00:00')
```

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

### 19.8.5 Custom Business Hour

New in version 0.18.1.

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```python
In [195]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [196]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [197]: dt = datetime(2014, 1, 17, 15)

In [198]: dt + bhour_us
Out[198]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [199]: dt + bhour_us * 2
Out[199]: Timestamp('2014-01-21 09:00:00')

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

In [200]: bhour_mon = CustomBusinessHour(start='10:00', weekmask='Tue Wed Thu Fri')

# Monday is skipped because it's a holiday, business hour starts from 10:00
```

(continues on next page)
19.8.6 Offset Aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as offset aliases.

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>
<tr>
<td>D</td>
<td>calendar day frequency</td>
</tr>
<tr>
<td>W</td>
<td>weekly frequency</td>
</tr>
<tr>
<td>M</td>
<td>month end frequency</td>
</tr>
<tr>
<td>SM</td>
<td>semi-month end frequency (15th and end of month)</td>
</tr>
<tr>
<td>BM</td>
<td>business month end frequency</td>
</tr>
<tr>
<td>CBM</td>
<td>custom business month end frequency</td>
</tr>
<tr>
<td>MS</td>
<td>month start frequency</td>
</tr>
<tr>
<td>SMS</td>
<td>semi-month start frequency (1st and 15th)</td>
</tr>
<tr>
<td>BMS</td>
<td>business month start frequency</td>
</tr>
<tr>
<td>CBMS</td>
<td>custom business month start frequency</td>
</tr>
<tr>
<td>Q</td>
<td>quarter end frequency</td>
</tr>
<tr>
<td>BQ</td>
<td>business quarter end frequency</td>
</tr>
<tr>
<td>QS</td>
<td>quarter start frequency</td>
</tr>
<tr>
<td>BQS</td>
<td>business quarter start frequency</td>
</tr>
<tr>
<td>A, Y</td>
<td>year end frequency</td>
</tr>
<tr>
<td>BA, BY</td>
<td>business year end frequency</td>
</tr>
<tr>
<td>AS, YS</td>
<td>year start frequency</td>
</tr>
<tr>
<td>BAS, BYS</td>
<td>business year start frequency</td>
</tr>
<tr>
<td>BH</td>
<td>business hour frequency</td>
</tr>
<tr>
<td>H</td>
<td>hourly frequency</td>
</tr>
<tr>
<td>T, min</td>
<td>minutely frequency</td>
</tr>
<tr>
<td>S</td>
<td>secondly frequency</td>
</tr>
<tr>
<td>L, ms</td>
<td>milliseconds</td>
</tr>
<tr>
<td>U, us</td>
<td>microseconds</td>
</tr>
<tr>
<td>N</td>
<td>nanoseconds</td>
</tr>
</tbody>
</table>

19.8.7 Combining Aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:
You can combine together day and intraday offsets:

```python
In [204]: pd.date_range(start, periods=10, freq='2h20min')
Out[204]:
```
datetime64[ns], freq='140T')
```

```python
In [205]: pd.date_range(start, periods=10, freq='1D10U')
```

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as ‘W’</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as ‘Q’</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
</tbody>
</table>
### Table 2 – continued from previous page

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to `date_range`, `bdelta_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

#### 19.8.9 Anchored Offset Semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When \( n \) is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved \( |n|-1 \) additional steps forwards or backwards.

```python
In [206]: pd.Timestamp('2014-01-02') + MonthBegin(n=1)
Out[206]: Timestamp('2014-02-01 00:00:00')

In [207]: pd.Timestamp('2014-01-02') + MonthEnd(n=1)
Out[207]: Timestamp('2014-01-31 00:00:00')
```

(continues on next page)
In [208]: pd.Timestamp('2014-01-02') - MonthBegin(n=1)
→ Timestamp('2014-01-01 00:00:00')

Out[208]:

In [209]: pd.Timestamp('2014-01-02') - MonthEnd(n=1)
→ Timestamp('2013-12-31 00:00:00')

In [210]: pd.Timestamp('2014-01-02') + MonthBegin(n=4)
→ Timestamp('2014-05-01 00:00:00')

In [211]: pd.Timestamp('2014-01-02') - MonthBegin(n=4)
→ Timestamp('2013-10-01 00:00:00')

If the given date is on an anchor point, it is moved $|n|$ points forwards or backwards.

In [212]: pd.Timestamp('2014-01-01') + MonthBegin(n=1)
Out[212]: Timestamp('2014-02-01 00:00:00')

In [213]: pd.Timestamp('2014-01-31') + MonthEnd(n=1)
→ Timestamp('2014-02-28 00:00:00')

In [214]: pd.Timestamp('2014-01-01') - MonthBegin(n=1)
→ Timestamp('2013-12-01 00:00:00')

In [215]: pd.Timestamp('2014-01-31') - MonthEnd(n=1)
→ Timestamp('2013-12-31 00:00:00')

In [216]: pd.Timestamp('2014-01-01') + MonthBegin(n=4)
→ Timestamp('2014-05-01 00:00:00')

In [217]: pd.Timestamp('2014-01-31') - MonthBegin(n=4)
→ Timestamp('2013-10-01 00:00:00')

For the case when $n=0$, the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

In [218]: pd.Timestamp('2014-01-02') + MonthBegin(n=0)
Out[218]: Timestamp('2014-02-01 00:00:00')

In [219]: pd.Timestamp('2014-01-02') + MonthEnd(n=0)
→ Timestamp('2014-01-31 00:00:00')

In [220]: pd.Timestamp('2014-01-01') + MonthBegin(n=0)
→ Timestamp('2014-01-01 00:00:00')

In [221]: pd.Timestamp('2014-01-31') + MonthEnd(n=0)
→ Timestamp('2014-01-31 00:00:00')
19.8.10 Holidays / Holiday Calendars

Holidays and calendars provide a simple way to define holiday rules to be used with CustomBusinessDay or in other analysis that requires a predefined set of holidays. The AbstractHolidayCalendar class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the start_date and end_date class attributes determine over what date range holidays are generated. These should be overwritten on the AbstractHolidayCalendar class to have the range apply to all calendar subclasses. USFederalHolidayCalendar is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sunday_to_monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tuesday</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:

```python
In [222]: from pandas.tseries.holiday import Holiday, USMemorialDay, AbstractHolidayCalendar, nearest_workday, MO

In [223]: class ExampleCalendar(AbstractHolidayCalendar):
   ....:     rules = [
   ....:         USMemorialDay,
   ....:         Holiday('July 4th', month=7, day=4, observance=nearest_workday),
   ....:         Holiday('Columbus Day', month=10, day=1, offset=DateOffset(weekday=MO(2))), # same as 2*Week(weekday=2)
   ....:     ]

In [224]: cal = ExampleCalendar()

In [225]: cal.holidays(datetime(2012, 1, 1), datetime(2012, 12, 31))
```

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetime or Timestamp objects.

```python
In [226]: from pandas.tseries.offsets import CDay

In [227]: pd.DatetimeIndex(start='7/1/2012', end='7/10/2012', freq=CDay(calendar=cal)).to_pydatetime()
```

(continues on next page)
Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [233]: AbstractHolidayCalendar.start_date
Out[233]: Timestamp('1970-01-01 00:00:00')
In [234]: AbstractHolidayCalendar.end_date
Out[234]: Timestamp('2030-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [235]: AbstractHolidayCalendar.start_date = datetime(2012, 1, 1)
In [236]: AbstractHolidayCalendar.end_date = datetime(2012, 12, 31)
In [237]: cal.holidays()
Out[237]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [238]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,
           USLaborDay
In [239]: cal = get_calendar('ExampleCalendar')
In [240]: cal.rules
Out[240]: [Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
       Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x1c36e47158>),
       Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
In [241]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)
```
19.9 Time Series-Related Instance Methods

19.9.1 Shifting / Lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```python
In [243]: ts = ts[:5]
In [244]: ts.shift(1)
Out[244]:
2011-01-31   NaN
2011-02-28  -1.281247
2011-03-31  -0.727707
2011-04-29  -0.121306
2011-05-31  -0.097883
Freq: BM, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an `offset alias`:

```python
In [245]: ts.shift(5, freq=offsets.BDay())
Out[245]:
2011-02-07  -1.281247
2011-03-07  -0.727707
2011-04-07  -0.121306
2011-05-06  -0.097883
2011-06-07   0.695775
```

```python
In [246]: ts.shift(5, freq='BM')
Out[246]:
2011-06-30  -1.281247
2011-07-29  -0.727707
2011-08-31  -0.121306
2011-09-30  -0.097883
2011-10-31   0.695775
Freq: BM, dtype: float64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```python
In [247]: ts.tshift(5, freq='D')
Out[247]:
(continues on next page)
```
2011-02-05  -1.281247
2011-03-05  -0.727707
2011-04-05  -0.121306
2011-05-04  -0.097883
2011-06-05   0.695775

dtype: float64

Note that with `tshift`, the leading entry is no longer NaN because the data is not being realigned.

## 19.9.2 Frequency Conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [248]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * offsets.BDay())
In [249]: ts = pd.Series(randn(3), index=dr)
In [250]: ts
Out[250]:
2010-01-01    0.155932
2010-01-06    1.486218
2010-01-11   -2.148675
Freq: 3B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [252]: ts.asfreq(BDay(), method='pad')
Out[252]:
2010-01-01    0.155932
2010-01-04     NaN
2010-01-05     NaN
2010-01-06    1.486218
2010-01-07     NaN
2010-01-08     NaN
2010-01-11   -2.148675
Freq: B, dtype: float64
```

## 19.9.3 Filling Forward / Backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the `missing data section`. 

968 Chapter 19. Time Series / Date functionality
19.9.4 Converting to Python Datetimes

DatetimeIndex can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

19.10 Resampling

**Warning:** The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the [whatsnew docs](#) for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`.resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some [cookbook examples](#) for some advanced strategies.

Starting in version 0.18.1, the `.resample()` function can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion [here](#).

19.10.1 Basics

```
In [253]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [254]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [255]: ts.resample('5Min').sum()
Out[255]:
2012-01-01    25653
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via `dispatching` is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [256]: ts.resample('5Min').mean()
Out[256]:
2012-01-01    256.53
Freq: 5T, dtype: float64
In [257]: ts.resample('5Min').ohlc()
2012-01-01    296  496   6  449
open    high   low    close
Freq: 5T, dtype: int64
In [258]: ts.resample('5Min').max()
(continues on next page)
```
For downsampling, `closed` can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```python
In [258]: ts.resample('5Min', closed='right').mean()
Out[258]:
2012-01-01 23:55:00 296.000000
2012-01-01 00:00:00 256.131313
Freq: 5T, dtype: float64
```

```python
In [259]: ts.resample('5Min', closed='left').mean()
```

```python
In [260]: ts.resample('5Min', label='left').mean()
Out[260]:
2012-01-01 256.53
Freq: 5T, dtype: float64
```

```python
In [261]: ts.resample('5Min', label='left', loffset='1s').mean()
```

```
Note: The default values for `label` and `closed` is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.
```
The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a DataFrame. `kind` can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation. `convention` can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

### 19.10.2 Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```python
# from secondly to every 250 milliseconds
In [269]: ts[:2].resample('250L').asfreq()
Out[269]:
2012-01-01 00:00:00.000    296.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000   199.0
Freq: 250L, dtype: float64
```

```python
In [270]: ts[:2].resample('250L').ffill()
Out[270]:
2012-01-01 00:00:00.000    296
2012-01-01 00:00:00.250    296
2012-01-01 00:00:00.500    296
2012-01-01 00:00:00.750    296
2012-01-01 00:00:01.000    199
Freq: 250L, dtype: int64
```
19.10.3 Sparse Resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [272]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [273]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [274]: ts.resample('3T').sum()
```

We can instead only resample those groups where we have points as follows:

```
In [275]: from functools import partial
In [276]: from pandas.tseries.frequencies import to_offset
In [277]: def round(t, freq):
       ....:     freq = to_offset(freq)
       ....:     return pd.Timestamp(t.value // freq.delta.value) * freq.delta.value
```
19.10.4 Aggregation

Similar to the aggregating API, groupby API, and the window functions API, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```python
In [279]: df = pd.DataFrame(np.random.randn(1000, 3),
                    index=pd.date_range('1/1/2012', freq='S', periods=1000),
                    columns=['A', 'B', 'C'])
In [280]: r = df.resample('3T')
In [281]: r.mean()
```

We can select a specific column or columns using standard getitem.

```python
In [282]: r['A'].mean()
```

(continues on next page)
Freq: 3T, Name: A, dtype: float64

In [283]: r[['A', 'B']].mean()

→

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-0.038580</td>
<td>-0.085117</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>0.052387</td>
<td>-0.061477</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>0.121377</td>
<td>-0.010630</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-0.106814</td>
<td>-0.053819</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>0.032560</td>
<td>0.080543</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>0.060486</td>
<td>-0.057602</td>
</tr>
</tbody>
</table>

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

In [284]: r['A'].agg([np.sum, np.mean, np.std])

Out[284]:

<table>
<thead>
<tr>
<th></th>
<th>sum</th>
<th>mean</th>
<th>std</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.944481</td>
<td>-0.038580</td>
<td>0.985150</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>9.429707</td>
<td>0.052387</td>
<td>1.078022</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>21.847876</td>
<td>0.121377</td>
<td>0.996365</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-19.226593</td>
<td>-0.106814</td>
<td>0.914070</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>5.860874</td>
<td>0.032560</td>
<td>1.100055</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>6.048588</td>
<td>0.060486</td>
<td>1.001532</td>
</tr>
</tbody>
</table>

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

In [285]: r.agg([np.sum, np.mean])

Out[285]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>mean</td>
<td>sum</td>
</tr>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.944481</td>
<td>-0.038580</td>
<td>-15.320993</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>9.429707</td>
<td>0.052387</td>
<td>-11.065916</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>21.847876</td>
<td>0.121377</td>
<td>-1.913420</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-19.226593</td>
<td>-0.106814</td>
<td>-9.687468</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>5.860874</td>
<td>0.032560</td>
<td>14.497725</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>6.048588</td>
<td>0.060486</td>
<td>-5.760208</td>
</tr>
</tbody>
</table>

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

In [286]: r.agg({'A' : np.sum, 'B' : lambda x: np.std(x, ddof=1)})

Out[286]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.944481</td>
<td>1.087752</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>9.429707</td>
<td>1.014552</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>21.847876</td>
<td>0.954588</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-19.226593</td>
<td>1.027990</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>5.860874</td>
<td>1.021503</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>6.048588</td>
<td>1.004984</td>
</tr>
</tbody>
</table>

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:
In [287]: `r.agg({'A' : 'sum', 'B' : 'std'})`  
Out[287]:  
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.944481</td>
<td>1.087752</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>9.429707</td>
<td>1.014552</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>21.847876</td>
<td>0.954588</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-19.226593</td>
<td>1.027990</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>5.860874</td>
<td>1.021503</td>
<td></td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>6.048588</td>
<td>1.004984</td>
<td></td>
</tr>
</tbody>
</table>

Furthermore, you can also specify multiple aggregation functions for each column separately.

In [288]: `r.agg({'A' : ['sum','std'], 'B' : ['mean','std'] })`  
Out[288]:  
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>std</td>
<td>mean</td>
<td>std</td>
</tr>
<tr>
<td>2012-01-01 00:00:00</td>
<td>-6.944481</td>
<td>0.985150</td>
<td>-0.085117</td>
<td>1.087752</td>
</tr>
<tr>
<td>2012-01-01 00:03:00</td>
<td>9.429707</td>
<td>1.078022</td>
<td>-0.061477</td>
<td>1.014552</td>
</tr>
<tr>
<td>2012-01-01 00:06:00</td>
<td>21.847876</td>
<td>0.996365</td>
<td>-0.010630</td>
<td>0.954588</td>
</tr>
<tr>
<td>2012-01-01 00:09:00</td>
<td>-19.226593</td>
<td>0.914070</td>
<td>-0.053819</td>
<td>1.027990</td>
</tr>
<tr>
<td>2012-01-01 00:12:00</td>
<td>5.860874</td>
<td>1.100055</td>
<td>0.080543</td>
<td>1.021503</td>
</tr>
<tr>
<td>2012-01-01 00:15:00</td>
<td>6.048588</td>
<td>1.001532</td>
<td>-0.057602</td>
<td>1.004984</td>
</tr>
</tbody>
</table>

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the on keyword.

In [289]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),  
                      'a': np.arange(5),  
                      index=pd.MultiIndex.from_arrays([  
                        [1,2,3,4,5],  
                        pd.date_range('2015-01-01', freq='W', periods=5)],  
                      names=['v','d']))

In [290]: df  
Out[290]:  
<table>
<thead>
<tr>
<th>date</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-01-04</td>
<td>0</td>
</tr>
<tr>
<td>2015-01-11</td>
<td>1</td>
</tr>
<tr>
<td>2015-01-18</td>
<td>2</td>
</tr>
<tr>
<td>2015-01-25</td>
<td>3</td>
</tr>
<tr>
<td>2015-02-01</td>
<td>4</td>
</tr>
</tbody>
</table>

In [291]: df.resample('M', on='date').sum()  

<table>
<thead>
<tr>
<th>date</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-01-31</td>
<td>6</td>
</tr>
<tr>
<td>2015-02-28</td>
<td>4</td>
</tr>
</tbody>
</table>

Similarly, if you instead want to resample by a datetimelike level of MultiIndex, its name or location can be passed to the level keyword.

In [292]: df.resample('M', level='d').sum()  

(continues on next page)
19.11 Time Span Representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

19.11.1 Period

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```python
In [293]: pd.Period('2012', freq='A-DEC')
Out[293]: Period('2012', 'A-DEC')
In [294]: pd.Period('2012-1-1', freq='D')
Out[294]: Period('2012-01-01', 'D')
In [295]: pd.Period('2012-1-1 19:00', freq='H')
Out[295]: Period('2012-01-01 19:00', 'H')
In [296]: pd.Period('2012-1-1 19:00', freq='5H')
Out[296]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```python
In [297]: p = pd.Period('2012', freq='A-DEC')
In [298]: p + 1
Out[298]: Period('2013', 'A-DEC')
In [299]: p - 3
Out[299]: Period('2009', 'A-DEC')
In [300]: p = pd.Period('2012-01', freq='2M')
In [301]: p + 2
Out[301]: Period('2012-05', '2M')
In [302]: p - 1
Out[302]: Period('2011-11', '2M')
In [303]: p == pd.Period('2012-01', freq='3M')
```

---

IncompatibleFrequency

Traceback (most recent call last)

(continues on next page)
If `Period` `freq` is daily or higher (D, H, T, S, L, U, N), offsets and `timedelta`-like can be added if the result can have the same freq. Otherwise, `ValueError` will be raised.

```
In [304]: p = pd.Period('2014-07-01 09:00', freq='H')
In [305]: p + Hour(2)
Out[305]: Period('2014-07-01 11:00', 'H')
In [306]: p + timedelta(minutes=120)
Out[306]: Period('2014-07-01 11:00', 'H')
In [307]: p + np.timedelta64(7200, 's')
Out[307]: Period('2014-07-01 11:00', 'H')
```

If `Period` has other `freq`, only the same offsets can be added. Otherwise, `ValueError` will be raised.

```
In [308]: p = pd.Period('2014-07', freq='M')
In [309]: p + MonthEnd(3)
Out[309]: Period('2014-10', 'M')
```

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

```
Out[310]: 10
```

### 19.11.2 PeriodIndex and `period_range`

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

```
In [311]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')
In [312]: prng
```

(continues on next page)
The `PeriodIndex` constructor can also be used directly:

```
In [313]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out[313]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

```
In [314]: pd.PeriodIndex(start='2014-01', freq='3M', periods=4)  
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```
In [315]: pd.PeriodIndex(start=pd.Period('2017Q1', freq='Q'),  
                      end=pd.Period('2017Q2', freq='Q'), freq='M')  
Out[315]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]', freq='M')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```
In [316]: ps = pd.Series(np.random.randn(len(prng)), prng)  
In [317]: ps
Out[317]:
2011-01  0.258318
2011-02 -2.503700
2011-03 -0.303053
2011-04  0.270509
2011-05  1.004841
2011-06 -0.129044
2011-07 -1.406335
2011-08 -1.310412
2011-09  0.769439
2011-10 -0.542325
2011-11  2.010541
2011-12  1.001558
2012-01 -0.087453
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```
In [318]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')  
In [319]: idx
Out[319]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',  
             '2014-07-01 12:00', '2014-07-01 13:00'],  
            dtype='period[H]', freq='H')
```
In [320]: idx + Hour(2)

→ PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
               '2014-07-01 14:00', '2014-07-01 15:00'],
              dtype='period[H]', freq='H')

In [321]: idx = pd.period_range('2014-07', periods=5, freq='M')

In [322]: idx

Out[322]:
            dtype='period[M]', freq='M')

In [323]: idx + MonthEnd(3)

               dtype='period[M]', freq='M')

PeriodIndex has its own dtype named period, refer to Period Dtypes.

19.11.3 Period Dtypes

New in version 0.19.0.

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the timezone aware dtype (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using frequency strings.

In [324]: pi = pd.period_range('2016-01-01', periods=3, freq='M')

In [325]: pi

Out[325]:
PeriodIndex(['2016-01', '2016-02', '2016-03'],
            dtype='period[M]', freq='M')

In [326]: pi.dtype

→ period[M]

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

# change monthly freq to daily freq
In [327]: pi.astype('period[D]')

Out[327]:
PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'],
            dtype='period[D]', freq='D')

# convert to DatetimeIndex
In [328]: pi.astype('datetime64[ns]')

→ DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'],
                dtype='datetime64[ns]',
                freq='MS')

# convert to PeriodIndex
In [329]: dti = pd.date_range('2011-01-01', freq='M', periods=3)
19.11.4 PeriodIndex Partial String Indexing

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to *DatetimeIndex Partial String Indexing*.

In [332]: ps['2011-01']
Out[332]: 0.25831819727391592

In [333]: ps[datetime(2011, 12, 25):]
Out[333]:
2011-12 1.001558
2012-01 -0.087453
Freq: M, dtype: float64

In [334]: ps['10/31/2011':'12/31/2011']
Out[334]:
2011-10 -0.542325
2011-11 2.010541
2011-12 1.001558
Freq: M, dtype: float64

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.

In [335]: ps['2011']
Out[335]:
2011-01 0.258318
2011-02 -2.503700
2011-03 -0.303053

19.11.5 Frequency Conversion and Resampling with PeriodIndex

The frequency of Period and PeriodIndex can be converted via the asfreq method. Let's start with the fiscal year 2011, ending in December:

```python
In [340]: p = pd.Period('2011', freq='A-DEC')
In [341]: p
Out[341]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the how parameter, we can specify whether to return the starting or ending month:

```python
In [342]: p.asfreq('M', how='start')
Out[342]: Period('2011-01', 'M')
In [343]: p.asfreq('M', how='end')
Out[343]: Period('2011-12', 'M')
```

The shorthands 's' and 'e' are provided for convenience:

```python
In [344]: p.asfreq('M', 's')
Out[344]: Period('2011-01', 'M')
In [345]: p.asfreq('M', 'e')
Out[345]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```python
In [346]: p = pd.Period('2011-12', freq='A-NOV')
In [347]: p.asfreq('A-DEC')
Out[347]: Period('2012', 'A-DEC')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:
Q-MAR defines fiscal year end in March:

```python
In [351]: p = pd.Period('2011Q4', freq='Q-MAR')
In [352]: p.asfreq('D', 's')
Out[352]: Period('2011-01-01', 'D')
In [353]: p.asfreq('D', 'e')
Out[353]: Period('2011-03-31', 'D')
```

## 19.12 Converting Between Representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```python
In [354]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [355]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [356]: ts
Out[356]:
2012-01-31   -0.898547
2012-02-29   -1.332247
2012-03-31   -0.741645
2012-04-30    0.094321
2012-05-31   -0.438813
Freq: M, dtype: float64

In [357]: ps = ts.to_period()
In [358]: ps
Out[358]:
2012-01    -0.898547
2012-02    -1.332247
2012-03    -0.741645
2012-04     0.094321
2012-05    -0.438813
Freq: M, dtype: float64

In [359]: ps.to_timestamp()
```

(continues on next page)
Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

```python
In [360]: ps.to_timestamp('D', how='s')
Out[360]:
2012-01-01 -0.898547
2012-02-01 -1.332247
2012-03-01 -0.741645
2012-04-01 0.094321
2012-05-01 -0.438813
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [361]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [362]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [363]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [364]: ts.head()
Out[364]:
1990-03-01 09:00 -0.564874
1990-06-01 09:00 -1.426510
1990-09-01 09:00 1.295437
1990-12-01 09:00 1.124017
1991-03-01 09:00 0.840428
Freq: H, dtype: float64
```

### 19.13 Representing Out-of-Bounds Spans

If you have data that is outside of the Timestamp bounds, see Timestamp limitations, then you can use a PeriodIndex and/or Series of Periods to do computations.

```python
In [365]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')
In [366]: span
Out[366]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10',
            ...]
1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
dtype='period[D]', length=60632, freq='D')
```

To convert from an int64 based YYYYMMDD representation.
In [367]: s = pd.Series([20121231, 20141130, 99991231])

In [368]: s
Out[368]:
0 20121231
1 20141130
2 99991231
dtype: int64

In [369]: def conv(x):
   .....:     return pd.Period(year = x // 10000, month = x//100 % 100, day = x%100,
   .....:     freq='D')
   .....:

In [370]: s.apply(conv)
Out[370]:
0 2012-12-31
1 2014-11-30
2 9999-12-31
dtype: object

In [371]: s.apply(conv)[2]
Out[371]: Period('9999-12-31', 'D')

These can easily be converted to a PeriodIndex:

In [372]: span = pd.PeriodIndex(s.apply(conv))

In [373]: span
Out[373]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'],
dtype='period[D]', freq='D')

19.14 Time Zone Handling

Pandas provides rich support for working with timestamps in different time zones using pytz and dateutil libraries. dateutil currently is only supported for fixed offset and tzfile zones. The default library is pytz. Support for dateutil is provided for compatibility with other applications e.g. if you use dateutil in other Python packages.

19.14.1 Working with Time Zones

By default, pandas objects are time zone unaware:

In [374]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')

In [375]: rng.tz
Out[375]: None

To supply the time zone, you can use the tz keyword to date_range and other functions. Dateutil time zone strings are distinguished from pytz time zones by starting with dateutil/.

- In pytz you can find a list of common (and less common) time zones using from pytz import common_timezones, all_timezones.
- dateutil uses the OS timezones so there isn’t a fixed list available. For common zones, the names are the same as pytz.

```python
# pytz
In [367]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                             tz='Europe/London')

In [377]: rng_pytz.tz
Out[377]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [378]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                                  tz='dateutil/Europe/London')

In [379]: rng_dateutil.tz
Out[379]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [380]: rng_utc = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                             tz=dateutil.tz.tzutc())

In [381]: rng_utc.tz
Out[381]: tzutc()
```

Note that the UTC timezone is a special case in dateutil and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other timezones explicitly first, which gives you more control over which time zone is used:

```python
# pytz
In [382]: tz_pytz = pytz.timezone('Europe/London')

In [383]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                               tz=tz_pytz)

In [384]: rng_pytz.tz == tz_pytz
Out[384]: True

# dateutil
In [385]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [386]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                                   tz=tz_dateutil)

In [387]: rng_dateutil.tz == tz_dateutil
Out[387]: True
```

Timestamps, like Python’s `datetime.datetime` object can be either time zone naive or time zone aware. Naive time series and `DatetimeIndex` objects can be `localized` using `tz_localize`:

```python
In [388]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [389]: ts_utc = ts.tz_localize('UTC')
```

(continues on next page)
In [390]: ts_utc
Out[390]:
2012-03-06 00:00:00+00:00  0.037206
2012-03-07 00:00:00+00:00  2.313998
2012-03-08 00:00:00+00:00  1.458296
2012-03-09 00:00:00+00:00  -0.620431
2012-03-10 00:00:00+00:00  -0.000111
2012-03-11 00:00:00+00:00  -0.342783
2012-03-12 00:00:00+00:00  -0.664322
2012-03-13 00:00:00+00:00  0.654814
2012-03-14 00:00:00+00:00  1.550680
2012-03-15 00:00:00+00:00  0.174511
2012-03-16 00:00:00+00:00  1.360491
2012-03-17 00:00:00+00:00  0.799737
2012-03-18 00:00:00+00:00  0.449149
2012-03-19 00:00:00+00:00  0.111346
2012-03-20 00:00:00+00:00  -0.435531
Freq: D, dtype: float64

Again, you can explicitly construct the timezone object first. You can use the `tz_convert` method to convert pandas objects to convert tz-aware data to another time zone:

In [391]: ts_utc.tz_convert('US/Eastern')
Out[391]:
2012-03-05 19:00:00-05:00  0.037206
2012-03-06 19:00:00-05:00  2.313998
2012-03-07 19:00:00-05:00  1.458296
2012-03-08 19:00:00-05:00  -0.620431
2012-03-09 19:00:00-05:00  -0.000111
2012-03-10 19:00:00-05:00  -0.342783
2012-03-11 20:00:00-04:00  -0.664322
2012-03-12 20:00:00-04:00  0.654814
2012-03-13 20:00:00-04:00  1.550680
2012-03-14 20:00:00-04:00  0.174511
2012-03-15 20:00:00-04:00  1.360491
2012-03-16 20:00:00-04:00  0.799737
2012-03-17 20:00:00-04:00  0.449149
2012-03-18 20:00:00-04:00  0.111346
2012-03-19 20:00:00-04:00  -0.435531
Freq: D, dtype: float64

**Warning:** Be wary of conversions between libraries. For some zones `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual time zones than for ‘standard’ zones like US/Eastern.

**Warning:** Be aware that a timezone definition across versions of timezone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** It is incorrect to pass a timezone directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=timezone('US/Eastern'))`). Instead, the `datetime` needs
to be localized using the localize method on the timezone.

Under the hood, all timestamps are stored in UTC. Scalar values from a `DatetimeIndex` with a time zone will have their fields (day, hour, minute) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```python
In [392]: rng_eastern = rng_utc.tz_convert('US/Eastern')
In [393]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')
In [394]: rng_eastern[5]
Out[394]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')
In [395]: rng_berlin[5]  
   \-------------------------------------------------\Out[395]:<timestamp '2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D'>
   \-------------------------------------------------\Out[396]:<true>
```

Like `Series`, `DataFrame`, and `DatetimeIndex`, `Timestamp`'s can be converted to other time zones using ``tz_convert``:

```python
In [397]: rng_eastern[5]  
   \-------------------------------------------------\Out[397]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')
In [398]: rng_berlin[5]  
   \-------------------------------------------------\Out[398]:<timestamp '2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D'>
In [399]: rng_eastern[5].tz_convert('Europe/Berlin')  
   \-------------------------------------------------\Out[399]:<timestamp '2012-03-11 01:00:00+0100', tz='Europe/Berlin'>
```

Localization of `Timestamp` functions just like `DatetimeIndex` and `Series`:

```python
In [400]: rng[5]  
   \-------------------------------------------------\Out[400]: Timestamp('2012-03-11 00:00:00', tz=None, freq='D')
In [401]: rng[5].tz_localize('Asia/Shanghai')  
   \-------------------------------------------------\Out[401]:Timestamp('2012-03-11_00:00:00+0800', tz='Asia/Shanghai')
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```python
In [402]: eastern = ts_utc.tz_convert('US/Eastern')
In [403]: berlin = ts_utc.tz_convert('Europe/Berlin')
In [404]: result = eastern + berlin
In [405]: result
   \-------------------------------------------------\Out[405]:  
   2012-03-06 00:00:00+00:00  0.074412
```

(continues on next page)
To remove timezone from tz-aware DatetimeIndex, use `tz_localize(None)` or `tz_convert(None)`.

`tz_localize(None)` will remove timezone holding local time representations. `tz_convert(None)` will remove timezone after converting to UTC time.
"2014-08-01 17:00:00", '2014-08-01 18:00:00',
'2014-08-01 19:00:00', '2014-08-01 20:00:00',
'2014-08-01 21:00:00', '2014-08-01 22:00:00'],
dtype='datetime64[ns]', freq='H')
# tz_convert(None) is identical with tz_convert('UTC').tz_localize(None)
In [411]: didx.tz_convert('UCT').tz_localize(None)

\[\ldots\]
Out[411]:
\[\ldots\]
ʻ2014-08-01 13:00:00', '2014-08-01 14:00:00',
'2014-08-01 15:00:00', '2014-08-01 16:00:00',
'2014-08-01 17:00:00', '2014-08-01 18:00:00',
'2014-08-01 19:00:00', '2014-08-01 20:00:00',
'2014-08-01 21:00:00', '2014-08-01 22:00:00'],
dtype='datetime64[ns]', freq='H')

19.14.2 Ambiguous Times when Localizing

In some cases, localize cannot determine the DST and non-DST hours when there are duplicates. This often happens when reading files or database records that simply duplicate the hours. Passing ambiguous='infer' into tz_localize will attempt to determine the right offset. Below the top example will fail as it contains ambiguous times and the bottom will infer the right offset.

In [412]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00',
.....: '11/06/2011 01:00', '11/06/2011 02:00',
.....: '11/06/2011 03:00'])

This will fail as there are ambiguous times

In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try_
→using the 'ambiguous' argument

In [413]: rng_hourly_eastern = rng_hourly.tz_localize('US/Eastern', ambiguous='infer')
In [414]: rng_hourly_eastern.tolist()
Out[414]:
[Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),
Timestamp('2011-11-06 01:00:00-0400', tz='US/Eastern'),
Timestamp('2011-11-06 01:00:00-0500', tz='US/Eastern'),
Timestamp('2011-11-06 02:00:00-0500', tz='US/Eastern'),
Timestamp('2011-11-06 03:00:00-0500', tz='US/Eastern')]

In addition to ‘infer’, there are several other arguments supported. Passing an array-like of bools or 0s/1s where True represents a DST hour and False a non-DST hour, allows for distinguishing more than one DST transition (e.g., if you have multiple records in a database each with their own DST transition). Or passing ‘NaT’ will fill in transition times with not-a-time values. These methods are available in the DatetimeIndex constructor as well as tz_localize.

In [415]: rng_hourly_dst = np.array([1, 1, 0, 0, 0])
In [416]: rng_hourly.tz_localize('US/Eastern', ambiguous=rng_hourly_dst).tolist()
Out[416]:
[Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0500', tz='US/Eastern'),

 dtype='datetime64[ns]', freq='H')

19.14. Time Zone Handling
19.14.3 TZ Aware Dtypes

Series/DatetimeIndex with a timezone naive value are represented with a dtype of \texttt{datetime64[ns]}.

\begin{verbatim}
In [423]: s_naive = pd.Series(pd.date_range('20130101', periods=3))

In [424]: s_naive
Out[424]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
dtype: datetime64[ns]
\end{verbatim}

Series/DatetimeIndex with a timezone aware value are represented with a dtype of \texttt{datetime64[ns, tz]}.

\begin{verbatim}
In [425]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))

In [426]: s_aware
Out[426]:
0  2013-01-01 00:00:00-05:00
1  2013-01-02 00:00:00-05:00
2  2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
\end{verbatim}

Both of these Series can be manipulated via the \texttt{.dt} accessor, see \texttt{here}.

For example, to localize and convert a naive stamp to timezone aware.

\begin{verbatim}
In [427]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[427]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
\end{verbatim}

Further more you can \texttt{.astype(...)} timezone aware (and naive). This operation is effectively a localize AND convert on a naive stamp, and a convert on an aware stamp.

\begin{verbatim}
# localize and convert a naive timezone
In [428]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[428]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
In [429]: s_aware.astype('datetime64[ns]')
\end{verbatim}

(continues on next page)
# convert to a new timezone
In [430]: s_aware.astype('datetime64[ns, CET]')

→
0   2013-01-01 06:00:00+01:00
1   2013-01-02 06:00:00+01:00
2   2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]

Note: Using the `.values` accessor on a Series, returns an NumPy array of the data. These values are converted to UTC, as NumPy does not currently support timezones (even though it is printing in the local timezone!).

In [431]: s_naive.values
Out[431]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
       '2013-01-03T00:00.000000000'], dtype='datetime64[ns]')

In [432]: s_aware.values
Out[432]:
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
       '2013-01-03T05:00.000000000'], dtype='datetime64[ns]')

Further note that once converted to a NumPy array these would lose the tz tenor.

In [433]: pd.Series(s_aware.values)
Out[433]:
0   2013-01-01 05:00:00
1   2013-01-02 05:00:00
2   2013-01-03 05:00:00
dtype: datetime64[ns]

However, these can be easily converted:

In [434]: pd.Series(s_aware.values).dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[434]:
0   2013-01-01 00:00:00-05:00
1   2013-01-02 00:00:00-05:00
2   2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of datetime.timedelta, and behaves in a similar manner, but allows compatibility with np.timedelta64 types as well as a host of custom representation, parsing, and attributes.

20.1 Parsing

You can construct a Timedelta scalar through various arguments:

```python
# strings
In [1]: pd.Timedelta('1 days')
Out[1]: Timedelta('1 days 00:00:00')

In [2]: pd.Timedelta('1 days 00:00:00')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 2 hours')
Out[3]: Timedelta('1 days 02:00:00')

In [4]: pd.Timedelta('-1 days 2 min 3us')
Out[4]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [5]: pd.Timedelta(days=1, seconds=1)
Out[5]: Timedelta('1 days 00:00:01')

# integers with a unit
In [6]: pd.Timedelta(1, unit='d')
Out[6]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [7]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[7]: Timedelta('1 days 00:00:01')

In [8]: pd.Timedelta(np.timedelta64(1, 'ms'))
```

(continues on next page)
# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [9]: pd.Timedelta('-1us')
Out[9]: Timedelta('-1 days +23:59:59.999999')

# a NaT
In [10]: pd.Timedelta('nan')
Out[10]: NaT

In [11]: pd.Timedelta('nat')
Out[11]: NaT

# ISO 8601 Duration strings
In [12]: pd.Timedelta('P0DT0H1M0S')
Out[12]: Timedelta('0 days 00:01:00')

In [13]: pd.Timedelta('P0DT0H0M0.000000123S')
Out[13]: Timedelta('0 days 00:00:00.000000')

New in version 0.23.0: Added constructor for ISO 8601 Duration strings

DateOffsets (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

In [14]: pd.Timedelta(Second(2))
Out[14]: Timedelta('0 days 00:00:02')

Further, operations among the scalars yield another scalar Timedelta.

In [15]: pd.Timedelta(Day(2)) + pd.Timedelta(Second(2)) + pd.Timedelta('00:00:00.000123')
Out[15]: Timedelta('2 days 00:00:02.000123')

## 20.1.1 to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format/value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

In [16]: pd.to_timedelta('1 days 06:05:01.00003')
Out[16]: Timedelta('1 days 06:05:01.000030')

In [17]: pd.to_timedelta('15.Sus')
Out[17]: Timedelta('0 days 00:00:00.000015')

or a list/array of strings:
In [18]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[18]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
                  dtype='timedelta64[ns]', freq=None)

The unit keyword argument specifies the unit of the Timedelta:

In [19]: pd.to_timedelta(np.arange(5), unit='s')
Out[19]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
                       dtype='timedelta64[ns]', freq=None)
In [20]: pd.to_timedelta(np.arange(5), unit='d')
Out[20]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
                       'timedelta64[ns]', freq=None)

20.1.2 Timedelta limitations

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

In [21]: pd.Timedelta.min
Out[21]: Timedelta('-106752 days +00:12:43.145224')
In [22]: pd.Timedelta.max
Out[22]: Timedelta('106751 days 23:47:16.854775')

20.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

In [23]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))
In [24]: td = pd.Series([ pd.Timedelta(days=i) for i in range(3) ])
In [25]: df = pd.DataFrame(dict(A = s, B = td))
In [26]: df
Out[26]:
   A         B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days
In [27]: df['C'] = df['A'] + df['B']
In [28]: df
Out[28]:
   A         B         C
0 2012-01-01 0 days 2012-01-01
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05

(continues on next page)
In [29]: df.dtypes
A datetime64[ns]
B timedelta64[ns]
C datetime64[ns]
dtype: object

In [30]: s - s.max()
0  -2 days
1  -1 days
2   0 days
dtype: timedelta64[ns]

In [31]: s - datetime.datetime(2011, 1, 1, 3, 5)
0 364 days 20:55:00
1 365 days 20:55:00
2 366 days 20:55:00
dtype: timedelta64[ns]

In [32]: s + datetime.timedelta(minutes=5)
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

In [33]: s + Minute(5)
0 2012-01-01 00:05:00
1 2012-01-02 00:05:00
2 2012-01-03 00:05:00
dtype: datetime64[ns]

In [34]: s + Minute(5) + Milli(5)
0 2012-01-01 00:05:00.005
1 2012-01-02 00:05:00.005
2 2012-01-03 00:05:00.005
dtype: datetime64[ns]

Operations with scalars from a timedelta64[ns] series:

In [35]: y = s - s[0]

In [36]: y
Out[36]:
0   0 days
1  1 days
Series of timedeltas with NaT values are supported:

```python
In [37]: y = s - s.shift()

In [38]: y
Out[38]:
0   NaT
1   1 days
2   1 days
dtype: timedelta64[ns]
```

Elements can be set to NaT using `np.nan` analogously to datetimes:

```python
In [39]: y[1] = np.nan

In [40]: y
Out[40]:
0   NaT
1   NaT
2   1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```python
In [41]: s.max() - s

Out[41]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]

In [42]: datetime.datetime(2011, 1, 1, 3, 5) - s
   \\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[42]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

In [43]: datetime.timedelta(minutes=5) + s
   \\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\n
In [43]:
```

min, max and the corresponding `idxmin`, `idxmax` operations are supported on frames:

```python
In [44]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [45]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [46]: df = pd.DataFrame(dict(A=A, B=B))
```

(continues on next page)
min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

You can fillna on timedeltas. Integers will be interpreted as seconds. You can pass a timedelta to get a particular value.
0 0 days
1 0 days
2 1 days
dtype: timedelta64[ns]

In [57]: y.fillna(10)
\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\\(continues from previous page)

You can also negate, multiply and use abs on Timedeltas:

In [59]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')

In [60]: td1
Out[60]: Timedelta('-2 days +21:59:57')

In [61]: -1 * td1
Out[61]: Timedelta('1 days 02:00:03')

In [62]: - td1
Out[62]: Timedelta('1 days 02:00:03')

In [63]: abs(td1)
Out[63]: Timedelta('1 days 02:00:03')

20.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

In [64]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat', '-1 days +00:00:05', '1 days']))

In [65]: y2
Out[65]:
0  -1 days +00:00:05
1  NaT
2  -1 days +00:00:05
3   1 days 00:00:00
dtype: timedelta64[ns]
In [66]: y2.mean()
→Timedelta('-1 days +16:00:03.333333')

In [67]: y2.median()
→Timedelta('-1 days +00:00:05')

In [68]: y2.quantile(.1)
→Timedelta('-1 days +00:00:05')

In [69]: y2.sum()
→Timedelta('-1 days +00:00:10')

20.4 Frequency Conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing
by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

In [70]: td = pd.Series(pd.date_range('20130101', periods=4)) - pd.Series(pd.date_range('20121201', periods=4))

In [71]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [72]: td[3] = np.nan

In [73]: td
Out[73]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3    NaT
dtype: timedelta64[ns]

# to days
In [74]: td / np.timedelta64(1, 'D')
→
0   31.000000
1   31.000000
2   31.003507
3  NaN
dtype: float64

In [75]: td.astype('timedelta64[D]')
→
0  31.0
1  31.0
2  31.0

(continues on next page)
3     NaN
dtype: float64

# to seconds
In [76]: td / np.timedelta64(1, 's')

→
0   2678400.0
1   2678400.0
2   2678703.0
3     NaN
dtype: float64

In [77]: td.astype('timedelta64[ns]')

→
0   2678400.0
1   2678400.0
2   2678703.0
3     NaN
dtype: float64

# to months (these are constant months)
In [78]: td / np.timedelta64(1, 'M')

→
0  1.018501
1  1.018501
2  1.018617
3   NaT
dtype: float64

Dividing or multiplying a timedelta64[ns] Series by an integer or integer Series yields another
timedelta64[ns] dtypes Series.

In [79]: td * -1
Out[79]:
0   -31 days +00:00:00
1   -31 days +00:00:00
2   -32 days +23:54:57
3      NaT
dtype: timedelta64[ns]

In [80]: td * pd.Series([1, 2, 3, 4])

→
0   31 days 00:00:00
1   62 days 00:00:00
2   93 days 00:15:09
3      NaT
dtype: timedelta64[ns]

Rounded division (floor-division) of a timedelta64[ns] Series by a scalar Timedelta gives a series of integers.

In [81]: td // pd.Timedelta(days=3, hours=4)
Out[81]:

(continues on next page)
The mod (%) and divmod operations are defined for `Timedelta` when operating with another timedelta-like or with a numeric argument.

```python
In [83]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[83]: Timedelta('0 days 01:00:00')
```

# divmod against a timedelta-like returns a pair (int, Timedelta)

```python
In [84]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[84]: (10, Timedelta('0 days 00:10:00'))
```

# divmod against a numeric returns a pair (Timedelta, Timedelta)

```python
In [85]: divmod(pd.Timedelta(hours=25), 8640000000000)
```

### 20.5 Attributes

You can access various components of the `Timedelta` or `TimedeltaIndex` directly using the attributes `days, seconds, microseconds, nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds $\geq 0$ and $< 1$ day. These are signed according to whether the `Timedelta` is signed.

These operations can also be directly accessed via the `.dt` property of the `Series` as well.

**Note:** Note that the attributes are NOT the displayed values of the `Timedelta`. Use `.components` to retrieve the displayed values.

For a `Series`:

```python
In [86]: td.dt.days
Out[86]:
```

```python
0 31.0
1 31.0
2 31.0
3 NaN
dtype: float64
```

```python
In [87]: td.dt.seconds
```

(continues on next page)
You can access the value of the fields for a scalar Timedelta directly.

```python
In [88]: tds = pd.Timedelta('31 days 5 min 3 sec')
In [89]: tds.days
Out[89]: 31
In [90]: tds.seconds
Out[90]: 303
In [91]: (-tds).seconds
Out[91]: 86097
```

You can use the `.components` property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the displayed values of the Timedelta.

```python
In [92]: tds.components
Out[92]:
    days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0  31.0      0.0       0.0       0.0             0.0             0.0       0.0
1  31.0      0.0       0.0       0.0             0.0             0.0       0.0
2  31.0      0.0       5.0       3.0             0.0             0.0       0.0
3  NaN       NaN       NaN       NaN             NaN             NaN       NaN
In [93]: tds.components.seconds
Out[93]:
    0  0.0  1  0.0  2  3.0  3  NaN
Name: seconds, dtype: float64
```

You can convert a Timedelta to an ISO 8601 Duration string with the `.isoformat` method.

New in version 0.20.0.

```python
In [94]: pd.Timedelta(days=6, minutes=50, seconds=3, milliseconds=10, microseconds=10, nanoseconds=12).isoformat()
Out[94]: 'P6DT0H50M3.010010012S'
```

### 20.6 TimedeltaIndex

To generate an index with time delta, you can use either the `TimedeltaIndex` or the `timedelta_range()` constructor.
Using TimedeltaIndex you can pass string-like, Timedelta, timedelta, or np.timedelta64 objects. Passing np.nan/pd.NaT/nat will represent missing values.

```
In [95]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
                          ....:'2 days 00:00:02']),
       dtype='timedelta64[ns]', freq=None)
```

## 20.6.1 Generating Ranges of Time Deltas

Similar to `date_range()`, you can construct regular ranges of a TimedeltaIndex using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [96]: pd.timedelta_range(start='1 days', periods=5)
Out[96]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
                     dtype='timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [97]: pd.timedelta_range(start='1 days', end='5 days')
Out[97]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
                       dtype='timedelta64[ns]', freq='D')
```

```
In [98]: pd.timedelta_range(end='10 days', periods=4)
Out[98]: TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'],
                        dtype='timedelta64[ns]', freq='D')
```

The `freq` parameter can passed a variety of `frequency aliases`:

```
In [99]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[99]: TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                        '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                        '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                        '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                        '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                        '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                        '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                        '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                        '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                        '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                        '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                        '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                        '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                        '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                        '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                        '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                        '2 days 00:00:00'],
                       dtype='timedelta64[ns]', freq='30T')
```

```
In [100]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
(continues on next page)
Out[100]:
 TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
     '7 days 15:00:00', '9 days 20:00:00'],
    dtype='timedelta64[ns]', freq='53H')

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced timedeltas from start to end inclusively, with periods number of elements in the resulting TimedeltaIndex:

In [101]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[101]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
    dtype='timedelta64[ns]', freq=None)

In [102]: pd.timedelta_range('0 days', '4 days', periods=10)
    
Out[102]:
 TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
     '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
     '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
     '4 days 00:00:00'],
    dtype='timedelta64[ns]', freq=None)

20.6.2 Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

In [103]: s = pd.Series(np.arange(100),
    index=pd.timedelta_range('1 days', periods=100, freq='h'))

In [104]: s
Out[104]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
   ..
4 days 21:00:00   93
4 days 22:00:00   94
4 days 23:00:00   95
5 days 00:00:00   96
5 days 01:00:00   97
5 days 02:00:00   98
5 days 03:00:00   99
Freq: H, Length: 100, dtype: int64

Selections work similarly, with coercion on string-likes and slices:
In [105]: s['1 day':'2 day']
Out[105]:
1 days 00:00:00  0
1 days 01:00:00  1
1 days 02:00:00  2
1 days 03:00:00  3
1 days 04:00:00  4
1 days 05:00:00  5
1 days 06:00:00  6
    ...
2 days 17:00:00 41
2 days 18:00:00 42
2 days 19:00:00 43
2 days 20:00:00 44
2 days 21:00:00 45
2 days 22:00:00 46
2 days 23:00:00 47
Freq: H, Length: 48, dtype: int64

In [106]: s['1 day 01:00:00']

In [107]: s[pd.Timedelta('1 day 1h')]

Furthermore you can use partial string selection and the range will be inferred:

In [108]: s['1 day':'1 day 5 hours']
Out[108]:
1 days 00:00:00 0
1 days 01:00:00 1
1 days 02:00:00 2
1 days 03:00:00 3
1 days 04:00:00 4
1 days 05:00:00 5
Freq: H, Length: 5, dtype: int64

20.6.3 Operations

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

In [109]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [110]: tdi.tolist()
Out[110]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [111]: dti = pd.date_range('20130101', periods=3)

In [112]: dti.tolist()
Out[112]: [Timestamp('2013-01-01 00:00:00', freq='D'),
          Timestamp('2013-01-02 00:00:00', freq='D'),
          Timestamp('2013-01-03 00:00:00', freq='D')]
In [113]: (dti + tdi).tolist()
Out[113]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [114]: (dti - tdi).tolist()
Out[114]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

20.6.4 Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

In [115]: tdi / np.timedelta64(1,'s')
Out[115]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [116]: tdi.astype('timedelta64[s]')
Out[116]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

Scalars type ops work as well. These can potentially return a different type of index.

# adding or timedelta and date -> datelike
In [117]: tdi + pd.Timestamp('20130101')
Out[117]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [118]: (pd.Timestamp('20130101') - tdi).tolist()
Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [119]: tdi + pd.Timedelta('10 days')
Out[119]: TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [120]: tdi / 2
Out[120]: TimedeltaIndex(['0 days 12:00:00', NaT, '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)

# or a Float64Index if the divisor is a Timedelta
In [121]: tdi / tdi[0]
Out[121]: Float64Index([1.0, nan, 2.0], dtype='float64')

20.7 Resampling

Similar to timeseries resampling, we can resample with a TimedeltaIndex.
In [122]: s.resample('D').mean()
Out[122]:
1 days  11.5
2 days  35.5
3 days  59.5
4 days  83.5
5 days  97.5
Freq: D, dtype: float64
CATEGORICAL DATA

This is an introduction to pandas categorical data type, including a short comparison with R’s factor.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories, levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, . . .) are not possible.

All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.

The categorical data type is useful in the following cases:

• A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.
• The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.
• As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the API docs on categoricals.

21.1 Object Creation

21.1.1 Series Creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying dtype="category" when constructing a Series:

In [1]: s = pd.Series(["a","b","c","a"], dtype="category")

In [2]: s
Out[2]:
0  a
1  b
2  c
3  a

(continues on next page)
By converting an existing Series or column to a **category** dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [4]: df["B"] = df["A"].astype('category')
In [5]: df
```

```
   A   B
0  a   a
1  b   b
2  c   c
3  a   a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the *example on tiling* in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})
In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
In [9]: df.head(10)
```

```
   value group
0   65  60 - 69
1   49  40 - 49
2   56  50 - 59
3   43  40 - 49
4   43  40 - 49
5   91  90 - 99
6   32  30 - 39
7   87  80 - 89
8   36  30 - 39
9    8   0 - 9
```

By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.

```
In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"], ordered=False)
In [11]: s = pd.Series(raw_cat)
In [12]: s
```

```
0   NaN
1     b
2     c
3   NaN
dtype: category
Categories (3, object): [b, c, d]
```
In [13]: df = pd.DataFrame({'A': ['a', 'b', 'c', 'a']})
In [14]: df['B'] = raw_cat
In [15]: df
Out[15]:
   A  B
0  a  NaN
1  b  b
2  c  c
3  a  NaN

Categorical data has a specific category dtype:

In [16]: df.dtypes
Out[16]:
A  object
B  category
dtype: object

### 21.1.2 DataFrame Creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying dtype="category" in the DataFrame constructor:

In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out[18]:
A  category
B  category
dtype: object

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

In [19]: df['A']
Out[19]:
   0  a
   1  b
   2  c
   3  a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df['B']
Out[20]:
   0  b
   1  c
   2  c
   3  d

(continues on next page)
New in version 0.23.0.

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A category
B category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out[24]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (3, object): [a, b, c]
In [25]: df_cat['B']
Out[25]:
0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

### 21.1.3 Controlling Behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `dtype='category'`, use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(['a', 'b', 'c', 'a'])
In [28]: cat_type = CategoricalDtype(categories=['b', 'c', 'd'], ordered=True)
```

(continues on next page)
Similarly, a CategoricalDtype can be used with a DataFrame to ensure that categories are consistent among all columns.

```
In [31]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))

In [32]: cat_type = CategoricalDtype(categories=list('abcd'), ordered=True)

In [33]: df_cat = df.astype(cat_type)

In [34]: df_cat['A']
Out[34]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (4, object): [a < b < c < d]

In [35]: df_cat['B']

0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (4, object): [a < b < c < d]
```

**Note:** To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the categories parameter can be determined programmatically by categories = pd.unique(df.values.ravel()).

If you already have codes and categories, you can use the from_codes() constructor to save the factorize step during normal constructor mode:

```
In [36]: splitter = np.random.choice([0,1], 5, p=[0.5,0.5])

In [37]: s = pd.Series(pd.Categorical.from_codes(splitter, categories=['train', 'test →']))
```
21.1.4 Regaining Original Data

To get back to the original Series or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```python
In [38]: s = pd.Series(['a', 'b', 'c', 'a'])

In [39]: s
Out[39]:
0  a
1  b
2  c
3  a
dtype: object

In [40]: s2 = s.astype('category')

In [41]: s2
Out[41]:
0  a
1  b
2  c
3  a
dtype: category
Categories (3, object): [a, b, c]

In [42]: s2.astype(str)
Out[42]:
0  a
1  b
2  c
3  a
dtype: object

In [43]: np.asarray(s2)
Out[43]:
array(['a', 'b', 'c', 'a'], dtype=object)
```

**Note:** In contrast to R’s `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

**Note:** In contrast to R’s `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

21.2 CategoricalDtype

Changed in version 0.21.0.

A categorical’s type is fully described by

1. `categories`: a sequence of unique values and no missing values
2. ordered: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```python
In [44]: from pandas.api.types import CategoricalDtype

In [45]: CategoricalDtype([ 'a', 'b', 'c' ])
Out[45]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=None)

In [46]: CategoricalDtype([ 'a', 'b', 'c' ], ordered=True)
CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [47]: CategoricalDtype()
CategoricalDtype(categories=None, ordered=None)
```

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

**Note:** As a convenience, you can use the string 'category' in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

### 21.2.1 Equality Semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```python
In [48]: c1 = CategoricalDtype([ 'a', 'b', 'c' ], ordered=False)
# Equal, since order is not considered when ordered=False
In [49]: c1 == CategoricalDtype([ 'b', 'c', 'a' ], ordered=False)
Out[49]: True

# Unequal, since the second CategoricalDtype is ordered
In [50]: c1 == CategoricalDtype([ 'a', 'b', 'c' ], ordered=True)
Out[50]: False
```

All instances of `CategoricalDtype` compare equal to the string 'category'.

```python
In [51]: c1 == 'category'
Out[51]: True
```

**Warning:** Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to 'category', all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False), regardless of categories or ordered.
21.3 Description

Using `describe()` on categorical data will produce similar output to a `Series` or `DataFrame` of type `string`.

```python
In [52]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])
In [53]: df = pd.DataFrame({"cat": cat, "s": ["a", "c", "c", np.nan]})
In [54]: df.describe()
Out[54]:
   cat  s
  count 3 3
  unique 2 2
     top  c  c
    freq 2 2
```

```python
In [55]: df["cat"].describe()
Out[55]:
       count 3
       unique 2
         top  c
         freq 2
Name: cat, dtype: object
```

21.4 Working with categories

Categorical data has a `categories` and an `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don’t manually specify categories and ordering, they are inferred from the passed arguments.

```python
In [56]: s = pd.Series(["a", "b", "c", "a"], dtype="category")
In [57]: s.cat.categories
Out[57]: Index(["a", "b", "c"], dtype='object')
In [58]: s.cat.ordered
Out[58]: False
```

It’s also possible to pass in the categories in a specific order:

```python
In [59]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], categories=["c","b","a"]))
In [60]: s.cat.categories
Out[60]: Index(["c", "b", "a"], dtype='object')
In [61]: s.cat.ordered
Out[61]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.
Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```
In [62]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd')))

In [63]: s
Out[63]:
0   b
1   a
2   b
3   c
dtype: category
Categories (4, object): [a, b, c, d]

# categories
In [64]: s.cat.categories
Out[64]:
[\ldots]

# uniques
In [65]: s.unique()
Out[65]:
[b, a, c]
Categories (3, object): [b, a, c]
```

### 21.4.1 Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```
In [66]: s = pd.Series(['a','b','c','a'], dtype='category')

In [67]: s
Out[67]:
0   a
1   b
2   c
3   a
dtype: category
Categories (3, object): [a, b, c]

In [68]: s.cat.categories = ['Group %s' % g for g in s.cat.categories]

In [69]: s
Out[69]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

(continues on next page)
In [70]: s.cat.rename_categories([1,2,3])

→
0 1
1 2
2 3
3 1
dtype: category
Categories (3, int64): [1, 2, 3]

In [71]: s

→
0 Group a
1 Group b
2 Group c
3 Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

# You can also pass a dict-like object to map the renaming
In [72]: s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

→
0 Group a
1 Group b
2 Group c
3 Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

In [73]: s

→
0 Group a
1 Group b
2 Group c
3 Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

Note: In contrast to R’s `factor`, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

Categories must be unique or a `ValueError` is raised:

In [74]: try:
   ....:     s.cat.categories = [1,1,1]
   ....: except ValueError as e:
   ....:     print("ValueError: " + str(e))
ValueError: Categorical categories must be unique

Categories must also not be NaN or a ValueError is raised:

```python
In [75]: try:
   ....: s.cat.categories = [1,2,np.nan]
   ....: except ValueError as e:
   ....:     print("ValueError: " + str(e))
   ....:
ValueError: Categorical categories cannot be null
```

### 21.4.2 Appending new categories

Appending categories can be done by using the `add_categories()` method:

```python
In [76]: s = s.cat.add_categories([4])
In [77]: s.cat.categories
Out[77]: Index(["Group a", 'Group b', 'Group c', 4], dtype='object')
```

```python
In [78]: s
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[78]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (4, object): [Group a, Group b, Group c, 4]
```

### 21.4.3 Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```python
In [79]: s = s.cat.remove_categories([4])
In [80]: s
Out[80]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

### 21.4.4 Removing unused categories

Removing unused categories can also be done:

```python
In [81]: s = pd.Series(pd.Categorical(['a','b','a'], categories=['a','b','c','d']))
```

(continues on next page)
21.4.5 Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [84]: s = pd.Series(['one', 'two', 'four', '-'], dtype='category')
In [85]: s
Out[85]:
0   one
1   two
2   four
3   -
dtype: category
Categories (4, object): [-, four, one, two]
In [86]: s = s.cat.set_categories(['one', 'two', 'three', 'four'])
In [87]: s
Out[87]:
0   one
1   two
2   four
3  NaN
```

**Note:** Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!
### 21.5 Sorting and Order

If categorical data is ordered (s.cat.ordered == True), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, .min()/.max() will raise a TypeError.

In [88]: s = pd.Series(pd.Categorical(["a","b","c","a"], ordered=False))
In [89]: s.sort_values(inplace=True)
In [90]: s = pd.Series(["a","b","c","a"]).astype(
    ....:     CategoricalDtype(ordered=True)
    ....: )
    ....:
In [91]: s.sort_values(inplace=True)

In [92]: s
Out[92]:
0  a
3  a
1  b
2  c
dtype: category
Categories (3, object): [a < b < c]

In [93]: s.min(), s.max()
\n→('a', 'c')

You can set categorical data to be ordered by using as_ordered() or unordered by using as_unordered(). These will by default return a new object.

In [94]: s.cat.as_ordered()
Out[94]:
0  a
3  a
1  b
2  c
dtype: category
Categories (3, object): [a < b < c]

In [95]: s.cat.as_unordered()
\n→
0  a
3  a
1  b
2  c
dtype: category
Categories (3, object): [a, b, c]

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

In [96]: s = pd.Series([1,2,3,1], dtype="category")
In [97]: s = s.cat.set_categories([2,3,1], ordered=True)
21.5.1 Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.
In [107]: s.min(), s.max()
→(2, 1)

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the Series, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the Series are changed.

Note: If the Categorical is not ordered, Series.min() and Series.max() will raise TypeError. Numeric operations like +, -, *, / and operations based on them (e.g. Series.median(), which would need to compute the mean between two values if the length of an array is even) do not work and raise a TypeError.

21.5.2 Multi Column Sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

In [108]: dfs = pd.DataFrame({'A' : pd.Categorical(list('bbeebbaa'), categories=['e', 'a', 'b'], ordered=True), 'B' : [1,2,1,2,2,1,2,1] })
.....:
In [109]: dfs.sort_values(by=['A', 'B'])
Out[109]:
A   B
2   e 1
3   e 2
7   a 1
6   a 2
0   b 1
5   b 1
1   b 2
4   b 2

Reordering the categories changes a future sort.

In [110]: dfs['A'] = dfs['A'].cat.reorder_categories(['a','b','e'])
In [111]: dfs.sort_values(by=['A', 'B'])
Out[111]:
A   B
7   a 1
6   a 2
0   b 1
5   b 1
1   b 2
4   b 2
2   e 1
3   e 2
21.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and !=) to a list-like object (list, Series, array, ...) of the same length as the categorical data.

- All comparisons (==, !=, >, >=, <, and <=) of categorical data to another categorical Series, when ordered==True and the categories are the same.

- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a TypeError.

**Note:** Any “non-equality” comparisons of categorical data with a Series, np.array, list or categorical data with different categories or ordering will raise a TypeError because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```python
In [112]: cat = pd.Series([1,2,3]).astype(CategoricalDtype([3, 2, 1], ordered=True))
   ....:     ...
   ....:

In [113]: cat_base = pd.Series([2,2,2]).astype(CategoricalDtype([3, 2, 1], ordered=True))
   ....:     ...
   ....:

In [114]: cat_base2 = pd.Series([2,2,2]).astype(CategoricalDtype(ordered=True))
   ....:     ...
   ....:

In [115]: cat
Out[115]:
0 1
1 2
2 3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [116]: cat_base
...
0 2
1 2
2 2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base2
...
0 2
1 2
```

(continues on next page)
Comparing to a categorical with the same categories and ordering or to a scalar works:

```python
In [118]: cat > cat_base
Out[118]:
0   True
1   False
2   False
dtype: bool

In [119]: cat > 2
Out[119]:
0   True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```python
In [120]: cat == cat_base
Out[120]:
0   False
1   True
2   False
dtype: bool

In [121]: cat == np.array([1,2,3])
Out[121]:
0   True
1   True
2   True
dtype: bool

In [122]: cat == 2
Out[122]:
0   False
1   True
2   False
dtype: bool
```

This doesn’t work because the categories are not the same:

```python
In [123]: try:
    ....:    cat > cat_base2
    ....: except TypeError as e:
    ....:      print("TypeError: " + str(e))
(...)
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:
```python
In [124]: base = np.array([1,2,3])

In [125]: try:
       ...:     cat > base
       ...: except TypeError as e:
       ...:     print(f"TypeError: {e}")
...
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [126]: np.asarray(cat) > base
Out[126]: array([False, False, False], dtype=bool)
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```python
In [127]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)
In [128]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)
In [129]: c1 == c2
Out[129]: array([ True, True], dtype=bool)
```

## 21.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

Series methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```python
In [130]: s = pd.Series(pd.Categorical(['a', 'b', 'c', 'c'], categories=['c', 'a', 'b', 'd']))
In [131]: s.value_counts()
Out[131]:
   c    2
   b    1
   a    1
   d    0
dtype: int64
```

Groupby will also show “unused” categories:

```python
In [132]: cats = pd.Categorical(['a', 'b', 'b', 'b', 'c', 'c', 'c'], categories=['a', 'b', 'c', 'd'])
In [133]: df = pd.DataFrame({'cats':cats, 'values':[1,2,2,3,4,5]})
In [134]: df.groupby("cats").mean()
Out[134]:
   values
cats  
   a    1.0
   b    2.3
   c    3.0
   d    nan
```

(continues on next page)
In [135]: cats2 = pd.Categorical(['a','a','b','b'], categories=['a','b','c'])

In [136]: df2 = pd.DataFrame({'cats':cats2, 'B':['c','d','c','d'], 'values':[1,2,3,4]})

In [137]: df2.groupby(['cats','B']).mean()

Out[137]:

<table>
<thead>
<tr>
<th>cats</th>
<th>B</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>c</td>
<td>1.0</td>
</tr>
<tr>
<td></td>
<td>d</td>
<td>2.0</td>
</tr>
<tr>
<td>b</td>
<td>c</td>
<td>3.0</td>
</tr>
<tr>
<td></td>
<td>d</td>
<td>4.0</td>
</tr>
<tr>
<td>c</td>
<td>c</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>d</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Pivot tables:

In [138]: raw_cat = pd.Categorical(['a','a','b','b'], categories=['a','b','c'])

In [139]: df = pd.DataFrame({'A':raw_cat, 'B':['c','d','c','d'], 'values':[1,2,3,4]})

In [140]: pd.pivot_table(df, values='values', index=['A', 'B'])

Out[140]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>a</td>
<td>c</td>
<td>1</td>
</tr>
<tr>
<td></td>
<td></td>
<td>d</td>
<td>2</td>
</tr>
<tr>
<td></td>
<td>b</td>
<td>c</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td>d</td>
<td>4</td>
</tr>
</tbody>
</table>

### 21.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in `categories` can be assigned.

#### 21.8.1 Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the category dtype is preserved.

In [141]: idx = pd.Index(['h', 'i', 'j', 'k', 'l', 'm', 'n',])

In [142]: cats = pd.Series(['a','b','b','b','c','c','c'], dtype='category', index=idx)

In [143]: values = [1,2,2,2,3,4,5]

In [144]: df = pd.DataFrame({'cats':cats, 'values':values}, index=idx)

In [145]: df.iloc[2:4,:]

Out[145]:

(continues on next page)
An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

```python
# get the complete "h" row as a Series
In [149]: df.loc["h", :]
Out[149]:
cats  a
values 1
Name: h, dtype: object
```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```python
In [150]: df.iat[0,0]
Out[150]: 'a'
```

```python
In [151]: df["cats"].cat.categories = ["x","y","z"]
```

```python
In [152]: df.at["h","cats"] # returns a string
Out[152]: 'x'
```

Note: The is in contrast to R’s `factor` function, where `factor(c(1,2,3))[1]` returns a single value `factor`. To get a single value Series of type `category`, you pass in a list with a single value:

```python
In [153]: df.loc["h","cats"]
Out[153]:
h  x
```

(continues on next page)
Name: cats, dtype: category
Categories (3, object): [x, y, z]

## 21.8.2 String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```python
In [154]: str_s = pd.Series(list('aabb'))
In [155]: str_cat = str_s.astype('category')
In [156]: str_cat
Out[156]:
0 a
1 a
2 b
3 b
dtype: category
Categories (2, object): [a, b]
In [157]: str_cat.str.contains("a")
Out[157]:
0   True
1   True
2  False
3  False
dtype: bool
In [158]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))
In [159]: date_cat = date_s.astype('category')
In [160]: date_cat
Out[160]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
dtype: category
In [161]: date_cat.dt.day
Out[161]:
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

**Note:** The returned `Series` (or DataFrame) is of the same type as if you used the `.str.<method>` /.dt. method.
<method> on a Series of that type (and not of type category!).

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type category will be equal:

```
In [162]: ret_s = str_s.str.contains("a")
In [163]: ret_cat = str_cat.str.contains("a")
In [164]: ret_s.dtype == ret_cat.dtype
Out[164]: True
```

```
In [165]: ret_s == ret_cat

Out[165]:
0   True
1   True
2   True
3   True
dtype: bool
```

**Note:** The work is done on the categories and then a new Series is constructed. This has some performance implication if you have a Series of type string, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type category and use .str.<method> or .dt.<property> on that.

### 21.8.3 Setting

Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```
In [166]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])  
In [167]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", "b"])  
In [168]: values = [1, 1, 1, 1, 1, 1, 1]  
In [169]: df = pd.DataFrame({"cats":cats,"values":values}, index=idx)  
In [170]: df.iloc[2:4, :].iloc = [["b", 2], ["b", 2]]
```

```
In [171]: df
Out[171]:
    cats values
   h   a   1
   i   a   1
   j   b   2
   k   b   2
   l   a   1
   m   a   1
   n   a   1
```

```
In [172]: try:
      .....: df.iloc[2:4, :].iloc = [["c", 3], ["c", 3]]
```

(continues on next page)
Setting values by assigning categorical data will also check that the categories match:

```python
In [173]: df.loc["j":"k","cats"] = pd.Categorical(["a","a"], categories=["a","b"])
In [174]: df
Out[174]:
     cats
   h  a  1
   i  a  1
   j  a  2
   k  a  2
   l  a  1
   m  a  1
   n  a  1
In [175]: try:
     .....: df.loc["j":"k","cats"] = pd.Categorical(["b","b"], categories=["a","b","c"])
     .....: except ValueError as e:
     .....:     print("ValueError: " + str(e))
     .....:
ValueError: Cannot setitem on a Categorical with a new category, set the categories first
```

Assigning a Categorical to parts of a column of other types will use the values:

```python
In [176]: df = pd.DataFrame({"a":[1,1,1,1,1], "b":["a","a","a","a","a"]})
In [177]: df.loc[1:2,"a"] = pd.Categorical(["b","b"], categories=["a","b"])
In [178]: df.loc[2:3,"b"] = pd.Categorical(["b","b"], categories=["a","b"])
In [179]: df
Out[179]:
   a  b
0  1  a
1  2  b
2  3  b
3  4  a
In [180]: df.dtypes
Out[180]:
   a  object
   b  object
dtype: object
```

21.8. Data munging
21.8.4 Merging

You can concat two DataFrames containing categorical data together, but the categories of these categoricals need to be the same:

```python
In [181]: cat = pd.Series(["a","b"], dtype=\"category\")
In [182]: vals = [1,2]
In [183]: df = pd.DataFrame({"cats":cat, "vals":vals})
In [184]: res = pd.concat([df,df])
In [185]: res
Out[185]:
   cats vals
0   a    1
1   b    2
0   a    1
1   b    2
```

In this case the categories are not the same, and therefore an error is raised:

```python
In [186]: res.dtypes
```

```python
Out[186]:
cats category
vals int64
dtype: object
```

The same applies to `df.append(df_different)`.
See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

21.8.5 Unioning

New in version 0.19.0.

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```python
In [190]: from pandas.api.types import union_categoricals
In [191]: a = pd.Categorical(["b", "c"],
In [192]: b = pd.Categorical(["a", "b"])
In [193]: union_categoricals([a, b])
```
By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
In [194]: union_categoricals([a, b], sort_categories=True)
Out[194]:
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```python
In [195]: a = pd.Categorical(["a", "b"], ordered=True)
In [196]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [197]: union_categoricals([a, b])
Out[197]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```python
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [198]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [199]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [200]: union_categoricals([a, b], ignore_order=True)
Out[200]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```python
In [201]: a = pd.Series(["b", "c"], dtype='category')
In [202]: b = pd.Series(["a", "b"], dtype='category')
In [203]: union_categoricals([a, b])
Out[203]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```
**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [204]: c1 = pd.Categorical(['b', 'c'])
In [205]: c2 = pd.Categorical(['a', 'b'])
In [206]: c1
Out[206]:
\[b, c\]
Categories (2, object): [b, c]

# "b" is coded to 0
In [207]: c1.codes
Out[207]: array([0, 1], dtype=int8)
In [208]: c2
\[a, b\]
Categories (2, object): [a, b]

# "b" is coded to 1
In [209]: c2.codes
Out[209]: array([0, 1], dtype=int8)
In [210]: c = union_categoricals([c1, c2])
In [211]: c
Out[211]:
\[b, c, a, b\]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [212]: c.codes
Out[212]: array([0, 1, 2, 0], dtype=int8)
```

21.8.6 Concatenation

This section describes concatenations specific to `category` dtype. See *Concatenating objects* for general description.

By default, `Series` or `DataFrame` concatenation which contains the same categories results in `category` dtype, otherwise results in `object` dtype. Use `.astype` or `union_categoricals` to get `category` result.

```python
# same categories
In [213]: s1 = pd.Series(['a', 'b'], dtype='category')
In [214]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')
In [215]: pd.concat([s1, s2])
Out[215]:
0    a
Name: 0, dtype: category
```

(continues on next page)
1 a
0 b
1 a
2 a
dtype: category
Categories (2, object): [a, b]

# different categories
In [216]: s3 = pd.Series(['b', 'c'], dtype='category')

In [217]: pd.concat([s1, s3])
Out[217]:
0 a
1 b
0 b
1 c
dtype: object

In [218]: pd.concat([s1, s3]).astype('category')
Out[218]:
0 a
1 b
0 b
1 c
dtype: category
Categories (3, object): [a, b, c]

In [219]: union_categoricals([s1.values, s3.values])

→ [a, b, b, c]
Categories (3, object): [a, b, c]

Following table summarizes the results of Categoricals related concatenations.

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category (identical categories)</td>
<td>category</td>
</tr>
<tr>
<td>category</td>
<td>category (different categories, both not ordered)</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category</td>
<td>category (different categories, either one is ordered)</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category</td>
<td>not category</td>
<td>object (dtype is inferred)</td>
</tr>
</tbody>
</table>

21.9 Getting Data In/Out

You can write data that contains category dtypes to a HDFStore. See here for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See here for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

In [220]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))
# rename the categories

(continues on next page)
In [221]: s.cat.categories = ["very good", "good", "bad"]
 # reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])
In [223]: df = pd.DataFrame({"cats":s, "vals":[1,2,3,4,5,6]})
In [224]: csv = StringIO()
In [225]: df.to_csv(csv)
In [226]: df2 = pd.read_csv(StringIO(csv.getvalue()))
In [227]: df2.dtypes
Out[227]:
<table>
<thead>
<tr>
<th></th>
<th>dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unnamed:</td>
<td>int64</td>
</tr>
<tr>
<td>cats</td>
<td>object</td>
</tr>
<tr>
<td>vals</td>
<td>int64</td>
</tr>
<tr>
<td>dtype:</td>
<td>object</td>
</tr>
</tbody>
</table>
In [228]: df2["cats"]

0  very good
1    good
2    good
3  very good
4  very good
5    bad
Name: cats, dtype: object

# Redo the category
In [229]: df2["cats"] = df2["cats"].astype("category")
In [230]: df2["cats"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"],
   .....:     inplace=True)
   .....:
In [231]: df2.dtypes
Out[231]:
<table>
<thead>
<tr>
<th></th>
<th>dtype</th>
</tr>
</thead>
<tbody>
<tr>
<td>Unnamed:</td>
<td>int64</td>
</tr>
<tr>
<td>cats</td>
<td>category</td>
</tr>
<tr>
<td>vals</td>
<td>int64</td>
</tr>
<tr>
<td>dtype:</td>
<td>object</td>
</tr>
</tbody>
</table>
In [232]: df2["cats"]

0  very good
1    good
2    good
3  very good
4  very good
5    bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
The same holds for writing to a SQL database with `to_sql`.

## 21.10 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the *Missing Data section*.

Missing values should **not** be included in the Categorical’s *categories*, only in the *values*. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s *codes*, missing values will always have a code of `-1`.

```python
In [233]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [234]: s
Out[234]:
0    a
1    b
2  NaN
3    a
dtype: category
Categories (2, object): [a, b]

In [235]: s.cat.codes
Out[235]:
0  0
1  1
2 -1
3  0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```python
In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [237]: s
Out[237]:
0    a
1    b
2  NaN
dtype: category
Categories (2, object): [a, b]

In [238]: pd.isna(s)
Out[238]:
0   False
1   False
2    True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0    a
```

(continues on next page)
21.11 Differences to R's \textit{factor}

The following differences to R's factor functions can be observed:

- R's \textit{levels} are named \textit{categories}.
- R's \textit{levels} are always of type string, while \textit{categories} in pandas can be of any dtype.
- It's not possible to specify labels at creation time. Use \texttt{s.cat.rename\_categories(new\_labels)} afterwards.
- In contrast to R's \textit{factor} function, using categorical data as the sole input to create a new categorical series will not remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its \textit{levels} (pandas' \textit{categories}). Pandas does not allow NaN categories, but missing values can still be in the \textit{values}.

21.12 Gotchas

21.12.1 Memory Usage

The memory usage of a \texttt{Categorical} is proportional to the number of categories plus the length of the data. In contrast, an \texttt{object} dtype is a constant times the length of the data.

\begin{Verbatim}
In [240]: s = pd.Series(['foo','bar']*1000)
# object dtype
In [241]: s.nbytes
Out[241]: 16000

# category dtype
In [242]: s.astype('category').nbytes
Out[242]: 2016
\end{Verbatim}

\textbf{Note:} If the number of categories approaches the length of the data, the \texttt{Categorical} will use nearly the same or more memory than an equivalent \texttt{object} dtype representation.

\begin{Verbatim}
In [243]: s = pd.Series(['foo%d' % i for i in range(2000)])
# object dtype
In [244]: s.nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype('category').nbytes
Out[245]: 20000
\end{Verbatim}
21.12.2 Categorical is not a numpy array

Currently, categorical data and the underlying Categorical is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn’t know about the new dtype:

```python
In [246]: try:
    ......:   np.dtype("category")
    ......: except TypeError as e:
    ......:   print("TypeError: " + str(e))
    ......:
TypeError: data type "category" not understood

In [247]: dtype = pd.Categorical(["a"]).dtype

In [248]: try:
    ......:   np.dtype(dtype)
    ......: except TypeError as e:
    ......:   print("TypeError: " + str(e))
    ......:
TypeError: data type not understood
```

Dtype comparisons work:

```python
In [249]: dtype == np.str_
Out[249]: False

In [250]: np.str_ == dtype
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```python
In [251]: hasattr(pd.Series(['a'], dtype='category'), 'cat')
Out[251]: True

In [252]: hasattr(pd.Series(['a']), 'cat')
```

Using NumPy functions on a Series of type category should not work as Categoricals are not numeric data (even in the case that .categories is numeric).

```python
In [253]: s = pd.Series(pd.Categorical([1,2,3,4]))

In [254]: try:
    ......:   np.sum(s)
    ......: except TypeError as e:
    ......:   print("TypeError: " + str(e))
    ......:
TypeError: Categorical cannot perform the operation sum
```

Note: If such a function works, please file a bug at https://github.com/pandas-dev/pandas!
21.12.3 dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object.

In [255]: df = pd.DataFrame({"a":[1,2,3,4],
......: "b": ["a","b","c","d"],
......: "cats":pd.Categorical([1,2,3,2])})

In [256]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[256]:
0 <class 'int'>
1 <class 'int'>
2 <class 'int'>
3 <class 'int'>
dtype: object

In [257]: df.apply(lambda col: col.dtype, axis=0)
Out[257]:
\_strings        int64
\cats            category
dtype: object

21.12.4 Categorical Index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

In [258]: cats = pd.Categorical([1,2,3,4], categories=[4,2,3,1])

In [259]: strings = ["a","b","c","d"]

In [260]: values = [4,2,3,1]

In [261]: df = pd.DataFrame({"strings":strings, "values":values}, index=cats)

In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')

# This now sorts by the categories order
In [263]: df.sort_index()
Out[263]:
\strings values
4  d  1
2  b  2
3  c  3
1  a  4
21.12.5 Side Effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```python
In [264]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])
In [265]: s = pd.Series(cat, name="cat")
In [266]: cat
Out[266]:
[1, 2, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
In [267]: s.iloc[0:2] = 10
In [268]: cat
Out[268]:
[10, 10, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
In [269]: df = pd.DataFrame(s)
In [270]: df["cat"].cat.categories = [1,2,3,4,5]
In [271]: cat
Out[271]:
[5, 5, 3, 5]  Categories (5, int64): [1, 2, 3, 4, 5]

Use `copy=True` to prevent such a behaviour or simply don’t reuse Categoricals:

```python
In [272]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]  Categories (5, int64): [1, 2, 3, 4, 10]
```

Note: This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. `np.array([1,2,3,4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a","b","c","a"])`) will not.
We use the standard convention for referencing the matplotlib API:

```python
In [1]: import matplotlib.pyplot as plt
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

**Note:** All calls to `np.random` are seeded with 123456.

### 22.1 Basic Plotting: plot

We will demonstrate the basics, see the cookbook for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```python
In [2]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', periods=1000))
In [3]: ts = ts.cumsum()
In [4]: ts.plot()
Out[4]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2e3b0ba8>
```
If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```python
In [5]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list('ABCD'))
In [6]: df = df.cumsum()
In [7]: plt.figure(); df.plot();
```
You can plot one column versus another using the `x` and `y` keywords in `plot()`:

```python
In [8]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [9]: df3['A'] = pd.Series(list(range(len(df))))
In [10]: df3.plot(x='A', y='B')
Out[10]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38114e10>
```
22.2 Other Plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the kind keyword argument to `plot()`, and include:

- 'bar' or 'barh' for bar plots
- 'hist' for histogram
- 'box' for boxplot
- 'kde' or 'density' for density plots
- 'area' for area plots
- 'scatter' for scatter plots
- 'hexbin' for hexagonal bin plots
- 'pie' for pie plots

For example, a bar plot can be created the following way:
You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```python
In [13]: df = pd.DataFrame()
In [14]: df.plot.<TAB>
    df.plot.area    df.plot.barh    df.plot.density    df.plot.hist    df.plot.line
    df.plot.scatter
    df.plot.bar    df.plot.box    df.plot.hexbin    df.plot.kde    df.plot.pie
```

In addition to these kinds, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several plotting functions in `pandas.plotting` that take a `Series` or `DataFrame` as an argument. These include:

- Scatter Matrix
- Andrews Curves
- Parallel Coordinates
- Lag Plot
• Autocorrelation Plot
• Bootstrap Plot
• RadViz

Plots may also be adorned with errorbars or tables.

22.2.1 Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

Calling a DataFrame’s `plot.bar()` method produces a multiple bar plot:

```
In [17]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [18]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```python
In [19]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [20]: df2.plot.barh(stacked=True);
```
22.2.2 Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [21]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.randn(1000),
                      'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])

In [22]: plt.figure();
In [23]: df4.plot.hist(alpha=0.5)
Out[23]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36abc470>
```
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```python
In [24]: plt.figure();
In [25]: df4.plot.hist(stacked=True, bins=20)
Out[25]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36ac4940>
```
You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```python
In [26]: plt.figure();

In [27]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
Out[27]: <matplotlib.axes._subplots.AxesSubplot at 0x1c369362b0>
```
See the `hist` method and the `matplotlib hist` documentation for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```python
In [28]: plt.figure();

In [29]: df['A'].diff().hist()
Out[29]: <matplotlib.axes._subplots.AxesSubplot at 0x1c388ceeb8>
```
`DataFrame.hist()` plots the histograms of the columns on multiple subplots:

```python
In [30]: plt.figure()
Out[30]: <Figure size 640x480 with 0 Axes>

In [31]: df.diff().hist(color='k', alpha=0.5, bins=50)
```

22.2. Other Plots 1057
The `by` keyword can be specified to plot grouped histograms:

```python
In [32]: data = pd.Series(np.random.randn(1000))
In [33]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
Out[33]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c36be2d30>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c2efde940>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1c2f002e48>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c33d2c198>]],
      dtype=object)
```
22.2.3 Box Plots

Boxplot can be drawn calling :meth:`Series.plot.box` and :meth:`DataFrame.plot.box`, or :meth:`DataFrame.boxplot` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```python
In [34]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
In [35]: df.plot.box()
Out[35]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38838f98>
```
Boxplot can be colorized by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [36]: color = dict(boxes='DarkGreen', whiskers='DarkOrange',
               medians='DarkBlue', caps='Gray')

In [37]: df.plot.box(color=color, sym='r+')
Out[37]: <matplotlib.axes._subplots.AxesSubplot at 0x1c378c4198>
```
Also, you can pass other keywords supported by matplotlib boxplot. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```python
In [38]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36a6ae10>
```
See the `boxplot` method and the `matplotlib` boxplot documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```python
In [39]: df = pd.DataFrame(np.random.rand(10,5))
In [40]: plt.figure();
In [41]: bp = df.boxplot()
```
You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```python
In [42]: df = pd.DataFrame(np.random.rand(10,2), columns=['Col1', 'Col2'])
In [43]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [44]: plt.figure();
In [45]: bp = df.boxplot(by='X')
```
You can also pass a subset of columns to plot, as well as group by multiple columns:

```python
In [46]: df = pd.DataFrame(np.random.rand(10,3), columns=['Col1', 'Col2', 'Col3'])
In [47]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [48]: df['Y'] = pd.Series(['A','B','A','B','A','B','A','B','A','B'])
In [49]: plt.figure();
In [50]: bp = df.boxplot(column=['Col1','Col2'], by=['X','Y'])
```
Warning: The default changed from 'dict' to 'axes' in version 0.19.0.

In boxplot, the return type can be controlled by the return_type keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by DataFrame.boxplot with the by keyword, will affect the output type as well:

<table>
<thead>
<tr>
<th>return_type=</th>
<th>Faceted</th>
<th>Output type</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>None</td>
<td>Yes</td>
<td>2-D ndarray of axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>Yes</td>
<td>Series of axes</td>
</tr>
<tr>
<td>'dict'</td>
<td>No</td>
<td>dict of artists</td>
</tr>
<tr>
<td>'dict'</td>
<td>Yes</td>
<td>Series of dicts of artists</td>
</tr>
<tr>
<td>'both'</td>
<td>No</td>
<td>namedtuple</td>
</tr>
<tr>
<td>'both'</td>
<td>Yes</td>
<td>Series of namedtuples</td>
</tr>
</tbody>
</table>

Groupby.boxplot always returns a Series of return_type.

In [51]: np.random.seed(1234)

In [52]: df_box = pd.DataFrame(np.random.randn(50, 2))
In [53]: df_box['g'] = np.random.choice(['A', 'B'], size=50)

In [54]: df_box.loc[df_box['g'] == 'B', 1] += 3

In [55]: bp = df_box.boxplot(by='g')

The subplots above are split by the numeric columns first, then the value of the \textit{g} column. Below the subplots are first split by the value of \textit{g}, then by the numeric columns.

In [56]: bp = df_box.groupby('g').boxplot()
22.2.4 Area Plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains `NaN`, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [57]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [58]: df.plot.area();
```
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [59]: df.plot.area(stacked=False);
```
22.2.5 Scatter Plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the x and y keywords.

```
In [60]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
In [61]: df.plot.scatter(x='a', y='b');
```
To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [62]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
In [63]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

```python
In [64]: df.plot.scatter(x='a', y='b', c='c', s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```python
In [65]: df.plot.scatter(x='a', y='b', s=df['c']*200);
```
See the `scatter` method and the matplotlib `scatter` documentation for more.

### 22.2.6 Hexagonal Bin Plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [66]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [67]: df['b'] = df['b'] + np.arange(1000)
In [68]: df.plot.hexbin(x='a', y='b', gridsize=25)
Out[68]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d4c09b0>
```
A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each \((x, y)\) point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. `mean`, `max`, `sum`, `std`). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy’s `max` function.

```python
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [70]: df['b'] = df['b'] = df['b'] + np.arange(1000)
In [71]: df['z'] = np.random.uniform(0, 3, 1000)
In [72]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max,
                   gridsize=25)
```

```
Out[72]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d567dd8>
```
See the `hexbin` method and the matplotlib hexbin documentation for more.

### 22.2.7 Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```python
In [73]: series = pd.Series(3 * np.random.rand(4), index=['a', 'b', 'c', 'd'], name='series')

In [74]: series.plot.pie(figsize=(6, 6))
Out[74]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d85c5f8>
```
For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned `axes` object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [75]: df = pd.DataFrame(3 * np.random.rand(4, 2), index=['a', 'b', 'c', 'd'],
                     columns=['x', 'y'])

In [76]: df.plot.pie(subplots=True, figsize=(8, 4))
Out[76]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x1c3d8c5940>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c3da4bd30>], dtype=object)
```
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with matplotlib.pyplot.pie() you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by matplotlib.pyplot.pie() can be used.

```python
In [77]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],
   ....:                                  autopct='%.2f', fontsize=20, figsize=(6, 6))
   ....:
Out[77]: <matplotlib.axes._subplots.AxesSubplot at 0x121551ba8>
```
If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [78]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
In [79]: series.plot.pie(figsize=(6, 6))
Out[79]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d8b22b0>
```
See the matplotlib pie documentation for more.

22.3 Plotting with Missing Data

Pandas tries to be pragmatic about plotting DataFrame or Series that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.
If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

## 22.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

### 22.4.1 Scatter Matrix Plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```python
In [80]: from pandas.plotting import scatter_matrix

In [81]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [82]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')

Out[82]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x1c381e89e8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c37c4da20>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c3781c898>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c376d50f0>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1c33b56320>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c33b56518>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c2f046550>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c2bdcf780>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1c370c6400>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c25a6a710>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c2f082a20>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c36ac3668>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1c33c43cf8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c37d01cc0>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c383a0358>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x1c38115470>]),
<dtype=object>)
```
22.4.2 Density Plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [83]: ser = pd.Series(np.random.randn(1000))
In [84]: ser.plot.kde()
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3842c908>
```
22.4.3 Andrews Curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available here.

```python
In [85]: from pandas.plotting import andrews_curves

In [86]: data = pd.read_csv('data/iris.data')

In [87]: plt.figure()
Out[87]: <Figure size 640x480 with 0 Axes>

In [88]: andrews_curves(data, 'Name')
```

![Andrews Curves Diagram](image)
22.4.4 Parallel Coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [89]: from pandas.plotting import parallel_coordinates

In [90]: data = pd.read_csv('data/iris.data')

In [91]: plt.figure()
Out[91]: <Figure size 640x480 with 0 Axes>

In [92]: parallel_coordinates(data, 'Name')
```

```
\\\\\\\\\\\\\\\\\\\\\\\\:\\\\\\\\\\\\\\\\\\\\\\\\\:\\\\\\\\\\\\\\\\\\\\\\\\\:\\\\\\\\\\\\\\\\\\\\\\\\\:\\\\\\\\\\\\\\\\\\\\\\\\\:\\\\\\\\\\\\\\\\\\\\\\\\\:Out[92]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38e62b38>
```

22.4. Plotting Tools
22.4.5 Lag Plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1] vs. data[1:]`.

```
In [93]: from pandas.plotting import lag_plot

In [94]: plt.figure()
Out[94]: <Figure size 640x480 with 0 Axes>

In [95]: data = pd.Series(0.1 * np.random.rand(1000) +
                      0.9 * np.sin(np.linspace(-99 * np.pi, 99 * np.pi, num=1000)))

In [96]: lag_plot(data)
Out[96]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2b26e208>
```
22.4.6 Autocorrelation Plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```
In [97]: from pandas.plotting import autocorrelation_plot

In [98]: plt.figure()
Out[98]: <Figure size 640x480 with 0 Axes>

In [99]: data = pd.Series(0.7 * np.random.rand(1000) +
.....:            0.3 * np.sin(np.linspace(-9 * np.pi, 9 * np.pi, num=1000)))
.....:

In [100]: autocorrelation_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37dd3588>
```
22.4.7 Bootstrap Plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

In [101]: from pandas.plotting import bootstrap_plot
In [102]: data = pd.Series(np.random.rand(1000))
In [103]: bootstrap_plot(data, size=50, samples=500, color='grey')
Out[103]: <Figure size 640x480 with 6 Axes>
22.4.8 RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package `Radviz` for more information.

Note: The “Iris” dataset is available here.

```
In [104]: from pandas.plotting import radviz

In [105]: data = pd.read_csv('data/iris.data')

In [106]: plt.figure()
Out[106]: <Figure size 640x480 with 0 Axes>

In [107]: radviz(data, 'Name')
```

---

22.4. Plotting Tools 1087
22.5 Plot Formatting

22.5.1 Setting the plot style

From version 1.5 and up, matplotlib offers a range of preconfigured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

22.5.2 General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```python
In [108]: plt.figure(); ts.plot(style='k--', label='Series');
```
For each kind of plot (e.g. line, bar, scatter) any additional arguments keywords are passed along to the corresponding matplotlib function (ax.plot(), ax.bar(), ax.scatter()). These can be used to control additional styling, beyond what pandas provides.

### 22.5.3 Controlling the Legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [109]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list('ABCD'))
In [110]: df = df.cumsum()
In [111]: df.plot(legend=False)
```

Out[111]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2a823fd0>
### 22.5.4 Scales

You may pass `logy` to get a log-scale Y axis.

```python
In [112]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', periods=1000))

In [113]: ts = np.exp(ts.cumsum())

In [114]: ts.plot(logy=True)
Out[114]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2f026080>
```
22.5.5 Plotting on a Secondary Y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```python
In [115]: df.A.plot()
Out[115]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37e6c7f0>

In [116]: df.B.plot(secondary_y=True, style='g')
```

See also the `logx` and `loglog` keyword arguments.
To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```python
In [117]: plt.figure()
Out[117]: <Figure size 640x480 with 0 Axes>

In [118]: ax = df.plot(secondary_y=['A', 'B'])

In [119]: ax.set_ylabel('CD scale')
Out[119]: Text(0,0.5,'CD scale')

In [120]: ax.right_ax.set_ylabel('AB scale')
```

Out[120]: Text(0,0.5,'AB scale')
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```python
In [121]: plt.figure()
Out[121]: <Figure size 640x480 with 0 Axes>

In [122]: df.plot(secondary_y=['A', 'B'], mark_right=False)
```

22.5. Plot Formatting
22.5.6 Suppressing Tick Resolution Adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```python
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>

In [124]: df.A.plot()
```

```python
Out[124]: <matplotlib.axes._subplots.AxesSubplot at 0x1c31f58a58>
```
Using the `x_compat` parameter, you can suppress this behavior:

```
In [125]: plt.figure()
Out[125]: <Figure size 640x480 with 0 Axes>

In [126]: df.A.plot(x_compat=True)
```
If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```python
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>

In [128]: with pd.plotting.plot_params.use('x_compat', True):
    ....:     df.A.plot(color='r')
    ....:     df.B.plot(color='g')
    ....:     df.C.plot(color='b')
    ....:
```
22.5.7 Automatic Date Tick Adjustment

New in version 0.20.0.

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the autofmt_xdate method and the matplotlib documentation for more.

22.5.8 Subplots

Each Series in a DataFrame can be plotted on a different axis with the subplots keyword:

```python
In [129]: df.plot(subplots=True, figsize=(6, 6));
```
22.5.9 Using Layout and Targeting Multiple Axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```python
In [130]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```
The above example is identical to using:

```
In [131]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don’t affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [132]: fig, axes = plt.subplots(4, 4, figsize=(6, 6));

In [133]: plt.subplots_adjust(wspace=0.5, hspace=0.5);

In [134]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
```

(continues on next page)
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```python
In [138]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [139]: df['A'].plot(ax=axes[0,0]); axes[0,0].set_title('A');
In [140]: df['B'].plot(ax=axes[0,1]); axes[0,1].set_title('B');
(continues on next page)
```
In [141]: df['C'].plot(ax=axes[1,0]); axes[1,0].set_title('C');
In [142]: df['D'].plot(ax=axes[1,1]); axes[1,1].set_title('D');

22.5.10 Plotting With Error Bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a `M` length `Series`, a `Mx2` array should be provided indicating lower and upper (or left and right) errors. For a `MxN DataFrame`, asymmetrical errors should be in a `Mx2xN` array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.
# Generate the data

```python
In [143]: ix3 = pd.MultiIndex.from_arrays([['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'], ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']], names=['letter', 'word'])
```

```python
In [144]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2], 'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)
```

# Group by index labels and take the means and standard deviations for each group

```python
In [145]: gp3 = df3.groupby(level=('letter', 'word'))
```

```python
In [146]: means = gp3.mean()
In [147]: errors = gp3.std()
```

```
Out[148]:

<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>3.5</td>
<td>6.0</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>2.5</td>
<td>5.5</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>2.5</td>
<td>5.5</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>3.0</td>
<td>4.5</td>
</tr>
</tbody>
</table>

Out[149]:

```

<table>
<thead>
<tr>
<th>letter</th>
<th>word</th>
<th>data1</th>
<th>data2</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>bar</td>
<td>0.707107</td>
<td>1.414214</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>0.707107</td>
<td>0.707107</td>
</tr>
<tr>
<td>b</td>
<td>bar</td>
<td>0.707107</td>
<td>0.707107</td>
</tr>
<tr>
<td></td>
<td>foo</td>
<td>1.414214</td>
<td>0.707107</td>
</tr>
</tbody>
</table>
```

# Plot

```python
In [150]: fig, ax = plt.subplots()
In [151]: means.plot.bar(yerr=errors, ax=ax)
```

```
Out[151]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3f1fd208>
```
22.5.11 Plotting Tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [152]: fig, ax = plt.subplots(1, 1)

In [153]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [154]: ax.get_xaxis().set_visible(False)  # Hide Ticks

In [155]: df.plot(table=True, ax=ax)
Out[155]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e719550>
```
Also, you can pass a different `DataFrame` or `Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```python
In [156]: fig, ax = plt.subplots(1, 1)
In [157]: ax.get_xaxis().set_visible(False)  # Hide Ticks
In [158]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e23f320>
```
There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` table has.

```python
In [159]: from pandas.plotting import table

In [160]: fig, ax = plt.subplots(1, 1)

In [161]: table(ax, np.round(df.describe(), 2),
        loc='upper right', colWidths=[0.2, 0.2, 0.2])

Out[161]: <matplotlib.table.Table at 0x1c382b3630>

In [162]: df.plot(ax=ax, ylim=(0, 2), legend=None)
```

There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` table has.

```python
In [159]: from pandas.plotting import table

In [160]: fig, ax = plt.subplots(1, 1)

In [161]: table(ax, np.round(df.describe(), 2),
        loc='upper right', colWidths=[0.2, 0.2, 0.2])

Out[161]: <matplotlib.table.Table at 0x1c382b3630>

In [162]: df.plot(ax=ax, ylim=(0, 2), legend=None)
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>a</code></td>
<td>0.13</td>
<td>0.9</td>
<td>0.45</td>
<td>0.54</td>
<td>0.13</td>
</tr>
<tr>
<td><code>b</code></td>
<td>0.97</td>
<td>0.38</td>
<td>0.84</td>
<td>0.37</td>
<td>0.86</td>
</tr>
</tbody>
</table>

22.5. Plot Formatting
**pandas**: powerful Python data analysis toolkit, Release 0.23.2

**22.5.12 Colormaps**

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

```python
In [163]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [164]: df = df.cumsum()
In [165]: plt.figure()
Out[165]: <Figure size 640x480 with 0 Axes>
In [166]: df.plot(colormap='cubehelix')
```

Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the matplotlib table documentation for more.
Alternatively, we can pass the colormap itself:

```python
In [167]: from matplotlib import cm

In [168]: plt.figure()
Out[168]: <Figure size 640x480 with 0 Axes>

In [169]: df.plot(colormap=cm.cubehelix)
```
Colormaps can also be used other plot types, like bar charts:

```
In [170]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [171]: dd = dd.cumsum()
In [172]: plt.figure()
Out[172]: <Figure size 640x480 with 0 Axes>
In [173]: dd.plot.bar(colormap='Greens')
```

```
Out[173]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e7c6b38>
```
Parallel coordinates charts:

```
In [174]: plt.figure()
Out[174]: <Figure size 640x480 with 0 Axes>

In [175]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
```

```
Out[175]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e3f3240>
```
Andrews curves charts:

```python
In [176]: plt.figure()
Out[176]: <Figure size 640x480 with 0 Axes>

In [177]: andrews_curves(data, 'Name', colormap='winter')
```

```
Out[177]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3ded0080>
```
22.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

In [178]: price = pd.Series(np.random.randn(150).cumsum(),
       index=pd.date_range('2000-1-1', periods=150, freq='B'))

In [179]: ma = price.rolling(20).mean()

In [180]: mstd = price.rolling(20).std()

In [181]: plt.figure()
Out[181]: <Figure size 640x480 with 0 Axes>

In [182]: plt.plot(price.index, price, 'k')

(continues on next page)
22.7 Trellis plotting interface

**Warning:** The `rplot` trellis plotting interface has been removed. Please use external packages like `seaborn` for similar but more refined functionality and refer to our 0.18.1 documentation [here](#) for how to convert to using it.
**CHAPTER TWENTYTHREE**

**STYLING**

*New in version 0.17.1*

Provisional: This is a new feature and still under development. We’ll be adding features and possibly making breaking changes in future releases. We’d love to hear your feedback.

This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

You can apply conditional formatting, the visual styling of a DataFrame depending on the data within, by using the `DataFrame.style` property. This is a property that returns a `Styler` object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return like-indexed DataFrames or Series with CSS "attribute: value" pairs for the values. These functions can be incrementally passed to the `Styler` which collects the styles before rendering.

### 23.1 Building Styles

Pass your style functions into one of the following methods:

- **Styler.applymap:** elementwise
- **Styler.apply:** column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. `Styler.applymap` works through the DataFrame elementwise. `Styler.apply` passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the axis keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the axis parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let’s see some examples.

In [2]:
import pandas as pd
import numpy as np
np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
               axis=1)
df.iloc[0, 2] = np.nan

Here’s a boring example of rendering a DataFrame, without any (visible) styles:
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [3]: df.style

Out[3]: <pandas.io.formats.style.Styler at 0x1119c4f98>

Note: The DataFrame.style attribute is a property that returns a Styler object. Styler has a _repr_html_ method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the .render() method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we’ve done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the .render method.

In [4]: df.style.highlight_null().render().split('\n')[:10]

Out[4]: ['<style type="text/css" >', '
  #T_2baa851c_80a0_11e8_ae45_186590cd1c87row0_col2 {', '
    background-color: red;', '
  }<style> ', '
  <table id="T_2baa851c_80a0_11e8_ae45_186590cd1c87" > ', '
    <thead> ', '
    <tr>', '
      <th class="blank level0"></th>', '
      <th class="col_heading level0 col0" >A</th> ', '
      <th class="col_heading level0 col1" >B</th>', '
      <th class="col_heading level0 col2" >C</th> '
  ']

The row0_col2 is the identifier for that particular cell. We’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page (you can set the uuid if you’d like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let’s write a simple style function that will color negative numbers red and positive numbers black.

In [5]: def color_negative_red(val):
    
    """ Takes a scalar and returns a string with the css property 'color: red' for negative strings, black otherwise. """
    color = 'red' if val < 0 else 'black'
    return 'color: %s' % color

In this case, the cell’s style depends only on it’s own value. That means we should use the Styler.applymap method which works elementwise.

In [6]: s = df.style.applymap(color_negative_red)

Out[6]: <pandas.io.formats.style.Styler at 0x113d34048>

Notice the similarity with the standard df.applymap, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a <style> tag. This will be a common theme.

Finally, the input shapes matched. Styler.applymap calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can’t use .applymap anymore since that operated elementwise. Instead, we’ll turn to .apply which operates columnwise (or rowwise using the axis keyword). Later on we’ll see that something like highlight_max is already defined on Styler so you wouldn’t need to write this yourself.
In [7]: ```python
def highlight_max(s):
    '''
    highlight the maximum in a Series yellow.
    '''
    is_max = s == s.max()
    return ['background-color: yellow' if v else '' for v in is_max]
```

In [8]: df.style.apply(highlight_max)

Out[8]: <pandas.io.formats.style.Styler at 0x113cec9e8>

In this case the input is a Series, one column at a time. Notice that the output shape of highlight_max matches the input shape, an array with \( \text{len}(s) \) items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

In [9]: df.style.\
    applymap(color_negative_red).\
    apply(highlight_max)

Out[9]: <pandas.io.formats.style.Styler at 0x113cec160>

Above we used Styler.apply to pass in each column one at a time.

**Debugging Tip**: If you’re having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use \( \text{.apply(function, axis=None)} \) to indicate that your function wants the entire table, not one column or row at a time. Let’s try that next.

We’ll rewrite our highlight-max to handle either Series (from \( \text{.apply(axis=0 or 1)} \)) or DataFrames (from \( \text{.apply(axis=None)} \)). We’ll also allow the color to be adjustable, to demonstrate that .apply and .applymap pass along keyword arguments.

In [10]: ```python
def highlight_max(data, color='yellow'):
    '''
    highlight the maximum in a Series or DataFrame
    '''
    attr = 'background-color: {}'.format(color)
    if data.ndim == 1:  # Series from .apply(axis=0) or axis=1
        is_max = data == data.max()
        return [attr if v else '' for v in is_max]
    else:  # from .apply(axis=None)
        is_max = data == data.max().max()
        return pd.DataFrame(np.where(is_max, attr, ''),
                           index=data.index, columns=data.columns)
```

When using Styler.apply(func, axis=None), the function must return a DataFrame with the same index and column labels.

In [11]: df.style.apply(highlight_max, color='darkorange', axis=None)

Out[11]: <pandas.io.formats.style.Styler at 0x113d214e0>

### 23.1.1 Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- Styler.applymap(func) for elementwise styles
- Styler.apply(func, axis=0) for columnwise styles
- Styler.apply(func, axis=1) for rowwise styles
• Styler.apply(func, axis=None) for tablewise styles
And crucially the input and output shapes of func must match. If x is the input then func(x).shape == x.shape.

23.2 Finer Control: Slicing

Both Styler.apply, and Styler.applymap accept a subset keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your style function.
The value passed to subset behaves similar to slicing a DataFrame.
• A scalar is treated as a column label
• A list (or series or numpy array)
• A tuple is treated as (row_indexer, column_indexer)
Consider using pd.IndexSlice to construct the tuple for the last one.
In [12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
Out[12]: <pandas.io.formats.style.Styler at 0x113d217b8>
For row and column slicing, any valid indexer to .loc will work.
In [13]: df.style.applymap(color_negative_red, subset=pd.IndexSlice[2:5, ['B', 'D']])
Out[13]: <pandas.io.formats.style.Styler at 0x113d21a20>
Only label-based slicing is supported right now, not positional.
If your style function uses a subset or axis keyword argument, consider wrapping your function in a
functools.partial, partialing out that keyword.
my_func2 = functools.partial(my_func, subset=42)

23.3 Finer Control: Display Values

We distinguish the display value from the actual value in Styler. To control the display value, the text is printed in each cell, use Styler.format. Cells can be formatted according to a format spec string or a callable that takes a single value and returns a string.
In [14]: df.style.format("{:.2%}"
Out[14]: <pandas.io.formats.style.Styler at 0x113d21dd8>
Use a dictionary to format specific columns.
In [15]: df.style.format({"B": "{:0<4.0f}", 'D': '{:+.2f}'})
Out[15]: <pandas.io.formats.style.Styler at 0x113d214a8>
Or pass in a callable (or dictionary of callables) for more flexible handling.
In [16]: df.style.format({"B": lambda x: "±{:.2f}".format(abs(x))})
Out[16]: <pandas.io.formats.style.Styler at 0x113d21b38>
23.4 Builtin Styles

Finally, we expect certain styling functions to be common enough that we’ve included a few “built-in” to the Styler, so you don’t have to write them yourself.

In [17]: df.style.highlight_null(null_color='red')
Out[17]: <pandas.io.formats.style.Styler at 0x113d216d8>

You can create “heatmaps” with the background_gradient method. These require matplotlib, and we’ll use Seaborn to get a nice colormap.

In [18]: import seaborn as sns

    cm = sns.light_palette("green", as_cmap=True)
    s = df.style.background_gradient(cmap=cm)

Out[18]: <pandas.io.formats.style.Styler at 0x113d21198>

Styler.background_gradient takes the keyword arguments low and high. Roughly speaking these extend the range of your data by low and high percent so that when we convert the colors, the colormap’s entire range isn’t used. This is useful so that you can actually read the text still.

In [19]: # Uses the full color range
    df.loc[:4].style.background_gradient(cmap='viridis')

Out[19]: <pandas.io.formats.style.Styler at 0x113d21a58>

In [20]: # Compress the color range
    (df.loc[:4]
     .style
     .background_gradient(cmap='viridis', low=.5, high=0)
     .highlight_null('red'))

Out[20]: <pandas.io.formats.style.Styler at 0x1a15a64908>

There’s also .highlight_min and .highlight_max.

In [21]: df.style.highlight_max(axis=0)
Out[21]: <pandas.io.formats.style.Styler at 0x113d215c0>

Use Styler.set_properties when the style doesn’t actually depend on the values.

In [22]: df.style.set_properties(**{'background-color': 'black',
    'color': 'lawngreen',
    'border-color': 'white'})

Out[22]: <pandas.io.formats.style.Styler at 0x1a15a64908>

23.4.1 Bar charts

You can include “bar charts” in your DataFrame.
In [23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
Out[23]: <pandas.io.formats.style.Styler at 0x1a15aea4e0>

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here’s how you can change the above with the new `align='mid'` option:

In [24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
Out[24]: <pandas.io.formats.style.Styler at 0x1a15bbbe10>

The following example aims to give a highlight of the behavior of the new align options:

In [25]: import pandas as pd
import IPython.display import HTML

# Test series
test1 = pd.Series([-100,-60,-30,-20], name='All Negative')
test2 = pd.Series([10,20,50,100], name='All Positive')
test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

head = ""
<table>
  <thead>
    <th>Align</th>
    <th>All Negative</th>
    <th>All Positive</th>
    <th>Both Neg and Pos</th>
  </thead>
  <tbody>
    for align in aligns:
      row = "<tr><th>{}</th>".format(align)
      for serie in [test1,test2,test3]:
        s = serie.copy()
        s.name=''
        row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
          color=['#d65f5f', '#5fba7d'],
          width=100).render()) #testn['width']
      row += '</tr>'
      head += row

    HTML(head)
Out[25]: <IPython.core.display.HTML object>
23.5 Sharing Styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df1.style.set`.

```
In [26]: df2 = -df
   ...: style1 = df.style.applymap(color_negative_red)
   ...: style1

Out[26]: <pandas.io.formats.style.Styler at 0x1a15aea6d8>

In [27]: style2 = df2.style
   ...: style2.use(style1.export())
   ...: style2

Out[27]: <pandas.io.formats.style.Styler at 0x1a15be6978>
```

Notice that you’re able share the styles even though they’re data aware. The styles are re-evaluated on the new DataFrame they’ve been used upon.

23.6 Other Options

You’ve seen a few methods for data-driven styling. `Styler` also provides a few other options for styles that don’t depend on the data.

- precision
- captions
- table-wide styles
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the `Styler` constructor when building many styled DataFrames that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

23.6.1 Precision

You can control the precision of floats using pandas’ regular `display.precision` option.

```
In [28]: with pd.option_context('display.precision', 2):
   ...:     html = (df.style
   ...:         .applymap(color_negative_red)
   ...:         .apply(highlight_max))
   ...:     html

Out[28]: <pandas.io.formats.style.Styler at 0x1a15aea518>
```

Or through a `set_precision` method.

```
In [29]: df.style
   ...:     .applymap(color_negative_red)
   ...:     .apply(highlight_max)
   ...:     .set_precision(2)
```
Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use \texttt{df.round(2).style} if you'd prefer to round from the start.

### 23.6.2 Captions

Regular table captions can be added in a few ways.

\texttt{In [30]: df.style.set_caption('Colormaps, with a caption.')}\texttt{
.background_gradient(cmap=cm)}

\texttt{Out[30]: <pandas.io.formats.style.Styler at 0x1a15aea3c8>}

### 23.6.3 Table Styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytling, including pseudo-selectors like :hover can only be used this way.

\texttt{In [31]: from IPython.display import HTML}

\begin{verbatim}
def hover(hover_color="#ffff99"):
    return dict(selector="tr:hover",
                props=[("background-color", "$s % hover_color")])

styles = [
    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                                ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])
]

html = (df.style.set_table_styles(styles)
            .set_caption("Hover to highlight."))

Out[31]: <pandas.io.formats.style.Styler at 0x1a15bdfbe0>
\end{verbatim}

\texttt{table_styles} should be a list of dictionaries. Each dictionary should have the \texttt{selector} and \texttt{props} keys. The value for \texttt{selector} should be a valid CSS selector. Recall that all the styles are already attached to an \texttt{id}, unique to each \texttt{Styler}. This selector is in addition to that \texttt{id}. The value for \texttt{props} should be a list of tuples of ('attribute', 'value').

\texttt{table_styles} are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that \textit{builds on top} the tools here.

### 23.6.4 Hiding the Index or Columns

The index can be hidden from rendering by calling \texttt{Styler.hide_index}. Columns can be hidden from rendering by calling \texttt{Styler.hide_columns} and passing in the name of a column, or a slice of columns.

\texttt{In [32]: df.style.hide_index()}

\texttt{Out[32]: <pandas.io.formats.style.Styler at 0x1a15aea4a8>}

\texttt{In [33]: df.style.hide_columns(['C','D'])}
23.6.5 CSS Classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
- `level<k>` where `k` is the level in a MultiIndex
- Column label cells include
  - `col_heading`
  - `col<n>` where `n` is the numeric position of the column
- `level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

23.6.6 Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn’t great; this is intended for summary DataFrames
- You can only style the `values`, not the index or columns
- You can only apply styles, you can’t insert new HTML entities

Some of these will be addressed in the future.

23.6.7 Terms

- Style function: a function that’s passed into `Styler.apply` or `Styler.applymap` and returns values like `css attribute: value`
- Builtin style functions: style functions that are methods on `Styler`
- `table style`: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

23.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you’re viewing this online instead of running the notebook yourself, you’re missing out on interactively adjusting the color palette.
In [34]: from IPython.html import widgets
@widgets.interact
def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
    return df.style.background_gradient(
        cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l, as_cmap=True)
    )

In [35]: def magnify():
    return [dict(selector="th",
        props=[('font-size', '4pt')]),
    dict(selector="td",
        props=[('padding', '0em 0em')]),
    dict(selector="th:hover",
        props=[('font-size', '12pt')]),
    dict(selector="tr:hover td:hover",
        props=[('max-width', '200px'),
                ('font-size', '12pt')])
    ]

In [36]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()

    bigdf.style.background_gradient(cmap, axis=1)\
       .set_properties(**{'max-width': '80px', 'font-size': '1pt'})\n       .set_caption("Hover to magnify")\n       .set_precision(2)\n       .set_table_styles(magnify())

Out[36]: <pandas.io.formats.style.Styler at 0x1a1d6d4978>

23.8 Export to Excel

New in version 0.20.0

Experimental: This is a new feature and still under development. We’ll be adding features and possibly making breaking changes in future releases. We’d love to hear your feedback.

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their top, right, bottom, left variants
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
• vertical-align
• white-space: nowrap

Only CSS2 named colors and hex colors of the form #rgb or #rrggbb are currently supported.

In [37]: df.style.\applymap(color_negative_red).\apply(highlight_max).\to_excel('styled.xlsx', engine='openpyxl')

A screenshot of the output:

![Excel spreadsheet with styled DataFrame](image)

**23.9 Extensibility**

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that DataFrame.style accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

**23.9.1 Subclassing**

If the default template doesn’t quite suit your needs, you can subclass Styler and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

In [38]: from jinja2 import Environment, ChoiceLoader, FileSystemLoader
   from IPython.display import HTML
   from pandas.io.formats.style import Styler
This next cell writes the custom template. We extend the template `html.tpl`, which comes with pandas.

```python
In [40]: %
file templates/myhtml.tpl
{% extends "html.tpl" %}
{% block table %}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{% endblock table %}
```

Writing templates/myhtml.tpl

Now that we’ve created a template, we need to set up a subclass of `Styler` that knows about it.

```python
In [41]: class MyStyler(Styler):
    env = Environment(
        loader=ChoiceLoader([
            FileSystemLoader("templates"), # contains ours
            Styler.loader, # the default
        ])
    )
    template = env.get_template("myhtml.tpl")
```

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. Its `__init__` takes a DataFrame.

```python
In [42]: MyStyler(df)
Out[42]: <__main__.MyStyler at 0x1a1d6d44e0>
```

Our custom template accepts a `table_title` keyword. We can provide the value in the `.render` method.

```python
In [43]: HTML(MyStyler(df).render(table_title="Extending Example"))
Out[43]: <IPython.core.display.HTML object>
```

For convenience, we provide the `Styler.from_custom_template` method that does the same as the custom subclass.

```python
In [44]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")
EasyStyler(df)
Out[44]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at 0x1a1fd934e0>
```

Here’s the template structure:

```python
In [45]: with open("template_structure.html") as f:
    structure = f.read()

HTML(structure)
Out[45]: <IPython.core.display.HTML object>
```

See the template in the [GitHub repo](https://github.com/pandas-dev/pandas) for more details.
IO TOOLS (TEXT, CSV, HDF5, . . .)

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>
</tr>
<tr>
<td>text</td>
<td>JSON</td>
<td>read_json</td>
<td>to_json</td>
</tr>
<tr>
<td>text</td>
<td>HTML</td>
<td>read_html</td>
<td>to_html</td>
</tr>
<tr>
<td>text</td>
<td>Local clipboard</td>
<td>read_clipboard</td>
<td>to_clipboard</td>
</tr>
<tr>
<td>binary</td>
<td>MS Excel</td>
<td>read_excel</td>
<td>to_excel</td>
</tr>
<tr>
<td>binary</td>
<td>HDF5 Format</td>
<td>read_hdf</td>
<td>to_hdf</td>
</tr>
<tr>
<td>binary</td>
<td>Feather Format</td>
<td>read_feather</td>
<td>to_feather</td>
</tr>
<tr>
<td>binary</td>
<td>Parquet Format</td>
<td>read_parquet</td>
<td>to_parquet</td>
</tr>
<tr>
<td>binary</td>
<td>Msgpack</td>
<td>read_msgpack</td>
<td>to_msgpack</td>
</tr>
<tr>
<td>binary</td>
<td>Stata</td>
<td>read_stata</td>
<td>to_stata</td>
</tr>
<tr>
<td>binary</td>
<td>SAS</td>
<td>read_sas</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>Python Pickle Format</td>
<td>read_pickle</td>
<td>to_pickle</td>
</tr>
<tr>
<td>SQL</td>
<td>SQL</td>
<td>read_sql</td>
<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google Big Query</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

Here is an informal performance comparison for some of these IO methods.

Note: For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

24.1 CSV & Text files

The two workhorse functions for reading text files (a.k.a. flat files) are `read_csv()` and `read_table()`. They both use the same parsing code to intelligently convert tabular data into a `DataFrame` object. See the cookbook for some advanced strategies.

24.1.1 Parsing options

The functions `read_csv()` and `read_table()` accept the following common arguments:
24.1.1.1 Basic

filepath_or_buffer [various] Either a path to a file (a str, pathlib.Path, or py._path.local.LocalPath), URL (including http, ftp, and S3 locations), or any object with a read() method (such as an open file or StringIO).

sep [str, defaults to ', ' for read_csv(), \t for read_table()] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python's builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alternative argument name for sep.

delim_whitespace [boolean, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

New in version 0.18.1: support for the Python parser.

24.1.1.2 Column and Index Locations and Names

header [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names.

The header can be a list of ints that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None. Duplicates in this list will cause a UserWarning to be issued.

index_col [int or sequence or False, default None] Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider index_col=False to force pandas to not use the first column as the index (row names).

usecols [list-like or callable, default None] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz'].

Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:

```
In [1]: data = 'col1, col2, col3\na, b, 1\nb, 2\nc, d, 3'

In [2]: pd.read_csv(StringIO(data))
Out[2]:
   col1  col2  col3
0   a     b     1
1   b     2     c
2   c     d     3
```

(continues on next page)
Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default False] If the parsed data only contains one column then return a Series.

**prefix** [str, default None] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1, ...

**mangle_dupe_cols** [boolean, default True] Duplicate columns will be specified as ‘X’, ‘X.1’…’X.N’, rather than ‘X’…’X’. Passing in False will cause data to be overwritten if there are duplicate names in the columns.

### 24.1.1.3 General Parsing Configuration

**dtype** [Type name or dict of column -> type, default None] Data type for data or columns. E.g. {'a': np.float64, 'b': np.int32} (unsupported with engine='python'). Use str or object together with suitable na_values settings to preserve and not interpret dtype.

New in version 0.20.0: support for the Python parser.

**engine** [['c', 'python']] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default None] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, default None] Values to consider as True.

**false_values** [list, default None] Values to consider as False.

**skipinitialspace** [boolean, default False] Skip spaces after delimiter.

**skiprows** [list-like or integer, default None] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning True if the row should be skipped and False otherwise:
skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine=’c’).
nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.
low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)
memory_map [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

24.1.1.4 NA and Missing Data Handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na values const below for a list of the values interpreted as NaN by default.
keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:
   • If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
   • If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
   • If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
   • If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.
na_filter [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.
verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.
skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.

24.1.1.5 Datetime Handling

parse_dates [boolean or list of ints or names or list of lists or dict, default False.] If True -> try parsing the index.
   • If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
   • If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
   • If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.
infer_datetime_format [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datetime format to speed up the processing.
keep_date_col [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses datetime.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

dayfirst [boolean, default False] DD/MM format dates, international and European format.

24.1.1.6 Iteration

iterator [boolean, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

chunksize [int, default None] Return TextFileReader object for iteration. See iterating and chunking below.

24.1.1.7 Quoting, Compression, and File Format

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip, or xz if filepath_or_buffer is a string ending in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively, and no decompression otherwise. If using ‘zip’, the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for ‘zip’ and ‘xz’ compression.

thousands [str, default None] Thousands separator.

decimal [str, default ' '] Character to recognize as decimal point. E.g. use ', ' for European data.

float_precision [string, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

lineterminator [str (length 1), default None] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [boolean, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements inside a field as a single quotechar element.

escapechar [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

comment [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment='
', parsing '#empty
da,b,c
1,2,3' with header=0 will result in 'a,b,c' being treated as the header.

encoding [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.
dialect [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

tupleize_cols [boolean, default False]  
  Deprecated since version 0.21.0.  
  This argument will be removed and will always convert to MultiIndex  
  Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns).

24.1.1.8 Error Handling

error_bad_lines [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

warn_bad_lines [boolean, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

24.1.2 Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

In [7]: data = 'a,b,c\n1,2,3\n4,5,6\n7,8,9'

In [8]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [9]: df = pd.read_csv(StringIO(data), dtype=object)

In [10]: df
Out[10]:
a   b   c
0   1   2   3
1   4   5   6
2   7   8   9

In [11]: df['a'][0]
Out[11]: '1'

In [12]: df = pd.read_csv(StringIO(data), dtype={'b': object, 'c': np.float64})

In [13]: df.dtypes
Out[13]:
a    int64
b    object
c   float64
dtype: object

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you’re unfamiliar with these concepts, you can see here to learn more about dtypes, and here to learn more about object conversion in pandas.
For instance, you can use the converters argument of `read_csv()`:

```
In [14]: data = "col_1\n\n1\n\n2\n\n\n'A'\n\n4.22"

In [15]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [16]: df
Out[16]:
   col_1
0   1
1   2
2   A
3  4.22

In [17]: df['col_1'].apply(type).value_counts()

Out[17]:
<class 'str'>    4
Name: col_1, dtype: int64
```

Or you can use the `to_numeric()` function to coerce the dtypes after reading in the data,

```
In [18]: df2 = pd.read_csv(StringIO(data))

In [19]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')

In [20]: df2
Out[20]:
   col_1
0   1.00
1   2.00
2   NaN
3   4.22

In [21]: df2['col_1'].apply(type).value_counts()

Out[21]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then `to_numeric()` is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the converters argument of `read_csv()` would certainly be worth trying.

New in version 0.20.0: support for the Python parser.

The `dtype` option is supported by the ‘python’ engine.

**Note:** In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [22]: df = pd.DataFrame({'col_1': list(range(500000)) + ['a', 'b'] + list(range(500000)))})

In [23]: df.to_csv('foo.csv')
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.2

In [24]: mixed_df = pd.read_csv('foo.csv')

In [25]: mixed_df['col_1'].apply(type).value_counts()
Out[25]:
<class 'int'>  737858
<class 'str'>  262144
Name: col_1, dtype: int64

In [26]: mixed_df['col_1'].dtype

will result with mixed_df containing an int dtype for certain chunks of the column, and str for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of object, which is used for columns with mixed dtypes.

24.1.3 Specifying Categorical dtype

New in version 0.19.0.

Categorical columns can be parsed directly by specifying dtype='category' or dtype=CategoricalDtype(categories, ordered).

In [27]: data = 'col1,col2,col3
a,b,1
a,b,2
c,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
col1  col2  col3
0   a     b     1
1   a     b     2
2   c     d     3

In [29]: pd.read_csv(StringIO(data)).dtypes

Individual columns can be parsed as a Categorical using a dict specification:

In [30]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes

(continues on next page)
New in version 0.21.0.

Specifying dtype='category' will result in an unordered Categorical whose categories are the unique values observed in the data. For more control on the categories and order, create a CategoricalDtype ahead of time, and pass that for that column’s dtype.

```python
In [32]: from pandas.api.types import CategoricalDtype
In [33]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)
In [34]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
Out[34]:
       col1    col2    col3
dtype: category    object    int64
```

When using dtype=CategoricalDtype, “unexpected” values outside of dtype.categories are treated as missing values.

```python
In [35]: dtype = CategoricalDtype(['a', 'b', 'd'])  # No 'c'
In [36]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
Out[36]:
0   a
1   a
2   Na\nName: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of Categorical.set_categories().

**Note:** With dtype='category', the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the to_numeric() function, or as appropriate, another converter such as to_datetime().

When dtype is a CategoricalDtype with homogenous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```python
In [37]: df = pd.read_csv(StringIO(data), dtype='category')
In [38]: df.dtypes
Out[38]:
       col1    col2    col3
dtype: category    category    int64
In [39]: df['col3']
```

(continues on next page)
2 3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [40]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [41]: df['col3']
Out[41]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]

24.1.4 Naming and Using Columns

24.1.4.1 Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

In [42]: data = 'a,b,c
1,2,3
4,5,6
7,8,9'

In [43]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [44]: pd.read_csv(StringIO(data))

Out[44]:
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9

By specifying the names argument in conjunction with header you can indicate other names to use and whether or not to throw away the header row (if any):

In [45]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [46]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)

Out[46]:
     foo  bar  baz
0  1  2  3
1  4  5  6
2  7  8  9

In [47]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)

(continues on next page)
foo bar baz
0 a b c
1 1 2 3
2 4 5 6
3 7 8 9

If the header is in a row other than the first, pass the row number to header. This will skip the preceding rows:

```
In [48]: data = 'skip this skip it

a,b,c

1,2,3

4,5,6

7,8,9'

In [49]: pd.read_csv(StringIO(data), header=1)
Out[49]:
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9
```

Note: Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first nonblank line of the file, if column names are passed explicitly then the behavior is identical to header=None.

### 24.1.5 Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [50]: data = 'a,b,a

0,1,2

3,4,5'

In [51]: pd.read_csv(StringIO(data))
Out[51]:
   a  b  a.1
0  2  1  2
1  5  4  5
```

There is no more duplicate data because mangle_dupe_cols=True by default, which modifies a series of duplicate columns ‘X’, ‘X’, ‘X’ to become ‘X’, ‘X.1’, ‘X.2’. If mangle_dupe_cols=False, duplicate data can arise:

```
In [2]: data = 'a,b,a

0,1,2

3,4,5'

In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
0  1  2
1  3  4
```

To prevent users from encountering this problem with duplicate data, a ValueError exception is raised if mangle_dupe_cols != True:

```
In [2]: data = 'a,b,a

0,1,2

3,4,5'

In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
...  
ValueError: Setting mangle_dupe_cols=False is not supported yet
```
24.1.5.1 Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

New in version 0.20.0: support for callable `usecols` arguments

```
In [52]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'

In [53]: pd.read_csv(StringIO(data))
Out[53]:
   a  b  c  d
0  1  2  3  foo
1  4  5  6  bar
2  7  8  9  baz

In [54]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
Out[54]:
   b  d
0  2  foo
1  5  bar
2  8  baz

In [55]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
   a  c  d
0  1  3  foo
1  4  6  bar
2  7  9  baz

In [56]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
   a  c
0  1  3
1  4  6
2  7  9
```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```
In [57]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
Out[57]:
   b  d
0  2  foo
1  5  bar
2  8  baz
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

24.1.6 Comments and Empty Lines

24.1.6.1 Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.
In [58]: data = '\na,b,c
\n# commented line
1,2,3
4,5,6'

In [59]: print(data)
a,b,c
# commented line
1,2,3
4,5,6

In [60]: pd.read_csv(StringIO(data), comment='#')
Out[60]:
   a  b  c
0  1  2  3
1  4  5  6

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

In [61]: data = 'a,b,c

1,2,3

4,5,6'

In [62]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[62]:
   a  b  c
0  NaN NaN NaN
1  1.0  2.0  3.0
2  NaN NaN NaN
3  NaN NaN NaN
4  4.0  5.0  6.0

**Warning:** The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

In [63]: data = '#comment
na,b,c
A,B,C
1,2,3'

In [64]: pd.read_csv(StringIO(data), comment='#', header=1)
Out[64]:
   A  B  C
0  1  2  3

In [65]: data = 'A,B,C
#comment
na,b,c
1,2,3'

In [66]: pd.read_csv(StringIO(data), comment='#', skiprows=2)
Out[66]:
   a  b  c
0  1  2  3

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:
24.1.6.2 Comments

Sometimes comments or meta data may be included in a file:

```
In [70]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome
```

By default, the parser includes the comments in the output:

```
In [71]: df = pd.read_csv('tmp.csv')
In [72]: df
Out[72]:
   ID    level category
0 Patient1 123000   x # really unpleasant
1 Patient2 23000    y # wouldn't take his medicine
2 Patient3 1234018  z # awesome
```

We can suppress the comments using the `comment` keyword:

```
In [73]: df = pd.read_csv('tmp.csv', comment='#')
In [74]: df
Out[74]:
   ID    level category
0 Patient1 123000   x
1 Patient2 23000    y
2 Patient3 1234018  z
```
24.1.7 Dealing with Unicode Data

The encoding argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```python
In [75]: data = b'word,length
Träumen,7
Grüße,5'.decode('utf8').encode('latin-1')

In [76]: df = pd.read_csv(BytesIO(data), encoding='latin-1')

In [77]: df
Out[77]:
     word  length
0  Träumen   7
1    Grüße   5

In [78]: df['word'][1]
Out[78]: 'Grüße'
```

Some formats which encode all characters as multiple bytes, like UTF-16, won’t parse correctly at all without specifying the encoding. Full list of Python standard encodings.

24.1.8 Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame’s row names:

```python
In [79]: data = 'a,b,c
4,apple,bat,5.7
8,orange,cow,10'

In [80]: pd.read_csv(StringIO(data))
Out[80]:
     a    b    c
  4  apple  bat  5.7
  8  orange  cow  10.0

In [81]: data = 'index,a,b,c
4,apple,bat,5.7
8,orange,cow,10'

In [82]: pd.read_csv(StringIO(data), index_col=0)
Out[82]:
     a    b    c
index
  4  apple  bat  5.7
  8  orange  cow  10.0
```

Ordinarily, you can achieve this behavior using the index_col option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass index_col=False:

```python
In [83]: data = 'a,b,c
4,apple,bat,5.7
8,orange,cow,'

In [84]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,
```
If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```
In [87]: data = 'a,b,c
4,apple,bat,
8,orange,cow,'

In [88]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,

In [89]: pd.read_csv(StringIO(data), usecols=['b', 'c'])

In [90]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)
```

### 24.1.9 Date Handling

#### 24.1.9.1 Specifying Date Columns

To better facilitate working with datetime data, `read_csv()` and `read_table()` use the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass in `parse_dates=True`:

```
# Use a column as an index, and parse it as dates.
In [91]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)
```

```
Out[92]:
   A   B  C
date     
2009-01-01 a 1 2
2009-01-02 b 3 4
2009-01-03 c 4 5
```
# These are Python datetime objects

```python
In [93]: df.index

DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]',
name='date', freq=None)
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. The `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```python
In [94]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900

In [95]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])

In [96]: df

```

```python
Out[96]:

<table>
<thead>
<tr>
<th></th>
<th>1_2</th>
<th>1_3</th>
<th>0</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1999-01-27 19:00:00</td>
<td>1999-01-27 18:56:00</td>
<td>KORD</td>
<td>0.81</td>
</tr>
<tr>
<td>1</td>
<td>1999-01-27 20:00:00</td>
<td>1999-01-27 19:56:00</td>
<td>KORD</td>
<td>0.01</td>
</tr>
<tr>
<td>2</td>
<td>1999-01-27 21:00:00</td>
<td>1999-01-27 20:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
<tr>
<td>3</td>
<td>1999-01-27 21:00:00</td>
<td>1999-01-27 21:18:00</td>
<td>KORD</td>
<td>-0.99</td>
</tr>
<tr>
<td>4</td>
<td>1999-01-27 22:00:00</td>
<td>1999-01-27 21:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
<tr>
<td>5</td>
<td>1999-01-27 23:00:00</td>
<td>1999-01-27 22:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
</tbody>
</table>
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```python
In [97]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
                      keep_date_col=True)

In [98]: df
```

```python
Out[98]:

<table>
<thead>
<tr>
<th></th>
<th>1_2</th>
<th>1_3</th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1999-01-27 19:00:00</td>
<td>1999-01-27 18:56:00</td>
<td>KORD</td>
<td>19990127</td>
<td>19:00:00</td>
<td>18:56:00</td>
<td>0.81</td>
</tr>
<tr>
<td>1</td>
<td>1999-01-27 20:00:00</td>
<td>1999-01-27 19:56:00</td>
<td>KORD</td>
<td>19990127</td>
<td>20:00:00</td>
<td>19:56:00</td>
<td>0.01</td>
</tr>
<tr>
<td>2</td>
<td>1999-01-27 21:00:00</td>
<td>1999-01-27 20:56:00</td>
<td>KORD</td>
<td>19990127</td>
<td>21:00:00</td>
<td>20:56:00</td>
<td>-0.59</td>
</tr>
<tr>
<td>3</td>
<td>1999-01-27 21:00:00</td>
<td>1999-01-27 21:18:00</td>
<td>KORD</td>
<td>19990127</td>
<td>21:00:00</td>
<td>21:18:00</td>
<td>-0.99</td>
</tr>
<tr>
<td>4</td>
<td>1999-01-27 22:00:00</td>
<td>1999-01-27 21:56:00</td>
<td>KORD</td>
<td>19990127</td>
<td>22:00:00</td>
<td>21:56:00</td>
<td>-0.59</td>
</tr>
<tr>
<td>5</td>
<td>1999-01-27 23:00:00</td>
<td>1999-01-27 22:56:00</td>
<td>KORD</td>
<td>19990127</td>
<td>23:00:00</td>
<td>22:56:00</td>
<td>-0.59</td>
</tr>
</tbody>
</table>
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[[1, 2]]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[[1, 2]]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:
In [99]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [100]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec)

In [101]: df
Out[101]:
   nominal actual 0 4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The index_col specification is based off of this new set of columns rather than the original data columns:

In [102]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}

In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
   ....:   index_col=0) # index is the nominal column

In [104]: df
Out[104]:
   actual 0 4
nominal
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59

Note: If a column or index contains an unparseable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use to_datetime() after pd.read_csv.

Note: read_csv has a fast_path for parsing datetime strings in iso8601 format, e.g “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20x has been observed.

Note: When passing a dict as the parse_dates argument, the order of the columns prepended is not guaranteed, because dict objects do not impose an ordering on their keys. On Python 2.7+ you may use collections.OrderedDict instead of a regular dict if this matters to you. Because of this, when using a dict for ‘parse_dates’ in conjunction with the index_col argument, it’s best to specify index_col as a column label rather then as an index on the resulting frame.
**24.1.9.2 Date Parsing Functions**

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```python
In [105]: import pandas.io.date_converters as conv
In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
             ......:    date_parser=conv.parse_date_time)
             ......:
In [107]: df
Out[107]:
  nominal actual  0  4
  0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 0.81
  1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 0.01
  2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
  3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
  4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
  5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser(['2013', '2013'], ['1', '2'])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser(['2013 1', '2013 2'])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime()`: `date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

**24.1.9.3 Inferring Datetime Format**

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.
Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that `infer_datetime_format` is sensitive to `dayfirst`. With `dayfirst=True`, it will guess “01/12/2011” to be December 1st. With `dayfirst=False` (default) it will guess “01/12/2011” to be January 12th.

```python
# Try to infer the format for the index column
In [108]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                    ....:               infer_datetime_format=True)
In [109]: df
Out[109]:
     A  B  C
date
2009-01-01 a 1 2
2009-01-02 b 3 4
2009-01-03 c 4 5
```

### 24.1.9.4 International Date Formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a `dayfirst` keyword is provided:

```python
In [110]: print(open('tmp.csv').read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c
In [111]: pd.read_csv('tmp.csv', parse_dates=[0])
Out[111]:
      date  value  cat
0 2000-01-06   5  a
1 2000-02-06  10  b
2 2000-03-06  15  c
In [112]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
   date  value  cat
0 2000-06-01   5  a
1 2000-06-02  10  b
2 2000-06-03  15  c
```
24.1.10 Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```python
In [113]: val = '0.3066101993807095471566981359501369297504425048828125'
In [114]: data = 'a,b,c\n1,2,\n'.format(val)
In [115]: abs(pd.read_csv(StringIO(data), engine='c', float_precision=None)['c'][0] - float(val))
Out[115]: 1.1102230246251565e-16
In [116]: abs(pd.read_csv(StringIO(data), engine='c', float_precision='high')['c'][0] - float(val))
Out[116]: 5.5511151231257827e-17
In [117]: abs(pd.read_csv(StringIO(data), engine='c', float_precision='round_trip')['c'][0] - float(val))
```

24.1.11 Thousand Separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```python
In [118]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
In [119]: df = pd.read_csv('tmp.csv', sep='|')
In [120]: df
Out[120]:
   ID    level  category
0 Patient1  123,000   x
1 Patient2   23,000   y
2 Patient3  1,234,018  z
In [121]: df.level.dtype
```

The `thousands` keyword allows integers to be parsed correctly:

```python
In [122]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
```

(continues on next page)
24.1.12 NA Values

To control which values are parsed as missing values (which are signified by NaN), specify a string in `na_values`. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify `keep_default_na=False`.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A
N/A', '#N/A', 'N/A', 'n/a', 'NA', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```python
read_csv(path, na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```python
read_csv(path, keep_default_na=False, na_values=["\"])
```

Above, only an empty field will be recognized as NaN.

```python
read_csv(path, keep_default_na=False, na_values=["NA", "0"])
```

Above, both NA and 0 as strings are NaN.

```python
read_csv(path, na_values=["Nope"])
```

The default values, in addition to the string "Nope" are recognized as NaN.

24.1.13 Infinity

Inf like values will be parsed as np.inf (positive infinity), and -inf as -np.inf (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

24.1.14 Returning Series

Using the `squeeze` keyword, the parser will return output with a single column as a Series:
24.1.15 Boolean values

The common values `True`, `False`, `TRUE`, and `FALSE` are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the `true_values` and `false_values` options as follows:

```
In [130]: data = 'a,b,c
1,Yes,2
3,No,4'

In [131]: print(data)
a,b,c
1,Yes,2
3,No,4

In [132]: pd.read_csv(StringIO(data))
Out[132]:
a b c
0 1 Yes 2
1 3 No 4

In [133]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
Out[133]:
a b c
0 1 True 2
1 3 False 4
```

24.1.16 Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

```
In [27]: data = 'a,b,c
1,2,3
4,5,6,7
8,9,10'

In [28]: pd.read_csv(StringIO(data))
---------------------------------------------------------------------------
ParserError Traceback (most recent call last)
ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4
```
You can elect to skip bad lines:

```python
In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4
```

```
Out[29]:
    a  b  c
0  1  2  3
1  8  9 10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```python
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])
```

```
Out[30]:
    a  b  c
0  1  2  3
1  4  5  6
2  8  9 10
```

### 24.1.17 Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```python
In [134]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```python
In [135]: dia = csv.excel()
In [136]: dia.quoting = csv.QUOTE_NONE
In [137]: pd.read_csv(StringIO(data), dialect=dia)
```

```
Out[137]:
label1  label2  label3
index1   "a  c  e
index2    b  d  f
```

All of the dialect options can be specified separately by keyword arguments:

```python
In [138]: data = 'a,b,c~1,2,3~4,5,6'
In [139]: pd.read_csv(StringIO(data), lineterminator='~')
```

```
Out[139]:
    a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:
The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

### 24.1.18 Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the `escapechar` option:

```python
In [143]: data = 'a,b

"hello, "Bob", nice to see you",5'

In [144]: print(data)
print(a,b

"hello, "Bob", nice to see you",5

In [145]: pd.read_csv(StringIO(data), escapechar='\')
\\\\\\\\\\\\\\\\\\\\\Out[145]:
a b
0 hello, "Bob", nice to see you 5
```

### 24.1.19 Files with Fixed Width Columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- **colspecs**: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to]). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.

- **widths**: A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- **delimiter**: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

```python
In [146]: print(open('bar.csv').read())
id8141 360.242940 149.910199 11950.7
id1594 444.953632 166.985655 11788.4
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3
```
In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```python
# Column specifications are a list of half-intervals
In [147]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [148]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)

In [149]: df
Out[149]:
   0     1     2     3
0 id8141 360.242940 149.910199 11950.7
1 id1594 444.953632 166.985655 11788.4
2 id1849 364.136849 183.628767 11806.2
3 id1230 413.836124 184.375703 11916.8
4 id1948 502.953953 173.237159 12468.3
```

Note how the parser automatically picks column names X.<column number> when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```python
# Widths are a list of integers
In [150]: widths = [6, 14, 13, 10]

In [151]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [152]: df
Out[152]:
   0     1     2     3
0 id8141 360.242940 149.910199 11950.7
1 id1594 444.953632 166.985655 11788.4
2 id1849 364.136849 183.628767 11806.2
3 id1230 413.836124 184.375703 11916.8
4 id1948 502.953953 173.237159 12468.3
```

The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file’s `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided delimiter (default delimiter is whitespace).

```python
In [153]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [154]: df
Out[154]:
   0     1     2     3
0 id8141 360.242940 149.910199 11950.7
1 id1594 444.953632 166.985655 11788.4
2 id1849 364.136849 183.628767 11806.2
3 id1230 413.836124 184.375703 11916.8
4 id1948 502.953953 173.237159 12468.3
```

New in version 0.20.0.

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.
In [155]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[155]:
1  float64
2  float64
3  float64
dtype: object

In [156]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[156]:
0  object
1  float64
2  object
3  float64
dtype: object

24.1.20 Indexes

24.1.20.1 Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

In [157]:
print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5

In this special case, read_csv assumes that the first column is to be used as the index of the DataFrame:

In [158]: pd.read_csv('foo.csv')
Out[158]:
A  B  C
20090101 a 1 2
20090102 b 3 4
20090103 c 4 5

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

In [159]: df = pd.read_csv('foo.csv', parse_dates=True)

In [160]: df.index
Out[160]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype=˓→'datetime64[ns]', freq=None)

24.1.20.2 Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

In [161]:
print(open('data/mindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06

(continues on next page)
The `index_col` argument to `read_csv` and `read_table` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:

```python
In [162]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0,1])
```

```python
In [163]: df
Out[163]:
   zit  xit
year indiv
1977 A   1.20  0.60
         B   1.50  0.50
         C   1.70  0.80
1978 A   0.20  0.06
         B   0.70  0.20
         C   0.80  0.30
         D   0.90  0.50
         E   1.40  0.90
1979 C   0.20  0.15
         D   0.14  0.05
         E   0.50  0.15
         F   1.20  0.50
         G   3.40  1.90
         H   5.40  2.70
         I   6.40  1.20
```

24.1.20.3 Reading columns with a MultiIndex

By specifying list of row locations for the `header` argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```python
In [164]: df.loc[1978]
```

```python
In [165]: from pandas.util.testing import makeCustomDataframe as mkdf
```
In [166]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [167]: df.to_csv('mi.csv')

In [168]: print(open('mi.csv').read())

C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,

read_csv is also able to interpret a more common format of multi-columns indices.

In [170]: print(open('mi2.csv').read())

,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12

In [171]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)

<table>
<thead>
<tr>
<th></th>

</tr>
<tr>
<td>two</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>

Note: If an index_col is not specified (e.g. you don’t have an index, or wrote it with df.to_csv(..., index=False)), then any names on the columns index will be lost.

### 24.1.21 Automatically “sniffing” the delimiter

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the csv.Sniffer class of the csv module. For this, you have to specify `sep=None`.
24.1.22 Reading multiple files to create a single DataFrame

It’s best to use `concat()` to combine multiple files. See the cookbook for an example.

24.1.23 Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```python
In [174]: print(open('tmp.sv').read())
|0|1|2|3
0|0.469112 -0.282863 -1.509058 -1.135632
1|1.212112 -0.173215 0.119209 -1.044236
2|-0.861849 -0.494929 1.071804
3|0.721555 -0.706771 0.524989
4|-0.424972 0.276232 -1.087401
5|0.673690 0.524988
6|0.404705 0.134432 0.844885
7|1.075770 1.649388
8|0.357021 -0.968914
```

```python
In [175]: table = pd.read_table('tmp.sv', sep='|')
```

(continues on next page)
By specifying a chunksize to read_csv or read_table, the return value will be an iterable object of type TextFileReader:

```
In [177]: reader = pd.read_table('tmp.sv', sep='|', chunksize=4)
In [178]: reader
Out[178]: <pandas.io.parsers.TextFileReader at 0x1c2bb8f8d0>
```

```
In [179]: for chunk in reader: print(chunk)
......: Unnamed: 0  0  1  2  3
......:
   0   0  0.469112 -0.282863 -1.509059 -1.135632
   1   1  1.212112 -0.173215  0.119209 -1.044236
   2  -2 -0.861849 -2.104569  0.494929  1.071804
   3   3  0.721555 -0.706771 -1.039575  0.271860
   4  -4  0.424972  0.567020  0.276232 -1.087401
   5   5  0.673690  0.113648 -1.478427  0.524988
   6   6  0.404705  0.577046 -1.715002 -1.039268
   7  -7 -0.370647 -1.157892 -1.344312  0.844885
   8   8  1.075770 -0.109050  1.643563 -1.469388
   9   9  0.357021 -0.674600 -1.776904 -0.968914
```

Specifying iterator=True will also return the TextFileReader object:

```
In [180]: reader = pd.read_table('tmp.sv', sep='|', iterator=True)
In [181]: reader.get_chunk(5)
Out[181]: Unnamed: 0  0  1  2  3
   0   0  0.469112 -0.282863 -1.509059 -1.135632
   1   1  1.212112 -0.173215  0.119209 -1.044236
   2  -2 -0.861849 -2.104569  0.494929  1.071804
   3   3  0.721555 -0.706771 -1.039575  0.271860
   4  -4  0.424972  0.567020  0.276232 -1.087401
```

24.1. CSV & Text files 1155
24.1.24 Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as engine='c'), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None` with `delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

24.1.25 Reading remote files

You can pass in a URL to a CSV file:

```python
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item',
                 sep='\t')
```

S3 URLs are handled as well:

```python
df = pd.read_csv('s3://pandas-test/tips.csv')
```

24.1.26 Writing out Data

24.1.26.1 Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a StringIO
- `sep`: Field delimiter for the output file (default ",")
- `na_rep`: A string representation of a missing value (default '')
- `float_format`: Format string for floating point numbers
- `cols`: Columns to write (default None)
- `header`: Whether to write out the column names (default True)
- `index`: whether to write row (index) names (default True)
- `index_label`: Column label(s) for index column(s) if desired. If None (default), and `header` and `index` are True, then the index names are used. (A sequence should be given if the `DataFrame` uses MultiIndex).
- `mode`: Python write mode, default 'w'
- `encoding`: a string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default 'n')
- `quoting`: Set quoting rules as in csv module (default csv.QUOTE_MINIMAL). Note that if you have set a `float_format` then floats are converted to strings and csv.QUOTE_NONNUMERIC will treat them as non-numeric
• `quotechar`: Character used to quote fields (default `""`)
• `doublequote`: Control quoting of `quotechar` in fields (default True)
• `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default None)
• `chunksize`: Number of rows to write at a time
• `tupleize_cols`: If False (default), write as a list of tuples, otherwise write in an expanded line format suitable for `read_csv`
• `date_format`: Format string for datetime objects

24.1.26.2 Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

• `buf` default None, for example a `StringIO` object
• `columns` default None, which columns to write
• `col_space` default None, minimum width of each column.
• `na_rep` default `NaN`, representation of NA value
• `formatters` default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
• `float_format` default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`
• `sparsify` default True, set to False for a `DataFrame` with a hierarchical index to print every multiindex key at each row.
• `index_names` default True, will print the names of the indices
• `header` default True, will print the index (ie, row labels)
• `justify` default left, will print column headers left- or right-justified

The `Series` object also has a `to_string` method, but with only the `buf, na_rep, float_format` arguments. There is also a `length` argument which, if set to True, will additionally output the length of the `Series`.

24.2 JSON

Read and write JSON format files and strings.

24.2.1 Writing JSON

A `Series` or `DataFrame` can be converted to a valid JSON string. Use `to_json` with optional parameters:

• `path_or_buf`: the pathname or buffer to write the output This can be `None` in which case a JSON string is returned
• `orient`:
  
  **Series:**
pandas: powerful Python data analysis toolkit, Release 0.23.2

- default is `index`
- allowed values are `{split, records, index}`

**DataFrame:**

- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<table>
<thead>
<tr>
<th>keyword</th>
<th>format</th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like <code>{index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</code></td>
</tr>
<tr>
<td>records</td>
<td>list like <code>[{column -&gt; value}, ..., {column -&gt; value}]</code></td>
</tr>
<tr>
<td>index</td>
<td>dict like <code>{index -&gt; {column -&gt; value}}</code></td>
</tr>
<tr>
<td>columns</td>
<td>dict like <code>{column -&gt; {index -&gt; value}}</code></td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
</tbody>
</table>

- **date_format**: string, type of date conversion, ‘epoch’ for timestamp, ‘iso’ for ISO8601.
- **double_precision**: The number of decimal places to use when encoding floating point values, default 10.
- **force_ascii**: force encoded string to be ASCII, default True.
- **date_unit**: The time unit to encode to, governs timestamp and ISO8601 precision. One of ‘s’, ‘ms’, ‘us’ or ‘ns’ for seconds, milliseconds, microseconds and nanoseconds respectively. Default ‘ms’.
- **default_handler**: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- **lines**: If `records` orient, then will write each record per line as json.

Note `NaN`'s, `NaT`'s and `None` will be converted to `null` and `datetime` objects will be converted based on the `date_format` and `date_unit` parameters.

```
In [182]: dfj = pd.DataFrame(randn(5, 2), columns=list('AB'))
In [183]: json = dfj.to_json()
In [184]: json
Out[184]: 'A
    0 -1.2945235903
    1  0.2766617129
    2 -0.0139597524
    3  0.8957173022
    4  0.8052440254
   --
   B
    0  0.4137381054
    1 -0.472034511
    2 -0.3625429925
    3 -0.923060654
    4  0.8052440254

24.2.1 Orient Options

There are a number of different options for the format of the resulting JSON file / string. Consider the following DataFrame and Series:

```
In [185]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
                       columns=list('ABC'), index=list('xyz'))

In [186]: dfjo
Out[186]:
   A  B  C
x 1 4 7
y 2 5 8
z 3 6 9

```
In [187]: sjo = pd.Series(dict(x=15, y=16, z=17), name='D')

In [188]: sjo
Out[188]:
   x  15
   y  16
   z  17
Name: D, dtype: int64

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

In [189]: dfjo.to_json(orient="columns")
Out[189]: '{"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}}'

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

In [190]: dfjo.to_json(orient="index")

In [191]: sjo.to_json(orient="index")
   {'x':15,'y':16,'z':17}'

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

In [192]: dfjo.to_json(orient="records")
Out[192]: '[["A",1,"B",4,"C",7],
   ["A",2,"B",5,"C",8],

In [193]: sjo.to_json(orient="records")
   '[[15,16,17]]'

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

In [194]: dfjo.to_json(orient="values")
Out[194]: '[[1,4,7],[2,5,8],[3,6,9]]'

# Not available for Series

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

In [195]: dfjo.to_json(orient="split")
Out[195]: '{"columns": ["A","B","C"],
   "index": ["x","y","z"],
   "data": [[1,4,7],[2,5,8],[3,6,9]]}'

In [196]: sjo.to_json(orient="split")
   '{"name":"D","index": ["x","y","z"],
   "data": [15,16,17]}'
pandas: powerful Python data analysis toolkit, Release 0.23.2

Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not
limited to dtypes and index names.
Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels
during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

24.2.1.2 Date Handling
Writing in ISO date format:
In [197]: dfd = pd.DataFrame(randn(5, 2), columns=list('AB'))
In [198]: dfd['date'] = pd.Timestamp('20130101')
In [199]: dfd = dfd.sort_index(1, ascending=False)
In [200]: json = dfd.to_json(date_format='iso')
In [201]: json
Out[201]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00:00.000Z","2":
˓→"2013-01-01T00:00:00.000Z","3":"2013-01-01T00:00:00.000Z","4":"2013-01-01T00:00:00.
˓→000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4
˓→":-0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.
˓→4108345112,"4":0.1320031703}}'

Writing in ISO date format, with microseconds:
In [202]: json = dfd.to_json(date_format='iso', date_unit='us')
In [203]: json
Out[203]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00:00.000000Z
˓→","2":"2013-01-01T00:00:00.000000Z","3":"2013-01-01T00:00:00.000000Z","4":"2013-01˓→01T00:00:00.000000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3
˓→":0.8138502857,"4":-0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.
˓→1702987971,"3":0.4108345112,"4":0.1320031703}}'

Epoch timestamps, in seconds:
In [204]: json = dfd.to_json(date_format='epoch', date_unit='s')
In [205]: json
Out[205]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4
˓→":1356998400},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.
˓→8138502857,"4":-0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.
˓→1702987971,"3":0.4108345112,"4":0.1320031703}}'

Writing to a file, with a date index and a date column:
In [206]: dfj2 = dfj.copy()
In [207]: dfj2['date'] = pd.Timestamp('20130101')
In [208]: dfj2['ints'] = list(range(5))
In [209]: dfj2['bools'] = True
(continues on next page)

1160

Chapter 24. IO Tools (Text, CSV, HDF5, . . . )


In [210]: dfj2.index = pd.date_range('20130101', periods=5)
In [211]: dfj2.to_json('test.json')
In [212]: open('test.json').read()
Out[212]: '{"A":{"1356998400000":-1.2945235903,"1357084800000":0.2766617129,
  "1357171200000":-0.0139597524,"1357257600000":-0.0061535699,"1357344000000":0.
  
  → 8957130222},"B":{"1356998400000":0.4137381054,"1357084800000":-0.472034511,
  "1357171200000":-0.3625429925,"1357257600000":-0.92360654,"1357344000000":0.
  → 8052440254},"date":{"1356998400000":1356998400000,"1357084800000":1356998400000,
  "1357171200000":1356998400000,"1357257600000":1356998400000,"1357344000000":1356998400000,
  "ints":{"1356998400000":0,"1357084800000":1,"1357171200000":2,
  "1357257600000":3,"1357344000000":4},"bools":{"1356998400000":true,"1357084800000":false,"1357171200000":true,"1357257600000":true,"1357344000000":true})

24.2.1.3 Fallback Behavior
If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. np.complex) then the default_handler, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a to_dict method and call it. A to_dict method should return a dict which will then be JSON serialized.
  - invoke the default_handler if one was provided.
  - convert the object to a dict by traversing its contents. However this will often fail with an OverflowError or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a default_handler. For example:

```python
DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json()  # raises
```
RuntimeError: Unhandled numpy dtype 15
can be dealt with by specifying a simple default_handler:

```python
In [213]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[213]: '{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}'
```

24.2.2 Reading JSON
Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if typ is not supplied or is None. To explicitly force Series parsing, pass typ=series

- filepath_or_buffer: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file:///localhost/path/to/table.json
- typ: type of object to recover (series or frame), default ‘frame’
- orient: 1161
Series:
- default is `index`
- allowed values are `split, records, index`

DataFrame:
- default is `columns`
- allowed values are `split, records, index, columns, values, table`

The format of the JSON string:

<table>
<thead>
<tr>
<th>key</th>
<th>description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>split</code></td>
<td>dict like <code>{index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</code></td>
</tr>
<tr>
<td><code>records</code></td>
<td>list like <code>[{column -&gt; value}, ..., {column -&gt; value}]</code></td>
</tr>
<tr>
<td><code>index</code></td>
<td>dict like <code>{index -&gt; {column -&gt; value}}</code></td>
</tr>
<tr>
<td><code>columns</code></td>
<td>dict like <code>{column -&gt; {index -&gt; value}}</code></td>
</tr>
<tr>
<td><code>values</code></td>
<td>just the values array</td>
</tr>
<tr>
<td><code>table</code></td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- **dtype**: if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.
- **convert_axes**: boolean, try to convert the axes to the proper dtypes, default is True
- **convert_dates**: a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.
- **keep_default_dates**: boolean, default True. If parsing dates, then parse the default date-like columns.
- **numpy**: direct decoding to NumPy arrays. default is False; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if `numpy=True`.
- **precise_float**: boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.
- **date_unit**: string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- **lines**: reads file as one json object per line.
- **encoding**: The encoding to use to decode py3 bytes.
- **chunksize**: when used in combination with `lines=True`, return a JsonReader which reads in `chunksize` lines per iteration.

The parser will raise one of `ValueError/TypeError/AssertionError` if the JSON is not parseable.

If a non-default `orient` was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see `Orient Options` for an overview.

### 24.2.2.1 Data Conversion

The default of `convert_axes=True, dtype=True, and convert_dates=True` will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to `dtype`. `convert_axes` should only be set to False if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.
Note: Large integer values may be converted to dates if convert_dates=True and the data and/or column labels appear ‘date-like’. The exact threshold depends on the date_unit specified. ‘date-like’ means that the column label meets one of the following criteria:

- it ends with '_at'
- it ends with '_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

Warning: When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was float data will be converted to integer if it can be done safely, e.g. a column of 1.
- bool columns will be converted to integer on reconstruction

Thus there are times where you may want to specify specific dtypes via the dtype keyword argument.

Reading from a JSON string:

```
In [214]: pd.read_json(json)
Out[214]:
   date    B    A
0 2013-01-01  2.565646 -1.206412
1 2013-01-01  1.340309  1.431256
2 2013-01-01 -0.226169 -1.170299
3 2013-01-01  0.813850  0.410835
4 2013-01-01 -0.827317  0.132003
```

Reading from a file:

```
In [215]: pd.read_json('test.json')
Out[215]:
   date    A    B    date    ints    bools
2013-01-01 -1.294524  0.413738  2013-01-01   0   True
2013-01-02  0.276662 -0.472035  2013-01-01   1   True
2013-01-03 -0.013960 -0.362543  2013-01-01   2   True
2013-01-04 -0.006154 -0.923061  2013-01-01   3   True
2013-01-05  0.895717  0.805244  2013-01-01   4   True
```

Don’t convert any data (but still convert axes and dates):

```
In [216]: pd.read_json('test.json', dtype=object).dtypes
Out[216]:
       A    object
       B    object
date  object
ints  object
bools object
dtype: object
```
Specify dtypes for conversion:

```python
In [217]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
Out[217]:
A    float32
B    float64
date  datetime64[ns]
ints  int64
bools int8
dtype: object
```

Preserve string indices:

```python
In [218]: si = pd.DataFrame(np.zeros((4, 4)),
                      columns=list(range(4)),
                      index=[str(i) for i in range(4)])
In [219]: si
Out[219]:
      0  1  2  3
0   0.0  0.0  0.0  0.0
1   0.0  0.0  0.0  0.0
2   0.0  0.0  0.0  0.0
3   0.0  0.0  0.0  0.0
In [220]: si.index
Out[220]:
Index(['0', '1', '2', '3'], dtype='object')
In [221]: si.columns
Out[221]:
Int64Index([0, 1, 2, 3], dtype='int64')
In [222]: json = si.to_json()
In [223]: sij = pd.read_json(json, convert_axes=False)
In [224]: sij
Out[224]:
      0  1  2  3
0   0  0  0  0
1   0  0  0  0
2   0  0  0  0
3   0  0  0  0
In [225]: sij.index
Out[225]:
Index(['0', '1', '2', '3'], dtype='object')
In [226]: sij.columns
Out[226]:
Index(['0', '1', '2', '3'], dtype='object')
```

Dates written in nanoseconds need to be read back in nanoseconds:

```python
In [227]: json = dfj2.to_json(date_unit='ns')
```

(continues on next page)
# Try to parse timestamps as milliseconds -> Won't Work
In [228]: dfju = pd.read_json(json, date_unit='ms')

In [229]: dfju
Out[229]:
     A    B      date    ints    bools
1356998400000000000 -1.294524  0.413738 1356998400000000000 True
1357084800000000000  0.276662 -0.472035 1356998400000000000 True
1357171200000000000 -0.013960 -0.362543 1356998400000000000 True
1357257600000000000 -0.006154 -0.923061 1356998400000000000 True
1357344000000000000  0.895717  0.805244 1356998400000000000 True

# Let pandas detect the correct precision
In [230]: dfju = pd.read_json(json)

In [231]: dfju
Out[231]:
     A    B     date    ints    bools
2013-01-01 -1.294524  0.413738 2013-01-01 0 True
2013-01-02  0.276662 -0.472035 2013-01-01 1 True
2013-01-03 -0.013960 -0.362543 2013-01-01 2 True
2013-01-04 -0.006154 -0.923061 2013-01-01 3 True
2013-01-05  0.895717  0.805244 2013-01-01 4 True

# Or specify that all timestamps are in nanoseconds
In [232]: dfju = pd.read_json(json, date_unit='ns')

In [233]: dfju
Out[233]:
     A    B     date    ints    bools
2013-01-01 -1.294524  0.413738 2013-01-01 0 True
2013-01-02  0.276662 -0.472035 2013-01-01 1 True
2013-01-03 -0.013960 -0.362543 2013-01-01 2 True
2013-01-04 -0.006154 -0.923061 2013-01-01 3 True
2013-01-05  0.895717  0.805244 2013-01-01 4 True

### 24.2.2.2 The Numpy Parameter

**Note:** This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects. This can provide speedups if you are deserialising a large amount of numeric data:

In [234]: randfloats = np.random.uniform(-100, 1000, 10000)

In [235]: randfloats.shape = (1000, 10)

In [236]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))

In [237]: jsonfloats = dffloats.to_json()
Warning: Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

### 24.2.3 Normalization

pandas provides a utility function to take a dict or list of dicts and `normalize` this semi-structured data into a flat table.
24.2.4 Line delimited json

New in version 0.19.0.

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in chunksize lines at a time. This can be useful for large files or to read from a stream.
24.2.5 Table Schema

New in version 0.20.0.

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient table to build a JSON string with two fields, schema and data.

In [255]: df = pd.DataFrame(
    .....:     {'A': [1, 2, 3],
    .....:     'B': ['a', 'b', 'c'],
    .....:     'C': pd.date_range('2016-01-01', freq='d', periods=3),
    .....:     }, index=pd.Index(range(3), name='idx'))

In [256]: df
Out[256]:
   A  B          C
   idx
0  1  a 2016-01-01
1  2  b 2016-01-02
2  3  c 2016-01-03

In [257]: df.to_json(orient='table', date_format="iso")

The schema field contains the fields key, which itself contains a list of column name to type pairs, including the Index or MultiIndex (see below for a list of types). The schema field also contains a primaryKey field if the (Multi)index is unique.

The second field, data, contains the serialized data with the records orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:
Pandas type | Table Schema type  
---|---  
int64 | integer  
float64 | number  
bool | boolean  
datetime64[ns] | datetime  
timedelta64[ns] | duration  
categorical | any  
object | str

A few notes on the generated table schema:

- The schema object contains a pandas_version field. This contains the version of pandas’ dialect of the schema, and will be incremented with each revision.

- All dates are converted to UTC when serializing. Even timezone naïve values, which are treated as UTC with an offset of 0.

```python
In [258]: from pandas.io.json import build_table_schema

In [259]: s = pd.Series(pd.date_range('2016', periods=4))

In [260]: build_table_schema(s)
Out[260]:

{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime'}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- Datetimes with a timezone (before serializing), include an additional field tz with the time zone name (e.g. 'US/Central').

```python
In [261]: s_tz = pd.Series(pd.date_range('2016', periods=12,
                                        ....:       tz='US/Central'))

In [262]: build_table_schema(s_tz)
Out[262]:

{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain and additional field freq with the period’s frequency, e.g. 'A-DEC'.

```python
In [263]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
                                              ....:       periods=4))

In [264]: build_table_schema(s_per)
Out[264]:

{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
            {'name': 'values', 'type': 'integer'}],
'primaryKey': ['index'],
'pandas_version': '0.20.0'}
```
• Categoricals use the `any` type and an `enum` constraint listing the set of possible values. Additionally, an `ordered` field is included:

```
In [265]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))
In [266]: build_table_schema(s_cat)
Out[266]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'any',
             'constraints': {'enum': ['a', 'b']},
             'ordered': False},
            'primaryKey': ['index'],
            'pandas_version': '0.20.0'}
```

• A `primaryKey` field, containing an array of labels, is included if the index is unique:

```
In [267]: s_dupe = pd.Series([1, 2], index=[1, 1])
In [268]: build_table_schema(s_dupe)
Out[268]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
 'pandas_version': '0.20.0'}
```

• The `primaryKey` behavior is the same with MultiIndexes, but in this case the `primaryKey` is an array:

```
In [269]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
                                                            (0, 1)]))
In [270]: build_table_schema(s_multi)
Out[270]:
{'fields': [{'name': 'level_0', 'type': 'string'},
            {'name': 'level_1', 'type': 'integer'},
            {'name': 'values', 'type': 'integer'}],
 'primaryKey': FrozenList(['level_0', 'level_1']),
 'pandas_version': '0.20.0'}
```

• The default naming roughly follows these rules:

  – For series, the `object.name` is used. If that’s none, then the name is `values`
  
  – For DataFrames, the stringified version of the column name is used
  
  – For Index (not MultiIndex), `index.name` is used, with a fallback to `index` if that is None.
  
  – For MultiIndex, `mi.names` is used. If any level has no name, then `level_<i>` is used.

New in version 0.23.0.

`read_json` also accepts `orient='table'` as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```
In [271]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
                      'bar': ['a', 'b', 'c', 'd'],
                      'baz': pd.date_range('2018-01-01', freq='d', periods=4),
                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])}, index=pd.Index(range(4), name='idx'))
```

(continues on next page)
In [272]: df
Out[272]:
   foo bar  baz  qux
idx
0    1   a  2018-01-01  a
1    2   b  2018-01-02  b
2    3   c  2018-01-03  c
3    4   d  2018-01-04  c

In [273]: df.dtypes

Out[273]:
     foo    bar      baz     qux
dtype: object

In [274]: df.to_json('test.json', orient='table')

In [275]: new_df = pd.read_json('test.json', orient='table')

In [276]: new_df
Out[276]:
   foo bar  baz  qux
idx
0    1   a  2018-01-01  a
1    2   b  2018-01-02  b
2    3   c  2018-01-03  c
3    4   d  2018-01-04  c

In [277]: new_df.dtypes

Out[277]:
     foo    bar      baz     qux
dtype: object

Please note that the literal string ‘index’ as the name of an Index is not round-trippable, nor are any names beginning with ‘level_’ within a MultiIndex. These are used by default in DataFrame.to_json() to indicate missing values and the subsequent read cannot distinguish the intent.

In [278]: df.index.name = 'index'

In [279]: df.to_json('test.json', orient='table')

In [280]: new_df = pd.read_json('test.json', orient='table')

In [281]: print(new_df.index.name)
None
24.3 HTML

24.3.1 Reading HTML Content

Warning: We highly encourage you to read the HTML Table Parsing gotchas below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level read_html() function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let’s look at a few examples.

Note: read_html returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [282]: url = 'http://www.fdic.gov/bank/individual/failed/banklist.html'

In [283]: dfs = pd.read_html(url)

In [284]: dfs
Out[284]:

<table>
<thead>
<tr>
<th></th>
<th>Bank Name</th>
<th>Updated Date</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>Washington Federal Bank for Savings</td>
<td>February 21, 2018</td>
</tr>
<tr>
<td>1</td>
<td>The Farmers and Merchants State Bank of Argonia</td>
<td>February 21, 2018</td>
</tr>
<tr>
<td>2</td>
<td>Fayette County Bank</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>Guaranty Bank, (d/b/a BestBank in Georgia &amp; MI...</td>

[505 rows x 7 columns]
```

You can even pass in an instance of `StringIO` if you so desire:

```python
In [287]: with open(file_path, 'r') as f:
    .....:
    sio = StringIO(f.read())
    .....:
```
In [288]: dfs = pd.read_html(sio)

In [289]: dfs
Out[289]:

[505 rows x 7 columns]

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.

Read a URL and match a table that contains specific text:

```python
match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)
```

Specify a header row (by default `<th>` or `<td>` elements located within a `<thead>` are used to form the column index, if multiple rows are contained within `<thead>` then a multiindex is created); if specified, the header row is taken from the data minus the parsed header elements (`<th>` elements).

```python
dfs = pd.read_html(url, header=0)
```

Specify an index column:
dfs = pd.read_html(url, index_col=0)

Specify a number of rows to skip:

dfs = pd.read_html(url, skiprows=0)

Specify a number of rows to skip using a list (xrange (Python 2 only) works as well):

dfs = pd.read_html(url, skiprows=range(2))

Specify an HTML attribute:

dxsl = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})

print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True

Specify values that should be converted to NaN:

dfs = pd.read_html(url, na_values=['No Acquirer'])

New in version 0.19.

Specify whether to keep the default set of NaN values:

dfs = pd.read_html(url, keep_default_na=False)

New in version 0.19.

Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.

url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0, converters={'MNC': str})

New in version 0.19.

Use some combination of the above:

dfs = pd.read_html(url, match='Metcalf Bank', index_col=0)

Read in pandas to_html output (with some loss of floating point precision):

df = pd.DataFrame(randn(2, 2))
s = df.to_html(float_format='{{0:.40g}}'.format)
dfin = pd.read_html(s, index_col=0)

The lxml backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:

dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml'])

Or you could pass flavor='lxml' without a list:

dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor='lxml')
However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that as soon as a parse succeeds, the function will return.

```python
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml', 'bs4'])
```

### 24.3.2 Writing to HTML files

DataFrames have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for DataFrame.to_html are shown here for brevity's sake. See `to_html()` for the full set of options.

```python
In [290]: df = pd.DataFrame(randn(2, 2))

In [291]: df
Out[291]:
   0     1
0 -0.184744  0.496971
1 -0.856240  1.857977

In [292]: print(df.to_html())  # raw html
    \[table border="1" class="dataframe"
    \thead
    \th 0 \th 1
    \t0 -0.184744  0.496971
    \t1 -0.856240  1.857977

In [293]: print(df.to_html(columns=[0]))
    \[table border="1" class="dataframe"
    \thead
    \th 0
    \t0 -0.184744
    \t1 -0.856240
    \t0 1.857977

(continues on next page)
**HTML:**

`float_format` takes a Python callable to control the precision of floating point values:

```python
In [294]: print(df.to_html(float_format='{0:.10f}'.format))
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.1847438576</td>
<td>0.4969711327</td>
</tr>
<tr>
<th>1</th>
<td>-0.8562396763</td>
<td>1.8579766508</td>
</tr>
</tbody>
</table>
```

**HTML:**

`bold_rows` will make the row labels bold by default, but you can turn that off:

```python
In [295]: print(df.to_html(bold_rows=False))
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>-0.1847438576</td>
<td>0.4969711327</td>
</tr>
<tr>
<td>1</td>
<td>-0.8562396763</td>
<td>1.8579766508</td>
</tr>
</tbody>
</table>
```
The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are appended to the existing 'dataframe' class.

```python
In [296]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
```

```html
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
<thead>
<tr style="text-align: right;">  
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
<td>0.496971</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
<td>1.857977</td>
</tr>
</tbody>
</table>
```

Finally, the `escape` argument allows you to control whether the "<", ">" and "&" characters escaped in the resulting HTML (by default it is True). So to get the HTML without escaped characters pass `escape=False`

```python
In [297]: df = pd.DataFrame({'a': list('&<>'), 'b': randn(3)})
Escaped:
In [298]: print(df.to_html())
```

```html
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
<td>0.496971</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
<td>1.857977</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Not escaped:

```
In [299]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;"> 
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>&amp;</td>
<td>-0.474063</td>
</tr>
<tr>
<th>1</th>
<td>&lt;</td>
<td>-0.230305</td>
</tr>
<tr>
<th>2</th>
<td>&gt;</td>
<td>-0.400654</td>
</tr>
</tbody>
</table>
```

**Note:** Some browsers may not show a difference in the rendering of the previous two HTML tables.

### 24.3.3 HTML Table Parsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas io function `read_html`.
Issues with lxml

- Benefits
  - lxml is very fast.
  - lxml requires Cython to install correctly.
- Drawbacks
  - lxml does not make any guarantees about the results of its parse unless it is given strictly valid markup.
  - In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse.
  - It is therefore highly recommended that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.

Issues with BeautifulSoup4 using lxml as a backend

- The above issues hold here as well since BeautifulSoup4 is essentially just a wrapper around a parser backend.

Issues with Beautiful Soup 4 using html5lib as a backend

- Benefits
  - html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  - html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - html5lib is pure Python and requires no additional build steps beyond its own installation.
- Drawbacks
  - The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

24.4 Excel files

The read_excel() method can read Excel 2003 (.xls) and Excel 2007+ (.xlsx) files using the x1rd Python module. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

24.4.1 Reading Excel Files

In the most basic use-case, read_excel takes a path to an Excel file, and the sheet_name indicating which sheet to parse.

```python
# Returns a DataFrame
read_excel('path_to_file.xls', sheet_name='Sheet1')
```
24.4.1.1 ExcelFile class

To facilitate working with multiple sheets from the same file, the ExcelFile class can be used to wrap the file and can be passed into read_excel. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The ExcelFile class can also be used as a context manager.

```python
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The sheet_names property will generate a list of the sheet names in the file.

The primary use-case for an ExcelFile is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to read_excel with no loss in performance.

```python
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = read_excel(xls, 'Sheet2', index_col=1)

# equivalent using the read_excel function
data = read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'], index_col=None, na_values=['NA'])
```

24.4.1.2 Specifying Sheets

**Note:** The second argument is sheet_name, not to be confused with ExcelFile.sheet_names.

**Note:** An ExcelFile’s attribute sheet_names provides access to a list of sheets.

- The arguments sheet_name allows specifying the sheet or sheets to read.
- The default value for sheet_name is 0, indicating to read the first sheet.
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a None to return a dictionary of all available sheets.
# Returns a DataFrame
read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])

Using the sheet index:

# Returns a DataFrame
read_excel('path_to_file.xls', 0, index_col=None, na_values=['NA'])

Using all default values:

# Returns a DataFrame
read_excel('path_to_file.xls')

Using None to get all sheets:

# Returns a dictionary of DataFrames
read_excel('path_to_file.xls', sheet_name=None)

Using a list to get multiple sheets:

# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
read_excel('path_to_file.xls', sheet_name=['Sheet1', 3])

read_excel can read more than one sheet, by setting sheet_name to either a list of sheet names, a list of sheet positions, or None to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

## 24.4.1.3 Reading a MultiIndex

read_excel can read a MultiIndex index, by passing a list of columns to index_col and a MultiIndex column by passing a list of rows to header. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:

In [300]: df = pd.DataFrame({'a':[1, 2, 3, 4], 'b':[5, 6, 7, 8]},
.....:     index=pd.MultiIndex.from_product([['a', 'b'], ['c', 'd']])
.....:
In [301]: df.to_excel('path_to_file.xlsx')
In [302]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])
In [303]: df
Out[303]:
   a  b
a c 1 5
d 2 6
b c 3 7
d 4 8

If the index has level names, they will parsed as well, using the same parameters.

In [304]: df.index = df.index.set_names(['lv11', 'lv12'])
In [305]: df.to_excel('path_to_file.xlsx')

(continues on next page)
In [306]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [307]: df
Out[307]:
a b
lvl1 lvl2
a c 1 5
d 2 6
b c 3 7
d 4 8

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

In [308]: df.columns = pd.MultiIndex.from_product([['a'], ['b', 'd']], names=['c1', 'c2'])

In [309]: df.to_excel('path_to_file.xlsx')

In [310]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])

In [311]: df
Out[311]:
c1 a
c2 b d
lvl1 lvl2
a c 1 5
d 2 6
b c 3 7
d 4 8

### 24.4.1.4 Parsing Specific Columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

### 24.4.1.5 Parsing Dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that *look* like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:
24.4.1.6 Cell Converters

It is possible to transform the contents of Excel cells via the converters option. For instance, to convert a column to boolean:

```python
read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This options handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
cfun = lambda x: int(x) if x else -1
read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

24.4.1.7 dtype Specifications

New in version 0.20.

As an alternative to converters, the type for an entire column can be specified using the dtype keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type str or object.

```python
read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

24.4.2 Writing Excel Files

24.4.2.1 Writing Excel Files to Disk

To write a DataFrame object to a sheet of an Excel file, you can use the to_excel instance method. The arguments are largely the same as to_csv described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the DataFrame should be written. For example:

```python
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a .xls extension will be written using xlwt and those with a .xlsx extension will be written using xlsxwriter (if available) or openpyxl.

The DataFrame will be written in a way that tries to mimic the REPL output. The index_label will be placed in the second row instead of the first. You can place it in the first row by setting the merge_cells option in to_excel() to False:

```python
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate DataFrames to separate sheets in a single Excel file, one can pass an ExcelWriter.

```python
with ExcelWriter('path_to_file.xlsx') as writer:
df1.to_excel(writer, sheet_name='Sheet1')
df2.to_excel(writer, sheet_name='Sheet2')
```
24.4.2.2 Writing Excel Files to Memory

Pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

**Note:** engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

24.4.3 Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options io.excel.xlsx.writer and io.excel.xls.writer. pandas will fall back on openpyxl for .xlsx files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to to_excel and to ExcelWriter. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt
# By setting the 'engine' in the DataFrame and Panel `to_excel()` methods.
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')

# By setting the 'engine' in the ExcelWriter constructor.
writer = ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')

# Or via pandas configuration.
from pandas import options
options.io.excel.xlsx.writer = 'xlsxwriter'
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')

## 24.4.4 Style and Formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame's `to_excel` method.

- **float_format**: Format string for floating point numbers (default `None`).
- **freeze_panes**: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so `(1, 1)` will freeze the first row and first column (default `None`).

### 24.5 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_table` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x  1  4 p
y  2  5 q
z  3  6 r
```

And then import the data directly to a DataFrame by calling:

```python
clipdf = pd.read_clipboard()
```

```
In [312]: clipdf
Out[312]:
   A  B  C
0  x  1  4 p
1  y  2  5 q
2  z  3  6 r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```python
In [313]: df = pd.DataFrame(randn(5, 3))
In [314]: df
Out[314]:
   0  1  2
0  1  2  3
1  4  5  6
2  7  8  9
3 10 11 12
4 13 14 15
```

(continues on next page)
0 -0.288267 -0.084905 0.004772
1 1.382989 0.343635 -1.253994
2 -0.124925 0.212244 0.496654
3 0.525417 1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129

In [315]: df.to_clipboard()
In [316]: pd.read_clipboard()
Out[316]:
   0   1   2
0 -0.288267 -0.084905 0.004772
1 1.382989 0.343635 -1.253994
2 -0.124925 0.212244 0.496654
3 0.525417 1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129

We can see that we got the same content back, which we had earlier written to the clipboard.

Note: You may need to install xclip or xsel (with gtk, PyQt5, PyQt4 or qtpy) on Linux to use these methods.

24.6 Pickling

All pandas objects are equipped with to_pickle methods which use Python’s cPickle module to save data structures to disk using the pickle format.

In [317]: df
Out[317]:
   0   1   2
0 -0.288267 -0.084905 0.004772
1 1.382989 0.343635 -1.253994
2 -0.124925 0.212244 0.496654
3 0.525417 1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129

In [318]: df.to_pickle('foo.pkl')

The read_pickle function in the pandas namespace can be used to load any pickled pandas object (or any other pickled object) from file:

In [319]: pd.read_pickle('foo.pkl')
Out[319]:
   0   1   2
0 -0.288267 -0.084905 0.004772
1 1.382989 0.343635 -1.253994
2 -0.124925 0.212244 0.496654
3 0.525417 1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129

Warning: Loading pickled data received from untrusted sources can be unsafe.
Warning: Several internal refactorings have been done while still preserving compatibility with pickles created with older versions of pandas. However, for such cases, pickled DataFrames, Series etc, must be read with `pd.read_pickle`, rather than `pickle.load`.

See here and here for some examples of compatibility-breaking changes. See this question for a detailed explanation.

### 24.6.1 Compressed pickle files

New in version 0.20.0.

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of gzip, bz2, xz are supported for reading and writing. The zip file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If ‘infer’, then use gzip, bz2, zip, or xz if filename ends in ‘.gz’, ‘.bz2’, ‘.zip’, or ‘.xz’, respectively.

```python
In [320]: df = pd.DataFrame({
            'A': np.random.randn(1000),
            'B': 'foo',
            'C': pd.date_range('20130101', periods=1000, freq='s')})

In [321]: df
Out[321]:
   A    B     C
0  0.478412 foo 2013-01-01 00:00:00
1 -0.783748 foo 2013-01-01 00:00:01
2  1.403558 foo 2013-01-01 00:00:02
3 -0.539282 foo 2013-01-01 00:00:03
4 -1.651012 foo 2013-01-01 00:00:04
5  0.692072 foo 2013-01-01 00:00:05
6  1.022171 foo 2013-01-01 00:00:06
..    ...    ......
993 -1.613932 foo 2013-01-01 00:16:33
994  1.088104 foo 2013-01-01 00:16:34
995 -0.632963 foo 2013-01-01 00:16:35
996 -0.585314 foo 2013-01-01 00:16:36
997 -0.275038 foo 2013-01-01 00:16:37
998 -0.937512 foo 2013-01-01 00:16:38
999  0.632369 foo 2013-01-01 00:16:39
[1000 rows x 3 columns]
```

Using an explicit compression type:

```python
In [322]: df.to_pickle("data.pkl.compress", compression="gzip")
In [323]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
In [324]: rt
```

(continues on next page)
Inferring compression type from the extension:

In [325]: df.to_pickle("data.pkl.xz", compression="infer")

In [326]: rt = pd.read_pickle("data.pkl.xz", compression="infer")

In [327]: rt

Out[327]:

A   B     C
0 0.478412 foo 2013-01-01 00:00:00
1 -0.783748 foo 2013-01-01 00:00:01
2 1.403558 foo 2013-01-01 00:00:02
3 -0.539282 foo 2013-01-01 00:00:03
4 -1.651012 foo 2013-01-01 00:00:04
5 0.692072 foo 2013-01-01 00:00:05
6 1.022171 foo 2013-01-01 00:00:06
... ... ... ...
993 -1.613932 foo 2013-01-01 00:16:33
994 1.088104 foo 2013-01-01 00:16:34
995 -0.632963 foo 2013-01-01 00:16:35
996 -0.585314 foo 2013-01-01 00:16:36
997 -0.275038 foo 2013-01-01 00:16:37
998 -0.937512 foo 2013-01-01 00:16:38
999 0.632369 foo 2013-01-01 00:16:39

[1000 rows x 3 columns]

The default is to ‘infer’:

In [328]: df.to_pickle("data.pkl.gz")

In [329]: rt = pd.read_pickle("data.pkl.gz")

In [330]: rt

Out[330]:

A   B     C
0 0.478412 foo 2013-01-01 00:00:00

(continues on next page)

999   0.632369
Name: A, Length: 1000, dtype: float64

24.7 msgpack

pandas supports the msgpack format for object serialization. This is a lightweight portable binary format, similar to binary JSON, that is highly space efficient, and provides good performance both on the writing (serialization), and reading (deserialization).

**Warning:** This is a very new feature of pandas. We intend to provide certain optimizations in the io of the msgpack data. Since this is marked as an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

In [334]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))
In [335]: df.to_msgpack('foo.msg')

In [336]: pd.read_msgpack('foo.msg')
Out[336]:
      A     B
0  0.1708  0.895366
1  0.8382  0.052592
2  0.6641  0.289750
3  0.4495  0.872087
4  0.9836  0.744359

In [337]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))

You can pass a list of objects and you will receive them back on deserialization.

In [338]: pd.to_msgpack('foo.msg', df, 'foo', np.array([1, 2, 3]), s)

In [339]: pd.read_msgpack('foo.msg')
Out[339]:
[ A   B
0  0.1708  0.895366
1  0.8382  0.052592
2  0.6641  0.289750
3  0.4495  0.872087
4  0.9836  0.744359, 'foo', array([1, 2, 3]), 2013-01-01 0.548134
2013-01-02 0.503447
2013-01-03 0.348438
2013-01-04 0.707267
2013-01-05 0.261656
Freq: D, dtype: float64]

You can pass `iterator=True` to iterate over the unpacked results:

In [340]: for o in pd.read_msgpack('foo.msg', iterator=True):
   ....:     print(o)
   ....:
      A     B
0  0.1708  0.895366
1  0.8382  0.052592
2  0.6641  0.289750
3  0.4495  0.872087
4  0.9836  0.744359
foo
[1 2 3]
2013-01-01 0.548134
2013-01-02 0.503447
2013-01-03 0.348438
2013-01-04 0.707267
2013-01-05 0.261656
Freq: D, dtype: float64

You can pass `append=True` to the writer to append to an existing pack:

In [341]: df.to_msgpack('foo.msg', append=True)

In [342]: pd.read_msgpack('foo.msg')
Out[342]:
(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.2

(continued from previous page)

4 0.983618 0.744359]

0.548134

Unlike other io methods, to_msgpack is available on both a per-object basis, df.to_msgpack() and using the
top-level pd.to_msgpack(...) where you can pack arbitrary collections of Python lists, dicts, scalars, while
intermixing pandas objects.
In [343]: pd.to_msgpack('foo2.msg', {'dict': [{ 'df': df }, {'string': 'foo'},
.....:
{'scalar': 1.}, {'s': s}]})
.....:
In [344]: pd.read_msgpack('foo2.msg')
Out[344]:
{'dict': ({'df':
A
B
0 0.170801 0.895366
1 0.838238 0.052592
2 0.664140 0.289750
3 0.449593 0.872087
4 0.983618 0.744359},
{'string': 'foo'},
{'scalar': 1.0},
{'s': 2013-01-01
0.548134
2013-01-02
0.503447
2013-01-03
0.348438
2013-01-04
0.707267
2013-01-05
0.261656
Freq: D, dtype: float64})}

24.7.1 Read/Write API
Msgpacks can also be read from and written to strings.

In [345]: df.to_msgpack()
Out[345]: b'\x84\xa3typ\xadblock_
˓→manager\xa5klass\xa9DataFrame\xa4axes\x92\x86\xa3typ\xa5index\xa5klass\xa5Index\xa4name\xc0\xa5dtyp
˓→index\xa5klass\xaaRangeIndex\xa4name\xc0\xa5start\x00\xa4stop\x05\xa4step\x01\xa6blocks\x91\x86\xa4
˓→<\xfd\xd2f\xcf\xdc\xc5?0\x15\xebN\xd9\xd2\xea?,\x9c\x16A\xa2@\xe5?\xd8/\xdd\xf4
˓→"\xc6\xdc?\x11\x1e\x97\x1b\xcdy\xef?&\x1e<\xee\xd6\xa6\xec?p\xd3;\xb2N\xed\xaa?
˓→h\xcb\xb1\xbdB\x8b\xd2?\xaf4\x01r"\xe8\xeb?)G6\xd9\xc9\xd1\xe7?
˓→\xa5shape\x92\x02\x05\xa5dtype\xa7float64\xa5klass\xaaFloatBlock\xa8compress\xc0'

Furthermore you can concatenate the strings to produce a list of the original objects.
1192

Chapter 24. IO Tools (Text, CSV, HDF5, . . . )


24.8 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies

**Warning:** pandas requires PyTables >= 3.0.0. There is a indexing bug in PyTables < 3.2 which may appear when querying stores using an index. If you see a subset of results being returned, upgrade to PyTables >= 3.2. Stores created previously will need to be rewritten using the updated version.
# the type of stored data
In [357]: store.root.wp._v_attrs.pandas_type
Out[357]: 'wide'

In [358]: store

Out[358]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In a current or later Python session, you can retrieve stored objects:

# store.get('df') is an equivalent method
In [359]: store['df']

Out[359]:
   A     B     C
2000-01-01  0.887163  0.859588 -0.636524

2000-01-06 -0.202646 -0.655969  0.193421
2000-01-07  0.553439  1.318152 -0.469305
2000-01-08  0.675554 -1.817027 -0.183109

Deletion of the object specified by the key:

# store.remove('wp') is an equivalent method
In [361]: del store['wp']

In [362]: store

Out[362]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

Closing a Store and using a context manager:

In [363]: store.close()

In [364]: store

Out[364]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

(continues on next page)
In [365]: store.is_open
Out[365]: False

# Working with, and automatically closing the store using a context manager
In [366]: with pd.HDFStore('store.h5') as store:
    store.keys()

24.8.1 Read/Write API

HDFStore supports an top-level API using read_hdf for reading and to_hdf for writing, similar to how read_csv and to_csv work.

In [367]: df_tl = pd.DataFrame(dict(A=list(range(5)), B=list(range(5))))
In [368]: df_tl.to_hdf('store_tl.h5','table', append=True)
In [369]: pd.read_hdf('store_tl.h5', 'table', where=['index>2'])
Out[369]:
   A  B
0 3  3
1 4  4

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting dropna=True.

In [370]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
       'col2': [1, np.nan, np.nan]})
In [371]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
       format='table', mode='w')
In [372]: pd.read_hdf('file.h5', 'df_with_missing')
Out[372]:
   col1  col2
0  0.0  1.0
1  NaN  NaN
2  2.0  NaN

In [373]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
       format='table', mode='w', dropna=True)
In [374]: pd.read_hdf('file.h5', 'df_with_missing')
Out[374]:
   col1  col2
0  0.0  1.0
1  NaN  NaN
2  2.0  NaN

(continues on next page)
This is also true for the major axis of a Panel:

```python
In [376]: matrix = [[np.nan, np.nan, np.nan], [1, np.nan, np.nan], [np.nan, 5, 6], [np.nan, 3, np.nan]]

In [377]: panel_with_major_axis_all_missing=pd.Panel(matrix,
          items=['Item1', 'Item2', 'Item3'],
          major_axis=[1, 2],
          minor_axis=['A', 'B', 'C'])

In [378]: panel_with_major_axis_all_missing
Out[378]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 2 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item3
Major_axis axis: 1 to 2
Minor_axis axis: A to C

In [379]: panel_with_major_axis_all_missing.to_hdf('file.h5', 'panel',
          dropna=True,
          format='table',
          mode='w')

In [380]: reloaded = pd.read_hdf('file.h5', 'panel')

In [381]: reloaded
Out[381]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 1 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item3
Major_axis axis: 2 to 2
Minor_axis axis: A to C
```

24.8.2 Fixed Format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are not appendable once written (though you can simply remove them and rewrite). Nor are they queryable; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than table stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

**Warning:** A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```python
pd.DataFrame(randn(10, 2)).to_hdf('test_fixed.h5', 'df')
pd.read_hdf('test_fixed.h5', 'df', where='index>5')
```

**TypeError:** cannot pass a where specification when reading a fixed format. This store must be selected in its entirety.
24.8.3 Table Format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by format='table' or format='t' to append or put or to_hdf.

This format can be set as an option as well pd.set_option('io.hdf.default_format','table') to enable put/append/to_hdf to by default store in the table format.

In [382]: store = pd.HDFStore('store.h5')

In [383]: df1 = df[0:4]

In [384]: df2 = df[4:]

# append data (creates a table automatically)
In [385]: store.append('df', df1)

In [386]: store.append('df', df2)

In [387]: store

Out[387]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# select the entire object
In [388]: store.select('df')

A   B     C
2000-01-01 0.887163 0.859588 -0.636524
2000-01-02 0.015696 -2.242685 1.150036
2000-01-03 0.991946 0.953324 -2.021255
2000-01-04 -0.334077 0.002118 0.405453
2000-01-05 0.289092 1.321158 -1.546906
2000-01-06 -0.202646 -0.655969 0.193421
2000-01-07 0.553439 1.318152 -0.469305
2000-01-08 0.675554 -1.817027 -0.183109

# the type of stored data
In [389]: store.root.df._v_attrs.pandas_type

˓→'frame_table'

Note: You can also create a table by passing format='table' or format='t' to a put operation.

24.8.4 Hierarchical Keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. foo/bar/bah), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified with
out the leading ‘/’ and are always absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and below, so be careful.

```
In [390]: store.put('foo/bar/bah', df)
In [391]: store.append('food/orange', df)
In [392]: store.append('food/apple', df)
In [393]: store
Out[393]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
# a list of keys are returned
In [394]: store.keys()
Out[394]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']
# remove all nodes under this level
In [395]: store.remove('food')
In [396]: store
Out[396]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'
# you can directly access the actual PyTables node but using the root node
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
  children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array), 'axis1' (Array)]
```

Instead, use explicit string based keys:

```
In [397]: store['foo/bar/bah']
Out[397]:
     A       B       C
2000-01-01  0.887163  0.859588 -0.636524
2000-01-02  0.015696 -2.242685  1.150036
2000-01-03  0.991946  0.953324 -2.021255
2000-01-04 -0.334077  0.002118  0.405453
2000-01-05  0.289092  1.321158 -1.546906
2000-01-06 -0.202646 -0.655969  0.193421
2000-01-07  0.553439  1.318152 -0.183109
2000-01-08  0.675554 -1.817027 -0.183109
```

1198 Chapter 24. IO Tools (Text, CSV, HDF5, …)
24.8.5 Storing Types

24.8.5.1 Storing Mixed Types in a Table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={'values': size}` as a parameter to append will set a larger minimum for the string columns. Storing `floats, strings, ints, bools, datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this default to `nan`.

```python
In [398]: df_mixed = pd.DataFrame({'A': randn(8),
                               'B': randn(8),
                               'C': np.array(randn(8), dtype='float32'),
                               'string': 'string',
                               'int': 1,
                               'bool': True,
                               'datetime64': pd.Timestamp('20010102')},
                               index=list(range(8)))

In [399]: df_mixed.loc[df_mixed.index[3:5], ['A', 'B', 'string', 'datetime64']] = np.nan

In [400]: store.append('df_mixed', df_mixed, min_itemsize = {'values': 50})

In [401]: df_mixed1 = store.select('df_mixed')

In [402]: df_mixed1
Out[402]:
     A        B        C      string  int  bool      datetime64
0  0.704721  -1.152659  -0.430096        string    1   True 2001-01-02
1  0.246796   0.609329   0.308267        string    1   True 2001-01-02
2 -0.785435    0.502610    0.841324        string    1   True 2001-01-02
3  0.280445  -0.456176   0.694395        string    1   True 2001-01-02
4   NaN        NaN   0.270836          NaN    1   True     NaT
5 -0.926254    1.321106   0.079842        string    1   True 2001-01-02

   datetime64[ns]  1
dtype: int64

# we have provided a minimum string column size
In [404]: store.root.df_mixed.table
```

(continues on next page)
24.8.5.2 Storing Multi-Index DataFrames

Storing multi-index DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

```
In [405]: index = pd.MultiIndex(levels=[[['foo', 'bar', 'baz', 'qux'],
                                  ['one', 'two', 'three']],
                                 labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
                                  [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
                                 names=['foo', 'bar'])

In [406]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
                                 columns=['A', 'B', 'C'])

In [407]: df_mi
Out[407]:
   A    B    C
foo  bar
  foo one   -0.584718  0.816594 -0.081947
  two    -0.344766  0.528288 -1.068989
  three   -0.511881  0.291205  0.566534
  bar one   0.503592  0.285296  0.484288
  two     1.363482 -0.781105  0.468018
  baz two  1.224574 -1.281108  0.875476
  three   -1.710715  0.4050765  0.749164
  qux one  -0.203933 -0.182175  0.680656
  two    -1.818499  0.047072  0.394844
  three   -0.248432 -0.617707 -0.682884

In [408]: store.append('df_mi', df_mi)

In [409]: store.select('df_mi')
Out[409]:
   A    B    C
foo  bar
  foo one   -0.584718  0.816594 -0.081947
  two    -0.344766  0.528288 -1.068989

three -0.248432 -0.617707 -0.682884

# the levels are automatically included as data columns
In [410]: store.select('df_mi', 'foo=bar')

    foo  bar
bar one 0.503592 0.285296 0.484288
two   1.363482 -0.781105 -0.468018

24.8.6 Querying

24.8.6.1 Querying a Table

select and delete operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the Term class under the hood, as a boolean expression.

- index and columns are supported indexers of a DataFrame.
- major_axis, minor_axis, and items are supported indexers of the Panel.
- if data_columns are specified, these can be used as additional indexers.

Valid comparison operators are:

- =, ==, !=, >, >=, <, <=

Valid boolean expressions are combined with:

- |: or
- &: and
- (and): for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:

- "index >= date"
- "columns = ['A', 'D']"
- "columns in ['A', 'D']"
• 'columns = A'
• 'columns == A'
• 'index > df.index[3] & string = "bar"
• '(index > df.index[3] & index <= df.index[6]) | string = "bar"
• 'ts >= Timestamp('2012-02-01')'
• 'major_axis>=20130101'

The indexers are on the left-hand side of the sub-expression:
columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:
• functions that will be evaluated, e.g. Timestamp('2012-02-01')
• strings, e.g. "bar"
• date-like, e.g. 20130101, or "20130101"
• lists, e.g. "['A', 'B']"
• variables that are defined in the local names space, e.g. date

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this

```python
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this

```python
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will not work and will raise a SyntaxError. Note that there’s a single quote followed by a double quote in the string variable.

If you must interpolate, use the '%r' format specifier

```python
store.select('df', 'index == %r' % string)
```

which will quote string.

Here are some examples:

```python
In [411]: dfq = pd.DataFrame(randn(10, 4), columns=list('ABCD'),
    index=pd.date_range('20130101', periods=10))
    .....:
In [412]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.
In [413]: store.select('dfq', "index>pd.Timestamp('20130104') & columns=['A', 'B']")

Out[413]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>1.210384 0.797435</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>-0.850346 1.176812</td>
</tr>
<tr>
<td>2013-01-07</td>
<td>0.984188 -0.121728</td>
</tr>
<tr>
<td>2013-01-08</td>
<td>0.796595 -0.474021</td>
</tr>
<tr>
<td>2013-01-09</td>
<td>-0.804834 -2.123620</td>
</tr>
<tr>
<td>2013-01-10</td>
<td>0.334198 0.536784</td>
</tr>
</tbody>
</table>

Use and inline column reference

In [414]: store.select('dfq', where="A>0 or C>0")

Out[414]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
</tr>
<tr>
<td>2013-01-01</td>
<td>0.436258 -1.703013 0.393711 -0.479324</td>

<td>-0.299016 0.694103 0.678630 0.239556</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-03</td>
<td>0.151227 0.816127 1.893534 0.639633</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-04</td>
<td>-0.962029 -2.085266 1.930247 -1.735349</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-05</td>
<td>1.210384 0.797435 -0.379811 0.702562</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-07</td>
<td>0.984188 -0.121728 2.365769 0.496143</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-08</td>
<td>0.796595 -0.474021 -0.056696 1.357797</td>
<td></td>
<td></td>
</tr>
<tr>
<td>2013-01-10</td>
<td>0.334198 0.536784 -0.743830 -0.320204</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Works with a Panel as well.

In [415]: store.append('wp', wp)

In [416]: store

Out[416]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

In [417]: store.select('wp', "major_axis>pd.Timestamp('20000102') & minor_axis=['A', 'B']")

Out[417]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to B

The columns keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

In [418]: store.select('df', "columns=['A', 'B']")

Out[418]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
</tr>
<tr>
<td>2000-01-01</td>
<td>0.887163 0.859588</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>0.015696 -2.242685</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.991946 0.953324</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>-0.334077 0.002118</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.289092 1.321158</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>-0.202646 -0.655969</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.553439 1.318152</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.675554 -1.817027</td>
</tr>
</tbody>
</table>

start and stop parameters can be specified to limit the total search space. These are in terms of the total number
of rows in a table.

```
# this is effectively what the storage of a Panel looks like
In [419]: wp.to_frame()
Out[419]:
          Item1     Item2
major minor          
2000-01-01 A  1.058969  0.215269
    B   -0.397840  0.841009
    C    0.337438 -1.445810
    D   1.047579 -1.401973
2000-01-02 A  1.045938 -0.100918
    B   0.863717 -0.548242
    C  -0.122092 -0.144620
...      ...      ...
2000-01-04 B  0.036142  0.307969
    C  -2.074978 -0.208499
    D   0.247792  1.033801
2000-01-05 A -0.897157 -2.400454
    B  -0.136795  2.030604
    C   0.018289 -1.142631
    D   0.755414  0.211883
[20 rows x 2 columns]
```

# limiting the search
```
In [420]: store.select('wp', "major_axis>20000102 & minor_axis=['A', 'B']",
      start=0, stop=10)
```

Note: select will raise a ValueError if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

select will raise a SyntaxError if the query expression is not valid.

### 24.8.6.2 Using timedelta64[ns]

You can store and query using the `timedelta64[ns]` type. Terms can be specified in the format: `<float>(<unit>)`, where float may be signed (and fractional), and unit can be `D,s,ms,us,ns` for the timedelta. Here’s an example:

```
In [421]: from datetime import timedelta
In [422]: dftd = pd.DataFrame(dict(A = pd.Timestamp('20130101'), B = [ pd.Timestamp('20130101') + timedelta(days=i, seconds=10) for i in range(10) ]))
In [423]: dftd['C'] = dftd['A'] - dftd['B']
```
In [424]: dftd
Out[424]:
          A          B          C
0  2013-01-01  2013-01-01  00:00:10 -1 days +23:59:50
1  2013-01-01  2013-01-02  00:00:10 -2 days +23:59:50
2  2013-01-01  2013-01-03  00:00:10 -3 days +23:59:50
3  2013-01-01  2013-01-04  00:00:10 -4 days +23:59:50
4  2013-01-01  2013-01-05  00:00:10 -5 days +23:59:50
5  2013-01-01  2013-01-06  00:00:10 -6 days +23:59:50
6  2013-01-01  2013-01-07  00:00:10 -7 days +23:59:50
7  2013-01-01  2013-01-08  00:00:10 -8 days +23:59:50
8  2013-01-01  2013-01-09  00:00:10 -9 days +23:59:50
9  2013-01-01  2013-01-10  00:00:10 -10 days +23:59:50

In [425]: store.append('dftd', dftd, data_columns=True)

24.8.6.3 Indexing

You can create/modify an index for a table with `create_table_index` after data is already in the table (after and append/put operation). Creating a table index is **highly** encouraged. This will speed your queries a great deal when you use a `select` with the indexed dimension as the `where`.

**Note:** Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing `index=False` to `append`.

# we have automagically already created an index (in the first section)
In [427]: i = store.root.df.table.cols.index.index

In [428]: i.optlevel, i.kind
Out[428]: (6, 'medium')

# change an index by passing new parameters
In [429]: store.create_table_index('df', optlevel=9, kind='full')

In [430]: i = store.root.df.table.cols.index.index

In [431]: i.optlevel, i.kind
Out[431]: (9, 'full')

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.
In [432]: df_1 = pd.DataFrame(randn(10, 2), columns=list('AB'))
In [433]: df_2 = pd.DataFrame(randn(10, 2), columns=list('AB'))
In [434]: st = pd.HDFStore('appends.h5', mode='w')
In [435]: st.append('df', df_1, data_columns=['B'], index=False)
In [436]: st.append('df', df_2, data_columns=['B'], index=False)
In [437]: st.get_storer('df').table
Out[437]:
/df/table (Table(20,)) ''
   description := {
      "index": Int64Col(shape=(), dflt=0, pos=0),
      "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
      "B": Float64Col(shape=(), dflt=0.0, pos=2)}
   byteorder := 'little'
   chunkshape := (2730,)

Then create the index when finished appending.

In [438]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [439]: st.get_storer('df').table
Out[439]:
/df/table (Table(20,)) ''
   description := {
      "index": Int64Col(shape=(), dflt=0, pos=0),
      "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
      "B": Float64Col(shape=(), dflt=0.0, pos=2)}
   byteorder := 'little'
   chunkshape := (2730,)
   autoindex := True
   colindexes := {
      "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [440]: st.close()

See [here](#) for how to create a completely-sorted-index (CSI) on an existing store.

### 24.8.6.4 Query via Data Columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify data_columns = True to force all columns to be data_columns.

In [441]: df_dc = df.copy()
In [442]: df_dc['string'] = 'foo'
In [443]: df_dc.loc[df_dc.index[4:6], 'string'] = np.nan
In [444]: df_dc.loc[df_dc.index[7:9], 'string'] = 'bar'

(continues on next page)
In [445]: df_dc['string2'] = 'cool'

In [446]: df_dc.loc[df_dc.index[1:3], ['B', 'C']] = 1.0

In [447]: df_dc

</tr>
<tr>
<td>2000-01-04</td>
<td>-0.334</td>
<td>0.002</td>
<td>0.405</td>
<td>foo</td>
<td>cool</td>
</tr>
</tbody>
</table>

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as ``PyTables`` columns
In [452]: store.root.df_dc.table

```
description := {
  "index": Int64Col(shape=(), dflt=0, pos=0),
  "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
  "B": Float64Col(shape=(), dflt=0.0, pos=2),
  "C": Float64Col(shape=(), dflt=0.0, pos=3),
  "string": CategoricalCol(shape=(), dflt='foo', pos=4),
  "string2": CategoricalCol(shape=(), dflt='cool', pos=5)
}
```
There is some performance degradation by making lots of columns into data columns, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

24.8.6.5 Iterator

You can pass iterator=True or chunksize=number_in_a_chunk to select and select_as_multiple to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```python
In [453]: for df in store.select('df', chunksize=3):
    ....:     print(df)
```

```
A   B   C
2000-01-01 0.887163 0.859588 -0.636524
2000-01-02 0.015696 -2.242685 1.150036
2000-01-03 0.991946 0.953324 -2.021255
    A   B   C
2000-01-04 -0.334077 0.002118 0.405453
2000-01-05 0.289092 1.321158 -1.546906
2000-01-06 -0.202646 -0.655969 0.193421
    A   B   C
2000-01-07 0.553439 1.318152 -0.469305
2000-01-08 0.675554 -1.817027 -0.183109
```

Note: You can also use the iterator with read_hdf which will open, then automatically close the store when finished iterating.

```python
for df in pd.read_hdf('store.h5','df', chunksize=3):
    print(df)
```

Note, that the chunksize keyword applies to the source rows. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```python
In [454]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})

In [455]: dfeq
```

```
Out[455]:
   number
0      1
1      2
2      3
3      4
4      5
5      6
6      7
7      8
8      9
9     10
```
24.8.6.6 Advanced Queries

Select a Single Column

To retrieve a single indexable or data column, use the method `select_column`. This will, for example, enable you to get the index very quickly. These return a `Series` of the result, indexed by the row number. These do not currently accept the `where` selector.

```
in [461]: store.select_column('df_dc', 'index')
out[461]:
