# **pandas: powerful Python data analysis toolkit**

***Release 0.23.2***

**Wes McKinney & PyData Development Team**

**Jul 05, 2018**

# CONTENTS

<b>1</b>	<b>What's New</b>	<b>3</b>
1.1	v0.23.2	3
1.1.1	Logical Reductions over Entire DataFrame	3
1.1.2	Fixed Regressions	4
1.1.3	Build Changes	4
1.1.4	Bug Fixes	4
1.2	v0.23.1	5
1.2.1	Fixed Regressions	5
1.2.2	Performance Improvements	6
1.2.3	Bug Fixes	6
1.3	v0.23.0 (May 15, 2018)	8
1.3.1	New features	10
1.3.1.1	JSON read/write round-trippable with <code>orient='table'</code>	10
1.3.1.2	<code>.assign()</code> accepts dependent arguments	11
1.3.1.3	Merging on a combination of columns and index levels	12
1.3.1.4	Sorting by a combination of columns and index levels	13
1.3.1.5	Extending Pandas with Custom Types (Experimental)	13
1.3.1.6	New observed keyword for excluding unobserved categories in <code>groupby</code>	14
1.3.1.7	Rolling/Expanding.apply() accepts <code>raw=False</code> to pass a <code>Series</code> to the function	16
1.3.1.8	<code>DataFrame.interpolate</code> has gained the <code>limit_area</code> kwarg	17
1.3.1.9	<code>get_dummies</code> now supports <code>dtype</code> argument	18
1.3.1.10	<code>Timedelta</code> mod method	18
1.3.1.11	<code>.rank()</code> handles <code>inf</code> values when <code>NaN</code> are present	19
1.3.1.12	<code>Series.str.cat</code> has gained the <code>join</code> kwarg	20
1.3.1.13	<code>DataFrame.astype</code> performs column-wise conversion to <code>Categorical</code>	21
1.3.1.14	Other Enhancements	21
1.3.2	Backwards incompatible API changes	23
1.3.2.1	Dependencies have increased minimum versions	23
1.3.2.2	Instantiation from dicts preserves dict insertion order for python 3.6+	24
1.3.2.3	Deprecate Panel	24
1.3.2.4	<code>pandas.core.common</code> removals	25
1.3.2.5	Changes to make output of <code>DataFrame.apply</code> consistent	26
1.3.2.6	Concatenation will no longer sort	28
1.3.2.7	Build Changes	28
1.3.2.8	Index Division By Zero Fills Correctly	28
1.3.2.9	Extraction of matching patterns from strings	29
1.3.2.10	Default value for the <code>ordered</code> parameter of <code>CategoricalDtype</code>	30
1.3.2.11	Better pretty-printing of DataFrames in a terminal	31
1.3.2.12	Datetimelike API Changes	32
1.3.2.13	Other API Changes	33

1.3.3	Deprecations	35
1.3.4	Removal of prior version deprecations/changes	36
1.3.5	Performance Improvements	37
1.3.6	Documentation Changes	38
1.3.7	Bug Fixes	39
1.3.7.1	Categorical	39
1.3.7.2	Datetimelike	39
1.3.7.3	Timedelta	40
1.3.7.4	Timezones	41
1.3.7.5	Offsets	42
1.3.7.6	Numeric	42
1.3.7.7	Strings	42
1.3.7.8	Indexing	42
1.3.7.9	MultiIndex	43
1.3.7.10	I/O	44
1.3.7.11	Plotting	45
1.3.7.12	Groupby/Resample/Rolling	45
1.3.7.13	Sparse	46
1.3.7.14	Reshaping	46
1.3.7.15	Other	47
1.4	v0.22.0 (December 29, 2017)	48
1.4.1	Backwards incompatible API changes	48
1.4.1.1	Arithmetic Operations	48
1.4.1.2	Grouping by a Categorical	49
1.4.1.3	Resample	49
1.4.1.4	Rolling and Expanding	51
1.4.2	Compatibility	51
1.5	v0.21.1 (December 12, 2017)	52
1.5.1	Restore Matplotlib datetime Converter Registration	52
1.5.2	New features	53
1.5.2.1	Improvements to the Parquet IO functionality	53
1.5.2.2	Other Enhancements	53
1.5.3	Deprecations	53
1.5.4	Performance Improvements	53
1.5.5	Bug Fixes	53
1.5.5.1	Conversion	53
1.5.5.2	Indexing	54
1.5.5.3	I/O	54
1.5.5.4	Plotting	54
1.5.5.5	Groupby/Resample/Rolling	54
1.5.5.6	Reshaping	55
1.5.5.7	Numeric	55
1.5.5.8	Categorical	55
1.5.5.9	String	55
1.6	v0.21.0 (October 27, 2017)	55
1.6.1	New features	57
1.6.1.1	Integration with Apache Parquet file format	57
1.6.1.2	infer_objects type conversion	57
1.6.1.3	Improved warnings when attempting to create columns	58
1.6.1.4	drop now also accepts index/columns keywords	58
1.6.1.5	rename, reindex now also accept axis keyword	59
1.6.1.6	CategoricalDtype for specifying categoricals	60
1.6.1.7	GroupBy objects now have a pipe method	61
1.6.1.8	Categorical.rename_categories accepts a dict-like	62

1.6.1.9	Other Enhancements . . . . .	62
1.6.2	Backwards incompatible API changes . . . . .	64
1.6.2.1	Dependencies have increased minimum versions . . . . .	64
1.6.2.2	Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN . . . . .	64
1.6.2.3	Indexing with a list with missing labels is Deprecated . . . . .	65
1.6.2.4	NA naming Changes . . . . .	66
1.6.2.5	Iteration of Series/Index will now return Python scalars . . . . .	66
1.6.2.6	Indexing with a Boolean Index . . . . .	67
1.6.2.7	PeriodIndex resampling . . . . .	68
1.6.2.8	Improved error handling during item assignment in pd.eval . . . . .	69
1.6.2.9	Dtype Conversions . . . . .	70
1.6.2.10	MultiIndex Constructor with a Single Level . . . . .	71
1.6.2.11	UTC Localization with Series . . . . .	71
1.6.2.12	Consistency of Range Functions . . . . .	72
1.6.2.13	No Automatic Matplotlib Converters . . . . .	73
1.6.2.14	Other API Changes . . . . .	73
1.6.3	Deprecations . . . . .	74
1.6.3.1	Series.select and DataFrame.select . . . . .	75
1.6.3.2	Series.argmax and Series.argmin . . . . .	75
1.6.4	Removal of prior version deprecations/changes . . . . .	75
1.6.5	Performance Improvements . . . . .	76
1.6.6	Documentation Changes . . . . .	76
1.6.7	Bug Fixes . . . . .	76
1.6.7.1	Conversion . . . . .	76
1.6.7.2	Indexing . . . . .	77
1.6.7.3	I/O . . . . .	77
1.6.7.4	Plotting . . . . .	78
1.6.7.5	Groupby/Resample/Rolling . . . . .	78
1.6.7.6	Sparse . . . . .	79
1.6.7.7	Reshaping . . . . .	79
1.6.7.8	Numeric . . . . .	80
1.6.7.9	Categorical . . . . .	80
1.6.7.10	PyPy . . . . .	80
1.6.7.11	Other . . . . .	80
1.7	v0.20.3 (July 7, 2017) . . . . .	81
1.7.1	Bug Fixes . . . . .	81
1.7.1.1	Conversion . . . . .	81
1.7.1.2	Indexing . . . . .	81
1.7.1.3	I/O . . . . .	81
1.7.1.4	Plotting . . . . .	82
1.7.1.5	Reshaping . . . . .	82
1.7.1.6	Categorical . . . . .	82
1.8	v0.20.2 (June 4, 2017) . . . . .	82
1.8.1	Enhancements . . . . .	83
1.8.2	Performance Improvements . . . . .	83
1.8.3	Bug Fixes . . . . .	83
1.8.3.1	Conversion . . . . .	83
1.8.3.2	Indexing . . . . .	84
1.8.3.3	I/O . . . . .	84
1.8.3.4	Plotting . . . . .	84
1.8.3.5	Groupby/Resample/Rolling . . . . .	84
1.8.3.6	Sparse . . . . .	84
1.8.3.7	Reshaping . . . . .	85
1.8.3.8	Numeric . . . . .	85

	1.8.3.9	Categorical . . . . .	85
	1.8.3.10	Other . . . . .	85
1.9	v0.20.1 (May 5, 2017)	. . . . .	85
	1.9.1	New features . . . . .	87
	1.9.1.1	agg API for DataFrame/Series . . . . .	87
	1.9.1.2	dtype keyword for data IO . . . . .	89
	1.9.1.3	.to_datetime() has gained an origin parameter . . . . .	90
	1.9.1.4	Groupby Enhancements . . . . .	90
	1.9.1.5	Better support for compressed URLs in read_csv . . . . .	91
	1.9.1.6	Pickle file I/O now supports compression . . . . .	91
	1.9.1.7	UInt64 Support Improved . . . . .	92
	1.9.1.8	GroupBy on Categoricals . . . . .	93
	1.9.1.9	Table Schema Output . . . . .	94
	1.9.1.10	SciPy sparse matrix from/to SparseDataFrame . . . . .	94
	1.9.1.11	Excel output for styled DataFrames . . . . .	95
	1.9.1.12	IntervalIndex . . . . .	96
	1.9.1.13	Other Enhancements . . . . .	98
	1.9.2	Backwards incompatible API changes . . . . .	100
	1.9.2.1	Possible incompatibility for HDF5 formats created with pandas < 0.13.0 . . . . .	100
	1.9.2.2	Map on Index types now return other Index types . . . . .	101
	1.9.2.3	Accessing datetime fields of Index now return Index . . . . .	102
	1.9.2.4	pd.unique will now be consistent with extension types . . . . .	102
	1.9.2.5	S3 File Handling . . . . .	104
	1.9.2.6	Partial String Indexing Changes . . . . .	104
	1.9.2.7	Concat of different float dtypes will not automatically upcast . . . . .	105
	1.9.2.8	Pandas Google BigQuery support has moved . . . . .	105
	1.9.2.9	Memory Usage for Index is more Accurate . . . . .	105
	1.9.2.10	DataFrame.sort_index changes . . . . .	106
	1.9.2.11	Groupby Describe Formatting . . . . .	108
	1.9.2.12	Window Binary Corr/Cov operations return a MultiIndex DataFrame . . . . .	109
	1.9.2.13	HDFStore where string comparison . . . . .	110
	1.9.2.14	Index.intersection and inner join now preserve the order of the left Index . . . . .	110
	1.9.2.15	Pivot Table always returns a DataFrame . . . . .	111
	1.9.2.16	Other API Changes . . . . .	112
	1.9.3	Reorganization of the library: Privacy Changes . . . . .	113
	1.9.3.1	Modules Privacy Has Changed . . . . .	113
	1.9.3.2	pandas.errors . . . . .	114
	1.9.3.3	pandas.testing . . . . .	115
	1.9.3.4	pandas.plotting . . . . .	115
	1.9.3.5	Other Development Changes . . . . .	115
	1.9.4	Deprecations . . . . .	115
	1.9.4.1	Deprecate .ix . . . . .	115
	1.9.4.2	Deprecate Panel . . . . .	116
	1.9.4.3	Deprecate groupby.agg() with a dictionary when renaming . . . . .	117
	1.9.4.4	Deprecate .plotting . . . . .	119
	1.9.4.5	Other Deprecations . . . . .	119
	1.9.5	Removal of prior version deprecations/changes . . . . .	120
	1.9.6	Performance Improvements . . . . .	121
	1.9.7	Bug Fixes . . . . .	121
	1.9.7.1	Conversion . . . . .	121
	1.9.7.2	Indexing . . . . .	122
	1.9.7.3	I/O . . . . .	123
	1.9.7.4	Plotting . . . . .	124
	1.9.7.5	Groupby/Resample/Rolling . . . . .	125

	1.9.7.6	Sparse	125
	1.9.7.7	Reshaping	125
	1.9.7.8	Numeric	126
	1.9.7.9	Other	126
1.10	v0.19.2	(December 24, 2016)	126
	1.10.1	Enhancements	127
	1.10.2	Performance Improvements	127
	1.10.3	Bug Fixes	127
1.11	v0.19.1	(November 3, 2016)	128
	1.11.1	Performance Improvements	129
	1.11.2	Bug Fixes	129
1.12	v0.19.0	(October 2, 2016)	130
	1.12.1	New features	132
	1.12.1.1	<code>merge_asof</code> for asof-style time-series joining	132
	1.12.1.2	<code>.rolling()</code> is now time-series aware	134
	1.12.1.3	<code>read_csv</code> has improved support for duplicate column names	136
	1.12.1.4	<code>read_csv</code> supports parsing <code>Categorical</code> directly	137
	1.12.1.5	Categorical Concatenation	138
	1.12.1.6	Semi-Month Offsets	139
	1.12.1.7	New Index methods	139
	1.12.1.8	Google BigQuery Enhancements	140
	1.12.1.9	Fine-grained numpy errstate	141
	1.12.1.10	<code>get_dummies</code> now returns integer dtypes	141
	1.12.1.11	Downcast values to smallest possible dtype in <code>to_numeric</code>	141
	1.12.1.12	pandas development API	142
	1.12.1.13	Other enhancements	143
	1.12.2	API changes	145
	1.12.2.1	<code>Series.tolist()</code> will now return Python types	145
	1.12.2.2	<code>Series</code> operators for different indexes	146
	1.12.2.3	<code>Series</code> type promotion on assignment	149
	1.12.2.4	<code>.to_datetime()</code> changes	150
	1.12.2.5	Merging changes	150
	1.12.2.6	<code>.describe()</code> changes	151
	1.12.2.7	Period changes	153
	1.12.2.8	Index <code>+</code> / <code>-</code> no longer used for set operations	154
	1.12.2.9	Index <code>.difference</code> and <code>.symmetric_difference</code> changes	155
	1.12.2.10	Index <code>.unique</code> consistently returns Index	156
	1.12.2.11	MultiIndex constructors, <code>groupby</code> and <code>set_index</code> preserve categorical dtypes	156
	1.12.2.12	<code>read_csv</code> will progressively enumerate chunks	158
	1.12.2.13	Sparse Changes	158
	1.12.2.14	Indexer dtype changes	161
	1.12.2.15	Other API Changes	162
	1.12.3	Deprecations	163
	1.12.4	Removal of prior version deprecations/changes	163
	1.12.5	Performance Improvements	164
	1.12.6	Bug Fixes	165
1.13	v0.18.1	(May 3, 2016)	170
	1.13.1	New features	171
	1.13.1.1	Custom Business Hour	171
	1.13.1.2	<code>.groupby(...)</code> syntax with window and resample operations	172
	1.13.1.3	Method chaining improvements	174
	1.13.1.4	Partial string indexing on <code>DateTimeIndex</code> when part of a <code>MultiIndex</code>	176
	1.13.1.5	Assembling Datetimes	177
	1.13.1.6	Other Enhancements	178

1.13.2	Sparse changes	179
1.13.3	API changes	180
1.13.3.1	<code>.groupby(...).nth()</code> changes	180
1.13.3.2	numpy function compatibility	182
1.13.3.3	Using <code>.apply</code> on groupby resampling	182
1.13.3.4	Changes in <code>read_csv</code> exceptions	183
1.13.3.5	<code>to_datetime</code> error changes	184
1.13.3.6	Other API changes	185
1.13.3.7	Deprecations	185
1.13.4	Performance Improvements	185
1.13.5	Bug Fixes	186
1.14	v0.18.0 (March 13, 2016)	188
1.14.1	New features	190
1.14.1.1	Window functions are now methods	190
1.14.1.2	Changes to <code>rename</code>	192
1.14.1.3	Range Index	192
1.14.1.4	Changes to <code>str.extract</code>	193
1.14.1.5	Addition of <code>str.extractall</code>	194
1.14.1.6	Changes to <code>str.cat</code>	195
1.14.1.7	Datetimelike rounding	195
1.14.1.8	Formatting of Integers in <code>FloatIndex</code>	197
1.14.1.9	Changes to dtype assignment behaviors	198
1.14.1.10	<code>to_xarray</code>	199
1.14.1.11	Latex Representation	200
1.14.1.12	<code>pd.read_sas()</code> changes	200
1.14.1.13	Other enhancements	200
1.14.2	Backwards incompatible API changes	201
1.14.2.1	NaT and Timedelta operations	201
1.14.2.2	Changes to <code>msgpack</code>	202
1.14.2.3	Signature change for <code>.rank</code>	203
1.14.2.4	Bug in <code>QuarterBegin</code> with <code>n=0</code>	204
1.14.2.5	Resample API	204
1.14.2.6	Changes to <code>eval</code>	209
1.14.2.7	Other API Changes	211
1.14.2.8	Deprecations	212
1.14.2.9	Removal of deprecated float indexers	212
1.14.2.10	Removal of prior version deprecations/changes	215
1.14.3	Performance Improvements	215
1.14.4	Bug Fixes	215
1.15	v0.17.1 (November 21, 2015)	218
1.15.1	New features	219
1.15.1.1	Conditional HTML Formatting	219
1.15.2	Enhancements	219
1.15.3	API changes	221
1.15.3.1	Deprecations	221
1.15.4	Performance Improvements	221
1.15.5	Bug Fixes	222
1.16	v0.17.0 (October 9, 2015)	223
1.16.1	New features	225
1.16.1.1	Datetime with TZ	225
1.16.1.2	Releasing the GIL	227
1.16.1.3	Plot submethods	227
1.16.1.4	Additional methods for <code>dt</code> accessor	228
1.16.1.5	Period Frequency Enhancement	230

1.16.1.6	Support for SAS XPORT files . . . . .	230
1.16.1.7	Support for Math Functions in <code>.eval()</code> . . . . .	231
1.16.1.8	Changes to Excel with <code>MultiIndex</code> . . . . .	231
1.16.1.9	Google BigQuery Enhancements . . . . .	232
1.16.1.10	Display Alignment with Unicode East Asian Width . . . . .	233
1.16.1.11	Other enhancements . . . . .	233
1.16.2	Backwards incompatible API changes . . . . .	237
1.16.2.1	Changes to sorting API . . . . .	237
1.16.2.2	Changes to <code>to_datetime</code> and <code>to_timedelta</code> . . . . .	238
1.16.2.3	Changes to Index Comparisons . . . . .	239
1.16.2.4	Changes to Boolean Comparisons vs. <code>None</code> . . . . .	240
1.16.2.5	HDFStore dropna behavior . . . . .	241
1.16.2.6	Changes to <code>display.precision</code> option . . . . .	242
1.16.2.7	Changes to <code>Categorical.unique</code> . . . . .	242
1.16.2.8	Changes to <code>bool</code> passed as header in Parsers . . . . .	243
1.16.2.9	Other API Changes . . . . .	243
1.16.2.10	Deprecations . . . . .	244
1.16.2.11	Removal of prior version deprecations/changes . . . . .	245
1.16.3	Performance Improvements . . . . .	246
1.16.4	Bug Fixes . . . . .	247
1.17	v0.16.2 (June 12, 2015) . . . . .	250
1.17.1	New features . . . . .	251
1.17.1.1	Pipe . . . . .	251
1.17.1.2	Other Enhancements . . . . .	252
1.17.2	API Changes . . . . .	252
1.17.3	Performance Improvements . . . . .	252
1.17.4	Bug Fixes . . . . .	253
1.18	v0.16.1 (May 11, 2015) . . . . .	254
1.18.1	Enhancements . . . . .	255
1.18.1.1	<code>CategoricalIndex</code> . . . . .	255
1.18.1.2	<code>Sample</code> . . . . .	257
1.18.1.3	String Methods Enhancements . . . . .	258
1.18.1.4	Other Enhancements . . . . .	259
1.18.2	API changes . . . . .	261
1.18.2.1	Deprecations . . . . .	261
1.18.3	Index Representation . . . . .	261
1.18.4	Performance Improvements . . . . .	263
1.18.5	Bug Fixes . . . . .	263
1.19	v0.16.0 (March 22, 2015) . . . . .	265
1.19.1	New features . . . . .	266
1.19.1.1	<code>DataFrame</code> Assign . . . . .	266
1.19.1.2	Interaction with <code>scipy.sparse</code> . . . . .	267
1.19.1.3	String Methods Enhancements . . . . .	269
1.19.1.4	Other enhancements . . . . .	270
1.19.2	Backwards incompatible API changes . . . . .	271
1.19.2.1	Changes in <code>Timedelta</code> . . . . .	271
1.19.2.2	Indexing Changes . . . . .	272
1.19.2.3	Categorical Changes . . . . .	274

	1.28.8 Enhancements . . . . .	405
1.29	v0.10.1 (January 22, 2013) . . . . .	407
	1.29.1 API changes . . . . .	407
	1.29.2 New features . . . . .	408
	1.29.3 HDFStore . . . . .	408
1.30	v0.10.0 (December 17, 2012) . . . . .	413
	1.30.1 File parsing new features . . . . .	413
	1.30.2 API changes . . . . .	414
	1.30.3 New features . . . . .	419
	1.30.4 Wide DataFrame Printing . . . . .	419
	1.30.5 Updated PyTables Support . . . . .	421
	1.30.6 N Dimensional Panels (Experimental) . . . . .	424
1.31	v0.9.1 (November 14, 2012) . . . . .	425
	1.31.1 New features . . . . .	425
	1.31.2 API changes . . . . .	428
1.32	v0.9.0 (October 7, 2012) . . . . .	429
	1.32.1 New features . . . . .	429
	1.32.2 API changes . . . . .	430
1.33	v0.8.1 (July 22, 2012) . . . . .	431
	1.33.1 New features . . . . .	431
	1.33.2 Performance improvements . . . . .	431
1.34	v0.8.0 (June 29, 2012) . . . . .	431
	1.34.1 Support for non-unique indexes . . . . .	432
	1.34.2 NumPy datetime64 dtype and 1.6 dependency . . . . .	432
	1.34.3 Time series changes and improvements . . . . .	432
	1.34.4 Other new features . . . . .	433
	1.34.5 New plotting methods . . . . .	434

1.34.6	Other API changes	434
1.34.7	Potential porting issues for pandas <= 0.7.3 users	434
1.35	v.0.7.3 (April 12, 2012)	436
1.35.1	New features	437
1.35.2	NA Boolean Comparison API Change	438
1.35.3	Other API Changes	439
1.36	v.0.7.2 (March 16, 2012)	440
1.36.1	New features	440
1.36.2	Performance improvements	440
1.37	v.0.7.1 (February 29, 2012)	440
1.37.1	New features	441
1.37.2	Performance improvements	441
1.38	v.0.7.0 (February 9, 2012)	441
1.38.1	New features	441
1.38.2	API Changes to integer indexing	442
1.38.3	API tweaks regarding label-based slicing	444
1.38.4	Changes to Series [ ] operator	445
1.38.5	Other API Changes	446
1.38.6	Performance improvements	446
1.39	v.0.6.1 (December 13, 2011)	447
1.39.1	New features	447
1.39.2	Performance improvements	447
1.40	v.0.6.0 (November 25, 2011)	447
1.40.1	New Features	447
1.40.2	Performance Enhancements	449
1.41	v.0.5.0 (October 24, 2011)	449
1.41.1	New Features	449
1.41.2	Performance Enhancements	450
1.42	v.0.4.3 through v0.4.1 (September 25 - October 9, 2011)	450
1.42.1	New Features	450
1.42.2	Performance Enhancements	451
<b>2</b>	<b>Installation</b>	<b>453</b>
2.1	Plan for dropping Python 2.7	453
2.2	Python version support	453
2.3	Installing pandas	453
2.3.1	Installing with Anaconda	453
2.3.2	Installing with Miniconda	454
2.3.3	Installing from PyPI	455
2.3.4	Installing with ActivePython	455
2.3.5	Installing using your Linux distribution's package manager.	455
2.3.6	Installing from source	455
2.4	Running the test suite	455
2.5	Dependencies	456
2.5.1	Recommended Dependencies	456
2.5.2	Optional Dependencies	456
<b>3</b>	<b>Contributing to pandas</b>	<b>459</b>

<b>8</b>	<b>Intro to Data Structures</b>	<b>559</b>
8.1	Series . . . . .	559
8.1.1	Series is ndarray-like . . . . .	561
8.1.2	Series is dict-like . . . . .	562
8.1.3	Vectorized operations and label alignment with Series . . . . .	563
8.1.4	Name attribute . . . . .	564
8.2	DataFrame . . . . .	564
8.2.1	From dict of Series or dicts . . . . .	565
8.2.2	From dict of ndarrays / lists . . . . .	566
8.2.3	From structured or record array . . . . .	566
8.2.4	From a list of dicts . . . . .	567
8.2.5	From a dict of tuples . . . . .	567
8.2.6	From a Series . . . . .	567
8.2.7	Alternate Constructors . . . . .	567
8.2.8	Column selection, addition, deletion . . . . .	568
8.2.9	Assigning New Columns in Method Chains . . . . .	570
8.2.10	Indexing / Selection . . . . .	572
8.2.11	Data alignment and arithmetic . . . . .	573
8.2.12	Transposing . . . . .	576
8.2.13	DataFrame interoperability with NumPy functions . . . . .	576
8.2.14	Console display . . . . .	577
8.2.15	DataFrame column attribute access and IPython completion . . . . .	580
8.3	Panel . . . . .	580
8.3.1	From 3D ndarray with optional axis labels . . . . .	581
8.3.2	From dict of DataFrame objects . . . . .	581
8.3.3	From DataFrame using to_panel method . . . . .	582
8.3.4	Item selection / addition / deletion . . . . .	583
8.3.5	Transposing . . . . .	583
8.3.6	Indexing / Selection . . . . .	583
8.3.7	Squeezing . . . . .	584
8.3.8	Conversion to DataFrame . . . . .	584
8.4	Deprecate Panel . . . . .	585
<b>9</b>	<b>Essential Basic Functionality</b>	<b>589</b>
9.1	Head and Tail . . . . .	589

9.2	Attributes and the raw ndarray(s)	590
9.3	Accelerated operations	591
9.4	Flexible binary operations	591
9.4.1	Matching / broadcasting behavior	592
9.4.2	Missing data / operations with fill values	595
9.4.3	Flexible Comparisons	596
9.4.4	Boolean Reductions	596
9.4.5	Comparing if objects are equivalent	598
9.4.6	Comparing array-like objects	598
9.4.7	Combining overlapping data sets	599
9.4.8	General DataFrame Combine	600
9.5	Descriptive statistics	601
9.5.1	Summarizing data: describe	603
9.5.2	Index of Min/Max Values	606
9.5.3	Value counts (histogramming) / Mode	607
9.5.4	Discretization and quantiling	608
9.6	Function application	609
9.6.1	Tablewise Function Application	609
9.6.2	Row or Column-wise Function Application	611
9.6.3	Aggregation API	613
9.6.3.1	Aggregating with multiple functions	614
9.6.3.2	Aggregating with a dict	615
9.6.3.3	Mixed Dtypes	615
9.6.3.4	Custom describe	616
9.6.4	Transform API	616
9.6.4.1	Transform with multiple functions	618
9.6.4.2	Transforming with a dict	619
9.6.5	Applying Elementwise Functions	619
9.6.6	Applying with a Panel	621
9.7	Reindexing and altering labels	623
9.7.1	Reindexing to align with another object	625
9.7.2	Aligning objects with each other with <code>align</code>	626
9.7.3	Filling while reindexing	628
9.7.4	Limits on filling while reindexing	629
9.7.5	Dropping labels from an axis	630
9.7.6	Renaming / mapping labels	631
9.8	Iteration	632
9.8.1	<code>iteritems</code>	633
9.8.2	<code>iterrows</code>	634
9.8.3	<code>itertuples</code>	635
9.9	<code>.dt</code> accessor	636
9.10	Vectorized string methods	639
9.11	Sorting	640
9.11.1	By Index	640
9.11.2	By Values	641
9.11.3	By Indexes and Values	642
9.11.4	<code>searchsorted</code>	643
9.11.5	<code>smallest / largest values</code>	643
9.11.6	Sorting by a multi-index column	645
9.12	Copying	645
9.13	<code>dtypes</code>	645
9.13.1	<code>defaults</code>	648
9.13.2	<code>upcasting</code>	648
9.13.3	<code>astype</code>	649

9.13.4	object conversion . . . . .	651
9.13.5	gotchas . . . . .	654
9.14	Selecting columns based on dtype . . . . .	655
<b>10</b>	<b>Working with Text Data</b>	<b>659</b>
10.1	Splitting and Replacing Strings . . . . .	661
10.2	Concatenation . . . . .	664
10.2.1	Concatenating a single Series into a string . . . . .	664

**pandas** is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, **real world** data analysis in Python. Additionally, it has the broader goal of becoming **the most powerful and flexible open source data analysis / manipulation tool available in any language**. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, *Series* (1-dimensional) and *DataFrame* (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, *DataFrame* provides everything that R’s `data.frame` provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of **missing data** (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be **inserted and deleted** from DataFrame and higher dimensional objects
- Automatic and explicit **data alignment**: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let *Series*, *DataFrame*, etc. automatically align the data for you in computations
- Powerful, flexible **group by** functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it **easy to convert** ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based **slicing, fancy indexing**, and **subsetting** of large data sets
- Intuitive **merging** and **joining** data sets
- Flexible **reshaping** and pivoting of data sets
- **Hierarchical** labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from **flat files** (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast **HDF5 format**
- **Time series**-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.

Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is **fast**. Many of the low-level algorithmic bits have been extensively tweaked in [Cython](#) code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.
- pandas is a dependency of [statsmodels](#), making it an important part of the statistical computing ecosystem in Python.
- pandas has been used extensively in production in financial applications.

---

**Note:** This documentation assumes general familiarity with NumPy. If you haven't used NumPy much or at all, do invest some time in [learning about NumPy](#) first.

---

See the package overview for more detail about what's in the library.

## WHAT'S NEW

These are new features and improvements of note in each release.

### 1.1 v0.23.2

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

---

**Note:** Pandas 0.23.2 is first pandas release that's compatible with Python 3.7 ([GH20552](#))

---

#### What's new in v0.23.2

- *Logical Reductions over Entire DataFrame*
- *Fixed Regressions*
- *Build Changes*
- *Bug Fixes*

#### 1.1.1 Logical Reductions over Entire DataFrame

`DataFrame.all()` and `DataFrame.any()` now accept `axis=None` to reduce over all axes to a scalar ([GH19976](#))

```
In [1]: df = pd.DataFrame({"A": [1, 2], "B": [True, False]})
In [2]: df.all(axis=None)
Out[2]: False
```

This also provides compatibility with NumPy 1.15, which now dispatches to `DataFrame.all`. With NumPy 1.15 and pandas 0.23.1 or earlier, `numpy.all()` will no longer reduce over every axis:

```
>>> # NumPy 1.15, pandas 0.23.1
>>> np.any(pd.DataFrame({"A": [False], "B": [False]}))
A    False
B    False
dtype: bool
```

With pandas 0.23.2, that will correctly return False, as it did with NumPy < 1.15.

```
In [3]: np.any(pd.DataFrame({"A": [False], "B": [False]}))
Out[3]: False
```

### 1.1.2 Fixed Regressions

- Fixed regression in `to_csv()` when handling file-like object incorrectly (GH21471)
- Re-allowed duplicate level names of a `MultiIndex`. Accessing a level that has a duplicate name by name still raises an error (GH19029).
- Bug in both `DataFrame.first_valid_index()` and `Series.first_valid_index()` raised for a row index having duplicate values (GH21441)
- Fixed printing of DataFrames with hierarchical columns with long names (GH21180)
- Fixed regression in `reindex()` and `groupby()` with a `MultiIndex` or multiple keys that contains categorical datetime-like values (GH21390).
- Fixed regression in unary negative operations with object dtype (GH21380)
- Bug in `Timestamp.ceil()` and `Timestamp.floor()` when timestamp is a multiple of the rounding frequency (GH21262)
- Fixed regression in `to_clipboard()` that defaulted to copying dataframes with space delimited instead of tab delimited (GH21104)

### 1.1.3 Build Changes

- The source and binary distributions no longer include test data files, resulting in smaller download sizes. Tests relying on these data files will be skipped when using `pandas.test()`. (GH19320)

### 1.1.4 Bug Fixes

#### Conversion

- Bug in constructing `Index` with an iterator or generator (GH21470)
- Bug in `Series.nlargest()` for signed and unsigned integer dtypes when the minimum value is present (GH21426)

#### Indexing

- Bug in `Index.get_indexer_non_unique()` with categorical key (GH21448)
- Bug in comparison operations for `MultiIndex` where error was raised on equality / inequality comparison involving a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `DataFrame.drop()` behaviour is not consistent for unique and non-unique indexes (GH21494)
- Bug in `DataFrame.duplicated()` with a large number of columns causing a ‘maximum recursion depth exceeded’ (GH21524).

#### I/O

- Bug in `read_csv()` that caused it to incorrectly raise an error when `nrows=0`, `low_memory=True`, and `index_col` was not None (GH21141)
- Bug in `json_normalize()` when formatting the `record_prefix` with integer columns (GH21536)

### Categorical

- Bug in rendering *Series* with Categorical dtype in rare conditions under Python 2.7 (GH21002)

### Timezones

- Bug in *Timestamp* and *DatetimeIndex* where passing a *Timestamp* localized after a DST transition would return a datetime before the DST transition (GH20854)
- Bug in comparing *DataFrame*'s with tz-aware `:class:`DatetimeIndex` columns with a DST transition that raised a *KeyError* (GH19970)

### Timedelta

- Bug in *Timedelta* where non-zero timedeltas shorter than 1 microsecond were considered False (GH21484)

## 1.2 v0.23.1

This is a minor bug-fix release in the 0.23.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

### What's new in v0.23.1

- *Fixed Regressions*
- *Performance Improvements*
- *Bug Fixes*

### 1.2.1 Fixed Regressions

#### Comparing Series with `datetime.date`

We've reverted a 0.23.0 change to comparing a *Series* holding datetimes and a `datetime.date` object (GH21152). In pandas 0.22 and earlier, comparing a *Series* holding datetimes and `datetime.date` objects would coerce the `datetime.date` to a `datetime` before comparing. This was inconsistent with Python, NumPy, and *DatetimeIndex*, which never consider a `datetime` and `datetime.date` equal.

In 0.23.0, we unified operations between *DatetimeIndex* and *Series*, and in the process changed comparisons between a *Series* of datetimes and `datetime.date` without warning.

We've temporarily restored the 0.22.0 behavior, so datetimes and dates may again compare equal, but restore the 0.23.0 behavior in a future release.

To summarize, here's the behavior in 0.22.0, 0.23.0, 0.23.1:

```
# 0.22.0... Silently coerce the datetime.date
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0      True
1     False
dtype: bool

# 0.23.0... Do not coerce the datetime.date
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
0     False
1     False
```

(continues on next page)

(continued from previous page)

```

dtype: bool

# 0.23.1... Coerce the datetime.date with a warning
>>> Series(pd.date_range('2017', periods=2)) == datetime.date(2017, 1, 1)
/bin/python:1: FutureWarning: Comparing Series of datetimes with 'datetime.date'.
↳Currently, the
'datetime.date' is coerced to a datetime. In the future pandas will
not coerce, and the values not compare equal to the 'datetime.date'.
To retain the current behavior, convert the 'datetime.date' to a
datetime with 'pd.Timestamp'.
  #!/bin/python3
0      True
1     False
dtype: bool

```

In addition, ordering comparisons will raise a `TypeError` in the future.

### Other Fixes

- Reverted the ability of `to_sql()` to perform multivalue inserts as this caused regression in certain cases (GH21103). In the future this will be made configurable.
- Fixed regression in the `DatetimeIndex.date` and `DatetimeIndex.time` attributes in case of timezone-aware data: `DatetimeIndex.time` returned a tz-aware time instead of tz-naive (GH21267) and `DatetimeIndex.date` returned incorrect date when the input date has a non-UTC timezone (GH21230).
- Fixed regression in `pandas.io.json.json_normalize()` when called with `None` values in nested levels in JSON, and to not drop keys with value as `None` (GH21158, GH21356).
- Bug in `to_csv()` causes encoding error when compression and encoding are specified (GH21241, GH21118)
- Bug preventing pandas from being importable with -OO optimization (GH21071)
- Bug in `Categorical.fillna()` incorrectly raising a `TypeError` when `value` the individual categories are iterable and `value` is an iterable (GH21097, GH19788)
- Fixed regression in constructors coercing NA values like `None` to strings when passing `dtype=str` (GH21083)
- Regression in `pivot_table()` where an ordered `Categorical` with missing values for the pivot's index would give a mis-aligned result (GH21133)
- Fixed regression in merging on boolean index/columns (GH21119).

## 1.2.2 Performance Improvements

- Improved performance of `CategoricalIndex.is_monotonic_increasing()`, `CategoricalIndex.is_monotonic_decreasing()` and `CategoricalIndex.is_monotonic()` (GH21025)
- Improved performance of `CategoricalIndex.is_unique()` (GH21107)

## 1.2.3 Bug Fixes

### Groupby/Resample/Rolling

- Bug in `DataFrame.agg()` where applying multiple aggregation functions to a `DataFrame` with duplicated column names would cause a stack overflow (GH21063)

- Bug in `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` where the fill within a grouping would not always be applied as intended due to the implementations' use of a non-stable sort (GH21207)
- Bug in `pandas.core.groupby.GroupBy.rank()` where results did not scale to 100% when specifying `method='dense'` and `pct=True`
- Bug in `pandas.DataFrame.rolling()` and `pandas.Series.rolling()` which incorrectly accepted a 0 window size rather than raising (GH21286)

### Data-type specific

- Bug in `Series.str.replace()` where the method throws `TypeError` on Python 3.5.2 (GH21078)
- Bug in `Timedelta`: where passing a float with a unit would prematurely round the float precision (GH14156)
- Bug in `pandas.testing.assert_index_equal()` which raised `AssertionError` incorrectly, when comparing two `CategoricalIndex` objects with param `check_categorical=False` (GH19776)

### Sparse

- Bug in `SparseArray.shape` which previously only returned the shape `SparseArray.sp_values` (GH21126)

### Indexing

- Bug in `Series.reset_index()` where appropriate error was not raised with an invalid level name (GH20925)
- Bug in `interval_range()` when start/periods or end/periods are specified with float start or end (GH21161)
- Bug in `MultiIndex.set_names()` where error raised for a `MultiIndex` with `nlevels == 1` (GH21149)
- Bug in `IntervalIndex` constructors where creating an `IntervalIndex` from categorical data was not fully supported (GH21243, GH21253)
- Bug in `MultiIndex.sort_index()` which was not guaranteed to sort correctly with `level=1`; this was also causing data misalignment in particular `DataFrame.stack()` operations (GH20994, GH20945, GH21052)

### Plotting

- New keywords (`sharex`, `sharey`) to turn on/off sharing of x/y-axis by subplots generated with `pandas.DataFrame().groupby().boxplot()` (GH20968)

### I/O

- Bug in IO methods specifying `compression='zip'` which produced uncompressed zip archives (GH17778, GH21144)
- Bug in `DataFrame.to_stata()` which prevented exporting DataFrames to buffers and most file-like objects (GH21041)
- Bug in `read_stata()` and `StataReader` which did not correctly decode utf-8 strings on Python 3 from Stata 14 files (dta version 118) (GH21244)
- Bug in IO JSON `read_json()` reading empty JSON schema with `orient='table'` back to `DataFrame` caused an error (GH21287)

### Reshaping

- Bug in `concat()` where error was raised in concatenating *Series* with numpy scalar and tuple names (GH21015)
- Bug in `concat()` warning message providing the wrong guidance for future behavior (GH21101)

#### Other

- Tab completion on *Index* in IPython no longer outputs deprecation warnings (GH21125)
- Bug preventing pandas being used on Windows without C++ redistributable installed (GH21106)

## 1.3 v0.23.0 (May 15, 2018)

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- *Round-trippable JSON format with 'table' orient.*
- *Instantiation from dicts respects order for Python 3.6+.*
- *Dependent column arguments for assign.*
- *Merging / sorting on a combination of columns and index levels.*
- *Extending Pandas with custom types.*
- *Excluding unobserved categories from groupby.*
- *Changes to make output shape of DataFrame.apply consistent.*

Check the *API Changes* and *deprecations* before updating.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See *Plan for dropping Python 2.7* for more.

#### What's new in v0.23.0

- *New features*
  - *JSON read/write round-trippable with `orient='table'`*
  - *`.assign()` accepts dependent arguments*
  - *Merging on a combination of columns and index levels*
  - *Sorting by a combination of columns and index levels*
  - *Extending Pandas with Custom Types (Experimental)*
  - *New `observed` keyword for excluding unobserved categories in `groupby`*
  - *`Rolling/Expanding.apply()` accepts `raw=False` to pass a *Series* to the function*
  - *`DataFrame.interpolate` has gained the `limit_area` kwarg*
  - *`get_dummies` now supports `dtype` argument*
  - *`Timedelta` mod method*

- `.rank()` handles `inf` values when `NaN` are present
- `Series.str.cat` has gained the `join` kwarg
- `DataFrame.astype` performs column-wise conversion to `Categorical`
- Other Enhancements
- Backwards incompatible API changes
  - Dependencies have increased minimum versions
  - Instantiation from dicts preserves dict insertion order for python 3.6+
  - Deprecate `Panel`
  - `pandas.core.common` removals
  - Changes to make output of `DataFrame.apply` consistent
  - Concatenation will no longer sort
  - Build Changes
  - Index Division By Zero Fills Correctly
  - Extraction of matching patterns from strings
  - Default value for the `ordered` parameter of `CategoricalDtype`
  - Better pretty-printing of `DataFrames` in a terminal
  - Datetimelike API Changes
  - Other API Changes
- Deprecations
- Removal of prior version deprecations/changes
- Performance Improvements
- Documentation Changes
- Bug Fixes
  - `Categorical`
  - `Datetimelike`
  - `Timedelta`
  - `Timezones`
  - `Offsets`
  - `Numeric`
  - `Strings`
  - `Indexing`
  - `MultiIndex`
  - `I/O`
  - `Plotting`
  - `Groupby/Resample/Rolling`

- *Sparse*
- *Reshaping*
- *Other*

## 1.3.1 New features

### 1.3.1.1 JSON read/write round-trippable with `orient='table'`

A `DataFrame` can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see [GH18912](#) and [GH9146](#)). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.

```
In [1]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
...:                      'bar': ['a', 'b', 'c', 'd'],
...:                      'baz': pd.date_range('2018-01-01', freq='d', periods=4),
...:                      'qux': pd.Categorical(['a', 'b', 'c', 'c'])
...:                      }, index=pd.Index(range(4), name='idx'))

In [2]: df
Out[2]:
```

	foo	bar	baz	qux
idx				
0	1	a	2018-01-01	a
1	2	b	2018-01-02	b
2	3	c	2018-01-03	c
3	4	d	2018-01-04	c

```
In [3]: df.dtypes
//////////
foo          int64
bar          object
baz    datetime64[ns]
qux          category
dtype: object

In [4]: df.to_json('test.json', orient='table')

In [5]: new_df = pd.read_json('test.json', orient='table')

In [6]: new_df
Out[6]:
```

	foo	bar	baz	qux
idx				
0	1	a	2018-01-01	a
1	2	b	2018-01-02	b
2	3	c	2018-01-03	c
3	4	d	2018-01-04	c

```
In [7]: new_df.dtypes
//////////
foo          int64
```

(continues on next page)

**Warning:** This may subtly change the behavior of your code when you're using `.assign()` to update an existing column. Previously, callables referring to other variables being updated would get the “old” values

Previous Behavior:

```
In [2]: df = pd.DataFrame({"A": [1, 2, 3]})

In [3]: df.assign(A=lambda df: df.A + 1, C=lambda df: df.A * -1)
Out[3]:
```

	A	C
0	2	-1
1	3	-2
2	4	-3

New Behavior:

```
In [16]: df.assign(A=df.A+1, C= lambda df: df.A* -1)
Out[16]:
```

	A	C
0	2	-2
1	3	-3
2	4	-4

### 1.3.1.3 Merging on a combination of columns and index levels

Strings passed to `DataFrame.merge()` as the `on`, `left_on`, and `right_on` parameters may now refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes. See the *Merge on columns and levels* documentation section. (GH14355)

```
In [17]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [18]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                      'B': ['B0', 'B1', 'B2', 'B3'],
.....:                      'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                      index=left_index)
.....:

In [19]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [20]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3'],
.....:                        'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                        index=right_index)
.....:

In [21]: left.merge(right, on=['key1', 'key2'])
Out[21]:
```

	A	B	key2	C	D
key1					
K0	A0	B0	K0	C0	D0
K1	A2	B2	K0	C1	D1
K2	A3	B3	K1	C3	D3

#### 1.3.1.4 Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the `by` parameter may now refer to either column names or index level names. This enables sorting `DataFrame` instances by a combination of index levels and columns without resetting indexes. See the [Sorting by Indexes and Values](#) documentation section. (GH14353)

[illegible]

### 1.3.1.5 Extending Pandas with Custom Types (Experimental)

Pandas now supports storing array-like objects that aren't necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy's types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we'll use `cyberpandas`, which provides an `IPArray` type for storing ip addresses.

```
In [1]: from cyberpandas import IPArray

In [2]: values = IPArray([
...:     0,
...:     3232235777,
...:     42540766452641154071740215577757643572
```

---

(continues on next page)

(continued from previous page)

```
...: ])
```

IPArray isn't a normal 1-D NumPy array, but because it's a pandas `~pandas.api.extension.ExtensionArray`, it can be stored properly inside pandas' containers.

```
In [3]: ser = pd.Series(values)

In [4]: ser
Out[4]:
0          0.0.0.0
1      192.168.1.1
2  2001:db8:85a3::8a2e:370:7334
dtype: ip
```

Notice that the dtype is `ip`. The missing value semantics of the underlying array are respected:

```
In [5]: ser.isna()
Out[5]:
0      True
1     False
2     False
dtype: bool
```

For more, see the [extension types](#) documentation. If you build an extension array, publicize it on our [ecosystem page](#).

### 1.3.1.6 New observed keyword for excluding unobserved categories in groupby

Grouping by a categorical includes the unobserved categories in the output. When grouping by multiple categorical columns, this means you get the cartesian product of all the categories, including combinations where there are no observations, which can result in a large number of groups. We have added a keyword `observed` to control this behavior, it defaults to `observed=False` for backward-compatibility. (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583, GH20902)

```
In [27]: cat1 = pd.Categorical(["a", "a", "b", "b"],
...:                           categories=["a", "b", "z"], ordered=True)
...:
...:

In [28]: cat2 = pd.Categorical(["c", "d", "c", "d"],
...:                           categories=["c", "d", "y"], ordered=True)
...:
...:

In [29]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [30]: df['C'] = ['foo', 'bar'] * 2

In [31]: df
Out[31]:
   A  B  values  C
0  a  c        1  foo
1  a  d        2  bar
2  b  c        3  foo
3  b  d        4  bar
```

To show all values, the previous behavior:

```
In [32]: df.groupby(['A', 'B', 'C'], observed=False).count()
```

```
Out [32]:
```

```
      values
A B C
a c bar    NaN
   foo    1.0
   d bar    1.0
   foo    NaN
   y bar    NaN
   foo    NaN
b c bar    NaN
...      ...
   y foo    NaN
z c bar    NaN
   foo    NaN
   d bar    NaN
   foo    NaN
   y bar    NaN
   foo    NaN
```

```
[18 rows x 1 columns]
```

To show only observed values:

```
In [33]: df.groupby(['A', 'B', 'C'], observed=True).count()
```

```
Out [33]:
```

```
      values
A B C
a c foo     1
   d bar     1
b c foo     1
   d bar     1
```

For pivoting operations, this behavior is *already* controlled by the `dropna` keyword:

```
In [34]: cat1 = pd.Categorical(["a", "a", "b", "b"],
.....:                        categories=["a", "b", "z"], ordered=True)
.....:
```

```
In [35]: cat2 = pd.Categorical(["c", "d", "c", "d"],
.....:                        categories=["c", "d", "y"], ordered=True)
.....:
```

```
In [36]: df = DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})
```

```
In [37]: df
```

```
Out [37]:
```

```
   A B  values
0  a c       1
1  a d       2
2  b c       3
3  b d       4
```

```
In [38]: pd.pivot_table(df, values='values', index=['A', 'B'],
.....:                  dropna=True)
.....:
```

```
Out [38]:
```

(continues on next page)

(continued from previous page)

```

      values
A B
a c      1
  d      2
b c      3
  d      4

In [39]: pd.pivot_table(df, values='values', index=['A', 'B'],
      ....:               dropna=False)
      ....:

\\Out[39]:
↪
      values
A B
a c      1.0
  d      2.0
  y      NaN
b c      3.0
  d      4.0
  y      NaN
z c      NaN
  d      NaN
  y      NaN

```

### 1.3.1.7 Rolling/Expanding.apply() accepts raw=False to pass a Series to the function

`Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have gained a `raw=None` parameter. This is similar to `DataFrame.apply()`. This parameter, if `True` allows one to send a `np.ndarray` to the applied function. If `False` a `Series` will be passed. The default is `None`, which preserves backward compatibility, so this will default to `True`, sending an `np.ndarray`. In a future version the default will be changed to `False`, sending a `Series`. (GH5071, GH20584)

```

In [40]: s = pd.Series(np.arange(5), np.arange(5) + 1)

In [41]: s
Out[41]:
1      0
2      1
3      2
4      3
5      4
dtype: int64

```

Pass a Series:

```

In [42]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
Out[42]:
1      0.0
2      1.0
3      2.0
4      3.0
5      4.0
dtype: float64

```

Mimic the original behavior of passing a ndarray:

```
In [43]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
Out[43]:
1    0.0
2    1.0
3    2.0
4    3.0
5    4.0
dtype: float64
```

### 1.3.1.8 DataFrame.interpolate has gained the limit\_area kwarg

`DataFrame.interpolate()` has gained a `limit_area` parameter to allow further control of which NaNs are replaced. Use `limit_area='inside'` to fill only NaNs surrounded by valid values or use `limit_area='outside'` to fill only NaNs outside the existing valid values while preserving those inside. (GH16284) See the [full documentation here](#).

```
In [44]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.
    ↪ nan])

In [45]: ser
Out[45]:
0    NaN
1    NaN
2    5.0
3    NaN
4    NaN
5    NaN
6   13.0
7    NaN
8    NaN
dtype: float64
```

Fill one consecutive inside value in both directions

```
In [46]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
Out[46]:
0    NaN
1    NaN
2    5.0
3    7.0
4    NaN
5   11.0
6   13.0
7    NaN
8    NaN
dtype: float64
```

Fill all consecutive outside values backward

```
In [47]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[47]:
0    5.0
1    5.0
2    5.0
```

(continues on next page)

(continued from previous page)

```

3      NaN
4      NaN
5      NaN
6     13.0
7      NaN
8      NaN
dtype: float64

```

Fill all consecutive outside values in both directions

```

In [48]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[48]:
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7     13.0
8     13.0
dtype: float64

```

### 1.3.1.9 get\_dummies now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains `uint8`. (GH18330)

```

In [49]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
In [50]: pd.get_dummies(df, columns=['c']).dtypes
Out[50]:
a      int64
b      int64
c_5    uint8
c_6    uint8
dtype: object

In [51]: pd.get_dummies(df, columns=['c'], dtype=bool).dtypes
Out[51]:
a      int64
b      int64
c_5    bool
c_6    bool
dtype: object

```

### 1.3.1.10 Timedelta mod method

`mod (%)` and `divmod` operations are now defined on `Timedelta` objects when operating with either `timedelta`-like or with numeric arguments. See the [documentation here](#). (GH19365)

```

In [52]: td = pd.Timedelta(hours=37)

```

(continues on next page)

(continued from previous page)

```
In [53]: td % pd.Timedelta(minutes=45)
Out [53]: Timedelta('0 days 00:15:00')
```

### 1.3.1.11 .rank() handles inf values when NaN are present

In previous versions, `.rank()` would assign `inf` elements `NaN` as their ranks. Now ranks are calculated properly. (GH6945)

```
In [54]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])
In [55]: s
Out [55]:
0      -inf
1    0.000000
2    1.000000
3         NaN
4         inf
dtype: float64
```

Previous Behavior:

```
In [11]: s.rank()
Out [11]:
0      1.0
1      2.0
2      3.0
3      NaN
4      NaN
dtype: float64
```

Current Behavior:

```
In [56]: s.rank()
Out [56]:
0      1.0
1      2.0
2      3.0
3      NaN
4      4.0
dtype: float64
```

Furthermore, previously if you rank `inf` or `-inf` values together with `NaN` values, the calculation won't distinguish `NaN` from infinity when using 'top' or 'bottom' argument.

```
In [57]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])
In [58]: s
Out [58]:
0      NaN
1      NaN
2     -inf
3     -inf
dtype: float64
```

Previous Behavior:

```
In [15]: s.rank(na_option='top')
Out[15]:
0    2.5
1    2.5
2    2.5
3    2.5
dtype: float64
```

Current Behavior:

```
In [59]: s.rank(na_option='top')
Out[59]:
0    1.5
1    1.5
2    3.5
3    3.5
dtype: float64
```

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations ([GH15630](#))
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending=False` failed to return correct ranks for infinity if NaN were present ([GH19538](#))
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and NaN were present ([GH20561](#))

### 1.3.1.12 `Series.str.cat` has gained the `join` kwarg

Previously, `Series.str.cat()` did not – in contrast to most of pandas – align `Series` on their index before concatenation (see [GH18657](#)). The method has now gained a keyword `join` to control the manner of alignment, see examples below and [here](#).

In v.0.23 `join` will default to `None` (meaning no alignment), but this default will change to `'left'` in a future version of pandas.

```
In [60]: s = pd.Series(['a', 'b', 'c', 'd'])

In [61]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])

In [62]: s.str.cat(t)
Out[62]:
0    ab
1    bd
2    ce
3    dc
dtype: object

In [63]: s.str.cat(t, join='left', na_rep='-')
Out[63]:
0    a-
1    bb
2    cc
3    dd
dtype: object
```

Furthermore, `Series.str.cat()` now works for `CategoricalIndex` as well (previously raised a `ValueError`; see [GH20842](#)).

### 1.3.1.13 DataFrame.astype performs column-wise conversion to Categorical

`DataFrame.astype()` can now perform column-wise conversion to `Categorical` by supplying the string `'category'` or a `CategoricalDtype`. Previously, attempting this would raise a `NotImplementedError`. See the *Object Creation* section of the documentation for more details and examples. ([GH12860](#), [GH18099](#))

Supplying the string `'category'` performs column-wise conversion, with only labels appearing in a given column set as categories:

```
In [64]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [65]: df = df.astype('category')

In [66]: df['A'].dtype
Out[66]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [67]: df['B'].dtype
Out[67]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)
```

Supplying a `CategoricalDtype` will make the categories in each column consistent with the supplied dtype:

```
In [68]: from pandas.api.types import CategoricalDtype

In [69]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})

In [70]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)

In [71]: df = df.astype(cdt)

In [72]: df['A'].dtype
Out[72]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)

In [73]: df['B'].dtype
Out[73]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
```

### 1.3.1.14 Other Enhancements

- Unary `+` now permitted for `Series` and `DataFrame` as numeric operator ([GH16073](#))
- Better support for `to_excel()` output with the `xlsxwriter` engine. ([GH16149](#))
- `pandas.tseries.frequencies.to_offset()` now accepts leading `+` signs e.g. `‘+1h’`. ([GH18171](#))
- `MultiIndex.unique()` now supports the `level=` argument, to get unique values from a specific index level ([GH17896](#))
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output ([GH14194](#))
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output ([GH14194](#))

- Improved wording of `ValueError` raised in `to_datetime()` when `unit=` is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a `Series` or a `dict` as a value for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use `qtpy`, falling back to `PyQt5` and then `PyQt4`, adding compatibility with `Python3` and multiple `python-qt` bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when the `usecols` argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a `Series`. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe's columns (e.g. if both are `CategoricalIndex`) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an `index` argument which allows the user to exclude the index from the JSON output (GH17394)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)
- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- Resampler objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the `mean` method (GH17905).
- `is_scalar()` now returns `True` for `DateOffset` objects (GH18943).
- `DataFrame.pivot()` now accepts a list for the `values=` kwarg (GH17160).
- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See [Registering Custom Accessors](#) for more (GH14781).
- `IntervalIndex.astype` now supports conversions between subtypes when passed an `IntervalDtype` (GH19197)
- `IntervalIndex` and its associated constructor methods (`from_arrays`, `from_breaks`, `from_tuples`) have gained a `dtype` parameter (GH19262)
- Added `pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()` and `pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()` (GH17015)
- For subclassed `DataFrames`, `DataFrame.apply()` will now preserve the `Series` subclass (if defined) when passing the data to the applied function (GH19822)
- `DataFrame.from_dict()` now accepts a `columns` argument that can be used to specify the column names when `orient='index'` is used (GH18529)
- Added option `display.html.use_mathjax` so `MathJax` can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)

- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is `None` (GH19632)
- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)
- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)
- `DataFrame.to_sql()` now performs a multivalue insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multivalue inserts include: `mysql`, `postgresql`, `sqlite` and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)
- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (True by default) (GH20027)
- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)
- `quantile()` and `quantile()` now accept the `interpolation` keyword, `linear` by default (GH20497)
- zip compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()`. (GH17778)
- `WeekOfMonth` constructor now supports `n=0` (GH20517).
- `DataFrame` and `Series` now support matrix multiplication (`@`) operator (GH10259) for `Python>=3.5`
- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)
- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings up to 2,000,000 characters (GH16450)
- `to_hdf()` and `read_hdf()` now accept an `errors` keyword argument to control encoding error handling (GH20835)
- `cut()` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH20947)
- `date_range()`, `timedelta_range()`, and `interval_range()` now return a linearly spaced index if `start`, `stop`, and `periods` are specified, but `freq` is not. (GH20808, GH20983, GH20976)

## 1.3.2 Backwards incompatible API changes

### 1.3.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15184). If installed, we now require:

Package	Minimum Version	Required	Issue
python-dateutil	2.5.0	X	GH15184
openpyxl	2.4.0		GH15184
beautifulsoup4	4.2.1		GH20082
setuptools	24.2.0		GH20698

### 1.3.2.2 Instantiation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see [PEP 468](#). Pandas will use the dict's insertion order, when creating a `Series` or `DataFrame` from a dict and you're using Python version 3.6 or higher. ([GH19884](#))

Previous Behavior (and current behavior if on Python < 3.6):

```
pd.Series({'Income': 2000,
          'Expenses': -1500,
          'Taxes': -200,
          'Net result': 300})
Expenses    -1500
Income       2000
Net result    300
Taxes        -200
dtype: int64
```

Note the `Series` above is ordered alphabetically by the index values.

New Behavior (for Python >= 3.6):

```
In [74]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300})
Out[74]:
Income       2000
Expenses    -1500
Taxes        -200
Net result    300
dtype: int64
```

Notice that the `Series` is now ordered by insertion order. This new behavior is used for all relevant pandas types (`Series`, `DataFrame`, `SparseSeries` and `SparseDataFrame`).

If you wish to retain the old behavior while using Python >= 3.6, you can use `.sort_index()`:

```
In [75]: pd.Series({'Income': 2000,
.....:             'Expenses': -1500,
.....:             'Taxes': -200,
.....:             'Net result': 300}).sort_index()
Out[75]:
Expenses    -1500
Income       2000
Net result    300
Taxes        -200
dtype: int64
```

### 1.3.2.3 Deprecate Panel

`Panel` was deprecated in the 0.20.x release, showing as a `DeprecationWarning`. Using `Panel` will now show a `FutureWarning`. The recommended way to represent 3-D data are with a `MultiIndex` on a `DataFrame` via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion. For more details see [Deprecate Panel](#) documentation. ([GH13563](#), [GH18324](#)).

```
In [76]: p = tm.makePanel()
```

```
In [77]: p
```

```
Out [77]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

### Convert to a MultiIndex DataFrame

```
In [78]: p.to_frame()
```

```
Out [78]:
```

		ItemA	ItemB	ItemC
major	minor			
2000-01-03	A	1.474071	-0.964980	-1.197071
	B	0.781836	1.846883	-0.858447
	C	2.353925	-1.717693	0.384316
	D	-0.744471	0.901805	0.476720
2000-01-04	A	-0.064034	-0.845696	-1.066969
	B	-1.071357	-1.328865	0.306996
	C	0.583787	0.888782	1.574159
	D	0.758527	1.171216	0.473424
2000-01-05	A	-1.282782	-1.340896	-0.303421
	B	0.441153	1.682706	-0.028665
	C	0.221471	0.228440	1.588931
	D	1.729689	0.520260	-0.242861

### Convert to an xarray DataArray

```
In [79]: p.to_xarray()
```

```
Out [79]:
```

```
<xarray.DataArray (items: 3, major_axis: 3, minor_axis: 4)>
array([[[ 1.474071,  0.781836,  2.353925, -0.744471],
        [-0.064034, -1.071357,  0.583787,  0.758527],
        [-1.282782,  0.441153,  0.221471,  1.729689]],

        [[-0.96498 ,  1.846883, -1.717693,  0.901805],
        [-0.845696, -1.328865,  0.888782,  1.171216],
        [-1.340896,  1.682706,  0.22844 ,  0.52026 ]],

        [[-1.197071, -0.858447,  0.384316,  0.47672 ],
        [-1.066969,  0.306996,  1.574159,  0.473424],
        [-0.303421, -0.028665,  1.588931, -0.242861]]])
Coordinates:
  * items          (items) object 'ItemA' 'ItemB' 'ItemC'
  * major_axis     (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
  * minor_axis     (minor_axis) object 'A' 'B' 'C' 'D'
```

### 1.3.2.4 pandas.core.common removals

The following error & warning messages are removed from `pandas.core.common` ([GH13634](#), [GH19769](#)):

- `PerformanceWarning`
- `UnsupportedFunctionCall`

- `UnsortedIndexError`
- `AbstractMethodError`

These are available from import from `pandas.errors` (since 0.19.0).

### 1.3.2.5 Changes to make output of `DataFrame.apply` consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. tuple or list is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```
In [80]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1, columns=['A',  
→ 'B', 'C'])
```

```
In [81]: df  
Out[81]:
```

	A	B	C
0	1	2	3
1	1	2	3
2	1	2	3
3	1	2	3
4	1	2	3
5	1	2	3

Previous Behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.

```
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)  
Out[3]:
```

	A	B	C
0	1	2	3
1	1	2	3
2	1	2	3
3	1	2	3
4	1	2	3
5	1	2	3

```
In [4]: df.apply(lambda x: [1, 2], axis=1)  
Out[4]:
```

0	[1, 2]
1	[1, 2]
2	[1, 2]
3	[1, 2]
4	[1, 2]
5	[1, 2]

dtype: object

New Behavior: When the applied function returns a list-like, this will now *always* return a Series.

```
In [82]: df.apply(lambda x: [1, 2, 3], axis=1)
```

```
Out[82]:  
0    [1, 2, 3]  
1    [1, 2, 3]  
2    [1, 2, 3]
```

(continues on next page)

(continued from previous page)

```
3      [1, 2, 3]
4      [1, 2, 3]
5      [1, 2, 3]
dtype: object
```

```
In [83]: df.apply(lambda x: [1, 2], axis=1)
```

```
////////////////////////////////////
```

```
↪
0      [1, 2]
1      [1, 2]
2      [1, 2]
3      [1, 2]
4      [1, 2]
5      [1, 2]
dtype: object
```

To have expanded columns, you can use `result_type='expand'`

```
In [84]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='expand')
```

```
Out [84]:
   0  1  2
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use `result_type='broadcast'`. The shape must match the original columns.

```
In [85]: df.apply(lambda x: [1, 2, 3], axis=1, result_type='broadcast')
```

```
Out [85]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

Returning a `Series` allows one to control the exact return structure and column names:

```
In [86]: df.apply(lambda x: Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
```

```
Out [86]:
   D  E  F
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

### 1.3.2.6 Concatenation will no longer sort

In a future version of pandas `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```
In [87]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [88]: df2 = pd.DataFrame({"a": [4, 5]})
In [89]: pd.concat([df1, df2])
Out[89]:
```

	a	b
0	1	1.0
1	2	2.0
0	4	NaN
1	5	NaN

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```
In [90]: pd.concat([df1, df2], sort=True)
Out[90]:
```

	a	b
0	1	1.0
1	2	2.0
0	4	NaN
1	5	NaN

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.

### 1.3.2.7 Build Changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

### 1.3.2.8 Index Division By Zero Fills Correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous Behavior:

```
In [6]: index = pd.Int64Index([-1, 0, 1])
In [7]: index / 0
Out[7]: Int64Index([0, 0, 0], dtype='int64')

# Previous behavior yielded different results depending on the type of zero in the_
↳divisor
```

(continues on next page)

(continued from previous page)

```

In [8]: index / 0.0
Out[8]: Float64Index([-inf, nan, inf], dtype='float64')

In [9]: index = pd.UInt64Index([0, 1])

In [10]: index / np.array([0, 0], dtype=np.uint64)
Out[10]: UInt64Index([0, 0], dtype='uint64')

In [11]: pd.RangeIndex(1, 5) / 0
ZeroDivisionError: integer division or modulo by zero

```

**Current Behavior:**

```

In [91]: index = pd.Int64Index([-1, 0, 1])

# division by zero gives -infinity where negative, +infinity where positive, and NaN
↳ for 0 / 0
In [92]: index / 0
Out[92]: Float64Index([-inf, nan, inf], dtype='float64')

# The result of division by zero should not depend on whether the zero is int or float
In [93]: index / 0.0
Out[93]: Float64Index([-inf, nan, inf], dtype='float64')

In [94]: index = pd.UInt64Index([0, 1])

In [95]: index / np.array([0, 0], dtype=np.uint64)
Out[95]: Float64Index([nan, inf], dtype='float64')

In [96]: pd.RangeIndex(1, 5) / 0
Out[96]: Float64Index([inf, inf, inf, inf], dtype='float64')

```

**1.3.2.9 Extraction of matching patterns from strings**

By default, extracting matching patterns from strings with `str.extract()` used to return a Series if a single group was being extracted (a DataFrame if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a DataFrame, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. ([GH11386](#))

**Previous Behavior:**

```

In [1]: s = pd.Series(['number 10', '12 eggs'])

In [2]: extracted = s.str.extract('.*(\d\d).*')

In [3]: extracted
Out [3]:
0    10
1    12
dtype: object

In [4]: type(extracted)
Out [4]:
pandas.core.series.Series

```

New Behavior:

```
In [97]: s = pd.Series(['number 10', '12 eggs'])

In [98]: extracted = s.str.extract('.*(\d\d).*')

In [99]: extracted
Out[99]:
      0
0   10
1   12

In [100]: type(extracted)
Out[100]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```
In [101]: s = pd.Series(['number 10', '12 eggs'])

In [102]: extracted = s.str.extract('.*(\d\d).*', expand=False)

In [103]: extracted
Out[103]:
0    10
1    12
dtype: object

In [104]: type(extracted)
Out[104]: pandas.core.series.Series
```

### 1.3.2.10 Default value for the `ordered` parameter of `CategoricalDtype`

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of categories without impacting `ordered`. Behavior should remain consistent for downstream objects, such as `Categorical` (GH18790)

In previous versions, the default value for the `ordered` parameter was `False`. This could potentially lead to the `ordered` parameter unintentionally being changed from `True` to `False` when users attempt to update categories if `ordered` is not explicitly specified, as it would silently default to `False`. The new behavior for `ordered=None` is to retain the existing value of `ordered`.

New Behavior:

```
In [105]: from pandas.api.types import CategoricalDtype

In [106]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))

In [107]: cat
Out[107]:
[a, b, c, a, b, a]
Categories (3, object): [c < b < a]

In [108]: cdt = CategoricalDtype(categories=list('cbad'))

In [109]: cat.astype(cdt)
Out[109]:
```

(continues on next page)

(continued from previous page)

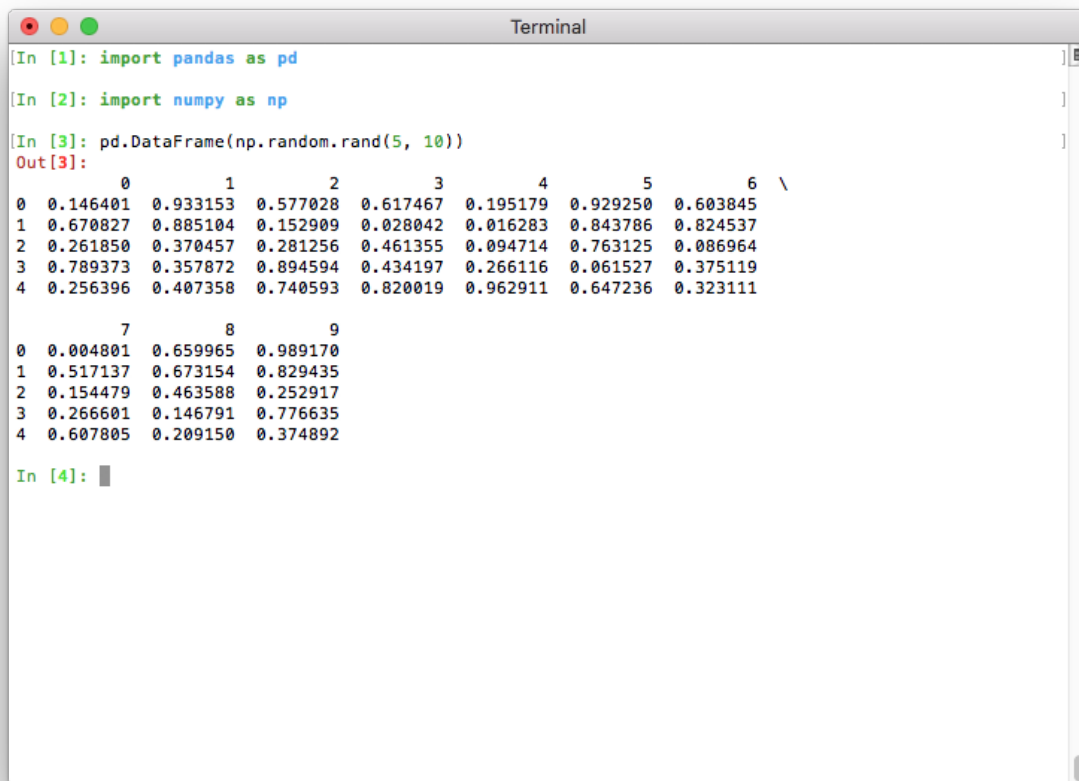

```
[a, b, c, a, b, a]
Categories (4, object): [c < b < a < d]
```

Notice in the example above that the converted Categorical has retained `ordered=True`. Had the default value for `ordered` remained as `False`, the converted Categorical would have become `unordered`, despite `ordered=False` never being explicitly specified. To change the value of `ordered`, explicitly pass it to the new dtype, e.g. `CategoricalDtype(categories=list('cbad'), ordered=False)`.

Note that the unintentional conversion of `ordered` discussed above did not arise in previous versions due to separate bugs that prevented `astype` from doing any type of category to category conversion ([GH10696](#), [GH18593](#)). These bugs have been fixed in this release, and motivated changing the default value of `ordered`.

### 1.3.2.11 Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was `pd.options.display.max_columns=20`. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:

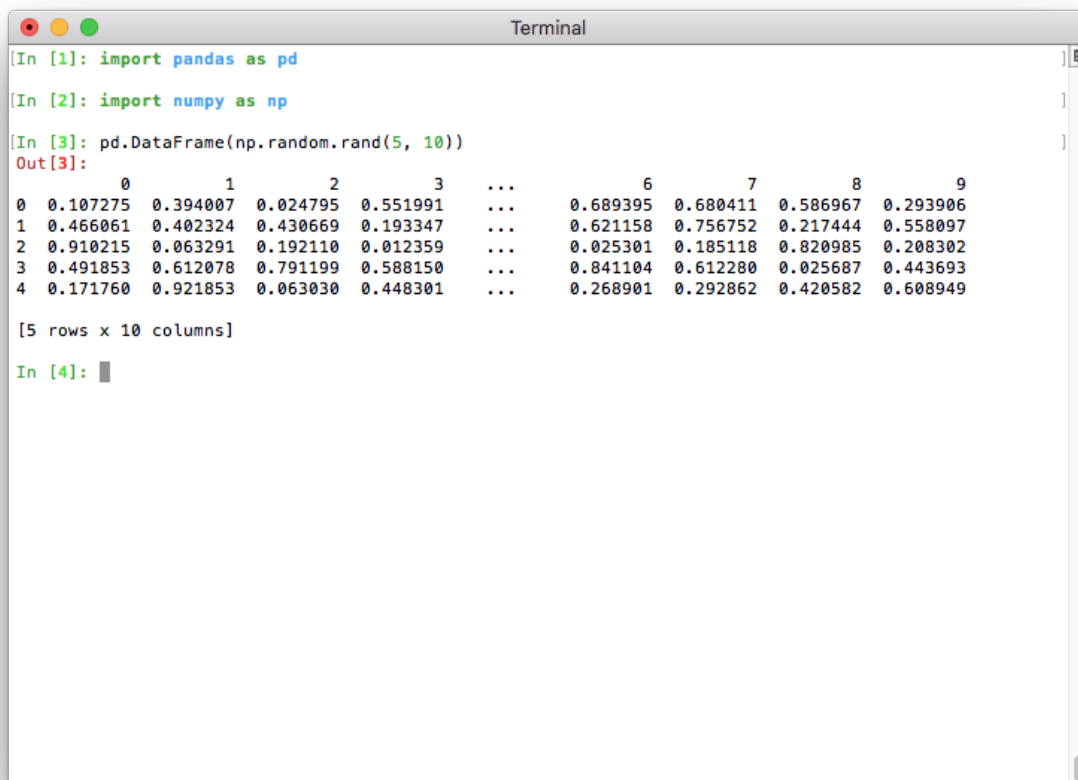

```
Terminal
[In [1]: import pandas as pd
[In [2]: import numpy as np
[In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
```

	0	1	2	3	4	5	6	7	8	9
0	0.146401	0.933153	0.577028	0.617467	0.195179	0.929250	0.603845	0.004801	0.659965	0.989170
1	0.670827	0.885104	0.152909	0.028042	0.016283	0.843786	0.824537	0.517137	0.673154	0.829435
2	0.261850	0.370457	0.281256	0.461355	0.094714	0.763125	0.086964	0.154479	0.463588	0.252917
3	0.789373	0.357872	0.894594	0.434197	0.266116	0.061527	0.375119	0.266601	0.146791	0.776635
4	0.256396	0.407358	0.740593	0.820019	0.962911	0.647236	0.323111	0.607805	0.209150	0.374892

```

In [4]:
```

If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) ([GH17023](#)). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:

```

Terminal
[In [1]: import pandas as pd
[In [2]: import numpy as np
[In [3]: pd.DataFrame(np.random.rand(5, 10))
Out[3]:
   0      1      2      3  ...      6      7      8      9
0  0.107275  0.394007  0.024795  0.551991  ...  0.689395  0.680411  0.586967  0.293906
1  0.466061  0.402324  0.430669  0.193347  ...  0.621158  0.756752  0.217444  0.558097
2  0.910215  0.063291  0.192110  0.012359  ...  0.025301  0.185118  0.820985  0.208302
3  0.491853  0.612078  0.791199  0.588150  ...  0.841104  0.612280  0.025687  0.443693
4  0.171760  0.921853  0.063030  0.448301  ...  0.268901  0.292862  0.420582  0.608949

[5 rows x 10 columns]
In [4]:

```

Note that if you don't like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```

### 1.3.2.12 Datetimelike API Changes

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)
- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)
- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)
- `DatetimeIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)
- Addition and subtraction of `NaN` from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)
- `NaT` division with `datetime.timedelta` will now return `NaN` instead of raising (GH17876)

- Operations between a *Series* with dtype `dtype='datetime64[ns]'` and a *PeriodIndex* will correctly raise `TypeError` (GH18850)
- Subtraction of *Series* with timezone-aware `dtype='datetime64[ns]'` with mis-matched timezones will raise `TypeError` instead of `ValueError` (GH18817)
- *Timestamp* will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)
- *Timestamp* will no longer silently ignore invalid `freq` arguments (GH5168)
- `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)
- `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)
- *Series.truncate()* and *DataFrame.truncate()* will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)
- *Series.first* and *DataFrame.first* will now raise a `TypeError` rather than `NotImplementedError` when index is not a *DatetimeIndex* (GH20725).
- *Series.last* and *DataFrame.last* will now raise a `TypeError` rather than `NotImplementedError` when index is not a *DatetimeIndex* (GH20725).
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).
- *pandas.merge()* provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)
- For *DatetimeIndex* and *TimedeltaIndex* with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise `NullFrequencyError` instead of `TypeError` (GH19895)
- *Timestamp* constructor now accepts a `nanosecond` keyword or positional argument (GH18898)
- *DatetimeIndex* will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)
- *DatetimeIndex* with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

### 1.3.2.13 Other API Changes

- *Series.astype()* and *Index.astype()* with an incompatible dtype will now raise a `TypeError` rather than a `ValueError` (GH18231)
- *Series* construction with an object dtyped tz-aware datetime and `dtype=object` specified, will now return an object dtyped *Series*, previously this would infer the datetime dtype (GH18231)
- A *Series* of `dtype=category` constructed from an empty dict will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed (GH18515)
- All-`NaN` levels in a *MultiIndex* are now assigned `float` rather than `object` dtype, promoting consistency with *Index* (GH17929).
- Levels names of a *MultiIndex* (when not `None`) are now required to be unique: trying to create a *MultiIndex* with repeated names will raise a `ValueError` (GH18872)
- Both construction and renaming of *Index*/*MultiIndex* with non-hashable name/names will now raise `TypeError` (GH20527)

- `Index.map()` can now accept `Series` and dictionary input objects (GH12756, GH18482, GH18509).
- `DataFrame.unstack()` will now default to filling with `np.nan` for object columns. (GH12815)
- `IntervalIndex` constructor will raise if the `closed` parameter conflicts with how the input data is inferred to be closed (GH18421)
- Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (`NaN`, `NaT`, etc.) regardless of the type passed in (GH18295)
- When created with duplicate labels, `MultiIndex` now raises a `ValueError`. (GH17464)
- `Series.fillna()` now raises a `TypeError` instead of a `ValueError` when passed a list, tuple or `DataFrame` as a value (GH18293)
- `pandas.DataFrame.merge()` no longer casts a float column to object when merging on int and float columns (GH16572)
- `pandas.merge()` now raises a `ValueError` when trying to merge on incompatible data types (GH9780)
- The default NA value for `UInt64Index` has changed from 0 to `NaN`, which impacts methods that mask with NA, such as `UInt64Index.where()` (GH18398)
- Refactored `setup.py` to use `find_packages` instead of explicitly listing out all subpackages (GH18535)
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` (GH16672)
- `wide_to_long()` previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible (GH17627)
- In `read_excel()`, the `comment` argument is now exposed as a named parameter (GH18735)
- Rearranged the order of keyword arguments in `read_excel()` to align with `read_csv()` (GH16672)
- The options `html.border` and `mode.use_inf_as_null` were deprecated in prior versions, these will now show `FutureWarning` rather than a `DeprecationWarning` (GH19003)
- `IntervalIndex` and `IntervalDtype` no longer support categorical, object, and string subtypes (GH19016)
- `IntervalDtype` now returns `True` when compared against 'interval' regardless of subtype, and `IntervalDtype.name` now returns 'interval' regardless of subtype (GH18980)
- `KeyError` now raises instead of `ValueError` in `drop()`, `drop()`, `drop()`, `drop()` when dropping a non-existent element in an axis with duplicates (GH19186)
- `Series.to_csv()` now accepts a compression argument that works in the same way as the compression argument in `DataFrame.to_csv()` (GH18958)
- Set operations (union, difference...) on `IntervalIndex` with incompatible index types will now raise a `TypeError` rather than a `ValueError` (GH19329)
- `DateOffset` objects render more simply, e.g. `<DateOffset: days=1>` instead of `<DateOffset: kwds={'days': 1}>` (GH19403)
- `Categorical.fillna` now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of `Series.fillna()` (GH19682)
- `pd.to_datetime('today')` now returns a `datetime`, consistent with `pd.Timestamp('today')`; previously `pd.to_datetime('today')` returned a `.normalized()` `datetime` (GH19935)
- `Series.str.replace()` now takes an optional `regex` keyword which, when set to `False`, uses literal string replacement rather than regex replacement (GH16808)
- `DatetimeIndex.strftime()` and `PeriodIndex.strftime()` now return an `Index` instead of a numpy array to be consistent with similar accessors (GH20127)

- Constructing a Series from a list of length 1 no longer broadcasts this list when a longer index is specified ([GH19714](#), [GH20391](#)).
- `DataFrame.to_dict()` with `orient='index'` no longer casts int columns to float for a DataFrame with only int and float columns ([GH18580](#)).
- A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now *always* be passed a Series, rather than a `np.array`; `.apply()` only has the `raw` keyword, see [here](#). This is consistent with the signatures of `.aggregate()` across pandas ([GH20584](#)).
- Rolling and Expanding types raise `NotImplementedError` upon iteration ([GH11704](#)).

### 1.3.3 Deprecations

- `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(...)` and `SparseSeries(...)` instead ([GH18213](#)).
- `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead ([GH18458](#)).
- `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead ([GH18572](#)).
- Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to 'by' will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple ([GH18314](#)).
- `Series.valid` is deprecated. Use `Series.dropna()` instead ([GH18800](#)).
- `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead ([GH18836](#)).
- `ExcelFile.parse()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `read_excel()` ([GH20920](#)).
- The `is_copy` attribute is deprecated and will be removed in a future version ([GH18801](#)).
- `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor ([GH19263](#)).
- `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order ([GH17320](#), [GH17312](#)).
- Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes ([GH17758](#)).
- The `broadcast` parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` ([GH18577](#)).
- The `reduce` parameter of `.apply()` is deprecated in favor of `result_type='reduce'` ([GH18577](#)).
- The `order` parameter of `factorize()` is deprecated and will be removed in a future release ([GH19727](#)).
- `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` ([GH12806](#)).
- `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead ([GH18627](#)).
- `Index.summary()` is deprecated and will be removed in a future version ([GH18217](#)).
- `NDFrame.get_ftype_counts()` is deprecated and will be removed in a future version ([GH18243](#)).

- The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).
- `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have deprecated passing an `np.array` by default. One will need to pass the new `raw` parameter to be explicit about what is passed (GH20584)
- The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).
- `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716)
- Floor division between an integer ndarray and a `Timedelta` is deprecated. Divide by `Timedelta.value` instead (GH19761)
- Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678)
- `Index.get_duplicates()` is deprecated and will be removed in a future version (GH20239)
- The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).
- Passing multiple axes to the `axis` parameter in `DataFrame.dropna()` has been deprecated and will be removed in a future version (GH20987)

### 1.3.4 Removal of prior version deprecations/changes

- Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074)
- The `levels` and `labels` attributes of a `MultiIndex` can no longer be set directly (GH4039).
- `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370)
- `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in `Datetime`-likes instead (GH18370)
- `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459)
- The `SparseList` class has been removed (GH14007)
- The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735)
- `Categorical.from_array` has been removed (GH13854)
- The `freq` and `how` parameters have been removed from the `rolling/expanding/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, `resample` before calling the methods. (GH18601 & GH18668)
- `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113)
- `read_csv()` has dropped the `skip_footer` parameter (GH13386)
- `read_csv()` has dropped the `as_reccarray` parameter (GH13373)
- `read_csv()` has dropped the `buffer_lines` parameter (GH13360)

- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)
- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)
- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)
- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)
- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)
- The `Panel4D` and `PanelND` classes have been removed (GH13776)
- The `Panel` class has dropped the `to_long` and `toLong` methods (GH19077)
- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
- The `labels` attribute of the `Categorical` class has been removed in favor of `Categorical.codes` (GH7768)
- The `flavor` parameter have been removed from func:`to_sql` method (GH13611)
- The modules `pandas.tools.hashing` and `pandas.util.hashing` have been removed (GH16223)
- The top-level functions `pd.rolling_*`, `pd.expanding_*` and `pd.ewm*` have been removed (Deprecated since v0.18). Instead, use the `DataFrame/Series` methods `rolling`, `expanding` and `ewm` (GH18723)
- Imports from `pandas.core.common` for functions such as `is_datetime64_dtype` are now removed. These are located in `pandas.api.types`. (GH13634, GH19769)
- The `infer_dst` keyword in `Series.tz_localize()`, `DatetimeIndex.tz_localize()` and `DatetimeIndex` have been removed. `infer_dst=True` is equivalent to `ambiguous='infer'`, and `infer_dst=False` to `ambiguous='raise'` (GH7963).
- When `.resample()` was changed from an eager to a lazy operation, like `.groupby()` in v0.18.0, we put in place compatibility (with a `FutureWarning`), so operations would continue to work. This is now fully removed, so a `Resampler` will no longer forward compat operations (GH20554)
- Remove long deprecated `axis=None` parameter from `.replace()` (GH20271)

### 1.3.5 Performance Improvements

- Indexers on `Series` or `DataFrame` no longer create a reference cycle (GH17956)
- Added a keyword argument, `cache`, to `to_datetime()` that improved the performance of converting duplicate datetime arguments (GH11665)
- `DateOffset` arithmetic performance is improved (GH18218)
- Converting a `Series` of `Timedelta` objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)
- Improved performance of `.map()` with a `Series/dict` input (GH15081)
- The overridden `Timedelta` properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)
- `Series` construction will reduce the number of copies made of the input data in certain cases (GH17449)
- Improved performance of `Series.dt.date()` and `DatetimeIndex.date()` (GH18058)
- Improved performance of `Series.dt.time()` and `DatetimeIndex.time()` (GH18461)

- Improved performance of `IntervalIndex.symmetric_difference()` (GH18475)
- Improved performance of `DatetimeIndex` and `Series` arithmetic operations with `Business-Month` and `Business-Quarter` frequencies (GH18489)
- `Series()` / `DataFrame()` tab completion limits to 100 values, for better performance. (GH18587)
- Improved performance of `DataFrame.median()` with `axis=1` when `bottleneck` is not installed (GH16468)
- Improved performance of `MultiIndex.get_loc()` for large indexes, at the cost of a reduction in performance for small ones (GH18519)
- Improved performance of `MultiIndex.remove_unused_levels()` when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)
- Improved performance of `Index.get_loc()` for non-unique indexes (GH19478)
- Improved performance of pairwise `.rolling()` and `.expanding()` with `.cov()` and `.corr()` operations (GH17917)
- Improved performance of `pandas.core.groupby.GroupBy.rank()` (GH15779)
- Improved performance of variable `.rolling()` on `.min()` and `.max()` (GH19521)
- Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
- Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
- Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
- Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
- Improved performance of `getattr(Series, attr)` when the `Series` has certain index types. This manifested in slow printing of large `Series` with a `DatetimeIndex` (GH19764)
- Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)
- Improved performance of `pandas.core.arrays.Categorical.from_codes()` (GH18501)

### 1.3.6 Documentation Changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the *API docstrings* have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this [GitHub search](#) should give you an idea of how many docstrings were improved.

Special thanks to [Marc Garcia](#) for organizing the sprint. For more information, read the [NumFOCUS blogpost](#) recapping the sprint.

- Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
- Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
- Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)

## 1.3.7 Bug Fixes

### 1.3.7.1 Categorical

**Warning:** A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

- Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order ([GH16603](#))
- Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with `Categorical` data ([GH19096](#)).
- Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order ([GH19551](#))
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when target was an unordered `Categorical` that had the same categories as `self` but in a different order ([GH19551](#))
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index ([GH18630](#))
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated ([GH10696](#), [GH18593](#))
- Bug in `Series.str.split()` with `expand=True` incorrectly raising an `IndexError` on empty strings ([GH20002](#)).
- Bug in `Index` constructor with `dtype=CategoricalDtype(...)` where categories and ordered are not maintained ([GH19032](#))
- Bug in `Series` constructor with scalar and `dtype=CategoricalDtype(...)` where categories and ordered are not maintained ([GH19565](#))
- Bug in `Categorical.__iter__` not converting to Python types ([GH19909](#))
- Bug in `pandas.factorize()` returning the unique codes for the uniques. This now returns a `Categorical` with the same dtype as the input ([GH19721](#))
- Bug in `pandas.factorize()` including an item for missing values in the uniques return value ([GH19721](#))
- Bug in `Series.take()` with categorical data interpreting `-1` in `indices` as missing value markers, rather than the last element of the `Series` ([GH20664](#))

### 1.3.7.2 Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond `np.datetime64` object from a `Series` gave incorrect results ([GH7996](#))
- Bug in `DatetimeIndex`, `TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results ([GH19012](#))

- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of `DateOffset` objects either raised `(np.array, pd.Index)` or broadcast incorrectly `(pd.Series)` (GH18849)
- Bug in `Series.__add__()` adding `Series` with dtype `timedelta64[ns]` to a timezone-aware `DatetimeIndex` incorrectly dropped timezone information (GH13905)
- Adding a `Period` object to a `datetime` or `Timestamp` object will now correctly raise a `TypeError` (GH17983)
- Bug in `Timestamp` where comparison with an array of `Timestamp` objects would result in a `RecursionError` (GH15183)
- Bug in `Series` floor-division where operating on a scalar `timedelta` raises an exception (GH18846)
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., `23:59:59.999999999`) (GH19030)
- Bug in `.astype()` to non-ns `timedelta` units would hold the incorrect dtype (GH19176, GH19223, GH12425)
- Bug in subtracting `Series` from `NaT` incorrectly returning `NaT` (GH19158)
- Bug in `Series.truncate()` which raises `TypeError` with a monotonic `PeriodIndex` (GH17717)
- Bug in `pct_change()` using periods and freq returned different length outputs (GH7292)
- Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of all-False and all-True, respectively (GH19301)
- Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` (GH19382)
- Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly (GH19206)
- Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` (GH19612)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. (GH19744)
- Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` (GH19847)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported (GH20678)

### 1.3.7.3 Timedelta

- Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` (GH19819)
- Bug in `Series` with dtype `'timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to dtype `'int64'` (GH17250)
- Bug in `Series` with dtype `'timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)
- Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)
- Bug where dividing a scalar `timedelta`-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)

- Bug in `TimedeltaIndex` where division by a `Series` would return a `TimedeltaIndex` instead of a `Series` (GH19042)
- Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` (GH19738)
- Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)
- Bug in `Period.asfreq()` where periods near `datetime(1, 1, 1)` could be converted incorrectly (GH19643, GH19834)
- Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds()==30.000000000000004` (GH19458)
- Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)
- Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match (GH19333)
- Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` (GH20393)

#### 1.3.7.4 Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose `dtype` is tz-aware instead of object (GH16406)
- Bug in comparison of timezone-aware `DatetimeIndex` against `NaT` incorrectly raising `TypeError` (GH19276)
- Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive (GH18951)
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype (GH174151)
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with `dtype='timedelta64[ns]'` was incorrect (GH17558)
- Bug in `DatetimeIndex.insert()` where inserting `NaT` into a timezone-aware index incorrectly raised (GH16357)
- Bug in `DataFrame` constructor, where tz-aware `DatetimeIndex` and a given column name will result in an empty `DataFrame` (GH19157)
- Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)
- Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)
- Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)
- Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)

- Bug in `DataFrame.count()` that raised an `ValueError`, if `DataFrame.dropna()` was called for a single column with timezone-aware values. (GH13407)

### 1.3.7.5 Offsets

- Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)
- Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` (GH19142)
- Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)
- Bug in `FY5253` where `datetime` addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)
- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operations (GH14774)

### 1.3.7.6 Numeric

- Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)
- Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)
- Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)
- Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)
- Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or other has length zero (GH19522)
- Multiplication and division of numeric-dtyped `Index` objects with timedelta-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)
- Bug where `NaN` was returned instead of `0` by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)

### 1.3.7.7 Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

### 1.3.7.8 Indexing

- Bug in `Index` construction from list of mixed type tuples (GH18505)
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)

- Bug in indexing a datetimelike Index that raised `ValueError` instead of `IndexError` (GH18386).
- `Index.to_series()` now accepts index and name kwargs (GH18699)
- `DatetimeIndex.to_series()` now accepts index and name kwargs (GH18699)
- Bug in indexing non-scalar value from Series having non-unique Index will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a `DataFrame` with a 2-d boolean ndarray (GH18582)
- Bug in `str.extractall` when there were no matches empty `Index` was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
- Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-`IntervalIndex` did not raise (GH18475)
- Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype (GH19101)
- Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that don't exist on the `DataFrame` (GH19726)
- Bug in Index subclasses constructors that ignore unexpected keyword arguments (GH19348)
- Bug in `Index.difference()` when taking difference of an Index with itself (GH20040)
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence of entire rows of NaNs in the middle of values (GH20499).
- Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-monotonic uint64 data (GH20636)
- Bug in `Series.is_unique` where extraneous output in stderr is shown if Series contains objects with `__ne__` defined (GH20661)
- Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)
- Bug in partial string indexing on a Series/DataFrame with a monotonic decreasing `DatetimeIndex` (GH19362)
- Bug in performing in-place operations on a `DataFrame` with a duplicate Index (GH17105)
- Bug in `IntervalIndex.get_loc()` and `IntervalIndex.get_indexer()` when used with an `IntervalIndex` containing a single interval (GH17284, GH20921)
- Bug in `.loc` with a uint64 indexer (GH20722)

#### 1.3.7.9 MultiIndex

- Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been dropped (GH19027)
- Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels if the `level` argument is not 0 or a list like `[0, 1, ...]` (GH19057)

- Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with missing values (GH17924)
- Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)
- Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)
- Bug in `MultiIndex.remove_unused_levels()` which would fill nan values (GH18417)
- Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)
- Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int (GH18818, GH15994)
- Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)
- Bug in `MultiIndex.get_loc()` which would fail to locate keys containing NaN (GH18485)
- Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes (GH18520)
- Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

### 1.3.7.10 I/O

- `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a different parser (GH17975)
- `DataFrame.to_html()` now has an option to add an id to the leading `<table>` tag (GH8496)
- Bug in `read_msgpack()` with a non-existent file is passed in Python 2 (GH15296)
- Bug in `read_csv()` where a `MultiIndex` with duplicate columns was not being mangled appropriately (GH18062)
- Bug in `read_csv()` where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
- Bug in `read_csv()` causing heap corruption on 32-bit, big-endian architectures (GH20785)
- Bug in `read_sas()` where a file with 0 variables gave an `AttributeError` incorrectly. Now it gives an `EmptyDataError` (GH18184)
- Bug in `DataFrame.to_latex()` where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
- Bug in `DataFrame.to_latex()` where a NaN in a `MultiIndex` would cause an `IndexError` or incorrect output (GH14249)
- Bug in `DataFrame.to_latex()` where a non-string index-level name would result in an `AttributeError` (GH19981)
- Bug in `DataFrame.to_latex()` where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)
- Bug in `DataFrame.to_latex()` where a `MultiIndex` with an empty string as its name would result in incorrect output (GH18669)
- Bug in `DataFrame.to_latex()` where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)
- Bug in `read_json()` where large numeric values were causing an `OverflowError` (GH18842)
- Bug in `DataFrame.to_parquet()` where an exception was raised if the write destination is S3 (GH19134)

- `Interval` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242)
- `Timedelta` now supported in `DataFrame.to_excel()` for all Excel file types (GH19242, GH9155, GH19900)
- Bug in `pandas.io.stata.StataReader.value_labels()` raising an `AttributeError` when called on very old files. Now returns an empty dict (GH19417)
- Bug in `read_pickle()` when unpickling objects with `TimedeltaIndex` or `Float64Index` created with pandas prior to version 0.20 (GH19939)
- Bug in `pandas.io.json.json_normalize()` where subrecords are not properly normalized if any subrecords values are `NoneType` (GH20030)
- Bug in `usecols` parameter in `read_csv()` where error is not raised correctly when passing a string. (GH20529)
- Bug in `HDFStore.keys()` when reading a file with a softlink causes exception (GH20523)
- Bug in `HDFStore.select_column()` where a key which is not a valid store raised an `AttributeError` instead of a `KeyError` (GH17912)

### 1.3.7.11 Plotting

- Better error message when attempting to plot but matplotlib is not installed (GH19810).
- `DataFrame.plot()` now raises a `ValueError` when the `x` or `y` argument is improperly formed (GH18671)
- Bug in `DataFrame.plot()` when `x` and `y` arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056)
- Bug in formatting tick labels with `datetime.time()` and fractional seconds (GH18478).
- `Series.plot.kde()` has exposed the args `ind` and `bw_method` in the docstring (GH18461). The argument `ind` may now also be an integer (number of sample points).
- `DataFrame.plot()` now supports multiple columns to the `y` argument (GH19699)

### 1.3.7.12 Groupby/Resample/Rolling

- Bug when grouping by a single column and aggregating with a class like `list` or `tuple` (GH18079)
- Fixed regression in `DataFrame.groupby()` which would not emit an error when called with a tuple key not in the index (GH18798)
- Bug in `DataFrame.resample()` which silently ignored unsupported (or mistyped) options for `label`, `closed` and `convention` (GH19303)
- Bug in `DataFrame.groupby()` where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)
- Bug in `DataFrame.groupby()` where aggregation by `first/last/min/max` was causing timestamps to lose precision (GH19526)
- Bug in `DataFrame.transform()` where particular aggregation functions were being incorrectly cast to match the dtype(s) of the grouped data (GH19200)
- Bug in `DataFrame.groupby()` passing the `on=` kwarg, and subsequently using `.apply()` (GH17813)
- Bug in `DataFrame.resample().aggregate` not raising a `KeyError` when aggregating a non-existent column (GH16766, GH19566)

- Bug in `DataFrameGroupBy.cumsum()` and `DataFrameGroupBy.cumprod()` when `skipna` was passed (GH19806)
- Bug in `DataFrame.resample()` that dropped timezone information (GH13238)
- Bug in `DataFrame.groupby()` where transformations using `np.all` and `np.any` were raising a `ValueError` (GH20653)
- Bug in `DataFrame.resample()` where `ffill`, `bfill`, `pad`, `backfill`, `fillna`, `interpolate`, and `asfreq` were ignoring `loffset`. (GH20744)
- Bug in `DataFrame.groupby()` when applying a function that has mixed data types and the user supplied function can fail on the grouping column (GH20949)
- Bug in `DataFrameGroupBy.rolling().apply()` where operations performed against the associated `DataFrameGroupBy` object could impact the inclusion of the grouped item(s) in the result (GH14013)

### 1.3.7.13 Sparse

- Bug in which creating a `SparseDataFrame` from a dense `Series` or an unsupported type raised an uncontrolled exception (GH19374)
- Bug in `SparseDataFrame.to_csv` causing exception (GH19384)
- Bug in `SparseSeries.memory_usage` which caused segfault by accessing non sparse elements (GH19368)
- Bug in constructing a `SparseArray`: if data is a scalar and index is defined it will coerce to `float64` regardless of scalar's dtype. (GH19163)

### 1.3.7.14 Reshaping

- Bug in `DataFrame.merge()` where referencing a `CategoricalIndex` by name, where the `by` kwarg would `KeyError` (GH20777)
- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)
- Bug in `DataFrame.unstack()` which casts `int` to `float` if `columns` is a `MultiIndex` with unused levels (GH17845)
- Bug in `DataFrame.unstack()` which raises an error if index is a `MultiIndex` with unused labels on the unstacked level (GH18562)
- Fixed construction of a `Series` from a dict containing `NaN` as key (GH18480)
- Fixed construction of a `DataFrame` from a dict containing `NaN` as key (GH18455)
- Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)
- Suppressed error in the construction of a `DataFrame` from a dict containing scalar values when the corresponding keys are not included in the passed index (GH18600)
- Fixed (changed from object to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)
- Bug in `Series.rank()` where `Series` containing `NaT` modifies the `Series` inplace (GH18521)
- Bug in `cut()` which fails when using readonly arrays (GH18773)
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)

- Bug in `DataFrame.merge()` in which merging using Index objects as vectors raised an Exception (GH19038)
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)
- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)
- Bug in `concat()` when concatting sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)
- Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)
- Bug in `DataFrame.join()` which does an outer instead of a left join when being called with multiple DataFrames and some have non-unique indices (GH19624)
- `Series.rename()` now accepts `axis` as a kwarg (GH18589)
- Bug in `rename()` where an Index of same-length tuples was converted to a MultiIndex (GH19497)
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the Index's name attribute (GH19582)
- Bug in `qcut()` where datetime and timedelta data with NaT present raised a `ValueError` (GH19768)
- Bug in `DataFrame.iterrows()`, which would infer strings not compliant to ISO8601 to datetimes (GH19671)
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)
- Bug in `cut()` and `qcut()` where timezone information was dropped (GH19872)
- Bug in `Series` constructor with a `dtype=str`, previously raised in some cases (GH19853)
- Bug in `get_dummies()`, and `select_dtypes()`, where duplicate column names caused incorrect behavior (GH20848)
- Bug in `isna()`, which cannot handle ambiguous typed lists (GH20675)
- Bug in `concat()` which raises an error when concatenating TZ-aware dataframes and all-NaT dataframes (GH12396)
- Bug in `concat()` which raises an error when concatenating empty TZ-aware series (GH18447)

#### 1.3.7.15 Other

- Improved error message when attempting to use a Python keyword as an identifier in a numexpr backed query (GH18221)
- Bug in accessing a `pandas.get_option()`, which raised `KeyError` rather than `OptionError` when looking up a non-existent option key in some cases (GH19789)
- Bug in `testing.assert_series_equal()` and `testing.assert_frame_equal()` for `Series` or `DataFrames` with differing unicode data (GH20503)

## 1.4 v0.22.0 (December 29, 2017)

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

### 1.4.1 Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-NA sums and products. The summary is that

- The sum of an empty or all-NA Series is now 0
- The product of an empty or all-NA Series is now 1
- We've added a `min_count` parameter to `.sum()` and `.prod()` controlling the minimum number of valid values for the result to be valid. If fewer than `min_count` non-NA values are present, the result is NA. The default is 0. To return NaN, the 0.21 behavior, use `min_count=1`.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-NA series depending on whether or not bottleneck was installed. See [Sum/Prod of all-NA or empty Series/DataFrames is now consistently NaN](#). At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we've partially reverted those changes.

#### 1.4.1.1 Arithmetic Operations

The default sum for empty or all-NA Series is now 0.

*pandas 0.21.x*

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

*pandas 0.22.0*

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()
Out[2]: 0.0
```

The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy's `np.nansum` on empty and all-NA arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the `min_count` keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the `skipna` parameter, the `.sum` on an all-NA series is conceptually the same as the `.sum` of an empty one with `skipna=True` (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1) # skipna=True by default
Out[4]: nan
```

The `min_count` parameter refers to the minimum number of *non-null* values required for a non-NA sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

#### 1.4.1.2 Grouping by a Categorical

Grouping by a `Categorical` and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

*pandas 0.21.x*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a      3.0
b      NaN
dtype: float64
```

*pandas 0.22*

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])
In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
a      3
b      0
dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use `min_count>=1`.

```
In [10]: pd.Series([1, 2]).groupby(grouper).sum(min_count=1)
Out[10]:
a      3.0
b      NaN
dtype: float64
```

#### 1.4.1.3 Resample

The sum and product of all-NA bins has changed from NaN to 0 for sum and 1 for product.

*pandas 0.21.x*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
....:                  index=pd.date_range('2017', periods=4))
....: s
Out[11]:
2017-01-01    1.0
2017-01-02    1.0
2017-01-03    NaN
2017-01-04    NaN
Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01    2.0
2017-01-03    NaN
Freq: 2D, dtype: float64
```

*pandas 0.22.0*

```
In [11]: s = pd.Series([1, 1, np.nan, np.nan],
....:                  index=pd.date_range('2017', periods=4))
....:
In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01    2.0
2017-01-03    0.0
dtype: float64
```

To restore the 0.21 behavior of returning NaN, use `min_count>=1`.

```
In [13]: s.resample('2d').sum(min_count=1)
Out[13]:
2017-01-01    2.0
2017-01-03    NaN
dtype: float64
```

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

*pandas 0.21.x*

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
Out[15]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, dtype: float64
```

*pandas 0.22.0*

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
Out[15]:
2017-01-01 00:00:00    1
```

(continues on next page)

(continued from previous page)

```
2017-01-01 12:00:00    0
2017-01-02 00:00:00    2
Freq: 12H, dtype: int64
```

Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
Out[16]:
2017-01-01 00:00:00    1.0
2017-01-01 12:00:00    NaN
2017-01-02 00:00:00    2.0
Freq: 12H, dtype: float64
```

#### 1.4.1.4 Rolling and Expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned `NaN`, when fewer than `min_periods` non-NA values were in the window. Now it returns 0.

*pandas 0.21.1*

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    NaN
1    NaN
dtype: float64
```

*pandas 0.22.0*

```
In [17]: s = pd.Series([np.nan, np.nan])
In [18]: s.rolling(2, min_periods=0).sum()
Out[18]:
0    0.0
1    0.0
dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

## 1.4.2 Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With `setuptools`, in your `setup.py` use:

```
install_requires=['pandas!=0.21.*', ...]
```

With `conda`, use

```
requirements:
  run:
    - pandas !=0.21.0,!=0.21.1
```

Note that the inconsistency in the return value for all-NA series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

## 1.5 v0.21.1 (December 12, 2017)

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See [here](#).
- Improvements to the Parquet IO functions introduced in 0.21.0. See [here](#).

### What's new in v0.21.1

- *Restore Matplotlib datetime Converter Registration*
- *New features*
  - *Improvements to the Parquet IO functionality*
  - *Other Enhancements*
- *Deprecations*
- *Performance Improvements*
- *Bug Fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Groupby/Resample/Rolling*
  - *Reshaping*
  - *Numeric*
  - *Categorical*
  - *String*

### 1.5.1 Restore Matplotlib datetime Converter Registration

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with `datetime` or `Period` values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of `import pandas`.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular `matplotlib.pyplot` plotting methods, so we're temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We've added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas' formatters and restore any converters we overwrote when registering them (GH18301).

We're working with the matplotlib developers to make this easier. We're trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn't have the side effect of overwriting any custom converters you've already set). In the future we hope to have most of the date-time formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We'll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

## 1.5.2 New features

### 1.5.2.1 Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

### 1.5.2.2 Other Enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

## 1.5.3 Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters()` (GH18301)

## 1.5.4 Performance Improvements

- Improved performance of plotting large series/dataframes (GH18236).

## 1.5.5 Bug Fixes

### 1.5.5.1 Conversion

- Bug in `TimedeltaIndex` subtraction could incorrectly overflow when `NaT` is present (GH17791)
- Bug in `DatetimeIndex` subtracting datetimelike from `DatetimeIndex` could fail to overflow (GH18020)
- Bug in `IntervalIndex.copy()` when copying and `IntervalIndex` with non-default closed (GH18339)
- Bug in `DataFrame.to_dict()` where columns of datetime that are tz-aware were not converted to required arrays when used with `orient='records'`, raising `TypeError` (GH18372)
- Bug in `DatetimeIndex` and `date_range()` where mismatching tz-aware start and end timezones would not raise an err if `end.tzinfo` is `None` (GH18431)
- Bug in `Series.fillna()` which raised when passed a long integer on Python 2 (GH18159).

### 1.5.5.2 Indexing

- Bug in a boolean comparison of a `datetime.datetime` and a `datetime64[ns]` dtype Series (GH17965)
- Bug where a `MultiIndex` with more than a million records was not raising `AttributeError` when trying to access a missing attribute (GH18165)
- Bug in `IntervalIndex` constructor when a list of intervals is passed with non-default `closed` (GH18334)
- Bug in `Index.putmask` when an invalid mask passed (GH18368)
- Bug in masked assignment of a `timedelta64[ns]` dtype Series, incorrectly coerced to float (GH18493)

### 1.5.5.3 I/O

- Bug in class:~`pandas.io.stata.StataReader` not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in `read_csv()` when reading a compressed UTF-16 encoded file (GH18071)
- Bug in `read_csv()` for handling null values in index columns when specifying `na_filter=False` (GH5239)
- Bug in `read_csv()` when reading numeric category fields with high cardinality (GH18186)
- Bug in `DataFrame.to_csv()` when the table had `MultiIndex` columns, and a list of strings was passed in for header (GH5539)
- Bug in parsing integer datetime-like columns with specified format in `read_sql` (GH17855).
- Bug in `DataFrame.to_msgpack()` when serializing data of the `numpy.bool_` datatype (GH18390)
- Bug in `read_json()` not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in `pandas.io.json.json_normalize()` to avoid modification of meta (GH18610)
- Bug in `to_latex()` where repeated multi-index values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in `HDFStore` (GH18413)
- Bug in `DataFrame.to_latex()` with `longtable=True` where a latex multicolumn always spanned over three columns (GH17959)

### 1.5.5.4 Plotting

- Bug in `DataFrame.plot()` and `Series.plot()` with `DatetimeIndex` where a figure generated by them is not pickleable in Python 3 (GH18439)

### 1.5.5.5 Groupby/Resample/Rolling

- Bug in `DataFrame.resample(...).apply(...)` when there is a callable that returns different columns (GH15169)
- Bug in `DataFrame.resample(...)` when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
- Bug in `pd.DataFrameGroupBy.count()` when counting over a datetimelike column (GH13393)
- Bug in `rolling.var` where calculation is inaccurate with a zero-valued array (GH18430)

### 1.5.5.6 Reshaping

- Error message in `pd.merge_asof()` for key datatype mismatch now includes datatype of left and right key ([GH18068](#))
- Bug in `pd.concat` when empty and non-empty DataFrames or Series are concatenated ([GH18178](#) [GH18187](#))
- Bug in `DataFrame.filter(...)` when unicode is passed as a condition in Python 2 ([GH13101](#))
- Bug when merging empty DataFrames when `np.seterr(divide='raise')` is set ([GH17776](#))

### 1.5.5.7 Numeric

- Bug in `pd.Series.rolling.skew()` and `rolling.kurt()` with all equal values has floating issue ([GH18044](#))

### 1.5.5.8 Categorical

- Bug in `DataFrame.astype()` where casting to 'category' on an empty DataFrame causes a segmentation fault ([GH18004](#))
- Error messages in the testing module have been improved when items have different `CategoricalDtype` ([GH18069](#))
- `CategoricalIndex` can now correctly take a `pd.api.types.CategoricalDtype` as its dtype ([GH18116](#))
- Bug in `Categorical.unique()` returning read-only codes array when all categories were NaN ([GH18051](#))
- Bug in `DataFrame.groupby(axis=1)` with a `CategoricalIndex` ([GH18432](#))

### 1.5.5.9 String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None ([GH18450](#))

## 1.6 v0.21.0 (October 27, 2017)

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with [Apache Parquet](#), including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see [here](#).
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see [here](#).
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether `bottleneck` is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see [here](#).
- Compatibility fixes for pypy, see [here](#).
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see [here](#).

- Addition of the new methods `DataFrame.infer_objects` (see [here](#)) and `GroupBy.pipe` (see [here](#)).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a `KeyError` in a future version, see [here](#).

Check the *API Changes* and *deprecations* before updating.

### What's new in v0.21.0

- *New features*
  - *Integration with Apache Parquet file format*
  - *infer\_objects type conversion*
  - *Improved warnings when attempting to create columns*
  - *drop now also accepts index/columns keywords*
  - *rename, reindex now also accept axis keyword*
  - *CategoricalDtype for specifying categoricals*
  - *GroupBy objects now have a pipe method*
  - *Categorical.rename\_categories accepts a dict-like*
  - *Other Enhancements*
- *Backwards incompatible API changes*
  - *Dependencies have increased minimum versions*
  - *Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN*
  - *Indexing with a list with missing labels is Deprecated*
  - *NA naming Changes*
  - *Iteration of Series/Index will now return Python scalars*
  - *Indexing with a Boolean Index*
  - *PeriodIndex resampling*
  - *Improved error handling during item assignment in pd.eval*
  - *Dtype Conversions*
  - *MultiIndex Constructor with a Single Level*
  - *UTC Localization with Series*
  - *Consistency of Range Functions*
  - *No Automatic Matplotlib Converters*
  - *Other API Changes*
- *Deprecations*
  - *Series.select and DataFrame.select*
  - *Series.argmax and Series.argmin*
- *Removal of prior version deprecations/changes*
- *Performance Improvements*

- *Documentation Changes*
- *Bug Fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Groupby/Resample/Rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Categorical*
  - *PyPy*
  - *Other*

## 1.6.1 New features

### 1.6.1.1 Integration with Apache Parquet file format

Integration with [Apache Parquet](#), including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see [here](#) (GH15838, GH17438).

[Apache Parquet](#) provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with timezones.

This functionality depends on either the [pyarrow](#) or [fastparquet](#) library. For more details, see [the IO docs on Parquet](#).

### 1.6.1.2 `infer_objects` type conversion

The `DataFrame.infer_objects()` and `Series.infer_objects()` methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated `convert_objects` method. See the documentation [here](#) for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': np.array([1, 2, 3], dtype='object'),
...:                      'C': ['1', '2', '3']})
...:

In [2]: df.dtypes
Out[2]:
A      int64
B      object
C      object
```

(continues on next page)

(continued from previous page)

```
dtype: object

In [3]: df.infer_objects().dtypes
\\Out[3]:
A      int64
B      int64
C      object
dtype: object
```

Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the `to_numeric()` function (or `to_datetime()`, `to_timedelta()`).

```
In [4]: df = df.infer_objects()

In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')

In [6]: df.dtypes
Out[6]:
A      int64
B      int64
C      int64
dtype: object
```

### 1.6.1.3 Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on DataFrame instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the DataFrame:

```
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In[2]: df.two = [4, 5, 6]
```

This does not raise any obvious exceptions, but also does not create a new column:

```
In[3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

Setting a list-like data structure into a new attribute now raises a `UserWarning` about the potential for unexpected behavior. See [Attribute Access](#).

### 1.6.1.4 drop now also accepts index/columns keywords

The `drop()` method has gained `index/columns` keywords as an alternative to specifying the axis. This is similar to the behavior of `reindex` (GH12392).

For example:

(continued from previous page)

```
In [15]: df.reindex([0, 1, 3], axis='index')
Out[15]:
```

	A	B
0	1.0	4.0
1	2.0	5.0
3	NaN	NaN

The “index, columns” style continues to work as before.

```
In [16]: df.rename(index=id, columns=str.lower)
Out[16]:
```

	a	b
4458898752	1	4
4458898784	2	5
4458898816	3	6

```
In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
Out[17]:
```

	A	B	C
0	1.0	4.0	NaN
1	2.0	5.0	NaN
3	NaN	NaN	NaN

We *highly* encourage using named arguments to avoid confusion when using either style.

### 1.6.1.6 CategoricalDtype for specifying categoricals

`pandas.api.types.CategoricalDtype` has been added to the public API and expanded to include the categories and ordered attributes. A `CategoricalDtype` can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a `Categorical` ([GH14711](#), [GH15078](#), [GH16015](#), [GH17643](#)):

```
In [18]: from pandas.api.types import CategoricalDtype

In [19]: s = pd.Series(['a', 'b', 'c', 'a']) # strings

In [20]: dtype = CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)

In [21]: s.astype(dtype)
Out[21]:
```

0	a
1	b
2	c
3	a

```
dtype: category
Categories (4, object): [a < b < c < d]
```

One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

```
In [22]: data = 'A,B\na,1\nb,2\nc,3'

In [23]: pd.read_csv(StringIO(data), dtype={'B': 'category'}).B.cat.categories
Out[23]: Index(['1', '2', '3'], dtype='object')
```

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

```
In [24]: dtype = {'B': CategoricalDtype([1, 2, 3])}

In [25]: pd.read_csv(StringIO(data), dtype=dtype).B.cat.categories
Out[25]: Int64Index([1, 2, 3], dtype='int64')
```

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string `'category'`. We'll take this moment to remind users that the *preferred* way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`.

See the [CategoricalDtype docs](#) for more.

### 1.6.1.7 GroupBy objects now have a pipe method

`GroupBy` objects now have a `pipe` method, similar to the one on `DataFrame` and `Series`, that allow for functions that take a `GroupBy` to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a `DataFrame` with columns for stores, products, revenue and sold quantity. We'd like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:

```
In [26]: import numpy as np

In [27]: n = 1000

In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                    'Product': np.random.choice(['Product_1', 'Product_2',
↪ 'Product_3'], n),
.....:                    'Revenue': (np.random.random(n)*50+10).round(2),
.....:                    'Quantity': np.random.randint(1, 10, size=n)})

In [29]: df.head(2)
Out[29]:
   Store  Product  Revenue  Quantity
0  Store_1  Product_3    54.28         3
1  Store_2  Product_2    30.91         1
```

Now, to find prices per store/product, we can simply do:

```
In [30]: (df.groupby(['Store', 'Product'])
.....:      .pipe(lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
.....:      .unstack().round(2))
Out[30]:
Product  Product_1  Product_2  Product_3
Store
```

(continues on next page)

(continued from previous page)

Store_1	6.37	6.98	7.49
Store_2	7.60	7.01	7.13

See the *documentation* for more.

### 1.6.1.8 Categorical.rename\_categories accepts a dict-like

`rename_categories()` now accepts a dict-like argument for `new_categories`. The previous categories are looked up in the dictionary's keys and replaced if found. The behavior of missing and extra keys is the same as in `DataFrame.rename()`.

```
In [31]: c = pd.Categorical(['a', 'a', 'b'])
In [32]: c.rename_categories({"a": "eh", "b": "bee"})
Out[32]:
[eh, eh, bee]
Categories (2, object): [eh, bee]
```

**Warning:** To assist with upgrading pandas, `rename_categories` treats Series as list-like. Typically, Series are considered to be dict-like (e.g. in `.rename`, `.map`). In a future version of pandas `rename_categories` will change to treat them as dict-like. Follow the warning message's recommendations for writing future-proof code.

```
In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))
FutureWarning: Treating Series 'new_categories' as a list-like and using the values.
In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()'
For list-like, use 'new_categories.values'.
Out[33]:
[0, 0, 1]
Categories (2, int64): [0, 1]
```

### 1.6.1.9 Other Enhancements

#### New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

#### New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the collections.Mapping subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)

- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter (GH16252). By default, this parameter is set to `HIGHEST_PROTOCOL`
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations (GH16359)
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. (GH15388)
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. (GH15972)
- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. (GH17048)
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. (GH17798)

## Various enhancements

- Improved the import time of pandas by about 2.25x. (GH16764)
- Support for PEP 519 – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`) (GH13823).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol (GH13823).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see [here](#) (GH16270)
- Added support for PEP 518 (`pyproject.toml`) to the build system (GH16745)
- `RangeIndex.append()` now returns a `RangeIndex` object when possible (GH16212)
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. (GH15704)
- `api.types.infer_dtype()` now infers decimals. (GH15690)
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. (GH16855)
- `date_range()` now accepts ‘YS’ in addition to ‘AS’ as an alias for start of year. (GH9313)
- `date_range()` now accepts ‘Y’ in addition to ‘A’ as an alias for end of year. (GH9313)
- `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the ‘%’ character. (GH17151)
- Read/write methods that infer compression (`read_csv()`, `read_table()`, `read_pickle()`, and `to_pickle()`) can now infer from path-like objects, such as `pathlib.Path`. (GH17206)
- `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
- `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
- `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
- `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned `False` in all cases. (GH16554)

- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of `**kwargs` for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for `tolerance`. (GH17367)

## 1.6.2 Backwards incompatible API changes

### 1.6.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

Package	Minimum Version	Required
Numpy	1.9.0	X
Matplotlib	1.4.3	
Scipy	0.14.0	
Bottleneck	1.0.0	

Additionally, support has been dropped for Python 3.4 (GH15251).

### 1.6.2.2 Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN

---

**Note:** The changes described here have been partially reverted. See the [v0.22.0 Whatsnew](#) for more.

---

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the [docs](#).

```
In [33]: s = Series([np.nan])
```

Previously WITHOUT `bottleneck` installed:

```
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH `bottleneck`:

```
In [2]: s.sum()
Out[2]: 0.0
```

New Behavior, without regard to the `bottleneck` installation:

```
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a `bottleneck` installation:

```
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-NaN case, this was changed to return NaN as well:

```
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

### 1.6.2.3 Indexing with a list with missing labels is Deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a `FutureWarning`. In the future this will raise a `KeyError` ([GH15747](#)). This warning will trigger on a `DataFrame` or a `Series` for using `.loc[]` or `[]` when passing a list-of-labels with at least 1 missing label. See the [deprecation docs](#).

```
In [36]: s = pd.Series([1, 2, 3])

In [37]: s
Out[37]:
0      1
1      2
2      3
dtype: int64
```

#### Previous Behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

#### Current Behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc or [] with any missing label will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
→listlike

Out[4]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`

```
In [38]: s.reindex([1, 2, 3])
Out[38]:
1      2.0
2      3.0
```

(continues on next page)

(continued from previous page)

```
3      NaN
dtype: float64
```

Selection with all keys found is unchanged.

```
In [39]: s.loc[[1, 2]]
Out[39]:
1      2
2      3
dtype: int64
```

### 1.6.2.4 NA naming Changes

In order to promote more consistency among the pandas API, we have added additional top-level functions `isna()` and `notna()` that are aliases for `isnull()` and `notnull()`. The naming scheme is now more consistent with methods like `.dropna()` and `.fillna()`. Furthermore in all cases where `.isnull()` and `.notnull()` methods are defined, these have additional methods named `.isna()` and `.notna()`, these are included for classes `Categorical`, `Index`, `Series`, and `DataFrame`. (GH15001).

The configuration option `pd.options.mode.use_inf_as_null` is deprecated, and `pd.options.mode.use_inf_as_na` is added as a replacement.

### 1.6.2.5 Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a `Series` with dtype `int` or `float`, you would receive a numpy scalar, e.g. a `np.int64`, rather than a Python `int`. Issue (GH10904) corrected this for `Series.tolist()` and `list(Series)`. This change makes all iteration methods consistent, in particular, for `__iter__()` and `.map()`; note that this only affects `int/float` dtypes. (GH13236, GH13258, GH14216).

```
In [40]: s = pd.Series([1, 2, 3])

In [41]: s
Out[41]:
0      1
1      2
2      3
dtype: int64
```

Previously:

```
In [2]: type(list(s)[0])
Out[2]: numpy.int64
```

New Behaviour:

```
In [42]: type(list(s)[0])
Out[42]: int
```

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

```
In [43]: d = {'a':[1], 'b':['b']}

In [44]: df = pd.DataFrame(d)
```

Previously:

```
In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64
```

New Behaviour:

```
In [45]: type(df.to_dict()['a'][0])
Out[45]: int
```

### 1.6.2.6 Indexing with a Boolean Index

Previously when passing a boolean Index to `.loc`, if the index of the Series/DataFrame had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. ([GH17738](#))

Previous Behavior:

```
In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])

In [47]: s
Out[47]:
False    1
True     2
False    3
dtype: int64
```

```
In [59]: s.loc[pd.Index([True, False, True])]
Out[59]:
True     2
False    1
False    3
True     2
dtype: int64
```

Current Behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False    1
False    3
dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously Behavior:

```
In [49]: s = pd.Series([1,2,3], index=['a', 'b', 'c'])

In [50]: s
Out[50]:
a     1
b     2
c     3
dtype: int64
```

```
In [39]: s.loc[pd.Index([True, False, True])]
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

#### Current Behavior

```
In [51]: s.loc[pd.Index([True, False, True])]
Out[51]:
a      1
c      3
dtype: int64
```

### 1.6.2.7 PeriodIndex resampling

In previous versions of pandas, resampling a Series/DataFrame indexed by a PeriodIndex returned a DatetimeIndex in some cases (GH12884). Resampling to a multiplied frequency now returns a PeriodIndex (GH15944). As a minor enhancement, resampling a PeriodIndex can now handle NaT values (GH13224)

#### Previous Behavior:

```
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [2]: s = pd.Series(np.arange(12), index=pi)
In [3]: resampled = s.resample('2Q').mean()
In [4]: resampled
Out[4]:
2017-03-31      1.0
2017-09-30      5.5
2018-03-31     10.0
Freq: 2Q-DEC, dtype: float64
In [5]: resampled.index
Out[5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype=
↳ 'datetime64[ns]', freq='2Q-DEC')
```

#### New Behavior:

```
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [53]: s = pd.Series(np.arange(12), index=pi)
In [54]: resampled = s.resample('2Q').mean()
In [55]: resampled
Out[55]:
2017Q1      2.5
2017Q3      8.5
Freq: 2Q-DEC, dtype: float64
In [56]: resampled.index
Out[56]:
PeriodIndex(['2017Q1', '2017Q3'], dtype='period[2Q-DEC]', freq='2Q-DEC')
```

Upsampling and calling `.ohlc()` previously returned a Series, basically identical to calling `.asfreq()`. OHLC upsampling now returns a DataFrame with columns open, high, low and close (GH13083). This is consistent with downsampling and DatetimeIndex behavior.

**New Behavior:**

#### 1.6.2.8 Improved error handling during item assignment in pd.eval

### 1.6. v0.21.0 (October 27, 2017)

```
In [61]: arr = np.array([1, 2, 3])
```

Previously, if you attempted the following expression, you would get a not very helpful error message:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
IndexError: only integers, slices (':'), ellipsis ('...'), numpy.newaxis ('None')
and integer or boolean arrays are valid indices
```

This is a very long way of saying numpy arrays don't support string-item indexing. With this change, the error message is now this:

```
In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
ValueError: Cannot assign expression output to target
```

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3
```

However, this input does not make much sense because the output is not being assigned to the target. Now, a `ValueError` will be raised when such an input is passed in:

```
In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...
ValueError: Cannot operate inplace if there is no assignment
```

### 1.6.2.9 Dtype Conversions

Previously assignments, `.where()` and `.fillna()` with a `bool` assignment, would coerce to same the type (e.g. `int` / `float`), or raise for datetimelikes. These will now preserve the bools with `object` dtypes. ([GH16821](#)).

```
In [62]: s = Series([1, 2, 3])
```

```
In [5]: s[1] = True

In [6]: s
Out[6]:
0    1
1    1
2    3
dtype: int64
```

New Behavior

```
In [63]: s[1] = True

In [64]: s
Out[64]:
0    1
1    True
2    3
dtype: object
```

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned ([GH14145](#)).

```
In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])
```

```
In [1]: s[1] = 1

In [2]: s
Out[2]:
0    2011-01-01 00:00:00.000000000
1    1970-01-01 00:00:00.000000001
dtype: datetime64[ns]
```

These now coerce to object dtype.

```
In [66]: s[1] = 1

In [67]: s
Out[67]:
0    2011-01-01 00:00:00
1
dtype: object
```

- Inconsistent behavior in `.where()` with datetimelikes which would raise rather than coerce to object ([GH16402](#))
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype ([GH14001](#))

### 1.6.2.10 MultiIndex Constructor with a Single Level

The `MultiIndex` constructors no longer squeezes a `MultiIndex` with all length-one levels down to a regular `Index`. This affects all the `MultiIndex` constructors. ([GH17178](#))

Previous behavior:

```
In [2]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[2]: Index(['a', 'b'], dtype='object')
```

Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a `MultiIndex` is always returned from all of the `MultiIndex` constructors:

```
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[68]:
MultiIndex(levels=[['a', 'b']],
            labels=[[0, 1]])
```

### 1.6.2.11 UTC Localization with Series

Previously, `to_datetime()` did not localize datetime Series data when `utc=True` was passed. Now, `to_datetime()` will correctly localize Series with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and `Index` data are handled. ([GH6415](#)).

Previous Behavior

```
In [69]: s = Series(['20130101 00:00:00'] * 3)
```

```
In [12]: pd.to_datetime(s, utc=True)
```

```
Out [12]:
```

```
0    2013-01-01
1    2013-01-01
2    2013-01-01
dtype: datetime64[ns]
```

### New Behavior

```
In [70]: pd.to_datetime(s, utc=True)
```

```
Out [70]:
```

```
0    2013-01-01 00:00:00+00:00
1    2013-01-01 00:00:00+00:00
2    2013-01-01 00:00:00+00:00
dtype: datetime64[ns, UTC]
```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

## 1.6.2.12 Consistency of Range Functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()`. (GH17471).

One of the inconsistent behaviors occurred when the start, end and period parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the period parameter, `period_range` ignored the end parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

### Previous Behavior:

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
```

```
Out [2]:
```

```
IntervalIndex([(0, 1], (1, 2], (2, 3]]
              closed='right',
              dtype='interval[int64]')
```

```
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
```

```
Out [3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'],
                    dtype='period[Q-DEC]', freq='Q-DEC')
```

### New Behavior:

```
In [2]: pd.interval_range(start=0, end=4, periods=6)
```

```
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be_
→ specified
```

```
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
```

```
-----
ValueError: Of the three parameters: start, end, and periods, exactly two must be_
→ specified
```

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous Behavior:

```
In [4]: pd.interval_range(start=0, end=4)
Out[4]:
IntervalIndex([(0, 1], (1, 2], (2, 3]]
              closed='right',
              dtype='interval[int64]')
```

New Behavior:

```
In [71]: pd.interval_range(start=0, end=4)
Out[71]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4]]
              closed='right',
              dtype='interval[int64]')
```

### 1.6.2.13 No Automatic Matplotlib Converters

Pandas no longer registers our date, time, datetime, datetime64, and Period converters with matplotlib when pandas is imported. Matplotlib plot methods (`plt.plot`, `ax.plot`, ...), will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

Pandas built-in `Series.plot` and `DataFrame.plot` *will* register these converters on first-use ([GH17710](#)).

---

**Note:** This change has been temporarily reverted in pandas 0.21.1, for more details see [here](#).

---

### 1.6.2.14 Other API Changes

- The Categorical constructor no longer accepts a scalar for the `categories` keyword. ([GH16022](#))
- Accessing a non-existent attribute on a closed `HDFStore` will now raise an `AttributeError` rather than a `ClosedFileError` ([GH16301](#))
- `read_csv()` now issues a `UserWarning` if the `names` parameter contains duplicates ([GH17095](#))
- `read_csv()` now treats `'null'` and `'n/a'` strings as missing values by default ([GH16471](#), [GH16078](#))
- `pandas.HDFStore`'s string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info()`. ([GH16503](#)).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if `complib` is missing and `complevel > 0` `zlib` is used ([GH15943](#))
- `Index.get_indexer_non_unique()` now returns a `ndarray` indexer rather than an `Index`; this is consistent with `Index.get_indexer()` ([GH16819](#))
- Removed the `@slow` decorator from `pandas.util.testing`, which caused issues for some downstream packages' test suites. Use `@pytest.mark.slow` instead, which achieves the same thing ([GH16850](#))
- Moved definition of `MergeError` to the `pandas.errors` module.

- The signature of `Series.set_axis()` and `DataFrame.set_axis()` has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a `FutureWarning` (GH14636)
- `Series.argmax()` and `Series.argmin()` will now raise a `TypeError` when used with object dtypes, instead of a `ValueError` (GH13595)
- `Period` is now immutable, and will now raise an `AttributeError` when a user tries to assign a new value to the ordinal or freq attributes (GH17116).
- `to_datetime()` when passed a tz-aware `origin=` kwarg will now raise a more informative `ValueError` rather than a `TypeError` (GH16842)
- `to_datetime()` now raises a `ValueError` when format includes `%W` or `%U` without also including day of the week and calendar year (GH16774)
- Renamed non-functional index to `index_col` in `read_stata()` to improve API consistency (GH16342)
- Bug in `DataFrame.drop()` caused boolean labels `False` and `True` to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a `ValueError` (GH16877)
- Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

### 1.6.3 Deprecations

- `DataFrame.from_csv()` and `Series.from_csv()` have been deprecated in favor of `read_csv()` (GH4191)
- `read_excel()` has deprecated `sheetname` in favor of `sheet_name` for consistency with `.to_excel()` (GH10559).
- `read_excel()` has deprecated `parse_cols` in favor of `usecols` for consistency with `read_csv()` (GH4988)
- `read_csv()` has deprecated the `tupleize_cols` argument. Column tuples will always be converted to a `MultiIndex` (GH17060)
- `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. Multi-index columns will be always written as rows in the CSV file (GH17060)
- The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948)
- `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).
- `SeriesGroupBy.nth()` has deprecated `True` in favor of `'all'` for its kwarg `dropna` (GH11038).
- `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302)
- `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747)
- `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the [documentation](#) for more details (GH17596)
- passing categories or ordered kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636)
- `.get_value` and `.set_value` on `Series`, `DataFrame`, `Panel`, `SparseSeries`, and `SparseDataFrame` are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269)

- Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295)
- `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968)
- Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column *labels* is now deprecated in favor of using `.rename`. `rename_axis` may still be used to alter the name of the index or columns (GH17833).
- `reindex_axis()` has been deprecated in favor of `reindex()`. See [here](#) for more (GH17833).

### 1.6.3.1 Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```
In [72]: df = DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])
```

```
In [3]: df.select(lambda x: x in ['bar', 'baz'])
```

FutureWarning: select is deprecated and will be removed in a future release. You can use `.loc[crit]` as a replacement

```
Out [3]:
```

```
      A
bar   2
baz   3
```

```
In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
```

```
Out [73]:
```

```
      A
bar   2
baz   3
```

### 1.6.3.2 Series.argmax and Series.argmin

The behavior of `Series.argmax()` and `Series.argmin()` have been deprecated in favor of `Series.idxmax()` and `Series.idxmin()`, respectively (GH16830).

For compatibility with NumPy arrays, `pd.Series` implements `argmax` and `argmin`. Since pandas 0.13.0, `argmax` has been an alias for `pandas.Series.idxmax()`, and `argmin` has been an alias for `pandas.Series.idxmin()`. They return the *label* of the maximum or minimum, rather than the *position*.

We've deprecated the current behavior of `Series.argmax` and `Series.argmin`. Using either of these will emit a `FutureWarning`. Use `Series.idxmax()` if you want the label of the maximum. Use `Series.values.argmax()` if you want the position of the maximum. Likewise for the minimum. In a future release `Series.argmax` and `Series.argmin` will return the position of the maximum or minimum.

## 1.6.4 Removal of prior version deprecations/changes

- `read_excel()` has dropped the `has_index_names` parameter (GH10967)
- The `pd.options.display.height` configuration has been dropped (GH3663)
- The `pd.options.display.line_width` configuration has been dropped (GH2881)
- The `pd.options.display.mpl_style` configuration has been dropped (GH12190)

- Index has dropped the `.sym_diff()` method in favor of `.symmetric_difference()` (GH12591)
- Categorical has dropped the `.order()` and `.sort()` methods in favor of `.sort_values()` (GH12882)
- `eval()` and `DataFrame.eval()` have changed the default of `inplace` from `None` to `False` (GH11149)
- The function `get_offset_name` has been dropped in favor of the `.freqstr` attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

## 1.6.5 Performance Improvements

- Improved performance of instantiating `SparseDataFrame` (GH16773)
- `Series.dt` no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of `set_categories()` by not materializing the values (GH17508)
- `Timestamp.microsecond` no longer re-computes on attribute access (GH17331)
- Improved performance of the `CategoricalIndex` for data that is already categorical dtype (GH17513)
- Improved performance of `RangeIndex.min()` and `RangeIndex.max()` by using `RangeIndex` properties to perform the computations (GH17607)

## 1.6.6 Documentation Changes

- Several NaT method docstrings (e.g. `NaT.ctime()`) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)

## 1.6.7 Bug Fixes

### 1.6.7.1 Conversion

- Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
- Fixed the return type of `IntervalIndex.is_non_overlapping_monotonic` to be a Python `bool` for consistency with similar attributes/methods. Previously returned a `numpy.bool_`. (GH17237)
- Bug in `IntervalIndex.is_non_overlapping_monotonic` when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in `Series.fillna()` returns frame when `inplace=True` and value is dict (GH16156)
- Bug in `Timestamp.weekday_name` returning a UTC-based weekday name when localized to a timezone (GH17354)
- Bug in `Timestamp.replace` when replacing `tzinfo` around DST changes (GH15683)
- Bug in `Timedelta` construction and arithmetic that would not propagate the `Overflow` exception (GH17367)

- Bug in `astype()` converting to object dtype when passed extension type classes (`DatetimeTZDtype`, `CategoricalDtype`) rather than instances. Now a `TypeError` is raised when a class is passed ([GH17780](#)).
- Bug in `to_numeric()` in which elements were not always being coerced to numeric when `errors='coerce'` ([GH17007](#), [GH17125](#))
- Bug in `DataFrame` and `Series` constructors where range objects are converted to `int32` dtype on Windows instead of `int64` ([GH16804](#))

### 1.6.7.2 Indexing

- When called with a null slice (e.g. `df.iloc[:]`), the `.iloc` and `.loc` indexers return a shallow copy of the original object. Previously they returned the original object. ([GH13873](#)).
- When called on an unsorted `MultiIndex`, the `loc` indexer now will raise `UnsortedIndexError` only if proper slicing is used on non-sorted levels ([GH16734](#)).
- Fixes regression in 0.20.3 when indexing with a string on a `TimedeltaIndex` ([GH16896](#)).
- Fixed `TimedeltaIndex.get_loc()` handling of `np.timedelta64` inputs ([GH16909](#)).
- Fix `MultiIndex.sort_index()` ordering when ascending argument is a list, but not all levels are specified, or are in a different order ([GH16934](#)).
- Fixes bug where indexing with `np.inf` caused an `OverflowError` to be raised ([GH16957](#))
- Bug in reindexing on an empty `CategoricalIndex` ([GH16770](#))
- Fixes `DataFrame.loc` for setting with alignment and tz-aware `DatetimeIndex` ([GH16889](#))
- Avoids `IndexError` when passing an `Index` or `Series` to `.iloc` with older numpy ([GH17193](#))
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 ([GH17099](#))
- Bug in `.iloc` when used with inplace addition or assignment and an int indexer on a `MultiIndex` causing the wrong indexes to be read from and written to ([GH17148](#))
- Bug in `.isin()` in which checking membership in empty `Series` objects raised an error ([GH16991](#))
- Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected ([GH17323](#))
- Bug in intersection of `RangeIndex` with negative step ([GH17296](#))
- Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes ([GH16417](#), [GH17271](#))
- Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry ([GH17400](#))
- Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. ([GH17407](#))
- Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. ([GH17704](#))

### 1.6.7.3 I/O

- Bug in `read_hdf()` when reading a timezone aware index from fixed format `HDFStore` ([GH17618](#))
- Bug in `read_csv()` in which columns were not being thoroughly de-duplicated ([GH17060](#))
- Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated ([GH17095](#))

- Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)
- Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
- Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
- Bug in `read_csv()` when called with a single-element list header would return a `DataFrame` of all NaN values (GH7757)
- Bug in `DataFrame.to_csv()` defaulting to 'ascii' encoding in Python 3, instead of 'utf-8' (GH17097)
- Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)
- Bug in `read_stata()` where the index was not set (GH16342)
- Bug in `read_html()` where import check fails when run in multiple threads (GH16928)
- Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)
- Bug in `DataFrame.to_html()` with `notebook=True` where `DataFrames` with named indices or non-`MultiIndex` indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)
- Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)
- Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring `VArray` (GH17021)
- Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)

#### 1.6.7.4 Plotting

- Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)
- Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)
- Line plots no longer assume monotonic x data when calculating xlimits, they show the entire lines now even for unsorted x data. (GH11310, GH11471)
- With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)
- Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed `color` (GH16822)
- Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

#### 1.6.7.5 Groupby/Resample/Rolling

- Bug in `DataFrame.resample(...).size()` where an empty `DataFrame` did not return a `Series` (GH14962)
- Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)
- Bug in `.rolling(...).quantile()` which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)

- Bug in `groupby.transform()` that would coerce boolean dtypes back to float ([GH16875](#))
- Bug in `Series.resample(...).apply()` where an empty Series modified the source index and did not return the name of a Series ([GH14313](#))
- Bug in `.rolling(...).apply(...)` with a DataFrame with a DatetimeIndex, a window of a timedelta-convertible and `min_periods >= 1` ([GH15305](#))
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis ([GH16859](#))
- Bug in `groupby.nunique()` with TimeGrouper which cannot handle NaT correctly ([GH17575](#))
- Bug in `DataFrame.groupby` where a single level selection from a MultiIndex unexpectedly sorts ([GH17537](#))
- Bug in `DataFrame.groupby` where spurious warning is raised when Grouper object is used to override ambiguous column name ([GH17383](#))
- Bug in TimeGrouper differs when passes as a list and as a scalar ([GH17530](#))

#### 1.6.7.6 Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data ([GH16905](#))
- Bug in `SparseDataFrame.fillna()` not filling all NaNs when frame was instantiated from SciPy sparse matrix ([GH16112](#))
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` ([GH16614](#), [GH15045](#))
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array dtype is object ([GH17574](#))
- `SparseArray.all()` and `SparseArray.any()` are now implemented to handle `SparseArray`, these were used but not implemented ([GH17570](#))

#### 1.6.7.7 Reshaping

- Joining/Merging with a non unique PeriodIndex raised a `TypeError` ([GH16871](#))
- Bug in `crosstab()` where non-aligned series of integers were casted to float ([GH17005](#))
- Bug in merging with categorical dtypes with datetimelikes incorrectly raised a `TypeError` ([GH16900](#))
- Bug when using `isin()` on a large object series and large comparison array ([GH16012](#))
- Fixes regression from 0.20, `Series.aggregate()` and `DataFrame.aggregate()` allow dictionaries as return values again ([GH16741](#))
- Fixes dtype of result with integer dtype input, from `pivot_table()` when called with `margins=True` ([GH17013](#))
- Bug in `crosstab()` where passing two Series with the same name raised a `KeyError` ([GH13279](#))
- `Series.argmax()`, `Series.argmin()`, and their counterparts on DataFrame and groupby objects work correctly with floating point data that contains infinite values ([GH13595](#)).
- Bug in `unique()` where checking a tuple of strings raised a `TypeError` ([GH17108](#))
- Bug in `concat()` where order of result index was unpredictable if it contained non-comparable elements ([GH17344](#))

- Fixes regression when sorting by multiple columns on a `datetime64` dtype Series with NaT values (GH16836)
- Bug in `pivot_table()` where the result's columns did not preserve the categorical dtype of columns when `dropna` was `False` (GH17842)
- Bug in `DataFrame.drop_duplicates` where dropping with non-unique column names raised a `ValueError` (GH17836)
- Bug in `unstack()` which, when called on a list of levels, would discard the `fillna` argument (GH13971)
- Bug in the alignment of range objects and other list-likes with `DataFrame` leading to operations being performed row-wise instead of column-wise (GH17901)

#### 1.6.7.8 Numeric

- Bug in `.clip()` with `axis=1` and a list-like for `threshold` is passed; previously this raised `ValueError` (GH15390)
- `Series.clip()` and `DataFrame.clip()` now treat NA values for upper and lower arguments as `None` instead of raising `ValueError` (GH17276).

#### 1.6.7.9 Categorical

- Bug in `Series.isin()` when called with a categorical (GH16639)
- Bug in the categorical constructor with empty values and categories causing the `.categories` to be an empty `Float64Index` rather than an empty `Index` with object dtype (GH17248)
- Bug in categorical operations with `Series.cat` not preserving the original Series' name (GH17509)
- Bug in `DataFrame.merge()` failing for categorical columns with boolean/int data types (GH17187)
- Bug in constructing a `Categorical/CategoricalDtype` when the specified categories are of categorical type (GH17884).

#### 1.6.7.10 PyPy

- Compatibility with PyPy in `read_csv()` with `usecols=[<unsorted ints>]` and `read_json()` (GH17351)
- Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with `float('nan')`, `np.nan` and `NAT` (GH17351)
- Fix `DataFrame.memory_usage()` to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

#### 1.6.7.11 Other

- Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
- Bug in `eval()` where the `inplace` parameter was being incorrectly handled (GH16732)

## 1.7 v0.20.3 (July 7, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

### What's new in v0.20.3

- *Bug Fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Reshaping*
  - *Categorical*

### 1.7.1 Bug Fixes

- Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame ([GH16789](#), [GH16825](#))
- Fixed a pytest marker failing downstream packages' tests suites ([GH16680](#))

#### 1.7.1.1 Conversion

- Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index ([GH16608](#))
- Bug in Series construction when passing a Series with dtype='category' ([GH16524](#)).
- Bug in `DataFrame.astype()` when passing a Series as the dtype kwarg. ([GH16717](#)).

#### 1.7.1.2 Indexing

- Bug in `Float64Index` causing an empty array instead of None to be returned from `.get(np.nan)` on a Series whose index did not contain any NaN s ([GH8569](#))
- Bug in `MultiIndex.isin` causing an error when passing an empty iterable ([GH16777](#))
- Fixed a bug in a slicing DataFrame/Series that have a `TimedeltaIndex` ([GH16637](#))

#### 1.7.1.3 I/O

- Bug in `read_csv()` in which files weren't opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail ([GH16039](#), [GH16559](#), [GH16675](#))
- Bug in `read_hdf()` in which reading a Series saved to an HDF file in 'fixed' format fails when an explicit `mode='r'` argument is supplied ([GH16583](#))

- Bug in `DataFrame.to_latex()` where `bold_rows` was wrongly specified to be `True` by default, whereas in reality row labels remained non-bold whatever parameter provided. (GH16707)
- Fixed an issue with `DataFrame.style()` where generated element ids were not unique (GH16780)
- Fixed loading a `DataFrame` with a `PeriodIndex`, from a `format='fixed'` `HDFStore`, in Python 3, that was written in Python 2 (GH16781)

#### 1.7.1.4 Plotting

- Fixed regression that prevented RGB and RGBA tuples from being used as color arguments (GH16233)
- Fixed an issue with `DataFrame.plot.scatter()` that incorrectly raised a `KeyError` when categorical data is used for plotting (GH16199)

#### 1.7.1.5 Reshaping

- `PeriodIndex / TimedeltaIndex.join` was missing the `sort=` kwarg (GH16541)
- Bug in joining on a `MultiIndex` with a `category` dtype for a level (GH16627).
- Bug in `merge()` when merging/joining with multiple categorical columns (GH16767)

#### 1.7.1.6 Categorical

- Bug in `DataFrame.sort_values` not respecting the `kind` parameter with categorical data (GH16793)

## 1.8 v0.20.2 (June 4, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

### What's new in v0.20.2

- *Enhancements*
- *Performance Improvements*
- *Bug Fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Groupby/Resample/Rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Categorical*

### 1.8.1 Enhancements

- Unblocked access to additional compression types supported in pytables: ‘blosc:blosclz’, ‘blosc:lz4’, ‘blosc:lz4hc’, ‘blosc:snappy’, ‘blosc:zlib’, ‘blosc:zstd’ (GH14478)
- `Series` provides a `to_latex` method (GH16180)
- A new `groupby` method `ngroup()`, parallel to the existing `cumcount()`, has been added to return the group order (GH11642); see [here](#).

### 1.8.2 Performance Improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for `MultiIndex`s (GH16319, GH16346)
- Improved performance of `.clip()` with scalar arguments (GH15400)
- Improved performance of `groupby` with categorical groupers (GH16413)
- Improved performance of `MultiIndex.remove_unused_levels()` (GH16556)

### 1.8.3 Bug Fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using `pathlib.Path` or `py.path.local` objects with io functions (GH16291)
- Bug in `Index.symmetric_difference()` on two equal `MultiIndex`’s, results in a `TypeError` (GH13490)
- Bug in `DataFrame.update()` with `overwrite=False` and `NaN` values (GH15593)
- Passing an invalid engine to `read_csv()` now raises an informative `ValueError` rather than `UnboundLocalError`. (GH16511)
- Bug in `unique()` on an array of tuples (GH16519)
- Bug in `cut()` when labels are set, resulting in incorrect label ordering (GH16459)
- Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on `Categoricals` (GH16409)

#### 1.8.3.1 Conversion

- Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
- Silence numpy warnings when broadcasting `DataFrame` to `Series` with comparison ops (GH16378, GH16306)

### 1.8.3.2 Indexing

- Bug in `DataFrame.reset_index(level=)` with single level index ([GH16263](#))
- Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds ([GH16515](#))
- Bug in `MultiIndex.remove_unused_levels()` that would not return a `MultiIndex` equal to the original. ([GH16556](#))

### 1.8.3.3 I/O

- Bug in `read_csv()` when `comment` is passed in a space delimited text file ([GH16472](#))
- Bug in `read_csv()` not raising an exception with nonexistent columns in `usecols` when it had the correct length ([GH14671](#))
- Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup ([GH16288](#))
- Bug that raised `IndexError` when HTML-rendering an empty `DataFrame` ([GH15953](#))
- Bug in `read_csv()` in which `tarfile` object inputs were raising an error in Python 2.x for the C engine ([GH16530](#))
- Bug where `DataFrame.to_html()` ignored the `index_names` parameter ([GH16493](#))
- Bug where `pd.read_hdf()` returns numpy strings for index names ([GH13492](#))
- Bug in `HDFStore.select_as_multiple()` where `start/stop` arguments were not respected ([GH16209](#))

### 1.8.3.4 Plotting

- Bug in `DataFrame.plot` with a single column and a list-like `color` ([GH3486](#))
- Bug in `plot` where `NaT` in `DatetimeIndex` results in `Timestamp.min` ([GH12405](#))
- Bug in `DataFrame.boxplot` where `figsize` keyword was not respected for non-grouped boxplots ([GH11959](#))

### 1.8.3.5 Groupby/Resample/Rolling

- Bug in creating a time-based rolling window on an empty `DataFrame` ([GH15819](#))
- Bug in `rolling.cov()` with offset window ([GH16058](#))
- Bug in `.resample()` and `.groupby()` when aggregating on integers ([GH16361](#))

### 1.8.3.6 Sparse

- Bug in construction of `SparseDataFrame` from `scipy.sparse.dok_matrix` ([GH16179](#))

### 1.8.3.7 Reshaping

- Bug in `DataFrame.stack` with unsorted levels in `MultiIndex` columns ([GH16323](#))
- Bug in `pd.wide_to_long()` where no error was raised when `i` was not a unique identifier ([GH16382](#))
- Bug in `Series.isin(..)` with a list of tuples ([GH16394](#))
- Bug in construction of a `DataFrame` with mixed dtypes including an all-`NaT` column. ([GH16395](#))
- Bug in `DataFrame.agg()` and `Series.agg()` with aggregating on non-callable attributes ([GH16405](#))

### 1.8.3.8 Numeric

- Bug in `.interpolate()`, where `limit_direction` was not respected when `limit=None` (default) was passed ([GH16282](#))

### 1.8.3.9 Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are unordered ([GH16014](#))

### 1.8.3.10 Other

- Bug in `DataFrame.drop()` with an empty-list with non-unique indices ([GH16270](#))

## 1.9 v0.20.1 (May 5, 2017)

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New `.agg()` API for `Series/DataFrame` similar to the `groupby-rolling-resample` API's, see [here](#)
- Integration with the `feather-format`, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- The `.ix` indexer has been deprecated, see [here](#)
- `Panel` has been deprecated, see [here](#)
- Addition of an `IntervalIndex` and `Interval` scalar type, see [here](#)
- Improved user API when grouping by index levels in `.groupby()`, see [here](#)
- Improved support for `UInt64` dtypes, see [here](#)
- A new orient for JSON serialization, `orient='table'`, that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see [here](#)
- Experimental support for exporting styled `DataFrames` (`DataFrame.style`) to Excel, see [here](#)
- Window binary `corr/cov` operations now return a `MultiIndexed DataFrame` rather than a `Panel`, as `Panel` is now deprecated, see [here](#)
- Support for S3 handling now uses `s3fs`, see [here](#)

- Google BigQuery support now uses the `pandas-gbq` library, see [here](#)

**Warning:** Pandas has changed the internal structure and layout of the codebase. This can affect imports that are not from the top-level `pandas.*` namespace, please see the changes [here](#).

Check the *API Changes* and *deprecations* before updating.

**Note:** This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas' `utils` routines. ([GH16250](#))

---

### What's new in v0.20.0

- *New features*
  - *agg API for DataFrame/Series*
  - *dtype keyword for data IO*
  - *.to\_datetime() has gained an origin parameter*
  - *Groupby Enhancements*
  - *Better support for compressed URLs in read\_csv*
  - *Pickle file I/O now supports compression*
  - *UInt64 Support Improved*
  - *GroupBy on Categoricals*
  - *Table Schema Output*
  - *SciPy sparse matrix from/to SparseDataFrame*
  - *Excel output for styled DataFrames*
  - *IntervalIndex*
  - *Other Enhancements*
- *Backwards incompatible API changes*
  - *Possible incompatibility for HDF5 formats created with pandas < 0.13.0*
  - *Map on Index types now return other Index types*
  - *Accessing datetime fields of Index now return Index*
  - *pd.unique will now be consistent with extension types*
  - *S3 File Handling*
  - *Partial String Indexing Changes*
  - *Concat of different float dtypes will not automatically upcast*
  - *Pandas Google BigQuery support has moved*
  - *Memory Usage for Index is more Accurate*
  - *DataFrame.sort\_index changes*

- *Groupby Describe Formatting*
- *Window Binary Corr/Cov operations return a MultiIndex DataFrame*
- *HDFStore where string comparison*
- *Index.intersection and inner join now preserve the order of the left Index*
- *Pivot Table always returns a DataFrame*
- *Other API Changes*
- *Reorganization of the library: Privacy Changes*
  - *Modules Privacy Has Changed*
  - `pandas.errors`
  - `pandas.testing`
  - `pandas.plotting`
  - *Other Development Changes*
- *Deprecations*
  - *Deprecate .ix*
  - *Deprecate Panel*
  - *Deprecate groupby.agg() with a dictionary when renaming*
  - *Deprecate .plotting*
  - *Other Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance Improvements*
- *Bug Fixes*
  - *Conversion*
  - *Indexing*
  - *I/O*
  - *Plotting*
  - *Groupby/Resample/Rolling*
  - *Sparse*
  - *Reshaping*
  - *Numeric*
  - *Other*

## 1.9.1 New features

### 1.9.1.1 agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and

`transform()`. The full documentation is [here](#) (GH1623).

Here is a sample

```
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...:                      index=pd.date_range('1/1/2000', periods=10))
...:

In [2]: df.iloc[3:7] = np.nan

In [3]: df
Out[3]:
```

	A	B	C
2000-01-01	1.682600	0.413582	1.689516
2000-01-02	-2.099110	-1.180182	1.595661
2000-01-03	-0.419048	0.522165	-1.208946
2000-01-04	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN
2000-01-08	0.955435	-0.133009	2.011466
2000-01-09	0.578780	0.897126	-0.980013
2000-01-10	-0.045748	0.361601	-0.208039

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to `.apply`.

```
In [4]: df.agg('sum')
Out[4]:
```

A	0.652908
B	0.881282
C	2.899645

dtype: float64

Multiple aggregations with a list of functions.

```
In [5]: df.agg(['sum', 'min'])
Out[5]:
```

	A	B	C
sum	0.652908	0.881282	2.899645
min	-2.099110	-1.180182	-1.208946

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will be NaN:

```
In [6]: df.agg({'A' : ['sum', 'min'], 'B' : ['min', 'max']})
Out[6]:
```

	A	B
max	NaN	0.897126
min	-2.099110	-1.180182
sum	0.652908	NaN

The API also supports a `.transform()` function for broadcasting results.

```
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out[7]:
```

(continues on next page)

(continued from previous page)

	A		B		C	
	abs	<lambda>	abs	<lambda>	abs	<lambda>
2000-01-01	1.682600	3.781710	0.413582	1.593764	1.689516	2.898461
2000-01-02	2.099110	0.000000	1.180182	0.000000	1.595661	2.804606
2000-01-03	0.419048	1.680062	0.522165	1.702346	1.208946	0.000000
2000-01-04	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-05	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-06	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-07	NaN	NaN	NaN	NaN	NaN	NaN
2000-01-08	0.955435	3.054545	0.133009	1.047173	2.011466	3.220412
2000-01-09	0.578780	2.677890	0.897126	2.077307	0.980013	0.228932
2000-01-10	0.045748	2.053362	0.361601	1.541782	0.208039	1.000907

When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how `groupby .agg()` works. (GH15015)

```
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
...:                      'B': [1., 2., 3.],
...:                      'C': ['foo', 'bar', 'baz'],
...:                      'D': pd.date_range('20130101', periods=3)})
...:

In [9]: df.dtypes
Out[9]:
A          int64
B          float64
C          object
D    datetime64[ns]
dtype: object
```

```
In [10]: df.agg(['min', 'sum'])
Out[10]:
   A    B      C      D
min 1  1.0    bar 2013-01-01
sum 6  6.0 foobarbaz      NaT
```

### 1.9.1.2 dtype keyword for data IO

The 'python' engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns (GH14295). See the *io docs* for more information.

```
In [11]: data = "a  b\n1  2\n3  4"

In [12]: pd.read_fwf(StringIO(data)).dtypes
Out[12]:
a    int64
b    int64
dtype: object

In [13]: pd.read_fwf(StringIO(data), dtype={'a': 'float64', 'b': 'object'}).dtypes
Out[13]:
a    float64
b    object
dtype: object
```

### 1.9.1.3 .to\_datetime() has gained an origin parameter

`to_datetime()` has gained a new parameter, `origin`, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific `unit` specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

```
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00, which is commonly called ‘unix epoch’ or POSIX time. This was the previous default, so this is a backward compatible change.

```
In [15]: pd.to_datetime([1, 2, 3], unit='D')
Out[15]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

### 1.9.1.4 Groupby Enhancements

Strings passed to `DataFrame.groupby()` as the `by` parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

```
In [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...:               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:
```

```
In [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

```
In [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                      'B': np.arange(8)},
.....:                      index=index)
.....:
```

```
In [19]: df
```

```
Out [19]:
```

		A	B
first	second		
bar	one	1	0
	two	1	1
baz	one	1	2
	two	1	3
foo	one	2	4
	two	2	5
qux	one	3	6
	two	3	7

```
In [20]: df.groupby(['second', 'A']).sum()
```

		B
second	A	
one	1	2
	2	4
	3	6

(continues on next page)

(continued from previous page)

```

two    1  4
       2  5
       3  7

```

### 1.9.1.5 Better support for compressed URLs in `read_csv`

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: `xz`, `bz2`, and `zip` (GH14570). Previously, only `gzip` compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for `bz2` compression in the python 2 C-engine improved (GH14874).

```

In [21]: url = 'https://github.com/{repo}/raw/{branch}/{path}'.format(
.....:     repo = 'pandas-dev/pandas',
.....:     branch = 'master',
.....:     path = 'pandas/tests/io/parser/data/salaries.csv.bz2',
.....: )
.....:

In [22]: df = pd.read_table(url, compression='infer') # default, infer compression

In [23]: df = pd.read_table(url, compression='bz2') # explicitly specify compression

In [24]: df.head(2)
Out[24]:
      S  X  E  M
0  13876  1  1  1
1  11608  1  3  0

```

### 1.9.1.6 Pickle file I/O now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See [the docs here](#).

```

In [25]: df = pd.DataFrame({
.....:     'A': np.random.randn(1000),
.....:     'B': 'foo',
.....:     'C': pd.date_range('20130101', periods=1000, freq='s')})
.....:

```

Using an explicit compression type

```

In [26]: df.to_pickle("data.pkl.compress", compression="gzip")

In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [28]: rt.head()
Out[28]:
      A      B      C
0  1.578227  foo  2013-01-01 00:00:00
1 -0.230575  foo  2013-01-01 00:00:01
2  0.695530  foo  2013-01-01 00:00:02
3 -0.466001  foo  2013-01-01 00:00:03
4 -0.154972  foo  2013-01-01 00:00:04

```

The default is to infer the compression type from the extension (`compression='infer'`):

```
In [29]: df.to_pickle("data.pkl.gz")

In [30]: rt = pd.read_pickle("data.pkl.gz")

In [31]: rt.head()
Out[31]:
```

	A	B	C
0	1.578227	foo	2013-01-01 00:00:00
1	-0.230575	foo	2013-01-01 00:00:01
2	0.695530	foo	2013-01-01 00:00:02
3	-0.466001	foo	2013-01-01 00:00:03
4	-0.154972	foo	2013-01-01 00:00:04

```
In [32]: df["A"].to_pickle("s1.pkl.bz2")

In [33]: rt = pd.read_pickle("s1.pkl.bz2")

In [34]: rt.head()
Out[34]:
```

0	1.578227
1	-0.230575
2	0.695530
3	-0.466001
4	-0.154972

```
Name: A, dtype: float64
```

### 1.9.1.7 UInt64 Support Improved

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created ([GH14937](#))

```
In [35]: idx = pd.UInt64Index([1, 2, 3])

In [36]: df = pd.DataFrame({'A': ['a', 'b', 'c']}, index=idx)

In [37]: df.index
Out[37]: UInt64Index([1, 2, 3], dtype='uint64')
```

- Bug in converting object elements of array-like objects to unsigned 64-bit integers ([GH4471](#), [GH14982](#))
- Bug in `Series.unique()` in which unsigned 64-bit integers were causing overflow ([GH14721](#))
- Bug in `DataFrame` construction in which unsigned 64-bit integer elements were being converted to objects ([GH14881](#))
- Bug in `pd.read_csv()` in which unsigned 64-bit integer elements were being improperly converted to the wrong data types ([GH14983](#))
- Bug in `pd.unique()` in which unsigned 64-bit integers were causing overflow ([GH14915](#))
- Bug in `pd.value_counts()` in which unsigned 64-bit integers were being erroneously truncated in the output ([GH14934](#))

### 1.9.1.8 GroupBy on Categoricals

In previous versions, `.groupby(..., sort=False)` would fail with a `ValueError` when grouping on a categorical series with some categories not appearing in the data. (GH13179)

```
In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]

In [39]: df = pd.DataFrame({
.....:     'A': np.random.randint(100),
.....:     'B': np.random.randint(100),
.....:     'C': np.random.randint(100),
.....:     'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
.....:                                     categories=chromosomes,
.....:                                     ordered=True)})

In [40]: df
Out[40]:
```

	A	B	C	chromosomes
0	80	36	94	12
1	80	36	94	X
2	80	36	94	19
3	80	36	94	22
4	80	36	94	17
5	80	36	94	6
6	80	36	94	13
..	..	..	..	...
93	80	36	94	21
94	80	36	94	20
95	80	36	94	11
96	80	36	94	16
97	80	36	94	21
98	80	36	94	18
99	80	36	94	8

[100 rows x 4 columns]

#### Previous Behavior:

```
In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
-----
ValueError: items in new_categories are not the same as in old categories
```

#### New Behavior:

```
In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:
```

	A	B	C
chromosomes			
2	320	144	376
3	400	180	470
4	240	108	282
5	240	108	282
6	400	180	470
7	400	180	470
8	480	216	564
...	...	...	...
19	400	180	470

1              0     0     0

```

```
[24 rows x 3 columns]
```

### 1.9.1.9 Table Schema Output

The new orient `'table'` for `DataFrame.to_json()` will generate a [Table Schema](#) compatible string representation of the data.

```

In [42]: df = pd.DataFrame(
.....:     {'A': [1, 2, 3],
.....:      'B': ['a', 'b', 'c'],
.....:      'C': pd.date_range('2016-01-01', freq='d', periods=3),
.....:     }, index=pd.Index(range(3), name='idx'))
.....:

```

```
In [43]: df
```

```

Out[43]:
   A  B      C
idx
0   1  a 2016-01-01
1   2  b 2016-01-02
2   3  c 2016-01-03

```

```
In [44]: df.to_json(orient='table')
```

```

////////////////////////////////////
↪ '{"schema": {"fields": [{"name": "idx", "type": "integer"}, {"name": "A", "type": "integer"},
↪ {"name": "B", "type": "string"}, {"name": "C", "type": "datetime"}], "primaryKey": ["idx"],
↪ "pandas_version": "0.20.0"}, "data": [{"idx": 0, "A": 1, "B": "a", "C": "2016-01-
↪ 01T00:00:00.000Z"}, {"idx": 1, "A": 2, "B": "b", "C": "2016-01-02T00:00:00.000Z"}, {"idx": 2,
↪ "A": 3, "B": "c", "C": "2016-01-03T00:00:00.000Z"}]}'

```

See [IO: Table Schema for more information](#).

Additionally, the repr for `DataFrame` and `Series` can now publish this JSON Table schema representation of the Series or DataFrame if you are using IPython (or another frontend like [interact](#) using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and [interact](#) more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

### 1.9.1.10 SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the [documentation](#) for more information. ([GH4343](#))

All sparse formats are supported, but matrices that are not in `COOrdinate` format will be converted, copying data as needed.

```

In [45]: from scipy.sparse import csr_matrix

In [46]: arr = np.random.random(size=(1000, 5))

In [47]: arr[arr < .9] = 0

In [48]: sp_arr = csr_matrix(arr)

In [49]: sp_arr
Out[49]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
      with 521 stored elements in Compressed Sparse Row format>

In [50]: sdf = pd.SparseDataFrame(sp_arr)

In [51]: sdf
Out[51]:
   0      1      2      3      4
0  NaN    NaN    NaN    NaN    NaN
1  NaN    NaN    NaN  0.955103  NaN
2  NaN    NaN    NaN  0.900469  NaN
3  NaN    NaN    NaN    NaN    NaN
4  NaN  0.924771    NaN    NaN    NaN
5  NaN    NaN    NaN    NaN    NaN
6  NaN    NaN    NaN    NaN    NaN
..  ..      ...      ...      ...      ...
993 NaN    NaN    NaN    NaN    NaN
994 NaN    NaN    NaN    NaN  0.972191
995 NaN  0.979898  0.97901    NaN    NaN
996 NaN    NaN    NaN    NaN    NaN
997 NaN    NaN    NaN    NaN    NaN
998 NaN    NaN    NaN    NaN    NaN
999 NaN    NaN    NaN    NaN    NaN

[1000 rows x 5 columns]

```

To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use:

```

In [52]: sdf.to_coo()
Out[52]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'
      with 521 stored elements in COOrdinate format>

```

### 1.9.1.11 Excel output for styled DataFrames

Experimental support has been added to export `DataFrame.style` formats to Excel using the `openpyxl` engine. (GH15530)

For example, after running the following, `styled.xlsx` renders as below:

```

In [53]: np.random.seed(24)

In [54]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})

In [55]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
      ....:                                     columns=list('BCDE'))],

```

(continues on next page)

(continued from previous page)

```

.....:                 axis=1)
.....:

In [56]: df.iloc[0, 2] = np.nan

In [57]: df
Out [57]:
   A         B         C         D         E
0  1.0  1.329212      NaN -0.316280 -0.990810

7  8.0  0.354493  1.037528 -0.385684  0.519818
8  9.0  1.686583 -1.325963  1.428984 -2.089354
9 10.0 -0.129820  0.631523 -0.586538  0.290720

In [58]: styled = df.style.\
.....:     applymap(lambda val: 'color: %s' % 'red' if val < 0 else 'black').\
.....:     highlight_max()
.....:

In [59]: styled.to_excel('styled.xlsx', engine='openpyxl')

```

	A	B	C	D	E	F
1		A	B	C	D	E
2	0	1	1.329212		-0.31628	-0.99081
3	1	2	-1.070816	-1.438713	0.564417	0.295722
4	2	3	-1.626404	0.219565	0.678805	1.889273
5	3	4	0.961538	0.104011	-0.481165	0.850229
6	4	5	1.453425	1.057737	0.165562	0.515018
7	5	6	-1.336936	0.562861	1.392855	-0.063328
8	6	7	0.121668	1.207603	-0.00204	1.627796
9	7	8	0.354493	1.037528	-0.385684	0.519818
10	8	9	1.686583	-1.325963	1.428984	-2.089354
11	9	10	-0.12982	0.631523	-0.586538	0.29072

See the [Style documentation](#) for more detail.

### 1.9.1.12 IntervalIndex

pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the [docs](#). ([GH7640](#), [GH8625](#))

The returned categories were strings, representing Intervals

New behavior:

Furthermore, this allows one to bin *other* data with these same bins, with `NaN` representing a missing value similar to other dtypes.

An IntervalIndex can also be used in Series and DataFrame as the index.

### 1.9. v0.20.1 (May 5, 2017)

Selecting via a specific interval:

```
In [66]: df.loc[pd.Interval(1.5, 3.0)]
Out [66]:
A      1
Name: (1.5, 3.0], dtype: int64
```

Selecting via a scalar value that is contained *in* the intervals.

```
In [67]: df.loc[0]
Out [67]:
      A
B
(-0.003, 1.5]  0
(-0.003, 1.5]  2
(-0.003, 1.5]  3
```

### 1.9.1.13 Other Enhancements

- `DataFrame.rolling()` now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the [documentation](#) (GH13965)
- Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see [here](#).
- `Series.str.replace()` now accepts a callable, as replacement, which is passed to `re.sub` (GH15055)
- `Series.str.replace()` now accepts a compiled regular expression as a pattern (GH15446)
- `Series.sort_index` accepts parameters `kind` and `na_position` (GH13589, GH14444)
- `DataFrame` and `DataFrame.groupby()` have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).
- `DataFrame` has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).
- `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930)
- Multiple offset aliases with decimal points are now supported (e.g. `0.5min` is parsed as `30s`) (GH8419)
- `.isnull()` and `.notnull()` have been added to `Index` object to make them more consistent with the `Series` API (GH15300)
- New `UnsortedIndexError` (subclass of `KeyError`) raised when indexing/slicing into an unsorted `MultiIndex` (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See [here](#)
- `MultiIndex` has gained a `.to_frame()` method to convert to a `DataFrame` (GH12397)
- `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798)
- `pd.qcut` has gained the `duplicates='raise'|'drop'` option to control whether to raise on duplicated edges (GH7751)
- `Series` provides a `to_excel` method to output Excel files (GH8825)
- The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154)
- The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882)
- The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755)

- `DataFrame.plot` now prints a title above each subplot if `suplots=True` and `title` is a list of strings ([GH14753](#))
- `DataFrame.plot` can pass the matplotlib 2.0 default color cycle as a single string as color parameter, see [here](#). ([GH15516](#))
- `Series.interpolate()` now supports `timedelta` as an index type with `method='time'` ([GH6424](#))
- Addition of a `level` keyword to `DataFrame/Series.rename` to rename labels in the specified level of a `MultiIndex` ([GH4160](#)).
- `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a `MultiIndex` ([GH16164](#))
- `Timedelta.isoformat` method added for formatting `Timedeltas` as an [ISO 8601 duration](#). See the [Timedelta docs](#) ([GH15136](#))
- `.select_dtypes()` now allows the string `datetimez` to generically select datetimes with `tz` ([GH14910](#))
- The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements
- `pd.merge_asof()` gained the option `direction='backward'|'forward'|'nearest'` ([GH14887](#))
- `Series/DataFrame.asfreq()` have gained a `fill_value` parameter, to fill missing values ([GH3715](#)).
- `Series/DataFrame.resample.asfreq` have gained a `fill_value` parameter, to fill missing values during resampling ([GH3715](#)).
- `pandas.util.hash_pandas_object()` has gained the ability to hash a `MultiIndex` ([GH15224](#))
- `Series/DataFrame.squeeze()` have gained the `axis` parameter. ([GH15339](#))
- `DataFrame.to_excel()` has a new `freeze_panes` parameter to turn on Freeze Panes when exporting to Excel ([GH15160](#))
- `pd.read_html()` will parse multiple header rows, creating a `MultiIndex` header. ([GH13434](#)).
- HTML table output skips `colspan` or `rowspan` attribute if equal to 1. ([GH15403](#))
- `pandas.io.formats.style.Styler` template now has blocks for easier extension, see the [example notebook](#) ([GH15649](#))
- `Styler.render()` now accepts `**kwargs` to allow user-defined variables in the template ([GH15649](#))
- Compatibility with Jupyter notebook 5.0; `MultiIndex` column labels are left-aligned and `MultiIndex` row-labels are top-aligned ([GH15379](#))
- `TimedeltaIndex` now has a custom date-tick formatter specifically designed for nanosecond level precision ([GH8711](#))
- `pd.api.types.union_categoricals` gained the `ignore_ordered` argument to allow ignoring the ordered attribute of unioned categoricals ([GH13410](#)). See the [categorical union docs](#) for more information.
- `DataFrame.to_latex()` and `DataFrame.to_string()` now allow optional header aliases. ([GH15536](#))
- Re-enable the `parse_dates` keyword of `pd.read_excel()` to parse string columns as dates ([GH14326](#))
- Added `.empty` property to subclasses of `Index`. ([GH15270](#))
- Enabled floor division for `Timedelta` and `TimedeltaIndex` ([GH15828](#))
- `pandas.io.json.json_normalize()` gained the option `errors='ignore'|'raise'`; the default is `errors='raise'` which is backward compatible. ([GH14583](#))

- `pandas.io.json.json_normalize()` with an empty list will return an empty DataFrame (GH15534)
- `pandas.io.json.json_normalize()` has gained a `sep` option that accepts `str` to separate joined fields; the default is “.”, which is backward compatible. (GH14883)
- `MultiIndex.remove_unused_levels()` has been added to facilitate *removing unused levels*. (GH15694)
- `pd.read_csv()` will now raise a `ParserError` error whenever any parsing error occurs (GH15913, GH15925)
- `pd.read_csv()` now supports the `error_bad_lines` and `warn_bad_lines` arguments for the Python parser (GH15925)
- The `display.show_dimensions` option can now also be used to specify whether the length of a `Series` should be shown in its repr (GH7117).
- `parallel_coordinates()` has gained a `sort_labels` keyword argument that sorts class labels and the colors assigned to them (GH15908)
- Options added to allow one to turn on/off using `bottleneck` and `numexpr`, see [here](#) (GH16157)
- `DataFrame.style.bar()` now accepts two more options to further customize the bar chart. Bar alignment is set with `align='left'|'mid'|'zero'`, the default is “left”, which is backward compatible; You can now pass a list of `color=[color_negative, color_positive]`. (GH14757)

## 1.9.2 Backwards incompatible API changes

### 1.9.2.1 Possible incompatibility for HDF5 formats created with pandas < 0.13.0

`pd.TimeSeries` was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of `pd.Series`. (GH15098).

This *may* cause HDF5 files that were created in prior versions to become unreadable if `pd.TimeSeries` was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```
In [2]: s = pd.TimeSeries([1,2,3], index=pd.date_range('20130101', periods=3))

In [3]: s
Out[3]:
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64

In [4]: type(s)
Out[4]: pandas.core.series.TimeSeries

In [5]: s = pd.Series(s)

In [6]: s
Out[6]:
2013-01-01    1
2013-01-02    2
2013-01-03    3
Freq: D, dtype: int64
```

(continues on next page)

```
In [76]: s = Series(date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H').tz_
↳ localize('Asia/Tokyo'))

In [77]: s
Out[77]:
0    2011-01-02 00:00:00+09:00
1    2011-01-02 01:00:00+09:00
2    2011-01-02 02:00:00+09:00
dtype: datetime64[ns, Asia/Tokyo]
```

Previous Behavior:

```
In [9]: s.map(lambda x: x.hour)
Out[9]:
0    0
1    1
2    2
dtype: int32
```

New Behavior:

```
In [78]: s.map(lambda x: x.hour)
Out[78]:
0    0
1    1
2    2
dtype: int64
```

### 1.9.2.3 Accessing datetime fields of Index now return Index

The datetime-related attributes (see [here](#) for an overview) of `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex` previously returned numpy arrays. They will now return a new `Index` object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [2]: idx.hour
Out[2]: array([ 0, 10, 20,  6, 16], dtype=int32)
```

New Behavior:

```
In [79]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')

In [80]: idx.hour
Out[80]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific `Index` methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, `Index` objects are not mutable. To get the original ndarray, you can always convert explicitly using `np.asarray(idx.hour)`.

### 1.9.2.4 `pd.unique` will now be consistent with extension types

In prior versions, using `Series.unique()` and `pandas.unique()` on Categorical and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

Previous behaviour:

```
# Series
In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                  pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out [5]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
               ↪dtype=object)

In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                             pd.Timestamp('20160101', tz='US/Eastern')]))
Out [6]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

# Index
In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                  pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out [7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/
               ↪Eastern]', freq=None)

In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
                  pd.Timestamp('20160101', tz='US/Eastern')])
Out [8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')
```

New Behavior:

```
# Series, returns an array of Timestamp tz-aware
In [81]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                  ....:      pd.Timestamp('20160101', tz='US/Eastern')]).unique()
                  ....:
Out [81]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
               ↪dtype=object)

In [82]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                  ....:      pd.Timestamp('20160101', tz='US/Eastern')]))
                  ....:
Out [82]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')], dtype=object)

# Index, returns a DatetimeIndex
In [83]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                  ....:      pd.Timestamp('20160101', tz='US/Eastern')]).unique()
                  ....:
Out [83]: DatetimeIndex(['2016-01-01 05:00:00-05:00'], dtype='datetime64[ns, US/Eastern]',
               ↪freq=None)

In [84]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                  ....:      pd.Timestamp('20160101', tz='US/Eastern')]))
                  ....:
Out [84]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]',
               ↪freq=None)
```

- Categoricals

Previous behaviour:

### 1.9.2.7 Concat of different float dtypes will not automatically upcast

Previously, concat of multiple objects with different float dtypes would automatically upcast results to a dtype of float64. Now the smallest acceptable dtype will be used ([GH13247](#))

```
In [88]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))

In [89]: df1.dtypes
Out[89]:
0    float32
dtype: object

In [90]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))

In [91]: df2.dtypes
Out[91]:
0    float32
dtype: object
```

Previous Behavior:

```
In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0    float64
dtype: object
```

New Behavior:

```
In [92]: pd.concat([df1, df2]).dtypes
Out[92]:
0    float32
dtype: object
```

### 1.9.2.8 Pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package `pandas-gbq`. You can `conda install pandas-gbq -c conda-forge` or `pip install pandas-gbq` to get it. The functionality of `read_gbq()` and `DataFrame.to_gbq()` remain the same with the currently released version of `pandas-gbq=0.1.4`. Documentation is now hosted [here](#) ([GH15347](#))

### 1.9.2.9 Memory Usage for Index is more Accurate

In previous versions, showing `.memory_usage()` on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for `Index` and `MultiIndex` and less-so for other index types. ([GH15237](#))

Previous Behavior:

```
In [8]: index = Index(['foo', 'bar', 'baz'])

In [9]: index.memory_usage(deep=True)
Out[9]: 180

In [10]: index.get_loc('foo')
Out[10]: 0
```

(continues on next page)

(continued from previous page)

```
In [11]: index.memory_usage(deep=True)
Out[11]: 180
```

New Behavior:

```
In [8]: index = Index(['foo', 'bar', 'baz'])

In [9]: index.memory_usage(deep=True)
Out[9]: 180

In [10]: index.get_loc('foo')
Out[10]: 0

In [11]: index.memory_usage(deep=True)
Out[11]: 260
```

### 1.9.2.10 DataFrame.sort\_index changes

In certain cases, calling `.sort_index()` on a MultiIndexed DataFrame would return the *same* DataFrame without seeming to sort. This would happen with a lexicographically sorted, but non-monotonic levels. ([GH15622](#), [GH15687](#), [GH14015](#), [GH13431](#), [GH15797](#))

This is *unchanged* from prior versions, but shown for illustration purposes:

```
In [93]: df = DataFrame(np.arange(6), columns=['value'], index=MultiIndex.from_
↳product([list('BA'), range(3)]))

In [94]: df
Out[94]:
   value
B 0      0
  1      1
  2      2
A 0      3
  1      4
  2      5
```

```
In [95]: df.index.is_lexsorted()
Out[95]: False

In [96]: df.index.is_monotonic
Out[96]: False
```

Sorting works as expected

```
In [97]: df.sort_index()
Out[97]:
   value
A 0      3
  1      4
  2      5
B 0      0
  1      1
  2      2
```

```
In [98]: df.sort_index().index.is_lexsorted()
Out[98]: True
```

```
In [99]: df.sort_index().index.is_monotonic
Out[99]: True
```

However, this example, which has a non-monotonic 2nd level, doesn't behave as desired.

```
In [100]: df = pd.DataFrame(
.....:     {'value': [1, 2, 3, 4]},
.....:     index=pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
.....:                           labels=[[0, 0, 1, 1], [0, 1, 0, 1]]))
.....:
```

```
In [101]: df
```

```
Out[101]:
      value
a bb      1
  aa      2
b bb      3
  aa      4
```

Previous Behavior:

```
In [11]: df.sort_index()
Out[11]:
      value
a bb      1
  aa      2
b bb      3
  aa      4

In [14]: df.sort_index().index.is_lexsorted()
Out[14]: True

In [15]: df.sort_index().index.is_monotonic
Out[15]: False
```

New Behavior:

```
In [102]: df.sort_index()
Out[102]:
      value
a aa      2
  bb      1
b aa      4
  bb      3

In [103]: df.sort_index().index.is_lexsorted()
Out[103]: True

In [104]: df.sort_index().index.is_monotonic
Out[104]: False
```

### 1.9.2.11 Groupby Describe Formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous Behavior:

```
In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
```

```
In [2]: df.groupby('A').describe()
```

Out [2] :

B

A

```
1 count 2.000000
```

```
mean    1.500000
```

std	0.707107
-----	----------

min	1.000000
-----	----------

25%	1.250000
-----	----------

50%	1.500000
-----	----------

75%	1.750000
-----	----------

max	2.000000
-----	----------

```
2 count 2.000000
```

```
mean    3.500000
```

std	0.707107
-----	----------

min	3.000000
-----	----------

25%	3.250000
-----	----------

50%	3.500000
-----	----------

75%	3.750000
-----	----------

max	4.000000
-----	----------

```
In [3]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])
```

Out [3] :

A

1	1.5	0.707107	1	2
---	-----	----------	---	---

2	3.5	0.707107	3	4
---	-----	----------	---	---

### 1.9.2.12 Window Binary Corr/Cov operations return a MultiIndex DataFrame

A binary window operation, like `.corr()` or `.cov()`, when operating on a `.rolling(...)`, `.expanding(...)`, or `.ewm(...)` object, will now return a 2-level MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see [here](#). These are equivalent in function, but a MultiIndexed DataFrame enjoys more support in pandas. See the section on *Windowed Binary Operations* for more information. (GH15677)

```
In [108]: np.random.seed(1234)

In [109]: df = pd.DataFrame(np.random.rand(100, 2),
.....:                      columns=pd.Index(['A', 'B'], name='bar'),
.....:                      index=pd.date_range('20160101',
.....:                                          periods=100, freq='D', name='foo'))

In [110]: df.tail()
Out[110]:
bar          A          B
foo
2016-04-05  0.640880  0.126205
2016-04-06  0.171465  0.737086
2016-04-07  0.127029  0.369650
2016-04-08  0.604334  0.103104
2016-04-09  0.802374  0.945553
```

Previous Behavior:

```
In [2]: df.rolling(12).corr()
Out[2]:
<class 'pandas.core.panel.Panel'>
Dimensions: 100 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: 2016-01-01 00:00:00 to 2016-04-09 00:00:00
Major_axis axis: A to B
Minor_axis axis: A to B
```

New Behavior:

```
In [111]: res = df.rolling(12).corr()

In [112]: res.tail()
Out[112]:
bar          A          B
foo    bar
2016-04-07 B   -0.132090  1.000000
2016-04-08 A    1.000000 -0.145775
          B   -0.145775  1.000000
2016-04-09 A    1.000000  0.119645
          B    0.119645  1.000000
```

Retrieving a correlation matrix for a cross-section

```
In [113]: df.rolling(12).corr().loc['2016-04-07']
Out[113]:
bar          A          B
foo    bar
2016-04-07 A    1.000000 -0.13209
          B   -0.13209  1.00000
```

### 1.9.2.13 HDFStore where string comparison

In previous versions most types could be compared to string column in a `HDFStore` usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a `TypeError` (GH15492)

```
In [114]: df = pd.DataFrame({'unparsed_date': ['2014-01-01', '2014-01-01']})

In [115]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)

In [116]: df.dtypes
Out[116]:
unparsed_date    object
dtype: object
```

Previous Behavior:

```
In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
      (unparsed_date > 1970-01-01 00:00:01.388552400)
                        ^
SyntaxError: invalid token
```

New Behavior:

```
In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
TypeError: Cannot compare 2014-01-01 00:00:00 of
type <class 'pandas.tslib.Timestamp'> to string column
```

### 1.9.2.14 Index.intersection and inner join now preserve the order of the left Index

`Index.intersection()` now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, `DataFrame.join()` and `merge()`, and the `.align` method.

- `Index.intersection`

```
In [117]: left = pd.Index([2, 1, 0])

In [118]: left
Out[118]: Int64Index([2, 1, 0], dtype='int64')

In [119]: right = pd.Index([1, 2, 3])

In [120]: right
Out[120]: Int64Index([1, 2, 3], dtype='int64')
```

Previous Behavior:

```
In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')
```

New Behavior:

```
In [121]: left.intersection(right)
Out[121]: Int64Index([2, 1], dtype='int64')
```

- `DataFrame.join` and `pd.merge`

```
In [122]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])

In [123]: left
Out[123]:
   a
2  20
1  10
0   0

In [124]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])

In [125]: right
Out[125]:
   b
1  100
2  200
3  300
```

Previous Behavior:

```
In [4]: left.join(right, how='inner')
Out[4]:
   a    b
1  10  100
2  20  200
```

New Behavior:

```
In [126]: left.join(right, how='inner')
Out[126]:
   a    b
2  20  200
1  10  100
```

### 1.9.2.15 Pivot Table always returns a DataFrame

The documentation for `pivot_table()` states that a `DataFrame` is *always* returned. Here a bug is fixed that allowed this to return a `Series` under certain circumstance. (GH4386)

```
In [127]: df = DataFrame({'col1': [3, 4, 5],
.....:                  'col2': ['C', 'D', 'E'],
.....:                  'col3': [1, 3, 9]})
.....:

In [128]: df
Out[128]:
   col1 col2 col3
0     3    C    1
1     4    D    3
2     5    E    9
```

Previous Behavior:

```
In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
col3  col2
1      C      3
3      D      4
9      E      5
Name: col1, dtype: int64
```

New Behavior:

```
In [129]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[129]:
           col1
col3 col2
1      C      3
3      D      4
9      E      5
```

### 1.9.2.16 Other API Changes

- `numexpr` version is now required to be  $\geq 2.4.6$  and it will not be used at all if this requisite is not fulfilled ([GH15213](#)).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future ([GH12665](#))
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively ([GH12855](#))
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` ([GH8222](#))
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` ([GH15999](#))
- `.loc` has compat with `.ix` for accepting iterators, and `NamedTuples` ([GH15120](#))
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. ([GH9217](#))
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the `dialect` parameter and the user ([GH14898](#))
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than one byte ([GH11592](#))
- `inplace` arguments now require a boolean value, else a `ValueError` is thrown ([GH14189](#))
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found ([GH15118](#))
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects ([GH15444](#))
- `Series.sort_values()` accepts a one element list of bool for consistency with the behavior of `DataFrame.sort_values()` ([GH15604](#))
- `.merge()` and `.join()` on category dtype columns will now preserve the category dtype when possible ([GH10409](#))

- `SparseDataFrame.default_fill_value` will be 0, previously was `nan` in the return from `pd.get_dummies(..., sparse=True)` ([GH15594](#))
- The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method ([GH5224](#)). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.
- `NaT` will now correctly report `False` for datetimelike boolean operations such as `is_month_start` ([GH15781](#))
- `NaT` will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` ([GH15782](#))
- `NaT` will now returns `NaT` for `tz_localize` and `tz_convert` methods ([GH15830](#))
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes ([GH15541](#))
- `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. ([GH15541](#))
- The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced ([GH15541](#))

## 1.9.3 Reorganization of the library: Privacy Changes

### 1.9.3.1 Modules Privacy Has Changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference theses modules. ([GH12588](#))

Previous Location	New Location	Deprecated
pandas.lib	pandas._libs.lib	X
pandas.tslib	pandas._libs.tslib	X
pandas.computation	pandas.core.computation	X
pandas.msgpack	pandas.io.msgpack	
pandas.index	pandas._libs.index	
pandas.algos	pandas._libs.algos	
pandas.hashtable	pandas._libs.hashtable	
pandas.indexes	pandas.core.indexes	
pandas.json	pandas._libs.json / pandas.io.json	X
pandas.parser	pandas._libs.parsers	X
pandas.formats	pandas.io.formats	
pandas.sparse	pandas.core.sparse	
pandas.tools	pandas.core.reshape	X
pandas.types	pandas.core.dtypes	X
pandas.io.sas.saslib	pandas.io.sas._sas	
pandas._join	pandas._libs.join	
pandas._hash	pandas._libs.hashing	
pandas._period	pandas._libs.period	
pandas._sparse	pandas._libs.sparse	
pandas._testing	pandas._libs.testing	
pandas._window	pandas._libs.window	

Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` (GH15998)
- The type import `pandas.tslib.NaTType` is deprecated and can be replaced by using type (`pandas.NaT`) (GH16146)
- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` (GH16223)
- The modules in `pandas.util`: `decorators`, `print_versions`, `doctools`, `validators`, `depr_module` are now private. Only the functions exposed in `pandas.util` itself are public (GH16223)

### 1.9.3.2 pandas.errors

We are adding a standard public module for all pandas exceptions & warnings `pandas.errors`. (GH14800). Previously these exceptions & warnings could be imported from `pandas.core.common` or `pandas.io.common`. These exceptions and warnings will be removed from the `*.common` locations in a future release. (GH15541)

The following are now part of this API:

```
[ 'DtypeWarning',
  'EmptyDataError',
  'OutOfBoundsDatetime',
  'ParserError',
```

(continues on next page)

(continued from previous page)

```
'ParserWarning',
'PerformanceWarning',
'UnsortedIndexError',
'UnsupportedFunctionCall']
```

### 1.9.3.3 pandas.testing

We are adding a standard module that exposes the public testing functions in `pandas.testing` ([GH9895](#)). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- `testing.assert_frame_equal()`
- `testing.assert_series_equal()`
- `testing.assert_index_equal()`

### 1.9.3.4 pandas.plotting

A new public `pandas.plotting` module has been added that holds plotting functionality that was previously in either `pandas.tools.plotting` or in the top-level namespace. See the [deprecations sections](#) for more details.

### 1.9.3.5 Other Development Changes

- Building pandas for development now requires `cython >= 0.23` ([GH14831](#))
- Require at least 0.23 version of cython to avoid problems with character encodings ([GH14699](#))
- Switched the test framework to use `pytest` ([GH13097](#))
- Reorganization of tests directory layout ([GH14854](#), [GH15707](#)).

## 1.9.4 Deprecations

### 1.9.4.1 Deprecate `.ix`

The `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers. `.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels*, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is [here](#). ([GH14218](#))

The recommended methods of indexing are:

- `.loc` if you want to *label* index
- `.iloc` if you want to *positionally* index.

Using `.ix` will now show a `DeprecationWarning` with a link to some examples of how to convert code [here](#).

```
In [130]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6]},
.....:                      index=list('abc'))
.....:
```

(continues on next page)

(continued from previous page)

```
In [131]: df
Out[131]:
   A  B
a  1  4
b  2  5
c  3  6
```

Previous Behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: df.ix[[0, 2], 'A']
Out[3]:
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [132]: df.loc[df.index[[0, 2]], 'A']
Out[132]:
a    1
c    3
Name: A, dtype: int64
```

Using `.iloc`. Here we will get the location of the 'A' column, then use *positional* indexing to select things.

```
In [133]: df.iloc[[0, 2], df.columns.get_loc('A')]
Out[133]:
a    1
c    3
Name: A, dtype: int64
```

### 1.9.4.2 Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` or with the `xarray` package. Pandas provides a `to_xarray()` method to automate this conversion. For more details see [Deprecate Panel](#) documentation. (GH13563).

```
In [134]: p = tm.makePanel()

In [135]: p
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame

```
In [136]: p.to_frame()
Out[136]:
           ItemA  ItemB  ItemC
major  minor
2000-01-03 A    0.628776 -1.409432  0.209395
```

(continues on next page)

(continued from previous page)

	B	0.988138	-1.347533	-0.896581
	C	-0.938153	1.272395	-0.161137
	D	-0.223019	-0.591863	-1.051539

        [-1.473116, -0.43155 ,  0.288377, -0.619993]])
Coordinates:
  * items      (items) object 'ItemA' 'ItemB' 'ItemC'
  * major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05
  * minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

### 1.9.4.3 Deprecate `groupby.agg()` with a dictionary when renaming

The `.groupby(...).agg(...)`, `.rolling(...).agg(...)`, and `.resample(...).agg(...)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(...)` can *also* accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

- We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.
- We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```
In [138]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2],
.....:                      'B': range(5),
.....:                      'C': range(5)})
.....:
```

(continues on next page)

(continued from previous page)

```
In [139]: df
Out[139]:
```

	A	B	C
0	1	0	0
1	1	1	1
2	1	2	2
3	2	3	3
4	2	4	4

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a `MultiIndex` for the columns (this is *not* deprecated).

```
In [140]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
Out[140]:
```

	B	C
A		
1	3	0
2	7	3

Here's an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```
In [6]: df.groupby('A').B.agg({'foo': 'count'})
FutureWarning: using a dict on a Series for aggregation
is deprecated and will be removed in a future version

Out[6]:
```

	foo
A	
1	3
2	2

You can accomplish the same operation, more idiomatically by:

```
In [141]: df.groupby('A').B.agg(['count']).rename(columns={'count': 'foo'})
Out[141]:
```

	foo
A	
1	3
2	2

Here's an example of the second deprecation, passing a dict-of-dict to a grouped `DataFrame`:

```
In [23]: (df.groupby('A')
          .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
          )
FutureWarning: using a dict with renaming is deprecated and
will be removed in a future version

Out[23]:
```

	B	C
	foo	bar
A		
1	3	0
2	7	3

You can accomplish nearly the same by:

```
In [142]: (df.groupby('A')
.....:      .agg({'B': 'sum', 'C': 'min'})
.....:      .rename(columns={'B': 'foo', 'C': 'bar'})
.....: )
Out[142]:
   foo  bar
A
1     3    0
2     7    3
```

#### 1.9.4.4 Deprecate .plotting

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` ([GH12548](#)).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:

```
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)
```

Should be changed to:

```
pd.plotting.scatter_matrix(df)
```

#### 1.9.4.5 Other Deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected ([GH14647](#))
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter ([GH14647](#))
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` ([GH12662](#))
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter ([GH15524](#))
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` ([GH12662](#))
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` ([GH12662](#))
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the `key` parameter in favor of `value` ([GH12662](#))
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` ([GH14878](#))
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` ([GH15099](#))
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports ([GH15358](#))

- `Series/DataFrame/Panel consolidate()` been deprecated as a public method. (GH15483)
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) (GH15257).
- The following top-level pandas functions have been deprecated and will be removed in a future version (GH13790, GH15940)
  - `pd.pnow()`, replaced by `Period.now()`
  - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the `where` clause when searching in `HDFStore`
  - `pd.Expr`, is removed, as it is not applicable to user code.
  - `pd.match()`, is removed.
  - `pd.groupby()`, replaced by using the `.groupby()` method directly on a `Series/DataFrame`
  - `pd.get_store()`, replaced by a direct call to `pd.HDFStore(...)`
- `is_any_int_dtype`, `is_floating_dtype`, and `is_sequence` are deprecated from `pandas.api.types` (GH16042)

### 1.9.5 Removal of prior version deprecations/changes

- The `pandas.rpy` module is removed. Similar functionality can be accessed through the [rpy2](#) project. See the [R interfacing docs](#) for more details.
- The `pandas.io.ga` module with a `google-analytics` interface is removed (GH11308). Similar functionality can be found in the [Google2Pandas](#) package.
- `pd.to_datetime` and `pd.to_timedelta` have dropped the `coerce` parameter in favor of errors (GH13602)
- `pandas.stats.fama_macbeth`, `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var`, as well as the top-level `pandas.fama_macbeth` and `pandas.ols` routines are removed. Similar functionality can be found in the [statsmodels](#) package. (GH11898)
- The `TimeSeries` and `SparseTimeSeries` classes, aliases of `Series` and `SparseSeries`, are removed (GH10890, GH15098).
- `Series.is_time_series` is dropped in favor of `Series.index.is_all_dates` (GH15098)
- The deprecated `irow`, `icol`, `iget` and `iget_value` methods are removed in favor of `iloc` and `iat` as explained [here](#) (GH10711).
- The deprecated `DataFrame.iterkv()` has been removed in favor of `DataFrame.iteritems()` (GH10711)
- The `Categorical` constructor has dropped the `name` parameter (GH10632)
- `Categorical` has dropped support for `NaN` categories (GH10748)
- The `take_last` parameter has been dropped from `uplicated()`, `drop_duplicates()`, `nlargest()`, and `nsmallest()` methods (GH10236, GH10792, GH10920)
- `Series`, `Index`, and `DataFrame` have dropped the `sort` and `order` methods (GH10726)
- Where clauses in `pytables` are only accepted as strings and expressions types and not other data-types (GH12027)
- `DataFrame` has dropped the `combineAdd` and `combineMult` methods in favor of `add` and `mul` respectively (GH10735)

## 1.9.6 Performance Improvements

- Improved performance of `pd.wide_to_long()` (GH14779)
- Improved performance of `pd.factorize()` by releasing the GIL with `object` dtype when inferred as strings (GH14859, GH16057)
- Improved performance of timeseries plotting with an irregular `DatetimeIndex` (or with `compat_x=True`) (GH15073).
- Improved performance of `groupby().cummin()` and `groupby().cummax()` (GH15048, GH15109, GH15561, GH15635)
- Improved performance and reduced memory when indexing with a `MultiIndex` (GH15245)
- When reading buffer object in `read_sas()` method without specified format, filepath string is inferred rather than buffer object. (GH14947)
- Improved performance of `.rank()` for categorical data (GH15498)
- Improved performance when using `.unstack()` (GH15503)
- Improved performance of merge/join on category columns (GH10409)
- Improved performance of `drop_duplicates()` on bool columns (GH12963)
- Improve performance of `pd.core.groupby.GroupBy.apply` when the applied function used the `.name` attribute of the group `DataFrame` (GH15062).
- Improved performance of `iloc` indexing with a list or array (GH15504).
- Improved performance of `Series.sort_index()` with a monotonic index (GH15694)
- Improved performance in `pd.read_csv()` on some platforms with buffered reads (GH16039)

## 1.9.7 Bug Fixes

### 1.9.7.1 Conversion

- Bug in `Timestamp.replace` now raises `TypeError` when incorrect argument names are given; previously this raised `ValueError` (GH15240)
- Bug in `Timestamp.replace` with `compat` for passing long integers (GH15030)
- Bug in `Timestamp` returning UTC based time/date attributes when a timezone was provided (GH13303, GH6538)
- Bug in `Timestamp` incorrectly localizing timezones during construction (GH11481, GH15777)
- Bug in `TimedeltaIndex` addition where overflow was being allowed without error (GH14816)
- Bug in `TimedeltaIndex` raising a `ValueError` when boolean indexing with `loc` (GH14946)
- Bug in catching an overflow in `Timestamp + Timedelta/Offset` operations (GH15126)
- Bug in `DatetimeIndex.round()` and `Timestamp.round()` floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
- Bug in `astype()` where `inf` values were incorrectly converted to integers. Now raises error now with `astype()` for `Series` and `DataFrames` (GH14265)
- Bug in `DataFrame(...).apply(to_numeric)` when values are of type `decimal.Decimal`. (GH14827)

- Bug in `describe()` when passing a numpy array which does not contain the median to the `percentiles` keyword argument ([GH14908](#))
- Cleaned up `PeriodIndex` constructor, including raising on floats more consistently ([GH13277](#))
- Bug in using `__deepcopy__` on empty `NDFrame` objects ([GH15370](#))
- Bug in `.replace()` may result in incorrect dtypes. ([GH12747](#), [GH15765](#))
- Bug in `Series.replace` and `DataFrame.replace` which failed on empty replacement dicts ([GH15289](#))
- Bug in `Series.replace` which replaced a numeric by string ([GH15743](#))
- Bug in `Index` construction with `NaN` elements and integer dtype specified ([GH15187](#))
- Bug in `Series` construction with a `datetimez` ([GH14928](#))
- Bug in `Series.dt.round()` inconsistent behaviour on `NaT` 's with different arguments ([GH14940](#))
- Bug in `Series` constructor when both `copy=True` and `dtype` arguments are provided ([GH15125](#))
- Incorrect dtypes `Series` was returned by comparison methods (e.g., `lt`, `gt`, ...) against a constant for an empty `DataFrame` ([GH15077](#))
- Bug in `Series.ffill()` with mixed dtypes containing tz-aware datetimes. ([GH14956](#))
- Bug in `DataFrame.fillna()` where the argument `downcast` was ignored when `fillna` value was of type `dict` ([GH15277](#))
- Bug in `.asfreq()`, where frequency was not set for empty `Series` ([GH14320](#))
- Bug in `DataFrame` construction with nulls and datetimes in a list-like ([GH15869](#))
- Bug in `DataFrame.fillna()` with tz-aware datetimes ([GH15855](#))
- Bug in `is_string_dtype`, `is_timedelta64_ns_dtype`, and `is_string_like_dtype` in which an error was raised when `None` was passed in ([GH15941](#))
- Bug in the return type of `pd.unique` on a `Categorical`, which was returning an `ndarray` and not a `Categorical` ([GH15903](#))
- Bug in `Index.to_series()` where the index was not copied (and so mutating later would change the original), ([GH15949](#))
- Bug in indexing with partial string indexing with a len-1 `DataFrame` ([GH16071](#))
- Bug in `Series` construction where passing invalid dtype didn't raise an error. ([GH15520](#))

### 1.9.7.2 Indexing

- Bug in `Index` power operations with reversed operands ([GH14973](#))
- Bug in `DataFrame.sort_values()` when sorting by multiple columns where one column is of type `int64` and contains `NaT` ([GH14922](#))
- Bug in `DataFrame.reindex()` in which method was ignored when passing columns ([GH14992](#))
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a `Series` indexer ([GH14730](#), [GH15424](#))
- Bug in `DataFrame.loc` with indexing a `MultiIndex` with a numpy array ([GH15434](#))
- Bug in `Series.asof` which raised if the series contained all `np.nan` ([GH15713](#))
- Bug in `.at` when selecting from a tz-aware column ([GH15822](#))
- Bug in `Series.where()` and `DataFrame.where()` where array-like conditionals were being rejected ([GH15414](#))

- Bug in `Series.where()` where TZ-aware data was converted to float representation ([GH15701](#))
- Bug in `.loc` that would not return the correct dtype for scalar access for a `DataFrame` ([GH11617](#))
- Bug in output formatting of a `MultiIndex` when names are integers ([GH12223](#), [GH15262](#))
- Bug in `Categorical.searchsorted()` where alphabetical instead of the provided categorical order was used ([GH14522](#))
- Bug in `Series.iloc` where a `Categorical` object for list-like indexes input was returned, where a `Series` was expected. ([GH14580](#))
- Bug in `DataFrame.isin` comparing datetimelike to empty frame ([GH15473](#))
- Bug in `.reset_index()` when an all NaN level of a `MultiIndex` would fail ([GH6322](#))
- Bug in `.reset_index()` when raising error for index name already present in `MultiIndex` columns ([GH16120](#))
- Bug in creating a `MultiIndex` with tuples and not passing a list of names; this will now raise `ValueError` ([GH15110](#))
- Bug in the HTML display with with a `MultiIndex` and truncation ([GH14882](#))
- Bug in the display of `.info()` where a qualifier (+) would always be displayed with a `MultiIndex` that contains only non-strings ([GH15245](#))
- Bug in `pd.concat()` where the names of `MultiIndex` of resulting `DataFrame` are not handled correctly when `None` is presented in the names of `MultiIndex` of input `DataFrame` ([GH15787](#))
- Bug in `DataFrame.sort_index()` and `Series.sort_index()` where `na_position` doesn't work with a `MultiIndex` ([GH14784](#), [GH16604](#))
- Bug in `pd.concat()` when combining objects with a `CategoricalIndex` ([GH16111](#))
- Bug in indexing with a scalar and a `CategoricalIndex` ([GH16123](#))

### 1.9.7.3 I/O

- Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted ([GH14941](#), [GH15005](#))
- Bug in `pd.read_fwf()` where the `skiprows` parameter was not being respected during column width inference ([GH11256](#))
- Bug in `pd.read_csv()` in which the `dialect` parameter was not being verified before processing ([GH14898](#))
- Bug in `pd.read_csv()` in which missing data was being improperly handled with `usecols` ([GH6710](#))
- Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash ([GH14125](#))
- Bug in `pd.read_csv()` for the C engine where `usecols` were being indexed incorrectly with `parse_dates` ([GH14792](#))
- Bug in `pd.read_csv()` with `parse_dates` when multiline headers are specified ([GH15376](#))
- Bug in `pd.read_csv()` with `float_precision='round_trip'` which caused a segfault when a text entry is parsed ([GH15140](#))
- Bug in `pd.read_csv()` when an index was specified and no values were specified as null values ([GH15835](#))
- Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash ([GH15337](#))

- Bug in `pd.read_csv()` in which invalid values for `nrows` and `chunksize` were allowed ([GH15767](#))
- Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred ([GH15910](#))
- Bug in `pd.read_csv()` in which the `skipfooter` parameter was not being properly validated ([GH15925](#))
- Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written ([GH15982](#))
- Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. ([GH15143](#))
- Bug in `.to_json()` where `lines=True` and contents (keys or values) contain escaped characters ([GH15096](#))
- Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode ([GH15344](#))
- Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where `frac` is odd and `diff` is exactly 0.5 ([GH15716](#), [GH15864](#))
- Bug in `pd.read_json()` for Python 2 where `lines=True` and contents contain non-ascii unicode characters ([GH15132](#))
- Bug in `pd.read_msgpack()` in which Series categoricals were being improperly processed ([GH14901](#))
- Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` ([GH15487](#))
- Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` ([GH15487](#))
- Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone ([GH13937](#))
- Bug in `DataFrame.to_records()` which failed with unicode characters in column names ([GH11879](#))
- Bug in `.to_sql()` when writing a `DataFrame` with numeric index names ([GH15404](#)).
- Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` ([GH14998](#))
- Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column ([GH15492](#))
- Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales ([GH13856](#))
- Bug in `StataReader` and `StataWriter` which allows invalid encodings ([GH15723](#))
- Bug in the `Series` repr not showing the length when the output was truncated ([GH15962](#)).

#### 1.9.7.4 Plotting

- Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) ([GH9351](#))
- Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes ([GH15108](#))
- Bug in the date and time converters pandas registers with matplotlib not handling multiple dimensions ([GH16026](#))
- Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both ([GH14855](#))

### 1.9.7.5 Groupby/Resample/Rolling

- Bug in `.groupby(...).resample()` when passed the `on=` kwarg. (GH15021)
- Properly set `__name__` and `__qualname__` for `Groupby.*` functions (GH14620)
- Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
- Bug in `.groupby(...).rolling(...)` when `on` is specified and using a `DatetimeIndex` (GH15130, GH13966)
- Bug in groupby operations with `timedelta64` when passing `numeric_only=False` (GH5724)
- Bug in `groupby.apply()` coercing object dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
- Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)
- Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
- Bug in `groupby().nunique()` with a datetimelike-grouper where bins counts were incorrect (GH13453)
- Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
- Bug in `groupby.agg()` incorrectly localizing timezone on datetime (GH15426, GH10668, GH13046)
- Bug in `.rolling/expanding()` functions where `count()` was not counting `np.Inf`, nor handling object dtypes (GH12541)
- Bug in `.rolling()` where `pd.Timedelta` or `datetime.timedelta` was not accepted as a window argument (GH15440)
- Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range `[0, 1]` (GH15463)
- Bug in `DataFrame.resample().median()` if duplicate column names are present (GH14233)

### 1.9.7.6 Sparse

- Bug in `SparseSeries.reindex` on single level with list of length 1 (GH15447)
- Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series (GH15488)
- Bug in `SparseDataFrame` construction with lists not coercing to dtype (GH15682)
- Bug in sparse array indexing in which indices were not being validated (GH15863)

### 1.9.7.7 Reshaping

- Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when multiple `by` was specified (GH15676)
- Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when `tolerance` was specified (GH15135)
- Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-NaN columns when the columns was a category dtype (GH15193)
- Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a `TypeError` (GH15348)

- Bug in `pd.pivot_table()` where no error was raised when values argument was not in the columns (GH14938)
- Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled (GH15328)
- Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes (GH15582)
- Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows (GH15297)
- Bug in `pandas.pivot_table()` incorrectly raising `UnicodeError` when passing unicode input for margins keyword (GH13292)

#### 1.9.7.8 Numeric

- Bug in `.rank()` which incorrectly ranks ordered categories (GH15420)
- Bug in `.corr()` and `.cov()` where the column and index were the same object (GH14617)
- Bug in `.mode()` where mode was not returned if was only a single value (GH15714)
- Bug in `pd.cut()` with a single bin on an all 0s array (GH15428)
- Bug in `pd.qcut()` with a single quantile and an array with identical values (GH15431)
- Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows (GH15265)
- Bug in `.eval()` which caused multiline evals to fail with local variables not on the first line (GH15342)

#### 1.9.7.9 Other

- Compat with SciPy 0.19.0 for testing on `.interpolate()` (GH15662)
- Compat for 32-bit platforms for `.qcut/cut`; bins will now be `int64` dtype (GH14866)
- Bug in interactions with Qt when a `QtApplication` already exists (GH14372)
- Avoid use of `np.finfo()` during `import pandas` removed to mitigate deadlock on Python GIL misuse (GH14641)

## 1.10 v0.19.2 (December 24, 2016)

This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Compatibility with Python 3.6
- Added a [Pandas Cheat Sheet](#). (GH13202).

#### What's new in v0.19.2

- *Enhancements*
- *Performance Improvements*

---

- *Bug Fixes*

---

### 1.10.1 Enhancements

The `pd.merge_asof()`, added in 0.19.0, gained some improvements:

- `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments ([GH14253](#))
- `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance ([GH13936](#))

### 1.10.2 Performance Improvements

- Performance regression with `PeriodIndex` ([GH14822](#))
- Performance regression in indexing with `getitem` ([GH14930](#))
- Improved performance of `.replace()` ([GH12745](#))
- Improved performance `Series` creation with a datetime index and dictionary data ([GH14894](#))

### 1.10.3 Bug Fixes

- Compat with python 3.6 for pickling of some offsets ([GH14685](#))
- Compat with python 3.6 for some indexing exception types ([GH14684](#), [GH14689](#))
- Compat with python 3.6 for deprecation warnings in the test suite ([GH14681](#))
- Compat with python 3.6 for Timestamp pickles ([GH14689](#))
- Compat with `dateutil==2.6.0`; segfault reported in the testing suite ([GH14621](#))
- Allow nanoseconds in `Timestamp.replace` as a kwarg ([GH14621](#))
- Bug in `pd.read_csv` in which aliasing was being done for `na_values` when passed in as a dictionary ([GH14203](#))
- Bug in `pd.read_csv` in which column indices for a dict-like `na_values` were not being respected ([GH14203](#))
- Bug in `pd.read_csv` where reading files fails, if the number of headers is equal to the number of lines in the file ([GH14515](#))
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes ([GH14582](#))
- Fix bugs ([GH14734](#), [GH13654](#)) in `pd.read_sas` and `pandas.io.sas.sas7bdat.SAS7BDATReader` that caused problems when reading a SAS file incrementally.
- Bug in `pd.read_csv` for the Python engine in which an unhelpful error message was being raised when `skipfooter` was not being respected by Python's CSV library ([GH13879](#))
- Bug in `.fillna()` in which timezone aware `datetime64` values were incorrectly rounded ([GH14872](#))
- Bug in `.groupby(..., sort=True)` of a non-lexsorted `MultiIndex` when grouping with multiple levels ([GH14776](#))
- Bug in `pd.cut` with negative values and a single bin ([GH14652](#))

- Bug in `pd.to_numeric` where a 0 was not unsigned on a `downcast='unsigned'` argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (`sharex=True` or `ax.twinx()`) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a `DatetimeIndex` in local TZ, covering a DST change, which would raise `AmbiguousTimeError` (GH14682)
- Bug in indexing that transformed `RecursionError` into `KeyError` or `IndexingError` (GH14554)
- Bug in `HDFStore` when writing a `MultiIndex` when using `data_columns=True` (GH14435)
- Bug in `HDFStore.append()` when writing a `Series` and passing a `min_itemsize` argument containing a value for the index (GH11412)
- Bug when writing to a `HDFStore` in table format with a `min_itemsize` value for the index and without asking to append (GH10381)
- Bug in `Series.groupby().nunique()` raising an `IndexError` for an empty `Series` (GH12553)
- Bug in `DataFrame.nlargest` and `DataFrame.nsmallest` when the index had duplicate values (GH13412)
- Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
- Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
- Bug in `.to_clipboard()` and Excel compat (GH12529)
- Bug in `DataFrame.combine_first()` for integer columns (GH14687).
- Bug in `pd.read_csv()` in which the `dtype` parameter was not being respected for empty data (GH14712)
- Bug in `pd.read_csv()` in which the `nrows` parameter was not being respected for large input when using the C engine for parsing (GH7626)
- Bug in `pd.merge_asof()` could not handle timezone-aware `DatetimeIndex` when a tolerance was specified (GH14844)
- Explicit check in `to_stata` and `StataWriter` for out-of-range values when writing doubles (GH14618)
- Bug in `.plot(kind='kde')` which did not drop missing values to generate the KDE Plot, instead generating an empty plot. (GH14821)
- Bug in `unstack()` if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to object (GH11847)

## 1.11 v0.19.1 (November 3, 2016)

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

### What's new in v0.19.1

- *Performance Improvements*
- *Bug Fixes*

### 1.11.1 Performance Improvements

- Fixed performance regression in factorization of `Period` data ([GH14338](#))
- Fixed performance regression in `Series.asof(where)` when `where` is a scalar ([GH14461](#))
- Improved performance in `DataFrame.asof(where)` when `where` is a scalar ([GH14461](#))
- Improved performance in `.to_json()` when `lines=True` ([GH14408](#))
- Improved performance in certain types of *loc* indexing with a `MultiIndex` ([GH14551](#)).

### 1.11.2 Bug Fixes

- Source installs from PyPI will now again work without `cython` installed, as in previous versions ([GH14204](#))
- Compat with Cython 0.25 for building ([GH14496](#))
- Fixed regression where user-provided file handles were closed in `read_csv(c engine)` ([GH14418](#)).
- Fixed regression in `DataFrame.quantile` when missing values were present in some columns ([GH14357](#)).
- Fixed regression in `Index.difference` where the `freq` of a `DatetimeIndex` was incorrectly set ([GH14323](#))
- Added back `pandas.core.common.array_equivalent` with a deprecation warning ([GH14555](#)).
- Bug in `pd.read_csv` for the C engine in which quotation marks were improperly parsed in skipped rows ([GH14459](#))
- Bug in `pd.read_csv` for Python 2.x in which Unicode quote characters were no longer being respected ([GH14477](#))
- Fixed regression in `Index.append` when categorical indices were appended ([GH14545](#)).
- Fixed regression in `pd.DataFrame` where constructor fails when given dict with `None` value ([GH14381](#))
- Fixed regression in `DatetimeIndex._maybe_cast_slice_bound` when index is empty ([GH14354](#)).
- Bug in localizing an ambiguous timezone when a boolean is passed ([GH14402](#))
- Bug in `TimedeltaIndex` addition with a `Datetime`-like object where addition overflow in the negative direction was not being caught ([GH14068](#), [GH14453](#))
- Bug in string indexing against data with object `Index` may raise `AttributeError` ([GH14424](#))
- Correctly raise `ValueError` on empty input to `pd.eval()` and `df.query()` ([GH13139](#))
- Bug in `RangeIndex.intersection` when result is a empty set ([GH14364](#)).
- Bug in groupby-transform broadcasting that could cause incorrect dtype coercion ([GH14457](#))
- Bug in `Series.__setitem__` which allowed mutating read-only arrays ([GH14359](#)).
- Bug in `DataFrame.insert` where multiple calls with duplicate columns can fail ([GH14291](#))
- `pd.merge()` will raise `ValueError` with non-boolean parameters in passed boolean type arguments ([GH14434](#))
- Bug in `Timestamp` where dates very near the minimum (1677-09) could underflow on creation ([GH14415](#))
- Bug in `pd.concat` where names of the keys were not propagated to the resulting `MultiIndex` ([GH14252](#))
- Bug in `pd.concat` where `axis` cannot take string parameters `'rows'` or `'columns'` ([GH14369](#))

- Bug in `pd.concat` with dataframes heterogeneous in length and tuple keys ([GH14438](#))
- Bug in `MultiIndex.set_levels` where illegal level values were still set after raising an error ([GH13754](#))
- Bug in `DataFrame.to_json` where `lines=True` and a value contained a `}` character ([GH14391](#))
- Bug in `df.groupby` causing an `AttributeError` when grouping a single index frame by a column and the index level ([GH14327](#))
- Bug in `df.groupby` where `TypeError` raised when `pd.Grouper(key=...)` is passed in a list ([GH14334](#))
- Bug in `pd.pivot_table` may raise `TypeError` or `ValueError` when index or columns is not scalar and values is not specified ([GH14380](#))

## 1.12 v0.19.0 (October 2, 2016)

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `merge_asof()` for asof-style time-series joining, see [here](#)
- `.rolling()` is now time-series aware, see [here](#)
- `read_csv()` now supports parsing Categorical data, see [here](#)
- A function `union_categorical()` has been added for combining categoricals, see [here](#)
- `PeriodIndex` now has its own `period` dtype, and changed to be more consistent with other `Index` classes. See [here](#)
- Sparse data structures gained enhanced support of `int` and `bool` dtypes, see [here](#)
- Comparison operations with `Series` no longer ignores the index, see [here](#) for an overview of the API changes.
- Introduction of a pandas development API for utility functions, see [here](#).
- Deprecation of `Panel4D` and `PanelND`. We recommend to represent these types of n-dimensional data with the `xarray` package.
- Removal of the previously deprecated modules `pandas.io.data`, `pandas.io.wb`, `pandas.tools.rplot`.

**Warning:** pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see [here](#).

### What's new in v0.19.0

- *New features*
  - *`merge_asof` for asof-style time-series joining*
  - *`.rolling()` is now time-series aware*
  - *`read_csv` has improved support for duplicate column names*
  - *`read_csv` supports parsing Categorical directly*

- *Categorical Concatenation*
- *Semi-Month Offsets*
- *New Index methods*
- *Google BigQuery Enhancements*
- *Fine-grained numpy errstate*
- *get\_dummies now returns integer dtypes*
- *Downcast values to smallest possible dtype in to\_numeric*
- *pandas development API*
- *Other enhancements*
- *API changes*
  - *Series.tolist() will now return Python types*
  - *Series operators for different indexes*
    - \* *Arithmetic operators*
    - \* *Comparison operators*
    - \* *Logical operators*
    - \* *Flexible comparison methods*
  - *Series type promotion on assignment*
  - *.to\_datetime() changes*
  - *Merging changes*
  - *.describe() changes*
  - *Period changes*
    - \* *PeriodIndex now has period dtype*
    - \* *Period('NaT') now returns pd.NaT*
    - \* *PeriodIndex.values now returns array of Period object*
  - *Index +/- no longer used for set operations*
  - *Index.difference and .symmetric\_difference changes*
  - *Index.unique consistently returns Index*
  - *MultiIndex constructors, groupby and set\_index preserve categorical dtypes*
  - *read\_csv will progressively enumerate chunks*
  - *Sparse Changes*
    - \* *int64 and bool support enhancements*
    - \* *Operators now preserve dtypes*
    - \* *Other sparse fixes*
  - *Indexer dtype changes*
  - *Other API Changes*

- *Deprecations*
- *Removal of prior version deprecations/changes*
- *Performance Improvements*
- *Bug Fixes*

## 1.12.1 New features

### 1.12.1.1 `merge_asof` for asof-style time-series joining

A long-time requested feature has been added through the `merge_asof()` function, to support asof style joining of time-series (GH1870, GH13695, GH13709, GH13902). Full documentation is [here](#).

The `merge_asof()` performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

```
In [1]: left = pd.DataFrame({'a': [1, 5, 10],
...:                        'left_val': ['a', 'b', 'c']})
...:
...:

In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...:                          'right_val': [1, 2, 3, 6, 7]})
...:
...:

In [3]: left
Out[3]:
   a left_val
0  1         a
1  5         b
2 10         c

In [4]: right
Out[4]:
   a right_val
0  1          1
1  2          2
2  3          3
3  6          6
4  7          7
```

We typically want to match exactly when possible, and use the most recent value otherwise.

```
In [5]: pd.merge_asof(left, right, on='a')
Out[5]:
   a left_val right_val
0  1         a         1
1  5         b         3
2 10         c         7
```

We can also match rows ONLY with prior data, and not an exact match.

```
In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
Out[6]:
   a left_val right_val
```

(continues on next page)

0	1	a	NaN
1	5	b	3.0
2	10	c	7.0

```
In [7]: trades = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                               '20160525 13:30:00.038',
...:                               '20160525 13:30:00.048',
...:                               '20160525 13:30:00.048',
...:                               '20160525 13:30:00.048']),
...:     'ticker': ['MSFT', 'MSFT',
...:                 'GOOG', 'GOOG', 'AAPL'],
...:     'price': [51.95, 51.95,
...:               720.77, 720.92, 98.00],
...:     'quantity': [75, 155,
...:                  100, 100, 100]},
...:     columns=['time', 'ticker', 'price', 'quantity'])
...:
```

```
In [8]: quotes = pd.DataFrame({
...:     'time': pd.to_datetime(['20160525 13:30:00.023',
...:                               '20160525 13:30:00.023',
...:                               '20160525 13:30:00.030',
...:                               '20160525 13:30:00.041',
...:                               '20160525 13:30:00.048',
...:                               '20160525 13:30:00.049',
...:                               '20160525 13:30:00.072',
...:                               '20160525 13:30:00.075']),
...:     'ticker': ['GOOG', 'MSFT', 'MSFT',
...:                 'MSFT', 'GOOG', 'AAPL', 'GOOG',
...:                 'MSFT'],
...:     'bid': [720.50, 51.95, 51.97, 51.99,
...:             720.50, 97.99, 720.50, 52.01],
...:     'ask': [720.93, 51.96, 51.98, 52.00,
...:             720.93, 98.01, 720.88, 52.03]},
...:     columns=['time', 'ticker', 'bid', 'ask'])
...:
```

```
In [9]: trades
Out[9]:
```

		time	ticker	price	quantity
0	2016-05-25	13:30:00.023	MSFT	51.95	75
1	2016-05-25	13:30:00.038	MSFT	51.95	155
2	2016-05-25	13:30:00.048	GOOG	720.77	100
3	2016-05-25	13:30:00.048	GOOG	720.92	100
4	2016-05-25	13:30:00.048	AAPL	98.00	100

```
In [10]: quotes
\\/////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
```

			time ticker		bid	ask
0	2016-05-25	13:30:00.023	GOOG		720.50	720.93
1	2016-05-25	13:30:00.023	MSFT		51.95	51.96

(continued from previous page)

2	2016-05-25 13:30:00.030	MSFT	51.97	51.98
3	2016-05-25 13:30:00.041	MSFT	51.99	52.00
4	2016-05-25 13:30:00.048	GOOG	720.50	720.93
5	2016-05-25 13:30:00.049	AAPL	97.99	98.01
6	2016-05-25 13:30:00.072	GOOG	720.50	720.88
7	2016-05-25 13:30:00.075	MSFT	52.01	52.03

An asof merge joins on the `on`, typically a datetimelike field, which is ordered, and in this case we are using a grouper in the `by` field. This is like a left-outer join, except that forward filling happens automatically taking the most recent non-NaN value.

```
In [11]: pd.merge_asof(trades, quotes,
.....:                  on='time',
.....:                  by='ticker')
.....:
Out [11]:
```

	time	ticker	price	quantity	bid	ask
0	2016-05-25 13:30:00.023	MSFT	51.95	75	51.95	51.96
1	2016-05-25 13:30:00.038	MSFT	51.95	155	51.97	51.98
2	2016-05-25 13:30:00.048	GOOG	720.77	100	720.50	720.93
3	2016-05-25 13:30:00.048	GOOG	720.92	100	720.50	720.93
4	2016-05-25 13:30:00.048	AAPL	98.00	100	NaN	NaN

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (`trades` in this case), with the fields of the quotes merged.

### 1.12.1.2 `.rolling()` is now time-series aware

`.rolling()` objects are now time-series aware and can accept a time-series offset (or convertible) for the window argument (GH13327, GH12995). See the full documentation [here](#).

```
In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00', periods=5, freq=
↪ 's'))
.....:

In [13]: dft
Out [13]:
```

	B
2013-01-01 09:00:00	0.0
2013-01-01 09:00:01	1.0
2013-01-01 09:00:02	2.0
2013-01-01 09:00:03	NaN
2013-01-01 09:00:04	4.0

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [14]: dft.rolling(2).sum()
Out [14]:
```

	B
2013-01-01 09:00:00	NaN
2013-01-01 09:00:01	1.0
2013-01-01 09:00:02	3.0
2013-01-01 09:00:03	NaN
2013-01-01 09:00:04	NaN

(continues on next page)

(continued from previous page)

```
In [15]: dft.rolling(2, min_periods=1).sum()
```

```

////////////////////////////////////
↪
      B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```
In [16]: dft.rolling('2s').sum()
```

```
Out [16]:
```

```

      B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```
In [17]: dft = DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                  index = pd.Index([pd.Timestamp('20130101 09:00:00'),
.....:                                     pd.Timestamp('20130101 09:00:02'),
.....:                                     pd.Timestamp('20130101 09:00:03'),
.....:                                     pd.Timestamp('20130101 09:00:05'),
.....:                                     pd.Timestamp('20130101 09:00:06')],
.....:                                     name='foo'))
```

```
In [18]: dft
```

```
Out [18]:
```

```

      B
foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0

```

```
In [19]: dft.rolling(2).sum()
```

```

////////////////////////////////////
↪
      B
foo
2013-01-01 09:00:00  NaN
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  NaN

```

Using the time-specification generates variable windows for this sparse data.

```
In [20]: dft.rolling('2s').sum()
Out[20]:
```

		B
foo		
2013-01-01	09:00:00	0.0
2013-01-01	09:00:02	1.0
2013-01-01	09:00:03	3.0
2013-01-01	09:00:05	NaN
2013-01-01	09:00:06	4.0

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a `DataFrame`.

```
In [21]: dft = dft.reset_index()
```

```
In [22]: dft
```

Out [22] :

			foo	B
0	2013-01-01	09:00:00	0.0	
1	2013-01-01	09:00:02	1.0	
2	2013-01-01	09:00:03	2.0	
3	2013-01-01	09:00:05	NaN	
4	2013-01-01	09:00:06	4.0	

```
In [23]: dft.rolling('2s', on='foo').sum()
```

---

```

      foo      B
0 2013-01-01 09:00:00 0.0
1 2013-01-01 09:00:02 1.0
2 2013-01-01 09:00:03 3.0
3 2013-01-01 09:00:05 NaN
4 2013-01-01 09:00:06 4.0

```

### 1.12.1.3 read\_csv has improved support for duplicate column names

*Duplicate column names* are now supported in `read_csv()` whether they are in the file or passed in as the `names` parameter ([GH7160](#), [GH9424](#))

```
In [24]: data = '0,1,2\n3,4,5'
```

```
In [25]: names = ['a', 'b', 'a']
```

**Previous behavior:**

```
In [2]: pd.read_csv(StringIO(data), names=names)
```

Out [2] :

	a	b	a
0	2	1	2
1	5	4	5

The first a column contained the same data as the second a column, when it should have contained the values [0, 3].

**New behavior:**

```
In [26]: pd.read_csv(StringIO(data), names=names)
Out[26]:
```

	a	b	a.1
0	0	1	2
1	3	4	5

#### 1.12.1.4 read\_csv supports parsing Categorical directly

The `read_csv()` function now supports parsing a Categorical column when specified as a dtype ([GH10153](#)). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to Categorical after parsing. See the [io docs here](#).

```
In [27]: data = 'coll,col2,col3\na,b,1\na,b,2\nc,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
```

	coll	col2	col3
0	a	b	1
1	a	b	2
2	c	d	3

```
In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
coll      object
col2      object
col3      int64
dtype: object

In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[30]:
coll      category
col2      category
col3      category
dtype: object
```

Individual columns can be parsed as a Categorical using a dict specification

```
In [31]: pd.read_csv(StringIO(data), dtype={'coll': 'category'}).dtypes
Out[31]:
```

	coll	col2	col3
0	a	b	1
1	a	b	2
2	c	d	3

```
dtype: object
```

**Note:** The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```
In [32]: df = pd.read_csv(StringIO(data), dtype='category')

In [33]: df.dtypes
Out[33]:
coll      category
```

(continues on next page)

(continued from previous page)

```

col2    category
col3    category
dtype: object

In [34]: df['col3']
Out[34]:
0    1
1    2
2    3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [36]: df['col3']
Out[36]:
0    1
1    2
2    3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]

```

### 1.12.1.5 Categorical Concatenation

- A function `union_categoricals()` has been added for combining categoricals, see *Unioning Categoricals* (GH13361, GH13763, GH13846, GH14173)

```

In [37]: from pandas.api.types import union_categoricals

In [38]: a = pd.Categorical(["b", "c"])

In [39]: b = pd.Categorical(["a", "b"])

In [40]: union_categoricals([a, b])
Out[40]:
[b, c, a, b]
Categories (3, object): [b, c, a]

```

- `concat` and `append` now can concat category dtypes with different categories as object dtype (GH13524)

```

In [41]: s1 = pd.Series(['a', 'b'], dtype='category')

In [42]: s2 = pd.Series(['b', 'c'], dtype='category')

```

#### Previous behavior:

```

In [1]: pd.concat([s1, s2])
ValueError: incompatible categories in categorical concat

```

#### New behavior:

```

In [43]: pd.concat([s1, s2])
Out[43]:

```

(continues on next page)

(continued from previous page)

```

0      a
1      b
0      b
1      c
dtype: object

```

### 1.12.1.6 Semi-Month Offsets

Pandas has gained new frequency offsets, `SemiMonthEnd` ('SM') and `SemiMonthBegin` ('SMS'). These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

```
In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin
```

#### SemiMonthEnd:

```

In [45]: Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')

In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)
Out[46]: DatetimeIndex(['2015-01-15', '2015-01-31', '2015-02-15', '2015-02-28'], dtype='datetime64[ns]', freq='SM-15')

```

#### SemiMonthBegin:

```

In [47]: Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')

In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
Out[48]: DatetimeIndex(['2015-01-01', '2015-01-15', '2015-02-01', '2015-02-15'], dtype='datetime64[ns]', freq='SMS-15')

```

Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```

In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'], dtype='datetime64[ns]', freq='SMS-16')

In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
Out[50]: DatetimeIndex(['2015-01-14', '2015-01-31', '2015-02-14', '2015-02-28'], dtype='datetime64[ns]', freq='SM-14')

```

### 1.12.1.7 New Index methods

The following methods and options are added to `Index`, to be more consistent with the `Series` and `DataFrame` API.

`Index` now supports the `.where()` function for same shape indexing (GH13170)

```

In [51]: idx = pd.Index(['a', 'b', 'c'])

In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')

```

Index now supports `.dropna()` to exclude missing values ([GH6194](#))

```
In [53]: idx = pd.Index([1, 2, np.nan, 4])

In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For `MultiIndex`, values are dropped if any level is missing by default. Specifying `how='all'` only drops values where all levels are missing.

[illegible]

Index now supports `.str.extractall()` which returns a DataFrame, see the [docs here](#) (GH10008, GH13156)

```
In [59]: idx = pd.Index(["a1a2", "b1", "c1"])

In [60]: idx.str.extractall("[ab](?P<digit>\\d)")
Out[60]:
      digit
match
0 0      1
  1      2
1 0      1
```

`Index.astype()` now accepts an optional boolean argument `copy`, which allows optional copying if the requirements on `dtype` are satisfied ([GH13209](#))

### 1.12.1.8 Google BigQuery Enhancements

- The `read_gbq()` method has gained the `dialect` argument to allow users to specify whether to use BigQuery's legacy SQL or BigQuery's standard SQL. See the [docs](#) for more details ([GH13615](#)).
- The `to_gbq()` method now allows the DataFrame column order to differ from the destination table schema ([GH11359](#)).

### 1.12.1.9 Fine-grained numpy errstate

Previous versions of pandas would permanently silence numpy’s ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaN s. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the `numpy.errstate` context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas codebase. ([GH13109](#), [GH13145](#))

After upgrading pandas, you may see *new* `RuntimeWarnings` being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use `numpy.errstate` around the source of the `RuntimeWarning` to control how these conditions are handled.

### 1.12.1.10 `get_dummies` now returns integer dtypes

The `pd.get_dummies` function now returns dummy-encoded columns as small integers, rather than floats ([GH8725](#)). This should provide an improved memory footprint.

**Previous behavior:**

```
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes

Out[1]:
a    float64
b    float64
c    float64
dtype: object
```

**New behavior:**

```
In [61]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
Out[61]:
a    uint8
b    uint8
c    uint8
dtype: object
```

### 1.12.1.11 Downcast values to smallest possible dtype in `to_numeric`

`pd.to_numeric()` now accepts a `downcast` parameter, which will downcast the data if possible to smallest specified numerical dtype ([GH13352](#))

```
In [62]: s = ['1', 2, 3]

In [63]: pd.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)

In [64]: pd.to_numeric(s, downcast='integer')
Out[64]: array([1, 2, 3], dtype=int8)
```

### 1.12.1.12 pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, `pandas.api` to hold public API's. We are starting by exposing type introspection functions in `pandas.api.types`. More sub-packages and officially sanctioned API's will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```
In [65]: import pprint

In [66]: from pandas.api import types

In [67]: funcs = [ f for f in dir(types) if not f.startswith('_') ]

In [68]: pprint.pprint(funcs)
['CategoricalDtype',
 'DatetimeTZDtype',
 'IntervalDtype',
 'PeriodDtype',
 'infer_dtype',
 'is_any_int_dtype',
 'is_array_like',
 'is_bool',
 'is_bool_dtype',
 'is_categorical',
 'is_categorical_dtype',
 'is_complex',
 'is_complex_dtype',
 'is_datetime64_any_dtype',
 'is_datetime64_dtype',
 'is_datetime64_ns_dtype',
 'is_datetime64tz_dtype',
 'is_datetimetz',
 'is_dict_like',
 'is_dtype_equal',
 'is_extension_type',
 'is_file_like',
 'is_float',
 'is_float_dtype',
 'is_floating_dtype',
 'is_hashable',
 'is_int64_dtype',
 'is_integer',
 'is_integer_dtype',
 'is_interval',
 'is_interval_dtype',
 'is_iterator',
 'is_list_like',
 'is_named_tuple',
 'is_number',
 'is_numeric_dtype',
 'is_object_dtype',
 'is_period',
 'is_period_dtype',
 'is_re',
 'is_re_compilable',
 'is_scalar',
```

(continues on next page)

(continued from previous page)

```
'is_sequence',
'is_signed_integer_dtype',
'is_sparse',
'is_string_dtype',
'is_timedelta64_dtype',
'is_timedelta64_ns_dtype',
'is_unsigned_integer_dtype',
'pandas_dtype',
'union_categoricals']
```

**Note:** Calling these functions from the internal module `pandas.core.common` will now show a `DeprecationWarning` ([GH13990](#))

### 1.12.1.13 Other enhancements

- `Timestamp` can now accept positional and keyword parameters similar to `datetime.datetime()` ([GH10758](#), [GH11630](#))

```
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')

In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
Out[70]: Timestamp('2012-01-01 08:30:00
↪')
```

- The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or MultiIndex level ([GH13500](#))

```
In [71]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W',
↪periods=5),
.....:                    'a': np.arange(5)},
.....:                    index=pd.MultiIndex.from_arrays([
.....:                        [1,2,3,4,5],
.....:                        pd.date_range('2015-01-01', freq='W',
↪periods=5)],
.....:                    names=['v','d']))

In [72]: df
Out[72]:
```

		date	a
v	d		
1	2015-01-04	2015-01-04	0
2	2015-01-11	2015-01-11	1
3	2015-01-18	2015-01-18	2
4	2015-01-25	2015-01-25	3
5	2015-02-01	2015-02-01	4

```
In [73]: df.resample('M', on='date').sum()
Out[73]:
```

	a
date	

(continues on next page)

(continued from previous page)

```
2015-01-31    6
2015-02-28    4
```

```
In [74]: df.resample('M', level='d').sum()
```

```

////////////////////////////////////
↪
          a
d
2015-01-31    6
2015-02-28    4

```

- The `.get_credentials()` method of `GbqConnector` can now first try to fetch the [application default credentials](#). See the docs for more details ([GH13577](#)).
- The `.tz_localize()` method of `DatetimeIndex` and `Timestamp` has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to `NaT`. The default behavior remains to raising a `NonExistentTimeError` ([GH13057](#)).
- `.to_hdf/read_hdf()` now accept path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path ([GH11773](#)).
- The `pd.read_csv()` with `engine='python'` has gained support for the `decimal` ([GH12933](#)), `na_filter` ([GH13321](#)) and the `memory_map` option ([GH13381](#)).
- Consistent with the Python API, `pd.read_csv()` will now interpret `+inf` as positive infinity ([GH13274](#)).
- The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options ([GH13461](#)).
- `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when `dtype` is categorical ([GH13209](#)).
- `DataFrame` has gained the `.asof()` method to return the last non-`NaN` values according to the selected subset ([GH13358](#)).
- The `DataFrame` constructor will now respect key ordering if a list of `OrderedDict` objects are passed in ([GH13304](#)).
- `pd.read_html()` has gained support for the `decimal` option ([GH12907](#)).
- `Series` has gained the properties `.is_monotonic`, `.is_monotonic_increasing`, `.is_monotonic_decreasing`, similar to `Index` ([GH13336](#)).
- `DataFrame.to_sql()` now allows a single value as the SQL type for all columns ([GH11886](#)).
- `Series.append` now supports the `ignore_index` option ([GH13677](#)).
- `.to_stata()` and `StataWriter` can now write variable labels to Stata dta files using a dictionary to make column names to labels ([GH13535](#), [GH13536](#)).
- `.to_stata()` and `StataWriter` will automatically convert `datetime64[ns]` columns to Stata format `%tc`, rather than raising a `ValueError` ([GH12259](#)).
- `read_stata()` and `StataReader` raise with a more explicit error message when reading Stata files with repeated value labels when `convert_categoricals=True` ([GH13923](#)).
- `DataFrame.style` will now render sparsified `MultiIndexes` ([GH11655](#)).
- `DataFrame.style` will now show column level names (e.g. `DataFrame.columns.names`) ([GH13775](#)).
- `DataFrame` has gained support to re-order the columns based on the values in a row using `df.sort_values(by='...', axis=1)` ([GH10806](#)).

```

In [75]: df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
.....:                    index=['row1', 'row2'])
.....:

In [76]: df
Out[76]:
   A  B  C
row1 2  3  4
row2 7  5  8

In [77]: df.sort_values(by='row2', axis=1)
Out[77]:
   B  A  C
row1 3  2  4
row2 5  7  8

```

- Added documentation to *I/O* regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)
- `to_html()` now has a `border` argument to control the value in the opening `<table>` tag. The default is the value of the `html.border` option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter's CSS includes a border-width attribute, the visual effect is the same. (GH11563).
- Raise `ImportError` in the `sql` functions when `sqlalchemy` is not installed and a connection string is used (GH11920).
- Compatibility with matplotlib 2.0. Older versions of pandas should also work with matplotlib 2.0 (GH13333)
- `Timestamp`, `Period`, `DatetimeIndex`, `PeriodIndex` and `.dt` accessor have gained a `.is_leap_year` property to check whether the date belongs to a leap year. (GH13727)
- `astype()` will now accept a dict of column name to data types mapping as the `dtype` argument. (GH12086)
- The `pd.read_json` and `DataFrame.to_json` has gained support for reading and writing json lines with `lines` option see *Line delimited json* (GH9180)
- `read_excel()` now supports the `true_values` and `false_values` keyword arguments (GH13347)
- `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-`MultiIndex` grouper. (GH13907)
- Non-convertible dates in an excel date column will be returned without conversion and the column will be `object` dtype, rather than raising an exception (GH10001).
- `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)
- `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)
- `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).

## 1.12.2 API changes

### 1.12.2.1 `Series.tolist()` will now return Python types

`Series.tolist()` will now return Python types in the output, mimicking `NumPy.tolist()` behavior (GH10904)

```
In [78]: s = pd.Series([1,2,3])
```

**Previous behavior:**

```
In [7]: type(s.tolist()[0])
Out[7]:
<class 'numpy.int64'>
```

**New behavior:**

```
In [79]: type(s.tolist()[0])
Out[79]: int
```

### 1.12.2.2 Series operators for different indexes

Following Series operators have been changed to make all operators consistent, including DataFrame ([GH1134](#), [GH4581](#), [GH13538](#))

- Series comparison operators now raise `ValueError` when index are different.
- Series logical operators align both index of left and right hand side.

**Warning:** Until 0.18.1, comparing Series with the same length, would succeed even if the `.index` are different (the result ignores `.index`). As of 0.19.0, this will raises `ValueError` to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like `.eq`.

As a result, Series and DataFrame operators behave as below:

#### Arithmetic operators

Arithmetic operators align both index (no changes).

```
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))
In [82]: s1 + s2
Out[82]:
A    3.0
B    4.0
C     NaN
D     NaN
dtype: float64

In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))
In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))
In [85]: df1 + df2
Out[85]:
   0
A  3.0
```

(continues on next page)

(continued from previous page)

```
B 4.0
C NaN
D NaN
```

## Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

**Previous Behavior** (Series):

Series compared values ignoring the `.index` as long as both had the same length:

```
In [1]: s1 == s2
Out[1]:
A    False
B     True
C    False
dtype: bool
```

**New behavior** (Series):

```
In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects
```

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```
In [86]: s1.values == s2.values
Out[86]: array([False,  True, False], dtype=bool)
```

If you want to compare Series aligning its `.index`, see flexible comparison methods section below:

```
In [87]: s1.eq(s2)
Out[87]:
A    False
B     True
C    False
D    False
dtype: bool
```

**Current Behavior** (DataFrame, no change):

```
In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects
```

## Logical operators

Logical operators align both `.index` of left and right hand side.

**Previous behavior** (Series), only left hand side index was kept:

```
In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A      True
B     False
C     False
dtype: bool
```

**New behavior** (Series):

```
In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [90]: s1 & s2
Out[90]:
A      True
B     False
C     False
D     False
dtype: bool
```

---

**Note:** Series logical operators fill a NaN result with False.

---

---

**Note:** To achieve the same result as previous versions (compare values based on only left hand side index), you can use `reindex_like`:

```
In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A      True
B     False
C     False
dtype: bool
```

---

**Current Behavior** (DataFrame, no change):

```
In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
In [94]: df1 & df2
Out[94]:
0
A      True
B     False
C      NaN
D      NaN
```

## Flexible comparison methods

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both index. Use these operators if you want to compare two Series which has the different index.

```
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])

In [97]: s1.eq(s2)
Out[97]:
a    False
b     True
c    False
d    False
dtype: bool

In [98]: s1.ge(s2)
Out[98]:
a    False
b     True
c     True
d    False
dtype: bool
```

Previously, this worked the same as comparison operators (see above).

### 1.12.2.3 Series type promotion on assignment

A Series will now correctly promote its dtype for assignment with incompat values to the current dtype ([GH13234](#))

```
In [99]: s = pd.Series()
```

**Previous behavior:**

```
In [2]: s["a"] = pd.Timestamp("2016-01-01")

In [3]: s["b"] = 3.0
TypeError: invalid type promotion
```

**New behavior:**

```
In [100]: s["a"] = pd.Timestamp("2016-01-01")
In [101]: s["b"] = 3.0

In [102]: s
Out[102]:
a    2016-01-01 00:00:00
b                      3
dtype: object

In [103]: s.dtype
Out[103]:
dtype('O')
```

#### 1.12.2.4 .to\_datetime() changes

Previously if `.to_datetime()` encountered mixed integers/floats and strings, but no datetimes with `errors='coerce'` it would convert all to `NaT`.

**Previous behavior:**

```
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)
```

**Current behavior:**

This will now convert integers/floats with the default unit of `ns`.

```
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype=
↳ 'datetime64[ns]', freq=None)
```

Bug fixes related to `.to_datetime()`:

- Bug in `pd.to_datetime()` when passing integers or floats, and no unit and `errors='coerce'` ([GH13180](#)).
- Bug in `pd.to_datetime()` when passing invalid datatypes (e.g. `bool`); will now respect the `errors` keyword ([GH13176](#))
- Bug in `pd.to_datetime()` which overflowed on `int8`, and `int16` dtypes ([GH13451](#))
- Bug in `pd.to_datetime()` raise `AttributeError` with `NaN` and the other string is not valid when `errors='ignore'` ([GH12424](#))
- Bug in `pd.to_datetime()` did not cast floats correctly when unit was specified, resulting in truncated datetime ([GH13834](#))

#### 1.12.2.5 Merging changes

Merging will now preserve the dtype of the join keys ([GH8596](#))

```
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})

In [106]: df1
Out[106]:
   key  v1
0    1  10

In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [108]: df2
Out[108]:
   key  v1
0    1  20
1    2  30
```

**Previous behavior:**

```
In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
   key    v1
0  1.0  10.0
```

(continues on next page)

(continued from previous page)

```

1  1.0  20.0
2  2.0  30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out[6]:
key      float64
v1       float64
dtype: object

```

**New behavior:**

We are able to preserve the join keys

```

In [109]: pd.merge(df1, df2, how='outer')
Out[109]:
   key  v1
0    1  10
1    1  20
2    2  30

In [110]: pd.merge(df1, df2, how='outer').dtypes
Out[110]:
key      int64
v1       int64
dtype: object

```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

```

In [111]: pd.merge(df1, df2, how='outer', on='key')
Out[111]:
   key  v1_x  v1_y
0    1  10.0   20
1    2   NaN   30

In [112]: pd.merge(df1, df2, how='outer', on='key').dtypes
Out[112]:
key      int64
v1_x     float64
v1_y     int64
dtype: object

```

**1.12.2.6 .describe() changes**

Percentile identifiers in the index of a `.describe()` output will now be rounded to the least precision that keeps them distinct ([GH13104](#))

```

In [113]: s = pd.Series([0, 1, 2, 3, 4])

In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])

```

**Previous behavior:**

The percentiles were rounded to at most one decimal place, which could raise `ValueError` for a data frame if the percentiles were duplicated.

```
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out [3]:
```

```
count      5.000000
mean       2.000000
std        1.581139
min        0.000000
0.0%       0.000400
0.1%       0.002000
0.1%       0.004000
50%        2.000000
99.9%      3.996000
100.0%     3.998000
100.0%     3.999600
max        4.000000
dtype: float64
```

```
In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out [4]:
```

```
...
ValueError: cannot reindex from a duplicate axis
```

#### New behavior:

```
In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
Out [115]:
```

```
count      5.000000
mean       2.000000
std        1.581139
min        0.000000
0.01%      0.000400
0.05%      0.002000
0.1%       0.004000
50%        2.000000
99.9%      3.996000
99.95%     3.998000
99.99%     3.999600
max        4.000000
dtype: float64
```

```
In [116]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
////////////////////////////////////
```

```
↪
      0
count  5.000000
mean   2.000000
std    1.581139
min    0.000000
0.01%  0.000400
0.05%  0.002000
0.1%   0.004000
50%    2.000000
99.9%  3.996000
99.95% 3.998000
99.99% 3.999600
max     4.000000
```

Furthermore:

- Passing duplicated percentiles will now raise a `ValueError`.
- Bug in `.describe()` on a `DataFrame` with a mixed-dtype column index, which would previously raise a `TypeError` ([GH13288](#))

### 1.12.2.7 Period changes

#### PeriodIndex now has period dtype

`PeriodIndex` now has its own period dtype. The period dtype is a pandas extension dtype like category or the *timezone aware dtype* (`datetime64[ns, tz]`) ([GH13941](#)). As a consequence of this change, `PeriodIndex` no longer has an integer dtype:

##### Previous behavior:

```
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')

In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True

In [4]: pi.dtype
Out[4]: dtype('int64')
```

##### New behavior:

```
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')

In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')

In [119]: pd.api.types.is_integer_dtype(pi)
Out[119]: False

In [120]: pd.api.types.is_period_dtype(pi)
Out[120]: True

In [121]: pi.dtype
Out[121]: period[D]

In [122]: type(pi.dtype)
Out[122]: pandas.core.dtypes.dtypes.PeriodDtype
```

#### Period('NaT') now returns pd.NaT

Previously, `Period` has its own `Period('NaT')` representation different from `pd.NaT`. Now `Period('NaT')` has been changed to return `pd.NaT`. ([GH12759](#), [GH13582](#))

##### Previous behavior:

```
In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')
```

**New behavior:**

These result in `pd.NaT` without providing `freq` option.

```
In [123]: pd.Period('NaT')
Out[123]: NaT

In [124]: pd.Period(None)
Out[124]: NaT
```

To be compatible with `Period` addition and subtraction, `pd.NaT` now supports addition and subtraction with `int`. Previously it raised `ValueError`.

**Previous behavior:**

```
In [5]: pd.NaT + 1
...
ValueError: Cannot add integral value to Timestamp without freq.
```

**New behavior:**

```
In [125]: pd.NaT + 1
Out[125]: NaT

In [126]: pd.NaT - 1
Out[126]: NaT
```

### **`PeriodIndex.values` now returns array of `Period` object**

`.values` is changed to return an array of `Period` objects, rather than an array of integers ([GH13988](#)).

**Previous behavior:**

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
array([492, 493])
```

**New behavior:**

```
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [128]: pi.values
Out[128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

### **1.12.2.8 Index + / – no longer used for set operations**

Addition and subtraction of the base `Index` type and of `DatetimeIndex` (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific `.union()` and `.difference()` methods), and is now disabled. When possible, `+` and `-` are now used for element-wise operations, for example for concatenating strings or subtracting datetimes ([GH8227](#), [GH14127](#)).

Previous behavior:

```
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .
↳union()
Out[1]: Index(['a', 'b', 'c'], dtype='object')
```

**New behavior:** the same operation will now perform element-wise addition:

```
In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out[129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

```
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

**Previous behavior:**

```
In [1]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
↳FutureWarning: using '-' to provide set differences with datetimelike Indexes is
↳deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

**New behavior:**

```
In [131]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
↳Out[131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)
```

### 1.12.2.9 Index.difference and .symmetric\_difference changes

Index.difference and Index.symmetric\_difference will now, more consistently, treat NaN values as any other values. (GH13514)

```
In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
In [133]: idx2 = pd.Index([0, 1, np.nan])
```

**Previous behavior:**

```
In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')

In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')
```

**New behavior:**

```
In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')

In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')
```

(continues on next page)

### 1.12.2.10 `Index.unique` consistently returns `Index`

`Index.unique()` now returns unique values as an `Index` of the appropriate dtype. (GH13395). Previously, most `Index` classes returned `np.ndarray`, and `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex` returned `Index` to keep metadata like timezone.

#### Previous behavior:

```
In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])

In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo').
↳unique()
Out[2]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
                '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

#### New behavior:

```
In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')

In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo
↳').unique()
Out[137]:
DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
                '2011-01-03 00:00:00+09:00'],
              dtype='datetime64[ns, Asia/Tokyo]', freq=None)
```

### 1.12.2.11 `MultiIndex` constructors, `groupby` and `set_index` preserve categorical dtypes

`MultiIndex.from_arrays` and `MultiIndex.from_product` will now preserve categorical dtype in `MultiIndex` levels (GH13743, GH13854).

```
In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))

In [139]: lvl1 = ['foo', 'bar']

In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])

In [141]: midx
Out[141]:
MultiIndex(levels=[['b', 'a', 'c'], ['bar', 'foo']],
            labels=[[1, 0], [1, 0]])
```

#### Previous behavior:

```
In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')

In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')
```

**New behavior:** the single level is now a CategoricalIndex:

```
In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ dtype='category')

In [143]: midx.get_level_values(0)
////////////////////////////////////
↳ CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False, dtype=
↳ 'category')
```

An analogous change has been made to `MultiIndex.from_product`. As a consequence, `groupby` and `set_index` also preserve categorical dtypes in indexes

```
In [144]: df = pd.DataFrame({'A': [0, 1], 'B': [10, 11], 'C': cat})

In [145]: df_grouped = df.groupby(by=['A', 'C']).first()

In [146]: df_set_idx = df.set_index(['A', 'C'])
```

**Previous behavior:**

```
In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [12]: df_grouped.reset_index().dtypes
Out[12]:
A      int64
C      object
B      float64
dtype: object

In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [14]: df_set_idx.reset_index().dtypes
Out[14]:
A      int64
C      object
B      int64
dtype: object
```

**New behavior:**

```
In [147]: df_grouped.index.levels[1]
Out[147]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
↳ name='C', dtype='category')

In [148]: df_grouped.reset_index().dtypes
////////////////////////////////////
↳
A      int64
C      category
B      float64
dtype: object

In [149]: df_set_idx.index.levels[1]
////////////////////////////////////
↳ CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False, name='C
↳ ', dtype='category')
```

(continues on next page)

(continued from previous page)

```
In [150]: df_set_idx.reset_index().dtypes
```

```

////////////////////////////////////
↪
A      int64
C      category
B      int64
dtype: object

```

### 1.12.2.12 read\_csv will progressively enumerate chunks

When `read_csv()` is called with `chunksize=n` and without specifying an index, each chunk used to have an independently generated index from 0 to `n-1`. They are now given instead a progressive index, starting from 0 for the first chunk, from `n` for the second, and so on, so that, when concatenated, they are identical to the result of calling `read_csv()` without the `chunksize=` argument (GH12185).

```
In [151]: data = 'A,B\n0,1\n2,3\n4,5\n6,7'
```

#### Previous behavior:

```
In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
```

```
Out[2]:
```

```

   A  B
0  0  1
1  2  3
0  4  5
1  6  7

```

#### New behavior:

```
In [152]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
```

```
Out[152]:
```

```

   A  B
0  0  1
1  2  3
2  4  5
3  6  7

```

### 1.12.2.13 Sparse Changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

#### int64 and bool support enhancements

Sparse data structures now gained enhanced support of `int64` and `bool` dtype (GH667, GH13849).

Previously, sparse data were `float64` dtype by default, even if all inputs were of `int` or `bool` dtype. You had to specify dtype explicitly to create sparse data with `int64` dtype. Also, `fill_value` had to be specified explicitly because the default was `np.nan` which doesn't appear in `int64` or `bool` data.

```

In [1]: pd.SparseArray([1, 2, 0, 0])
Out[1]:
[1.0, 2.0, 0.0, 0.0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

# specifying int64 dtype, but all values are stored in sp_values because
# fill_value default is np.nan
In [2]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[2]:
[1, 2, 0, 0]
Fill: nan
IntIndex
Indices: array([0, 1, 2, 3], dtype=int32)

In [3]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64, fill_value=0)
Out[3]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)

```

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate `fill_value` defaults (0 for `int64` dtype, `False` for `bool` dtype).

```

In [153]: pd.SparseArray([1, 2, 0, 0], dtype=np.int64)
Out[153]:
[1, 2, 0, 0]
Fill: 0
IntIndex
Indices: array([0, 1], dtype=int32)

In [154]: pd.SparseArray([True, False, False, False])
\\Out[154]:
↳
[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)

```

See the [docs](#) for more details.

## Operators now preserve dtypes

- Sparse data structure now can preserve dtype after arithmetic ops ([GH13848](#))

```

In [155]: s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)

In [156]: s.dtype
Out[156]: dtype('int64')

In [157]: s + 1
\\Out[157]:
0    1
1    3

```

(continues on next page)

(continued from previous page)

```

2      1
3      2
dtype: int64
BlockIndex
Block locations: array([1, 3], dtype=int32)
Block lengths: array([1, 1], dtype=int32)

```

- Sparse data structure now support `astype` to convert internal dtype ([GH13900](#))

```
In [158]: s = pd.SparseSeries([1., 0., 2., 0.], fill_value=0)
```

```
In [159]: s
```

```
Out[159]:
```

```

0      1.0
1      0.0
2      2.0
3      0.0
dtype: float64
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)

```

```
In [160]: s.astype(np.int64)
```

```

////////////////////////////////////
↪
0      1
1      0
2      2
3      0
dtype: int64
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)

```

`astype` fails if data contains values which cannot be converted to specified dtype. Note that the limitation is applied to `fill_value` which default is `np.nan`.

```
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.
↪int64)
```

```
Out [7]:
```

```
ValueError: unable to coerce current fill_value nan to int64 dtype
```

## Other sparse fixes

- Subclassed `SparseDataFrame` and `SparseSeries` now preserve class types when slicing or transposing. ([GH13787](#))
- `SparseArray` with `bool` dtype now supports logical (`bool`) operators ([GH14000](#))
- Bug in `SparseSeries` with `MultiIndex []` indexing may raise `IndexError` ([GH13144](#))
- Bug in `SparseSeries` with `MultiIndex []` indexing result may have normal `Index` ([GH13144](#))
- Bug in `SparseDataFrame` in which `axis=None` did not default to `axis=0` ([GH13048](#))
- Bug in `SparseSeries` and `SparseDataFrame` creation with `object` dtype may raise `TypeError` ([GH11633](#))

- Bug in `SparseDataFrame` doesn't respect passed `SparseArray` or `SparseSeries`'s `dtype` and `fill_value` (GH13866)
- Bug in `SparseArray` and `SparseSeries` don't apply `ufunc` to `fill_value` (GH13853)
- Bug in `SparseSeries.abs` incorrectly keeps negative `fill_value` (GH13853)
- Bug in single row slicing on multi-type `SparseDataFrame`s, types were previously forced to float (GH13917)
- Bug in `SparseSeries` slicing changes integer `dtype` to float (GH8292)
- Bug in `SparseDataFrame` comparison ops may raise `TypeError` (GH13001)
- Bug in `SparseDataFrame.isnull` raises `ValueError` (GH8276)
- Bug in `SparseSeries` representation with `bool` `dtype` may raise `IndexError` (GH13110)
- Bug in `SparseSeries` and `SparseDataFrame` of `bool` or `int64` `dtype` may display its values like `float64` `dtype` (GH13110)
- Bug in sparse indexing using `SparseArray` with `bool` `dtype` may return incorrect result (GH13985)
- Bug in `SparseArray` created from `SparseSeries` may lose `dtype` (GH13999)
- Bug in `SparseSeries` comparison with dense returns normal `Series` rather than `SparseSeries` (GH13999)

#### 1.12.2.14 Indexer dtype changes

**Note:** This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as `Index.get_indexer` that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like `numpy.take`. Previously, a platform int was defined as `np.int_` which corresponds to a C integer, but the correct type, and what is being used now, is `np.intp`, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, `np.int_` is 32 bits, and `np.intp` is 64 bits. Changing this behavior improves performance for many operations on that platform.

**Previous behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

**New behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```

### 1.12.2.15 Other API Changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to `stdout` ([GH14101](#)).
- `Series.unique()` with `datetime` and `timezone` now returns `array of Timestamp with timezone` ([GH13565](#)).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called ([GH13778](#)).
- `Index.reshape()` will raise a `NotImplementedError` exception when called ([GH12882](#)).
- `.filter()` enforces mutual exclusion of the keyword arguments ([GH12399](#)).
- `eval`'s upcasting rules for `float32` types have been updated to be more consistent with NumPy's rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` ([GH12388](#)).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on `groupby` or `resample` objects ([GH12811](#)).
- `__setitem__` will no longer apply a callable `rhs` as a function instead of storing it. Call `where` directly to get the previous behavior ([GH13299](#)).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` ([GH13161](#)).
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a `DataFrame` with identical columns and index labels ([GH13222](#)).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains `NaN` values ([GH13149](#)).
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` ([GH13209](#)).
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with `object` dtype ([GH13664](#)).
- `PeriodIndex.fillna` with `Period` has different `freq` now coerces to `object` dtype ([GH13664](#)).
- Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not `None`. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array ([GH12216](#), [GH7096](#)).
- `pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. ([GH13623](#))
- `pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the builtin `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x ([GH14086](#))
- More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CParserError` ([GH13652](#)).
- `pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long ([GH14065](#))
- `DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` ([GH10364](#), [GH13917](#))
- `.groupby.groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or `lists` ([GH14293](#))

### 1.12.3 Deprecations

- `Series.reshape` and `Categorical.reshape` have been deprecated and will be removed in a subsequent release ([GH12882](#), [GH12882](#))
- `PeriodIndex.to_datetime` has been deprecated in favor of `PeriodIndex.to_timestamp` ([GH8254](#))
- `Timestamp.to_datetime` has been deprecated in favor of `Timestamp.to_pydatetime` ([GH8254](#))
- `Index.to_datetime` and `DatetimeIndex.to_datetime` have been deprecated in favor of `pd.to_datetime` ([GH8254](#))
- `pandas.core.datetools` module has been deprecated and will be removed in a subsequent release ([GH14094](#))
- `SparseList` has been deprecated and will be removed in a future version ([GH13784](#))
- `DataFrame.to_html()` and `DataFrame.to_latex()` have dropped the `colSpace` parameter in favor of `col_space` ([GH13857](#))
- `DataFrame.to_sql()` has deprecated the `flavor` parameter, as it is superfluous when SQLAlchemy is not installed ([GH13611](#))
- Depreciated `read_csv` keywords:
  - `compact_ints` and `use_unsigned` have been deprecated and will be removed in a future version ([GH13320](#))
  - `buffer_lines` has been deprecated and will be removed in a future version ([GH13360](#))
  - `as_reccarray` has been deprecated and will be removed in a future version ([GH13373](#))
  - `skip_footer` has been deprecated in favor of `skipfooter` and will be removed in a future version ([GH13349](#))
- top-level `pd.ordered_merge()` has been renamed to `pd.merge_ordered()` and the original name will be removed in a future version ([GH13358](#))
- `Timestamp.offset` property (and named arg in the constructor), has been deprecated in favor of `freq` ([GH12160](#))
- `pd.tseries.util.pivot_annual` is deprecated. Use `pivot_table` as alternative, an example is [here](#) ([GH736](#))
- `pd.tseries.util.isleapyear` has been deprecated and will be removed in a subsequent release. `Datetime`-likes now have a `.is_leap_year` property ([GH13727](#))
- `Panel4D` and `PanelND` constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the [xarray package](#). Pandas provides a `to_xarray()` method to automate this conversion ([GH13564](#)).
- `pandas.tseries.frequencies.get_standard_freq` is deprecated. Use `pandas.tseries.frequencies.to_offset(freq).rule_code` instead ([GH13874](#))
- `pandas.tseries.frequencies.to_offset`'s `freqstr` keyword is deprecated in favor of `freq` ([GH13874](#))
- `Categorical.from_array` has been deprecated and will be removed in a future version ([GH13854](#))

### 1.12.4 Removal of prior version deprecations/changes

- The `SparsePanel` class has been removed ([GH13778](#))

- The `pd.sandbox` module has been removed in favor of the external library `pandas-qt` ([GH13670](#))
- The `pandas.io.data` and `pandas.io.wb` modules are removed in favor of the `pandas-datareader` package ([GH13724](#)).
- The `pandas.tools.rplot` module has been removed in favor of the `seaborn` package ([GH13855](#))
- `DataFrame.to_csv()` has dropped the `engine` parameter, as was deprecated in 0.17.1 ([GH11274](#), [GH13419](#))
- `DataFrame.to_dict()` has dropped the `outtype` parameter in favor of `orient` ([GH13627](#), [GH8486](#))
- `pd.Categorical` has dropped setting of the `ordered` attribute directly in favor of the `set_ordered` method ([GH13671](#))
- `pd.Categorical` has dropped the `levels` attribute in favor of `categories` ([GH8376](#))
- `DataFrame.to_sql()` has dropped the `mysql` option for the `flavor` parameter ([GH13611](#))
- `Panel.shift()` has dropped the `lags` parameter in favor of `periods` ([GH14041](#))
- `pd.Index` has dropped the `diff` method in favor of `difference` ([GH13669](#))
- `pd.DataFrame` has dropped the `to_wide` method in favor of `to_panel` ([GH14039](#))
- `Series.to_csv` has dropped the `nanRep` parameter in favor of `na_rep` ([GH13804](#))
- `Series.xs`, `DataFrame.xs`, `Panel.xs`, `Panel.major_xs`, and `Panel.minor_xs` have dropped the `copy` parameter ([GH13781](#))
- `str.split` has dropped the `return_type` parameter in favor of `expand` ([GH13701](#))
- Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) ([GH13590](#), [GH13868](#)). Now legacy time rules raises `ValueError`. For the list of currently supported off-sets, see [here](#).
- The default value for the `return_type` parameter for `DataFrame.plot.box` and `DataFrame.boxplot` changed from `None` to `"axes"`. These methods will now return a matplotlib axes by default instead of a dictionary of artists. See [here](#) ([GH6581](#)).
- The `tquery` and `uquery` functions in the `pandas.io.sql` module are removed ([GH5950](#)).

### 1.12.5 Performance Improvements

- Improved performance of sparse `IntIndex.intersect` ([GH13082](#))
- Improved performance of sparse arithmetic with `BlockIndex` when the number of blocks are large, though recommended to use `IntIndex` in such cases ([GH13082](#))
- Improved performance of `DataFrame.quantile()` as it now operates per-block ([GH11623](#))
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 ([GH13166](#), [GH13334](#))
- Improved performance of `DataFrameGroupBy.transform` ([GH12737](#))
- Improved performance of `Index` and `Series.duplicated` ([GH10235](#))
- Improved performance of `Index.difference` ([GH12044](#))
- Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` ([GH13749](#))
- Improved performance of datetime string parsing in `DatetimeIndex` ([GH13692](#))
- Improved performance of hashing `Period` ([GH12817](#))

- Improved performance of `factorize` of datetime with timezone (GH13750)
- Improved performance of by lazily creating indexing hashtables on larger Indexes (GH14266)
- Improved performance of `groupby.groups` (GH14293)
- Unnecessary materializing of a MultiIndex when introspecting for memory usage (GH14308)

### 1.12.6 Bug Fixes

- Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
- Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1`. (GH13994)
- Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
- Bug in `io.json.json_normalize()`, where non-ascii keys raised an exception (GH13213)
- Bug when passing a not-default-indexed Series as `xerr` or `yerr` in `.plot()` (GH11858)
- Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
- Bug in DataFrame assignment with an object-dtyped Index where the resultant column is mutable to the original object. (GH13522)
- Bug in matplotlib `AutoDataFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)
- Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range (GH8287)
- Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid ordered parameter was passed in (GH14058)
- Bug in Series construction from a tuple of integers on windows not returning default dtype (`int64`) (GH13646)
- Bug in `TimedeltaIndex` addition with a Datetime-like object where addition overflow was not being caught (GH14068)
- Bug in `.groupby(...).resample(...)` when the same object is called multiple times (GH13174)
- Bug in `.to_records()` when index name is a unicode string (GH13172)
- Bug in calling `.memory_usage()` on object which doesn't implement (GH12924)
- Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the Series with the quantile (GH13098, GH13146)
- Bug in `SeriesGroupBy.transform` with datetime values and missing groups (GH13191)
- Bug where empty Series were incorrectly coerced in datetime-like numeric operations (GH13844)
- Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones (GH14190)
- Bug in `Series.str.extractall()` with `str` index raises `ValueError` (GH13156)
- Bug in `Series.str.extractall()` with single group and quantifier (GH13382)
- Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` (GH13078)
- Bug in Index and Series created with NaN and NaT mixed data may not have `datetime64` dtype (GH13324)

- Bug in Index and Series may ignore `np.datetime64('nat')` and `np.timedelta64('nat')` to infer dtype ([GH13324](#))
- Bug in PeriodIndex and Period subtraction raises `AttributeError` ([GH13071](#))
- Bug in PeriodIndex construction returning a float64 index in some circumstances ([GH13067](#))
- Bug in `.resample(...)` with a PeriodIndex not changing its freq appropriately when empty ([GH13067](#))
- Bug in `.resample(...)` with a PeriodIndex not retaining its type or name with an empty DataFrame appropriately when empty ([GH13212](#))
- Bug in `groupby(...).apply(...)` when the passed function returns scalar values per group ([GH13468](#)).
- Bug in `groupby(...).resample(...)` where passing some keywords would raise an exception ([GH13235](#))
- Bug in `.tz_convert` on a tz-aware DateTimeIndex that relied on index being sorted for correct results ([GH13306](#))
- Bug in `.tz_localize` with `dateutil.tz.tzlocal` may return incorrect result ([GH13583](#))
- Bug in `DatetimeTZDtype` dtype with `dateutil.tz.tzlocal` cannot be regarded as valid dtype ([GH13583](#))
- Bug in `pd.read_hdf()` where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the key argument was set to the name of the dataset. ([GH13231](#))
- Bug in `.rolling()` that allowed a negative integer window in construction of the `Rolling()` object, but would later fail on aggregation ([GH13383](#))
- Bug in Series indexing with tuple-valued data and a numeric index ([GH13509](#))
- Bug in printing `pd.DataFrame` where unusual elements with the `object` dtype were causing segfaults ([GH13717](#))
- Bug in ranking Series which could result in segfaults ([GH13445](#))
- Bug in various index types, which did not propagate the name of passed index ([GH12309](#))
- Bug in `DatetimeIndex`, which did not honour the `copy=True` ([GH13205](#))
- Bug in `DatetimeIndex.is_normalized` returns incorrectly for normalized date\_range in case of local timezones ([GH13459](#))
- Bug in `pd.concat` and `.append` may coerces `datetime64` and `timedelta` to `object` dtype containing python built-in `datetime` or `timedelta` rather than `Timestamp` or `Timedelta` ([GH13626](#))
- Bug in `PeriodIndex.append` may raises `AttributeError` when the result is `object` dtype ([GH13221](#))
- Bug in `CategoricalIndex.append` may accept normal list ([GH13626](#))
- Bug in `pd.concat` and `.append` with the same timezone get reset to UTC ([GH7795](#))
- Bug in Series and DataFrame `.append` raises `AmbiguousTimeError` if data contains datetime near DST boundary ([GH13626](#))
- Bug in `DataFrame.to_csv()` in which float values were being quoted even though quotations were specified for non-numeric values only ([GH12922](#), [GH13259](#))
- Bug in `DataFrame.describe()` raising `ValueError` with only boolean columns ([GH13898](#))
- Bug in `MultiIndex` slicing where extra elements were returned when level is non-unique ([GH12896](#))
- Bug in `.str.replace` does not raise `TypeError` for invalid replacement ([GH13438](#))
- Bug in `MultiIndex.from_arrays` which didn't check for input array lengths matching ([GH13599](#))

- Bug in `cartesian_product` and `MultiIndex.from_product` which may raise with empty input arrays ([GH12258](#))
- Bug in `pd.read_csv()` which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances ([GH13703](#))
- Bug in `pd.read_csv()` which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` ([GH12224](#))
- Bug in `pd.read_csv()` which caused BOM files to be incorrectly parsed by not ignoring the BOM ([GH4793](#))
- Bug in `pd.read_csv()` with `engine='python'` which raised errors when a numpy array was passed in for `usecols` ([GH12546](#))
- Bug in `pd.read_csv()` where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter ([GH14066](#))
- Bug in `pd.read_csv()` with `engine='python'` in which NaN values weren't being detected after data was converted to numeric values ([GH13314](#))
- Bug in `pd.read_csv()` in which the `nrows` argument was not properly validated for both engines ([GH10476](#))
- Bug in `pd.read_csv()` with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly ([GH13274](#))
- Bug in `pd.read_csv()` with `engine='python'` in which trailing NaN values were not being parsed ([GH13320](#))
- Bug in `pd.read_csv()` with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 ([GH13398](#))
- Bug in `pd.read_csv()` that prevents `usecols` kwarg from accepting single-byte unicode strings ([GH13219](#))
- Bug in `pd.read_csv()` that prevents `usecols` from being an empty set ([GH13402](#))
- Bug in `pd.read_csv()` in the C engine where the NULL character was not being parsed as NULL ([GH14012](#))
- Bug in `pd.read_csv()` with `engine='c'` in which NULL `quotechar` was not accepted even though quoting was specified as `None` ([GH13411](#))
- Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric ([GH13411](#))
- Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data ([GH3404](#))
- Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF\_xx, utf\_xx) raised `UnicodeDecodeError` ([GH13549](#))
- Bug in `pd.read_csv`, `pd.read_table`, `pd.read_fwf`, `pd.read_stata` and `pd.read_sas` where files were opened by parsers but not closed if both `chunksize` and `iterator` were `None`. ([GH13940](#))
- Bug in `StataReader`, `StataWriter`, `XportReader` and `SAS7BDATReader` where a file was not properly closed when an error was raised. ([GH13940](#))
- Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list ([GH13354](#))
- Bug in `pd.Series.str.zfill`, `center`, `ljust`, `rjust`, and `pad` when passing non-integers, did not raise `TypeError` ([GH13598](#))
- Bug in checking for any null objects in a `TimedeltaIndex`, which always returned `True` ([GH13603](#))
- Bug in `Series` arithmetic raises `TypeError` if it contains datetime-like as object dtype ([GH13043](#))

- Bug `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)
- Bug `Series.fillna()` and `Series.dropna()` don't affect to `Period('NaT')` (GH13737)
- Bug in `.fillna(value=np.nan)` incorrectly raises `KeyError` on a category dtype Series (GH14021)
- Bug in extension dtype creation where the created types were not is/identical (GH13285)
- Bug in `.resample(...)` where incorrect warnings were triggered by IPython introspection (GH13618)
- Bug in `NaT - Period` raises `AttributeError` (GH13071)
- Bug in Series comparison may output incorrect result if rhs contains `NaT` (GH9005)
- Bug in Series and Index comparison may output incorrect result if it contains `NaT` with object dtype (GH13592)
- Bug in Period addition raises `TypeError` if Period is on right hand side (GH13069)
- Bug in Period and Series or Index comparison raises `TypeError` (GH13200)
- Bug in `pd.set_eng_float_format()` that would prevent `NaN` and `Inf` from formatting (GH11981)
- Bug in `.unstack` with Categorical dtype resets `.ordered` to `True` (GH13249)
- Clean some compile time warnings in datetime parsing (GH13607)
- Bug in `factorize` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)
- Bug in `.set_index` raises `AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)
- Bug in `.shift` raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)
- Bug in `pd.read_hdf()` returns incorrect result when a DataFrame with a categorical column and a query which doesn't match any values (GH13792)
- Bug in `.iloc` when indexing with a non lex-sorted MultiIndex (GH13797)
- Bug in `.loc` when indexing with date strings in a reverse sorted DatetimeIndex (GH14316)
- Bug in Series comparison operators when dealing with zero dim NumPy arrays (GH13006)
- Bug in `.combine_first` may return incorrect dtype (GH7630, GH10567)
- Bug in groupby where `apply` returns different result depending on whether first result is `None` or not (GH12824)
- Bug in `groupby(...).nth()` where the group key is included inconsistently if called after `.head()` / `.tail()` (GH12839)
- Bug in `.to_html`, `.to_latex` and `.to_string` silently ignore custom datetime formatter passed through the `formatters` key word (GH10690)
- Bug in `DataFrame.iterrows()`, not yielding a Series subclasse if defined (GH13977)
- Bug in `pd.to_numeric` when `errors='coerce'` and input contains non-hashable objects (GH13324)
- Bug in invalid Timedelta arithmetic and comparison may raise `ValueError` rather than `TypeError` (GH13624)
- Bug in invalid datetime parsing in `to_datetime` and `DatetimeIndex` may raise `TypeError` rather than `ValueError` (GH11169, GH11287)
- Bug in Index created with tz-aware Timestamp and mismatched `tz` option incorrectly coerces timezone (GH13692)

- Bug in `DatetimeIndex` with nanosecond frequency does not include timestamp specified with `end` ([GH13672](#))
- Bug in `Series` when setting a slice with a `np.timedelta64` ([GH14155](#))
- Bug in `Index` raises `OutOfBoundsDatetime` if datetime exceeds `datetime64[ns]` bounds, rather than coercing to object dtype ([GH13663](#))
- Bug in `Index` may ignore specified `datetime64` or `timedelta64` passed as dtype ([GH13981](#))
- Bug in `RangeIndex` can be created without no arguments rather than raises `TypeError` ([GH13793](#))
- Bug in `.value_counts()` raises `OutOfBoundsDatetime` if data exceeds `datetime64[ns]` bounds ([GH13663](#))
- Bug in `DatetimeIndex` may raise `OutOfBoundsDatetime` if input `np.datetime64` has other unit than `ns` ([GH9114](#))
- Bug in `Series` creation with `np.datetime64` which has other unit than `ns` as object dtype results in incorrect values ([GH13876](#))
- Bug in `resample` with `timedelta` data where data was casted to float ([GH13119](#)).
- Bug in `pd.isnull()` `pd.notnull()` raise `TypeError` if input datetime-like has other unit than `ns` ([GH13389](#))
- Bug in `pd.merge()` may raise `TypeError` if input datetime-like has other unit than `ns` ([GH13389](#))
- Bug in `HDFStore/read_hdf()` discarded `DatetimeIndex.name` if `tz` was set ([GH13884](#))
- Bug in `Categorical.remove_unused_categories()` changes `.codes` dtype to platform int ([GH13261](#))
- Bug in `groupby` with `as_index=False` returns all NaN's when grouping on multiple columns including a categorical one ([GH13204](#))
- Bug in `df.groupby(...)[...]` where `getitem` with `Int64Index` raised an error ([GH13731](#))
- Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned `"col_heading level<n> col<c>"` where `n` was the number of levels + 1. Now they are assigned `"index_name level<n>"`, where `n` is the correct level for that `MultiIndex`.
- Bug where `pd.read_gbq()` could throw `ImportError`: No module named `discovery` as a result of a naming conflict with another python package called `apiclient` ([GH13454](#))
- Bug in `Index.union` returns an incorrect result with a named empty index ([GH13432](#))
- Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes ([GH13432](#), [GH12814](#))
- Bug in subtract tz-aware `datetime.datetime` from tz-aware `datetime64` series ([GH14088](#))
- Bug in `.to_excel()` when `DataFrame` contains a `MultiIndex` which contains a label with a NaN value ([GH13511](#))
- Bug in invalid frequency offset string like `"D1"`, `"-2-3H"` may not raise `ValueError` ([GH13930](#))
- Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels ([GH13542](#)).
- Bug in `Series.str.contains()` for `Series` containing only NaN values of object dtype ([GH14171](#))
- Bug in `agg()` function on `groupby` dataframe changes dtype of `datetime64[ns]` column to `float64` ([GH12821](#))

- Bug in using NumPy ufunc with PeriodIndex to add or subtract integer raise IncompatibleFrequency. Note that using standard operator like + or - is recommended, because standard operators use more efficient path ([GH13980](#))
- Bug in operations on NaT returning float instead of datetime64[ns] ([GH12941](#))
- Bug in Series flexible arithmetic methods (like .add()) raises ValueError when axis=None ([GH13894](#))
- Bug in DataFrame.to\_csv() with MultiIndex columns in which a stray empty line was added ([GH6618](#))
- Bug in DatetimeIndex, TimedeltaIndex and PeriodIndex.equals() may return True when input isn't Index but contains the same values ([GH13107](#))
- Bug in assignment against datetime with timezone may not work if it contains datetime near DST boundary ([GH14146](#))
- Bug in pd.eval() and HDFStore query truncating long float literals with python 2 ([GH14241](#))
- Bug in Index raises KeyError displaying incorrect column when column is not in the df and columns contains duplicate values ([GH13822](#))
- Bug in Period and PeriodIndex creating wrong dates when frequency has combined offset aliases ([GH13874](#))
- Bug in .to\_string() when called with an integer line\_width and index=False raises an UnboundLocalError exception because idx referenced before assignment.
- Bug in eval() where the resolvers argument would not accept a list ([GH14095](#))
- Bugs in stack, get\_dummies, make\_axis\_dummies which don't preserve categorical dtypes in (multi)indexes ([GH13854](#))
- PeriodIndex can now accept list and array which contains pd.NaT ([GH13430](#))
- Bug in df.groupby where .median() returns arbitrary values if grouped dataframe contains empty bins ([GH13629](#))
- Bug in Index.copy() where name parameter was ignored ([GH14302](#))

## 1.13 v0.18.1 (May 3, 2016)

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- .groupby(...) has been enhanced to provide convenient syntax when working with .rolling(...), .expanding(...) and .resample(...) per group, see [here](#)
- pd.to\_datetime() has gained the ability to assemble dates from a DataFrame, see [here](#)
- Method chaining improvements, see [here](#).
- Custom business hour offset, see [here](#).
- Many bug fixes in the handling of sparse, see [here](#)
- Expanded the *Tutorials section* with a feature on modern pandas, courtesy of [@TomAugsburger](#). ([GH13045](#)).

**What's new in v0.18.1**

- *New features*
  - *Custom Business Hour*
  - *.groupby(..) syntax with window and resample operations*
  - *Method chaining improvements*
    - \* *.where() and .mask()*
    - \* *.loc[], .iloc[], .ix[]*
    - \* *[] indexing*
  - *Partial string indexing on DateTimeIndex when part of a MultiIndex*
  - *Assembling Datetimes*
  - *Other Enhancements*
- *Sparse changes*
- *API changes*
  - *.groupby(..).nth() changes*
  - *numpy function compatibility*
  - *Using .apply on groupby resampling*
  - *Changes in read\_csv exceptions*
  - *to\_datetime error changes*
  - *Other API changes*
  - *Deprecations*
- *Performance Improvements*
- *Bug Fixes*

**1.13.1 New features****1.13.1.1 Custom Business Hour**

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. For details, see *Custom Business Hour* (GH11514)

```
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```
In [4]: dt = datetime(2014, 1, 17, 15)
```

(continues on next page)

(continued from previous page)

```
In [5]: dt + bhour_us
Out[5]: Timestamp('2014-01-17 16:00:00')
```

Tuesday after MLK Day (Monday is skipped because it's a holiday)

```
In [6]: dt + bhour_us * 2
Out[6]: Timestamp('2014-01-20 09:00:00')
```

### 1.13.1.2 .groupby(...) syntax with window and resample operations

.groupby(...) has been enhanced to provide convenient syntax when working with .rolling(...), .expanding(...) and .resample(...) per group, see (GH12486, GH12738).

You can now use .rolling(...) and .expanding(...) as methods on groupbys. These return another deferred object (similar to what .rolling() and .expanding() do on ungrouped pandas objects). You can then operate on these RollingGroupby objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```
In [7]: df = pd.DataFrame({'A': [1] * 20 + [2] * 12 + [3] * 8,
...:                      'B': np.arange(40)})
...:

In [8]: df
Out[8]:
```

	A	B
0	1	0
1	1	1
2	1	2
3	1	3
4	1	4
5	1	5
6	1	6
..	..	..
33	3	33
34	3	34
35	3	35
36	3	36
37	3	37
38	3	38
39	3	39

[40 rows x 2 columns]

```
In [9]: df.groupby('A').apply(lambda x: x.rolling(4).B.mean())
Out[9]:
```

A		
1	0	NaN
	1	NaN
	2	NaN
	3	1.5
	4	2.5
	5	3.5
	6	4.5
	...	...

(continues on next page)

(continued from previous page)

```

3  33      NaN
   34      NaN
   35     33.5
   36     34.5
   37     35.5
   38     36.5
   39     37.5
Name: B, Length: 40, dtype: float64

```

Now you can do:

```

In [10]: df.groupby('A').rolling(4).B.mean()
Out[10]:
A
1  0      NaN
   1      NaN
   2      NaN
   3      1.5
   4      2.5
   5      3.5
   6      4.5
...
3  33      NaN
   34      NaN
   35     33.5
   36     34.5
   37     35.5
   38     36.5
   39     37.5
Name: B, Length: 40, dtype: float64

```

For `.resample(...)` type of operations, previously you would have to:

```

In [11]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
.....:                                           periods=4,
.....:                                           freq='W'),
.....:                      'group': [1, 1, 2, 2],
.....:                      'val': [5, 6, 7, 8]}).set_index('date')
.....:

In [12]: df
Out[12]:
           group  val
date
2016-01-03      1    5
2016-01-10      1    6
2016-01-17      2    7
2016-01-24      2    8

```

```

In [13]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())
Out[13]:
           group  val
group date
1  2016-01-03      1    5
   2016-01-04      1    5
   2016-01-05      1    5

```

(continues on next page)

(continued from previous page)

```

2016-01-06      1      5
2016-01-07      1      5
2016-01-08      1      5
2016-01-09      1      5
...
2    2016-01-18      2      7
    2016-01-19      2      7
    2016-01-20      2      7
    2016-01-21      2      7
    2016-01-22      2      7
    2016-01-23      2      7
    2016-01-24      2      8

[16 rows x 2 columns]
```

Now you can do:

```

In [14]: df.groupby('group').resample('1D').ffill()
Out[14]:
```

		group	val
group	date		
1	2016-01-03	1	5
	2016-01-04	1	5
	2016-01-05	1	5
	2016-01-06	1	5
	2016-01-07	1	5
	2016-01-08	1	5
	2016-01-09	1	5
...		...	...
2	2016-01-18	2	7
	2016-01-19	2	7
	2016-01-20	2	7
	2016-01-21	2	7
	2016-01-22	2	7
	2016-01-23	2	7
	2016-01-24	2	8

```

[16 rows x 2 columns]
```

### 1.13.1.3 Method chaining improvements

The following methods / indexers now accept a callable. It is intended to make these more useful in method chains, see the [documentation](#). (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[], iloc[]` and `.ix[]`
- `[]` indexing

#### `.where()` and `.mask()`

These can accept a callable for the condition and other arguments.

```
In [15]: df = pd.DataFrame({'A': [1, 2, 3],
.....:                    'B': [4, 5, 6],
.....:                    'C': [7, 8, 9]})
.....:

In [16]: df.where(lambda x: x > 4, lambda x: x + 10)
Out[16]:
```

	A	B	C
0	11	14	7
1	12	5	8
2	13	6	9

`.loc[], .iloc[], .ix[]`

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer's input.

```
# callable returns bool indexer
In [17]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[17]:
```

	B	C
1	5	8
2	6	9

```
# callable returns list of labels
In [18]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]
Out[18]:
```

	A	B
1	2	5
2	3	6

## [ ] indexing

Finally, you can use a callable in [ ] indexing of Series, DataFrame and Panel. The callable must return a valid input for [ ] indexing depending on its class and index type.

```
In [19]: df[lambda x: 'A']
Out[19]:
```

	A
0	1
1	2
2	3

Name: A, dtype: int64

Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [20]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [21]: (bb.groupby(['year', 'team'])
.....:      .sum()
.....:      .loc[lambda df: df.r > 100]
.....:      )
.....:
Out[21]:
```

#### 1.13.1.4 Partial string indexing on DateTimeIndex when part of a MultiIndex

Partial string indexing now matches on DateTimeIndex when part of a MultiIndex (GH10331)

```
In [22]: dft2 = pd.DataFrame(np.random.randn(20, 1),
.....:                      columns=['A'],
.....:                      index=pd.MultiIndex.from_product([pd.date_range('20130101
↪',
.....:
↪periods=10,
.....:
↪),
.....:                      freq='12H
.....:                      ['a', 'b']]))
```

In [23]: dft2

Out [23]:

```

```

### 1.13.1.5 Assembling Datetimes

`pd.to_datetime()` has gained the ability to assemble datetimes from a passed in `DataFrame` or a dict. (GH8158).

```

In [29]: df = pd.DataFrame({'year': [2015, 2016],
    ....:                    'month': [2, 3],
    ....:                    'day': [4, 5],

```

(continues on next page)

(continued from previous page)

```

.....:             'hour': [2, 3])
.....:
In [30]: df
Out[30]:
   year  month  day  hour
0  2015     2    4     2
1  2016     3    5     3

```

Assembling using the passed frame.

```

In [31]: pd.to_datetime(df)
Out[31]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]

```

You can pass only the columns that you need to assemble.

```

In [32]: pd.to_datetime(df[['year', 'month', 'day']])
Out[32]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]

```

### 1.13.1.6 Other Enhancements

- `pd.read_csv()` now supports `delim_whitespace=True` for the Python engine ([GH12958](#))
- `pd.read_csv()` now supports opening ZIP files that contains a single CSV, via extension inference or explicit `compression='zip'` ([GH12175](#))
- `pd.read_csv()` now supports opening files using xz compression, via extension inference or explicit `compression='xz'` is specified; xz compressions is also supported by `DataFrame.to_csv` in the same way ([GH11852](#))
- `pd.read_msgpack()` now always gives writeable ndarrays even when compression is used ([GH12359](#)).
- `pd.read_msgpack()` now supports serializing and de-serializing categoricals with msgpack ([GH12573](#))
- `.to_json()` now supports NDFrames that contain categorical and sparse data ([GH10778](#))
- `interpolate()` now supports `method='akima'` ([GH7588](#)).
- `pd.read_excel()` now accepts path objects (e.g. `pathlib.Path`, `py.path.local`) for the file path, in line with other `read_*` functions ([GH12655](#))
- Added `.weekday_name` property as a component to `DatetimeIndex` and the `.dt` accessor. ([GH11128](#))
- `Index.take` now handles `allow_fill` and `fill_value` consistently ([GH12631](#))

```

In [33]: idx = pd.Index([1., 2., 3., 4.], dtype='float')

# default, allow_fill=True, fill_value=None
In [34]: idx.take([2, -1])
Out[34]: Float64Index([3.0, 4.0], dtype='float64')

```

(continues on next page)

(continued from previous page)

```
In [35]: idx.take([2, -1], fill_value=True)
Out[35]: Float64Index([3.0,
nan], dtype='float64')
```

- Index now supports `.str.get_dummies()` which returns `MultiIndex`, see *Creating Indicator Variables* (GH10008, GH10103)

```
In [36]: idx = pd.Index(['a|b', 'a|c', 'b|c'])

In [37]: idx.str.get_dummies('|')
Out[37]:
MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
            labels=[[1, 1, 0], [1, 0, 1], [0, 1, 1]],
            names=['a', 'b', 'c'])
```

- `pd.crosstab()` has gained a `normalize` argument for normalizing frequency tables (GH12569). Examples in the updated docs [here](#).
- `.resample(...).interpolate()` is now supported (GH12925)
- `.isin()` now accepts passed sets (GH12988)

### 1.13.2 Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

`SparseArray.take` now returns a scalar for scalar input, `SparseArray` for others. Furthermore, it handles a negative indexer with the same rule as `Index` ([GH10560](#), [GH12796](#))

```
In [38]: s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])

In [39]: s.take(0)
Out[39]: nan

In [40]: s.take([1, 2, 3])
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[40]:
[nan, 1.0, 2.0]
Fill: nan
IntIndex
Indices: array([1, 2], dtype=int32)
```

- Bug in `SparseSeries[]` indexing with Ellipsis raises `KeyError` ([GH9467](#))
- Bug in `SparseArray[]` indexing with tuples are not handled properly ([GH12966](#))
- Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` ([GH10560](#))
- Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` ([GH10560](#))
- Bug in `SparseSeries.loc[], .iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` ([GH10560](#))
- Bug in `SparseDataFrame.loc[], .iloc[]` may results in dense `Series`, rather than `SparseSeries` ([GH12787](#))
- Bug in `SparseArray` addition ignores `fill_value` of right hand side ([GH12910](#))
- Bug in `SparseArray` mod raises `AttributeError` ([GH12910](#))

- Bug in `SparseArray` `pow` calculates `1 ** np.nan` as `np.nan` which must be 1 (GH12910)
- Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)
- Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)
- Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)
- Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)
- Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)
- Bug in `SparseArray.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)
- Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)
- Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)
- Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)
- Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)
- Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)
- Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)
- Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

## 1.13.3 API changes

### 1.13.3.1 `.groupby(...).nth()` changes

The index in `.groupby(...).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```
In [41]: df = DataFrame({'A' : ['a', 'b', 'a'],
.....:                  'B' : [1, 2, 3]})
.....:

In [42]: df
Out[42]:
   A  B
0  a  1
1  b  2
2  a  3
```

Previous Behavior:

```
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
0    1
1    2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
0    1
1    2
Name: B, dtype: int64
```

New Behavior:

```
In [43]: df.groupby('A', as_index=True)['B'].nth(0)
Out[43]:
A
a    1
b    2
Name: B, dtype: int64

In [44]: df.groupby('A', as_index=False)['B'].nth(0)
Out[44]:
0    1
1    2
Name: B, dtype: int64
```

Furthermore, previously, a `.groupby` would always sort, regardless if `sort=False` was passed with `.nth()`.

```
In [45]: np.random.seed(1234)

In [46]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])

In [47]: df['c'] = np.random.randint(0, 4, 100)
```

Previous Behavior:

```
In [4]: df.groupby('c', sort=True).nth(1)
Out[4]:
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [5]: df.groupby('c', sort=False).nth(1)
Out[5]:
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524
```

New Behavior:

```
In [48]: df.groupby('c', sort=True).nth(1)
Out[48]:
      a      b
c
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [49]: df.groupby('c', sort=False).nth(1)
Out[49]:
      a      b
c
```

(continues on next page)

(continued from previous page)

```

2 -0.720589  0.887163
3  0.859588 -0.636524
0 -0.334077  0.002118
1  0.036142 -2.074978

```

### 1.13.3.2 numpy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their `numpy` counterparts has been greatly increased by augmenting the signatures of the pandas methods so as to accept arguments that can be passed in from `numpy`, even if they are not necessarily used in the pandas implementation ([GH12644](#), [GH12638](#), [GH12687](#))

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function ([GH12238](#))
- Bug in `numpy` compatibility of `np.round()` on a `Series` ([GH12600](#))

An example of this signature augmentation is illustrated below:

```

In [50]: sp = pd.SparseDataFrame([1, 2, 3])

In [51]: sp
Out[51]:
   0
0  1
1  2
2  3

```

Previous behaviour:

```

In [2]: np.cumsum(sp, axis=0)
...
TypeError: cumsum() takes at most 2 arguments (4 given)

```

New behaviour:

```

In [52]: np.cumsum(sp, axis=0)
Out[52]:
   0
0  1
1  3
2  6

```

### 1.13.3.3 Using `.apply` on groupby resampling

Using `apply` on resampling groupby operations (using a `pd.TimeGrouper`) now has the same output types as similar `apply` calls on other groupby operations. ([GH11742](#)).

```

In [53]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']),
...:                        'value': [10, 13]})
...:
...:

In [54]: df
Out[54]:
   date  value
0 10/10/2000    10
1 11/10/2000    13

```

(continues on next page)

(continued from previous page)

```
0 2000-10-10    10
1 2000-11-10    13
```

Previous behavior:

```
In [1]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
↳sum())
Out[1]:
...
TypeError: cannot concatenate a non-NDFrame object

# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value']].
↳sum())
Out[2]:
date
2000-10-31  value    10
2000-11-30  value    13
dtype: int64
```

New Behavior:

```
# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
↳sum())
Out[55]:
date
2000-10-31    10
2000-11-30    13
Freq: M, dtype: int64

# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value
↳']].sum())
Out[56]:
      value
date
2000-10-31    10
2000-11-30    13
```

### 1.13.3.4 Changes in read\_csv exceptions

In order to standardize the `read_csv` API for both the `c` and `python` engines, both will now raise an `EmptyDataError`, a subclass of `ValueError`, in response to empty columns or header ([GH12493](#), [GH12506](#))

Previous behaviour:

```
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...
ValueError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...
StopIteration
```

New behaviour:

```
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...
pandas.io.common.EmptyDataError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...
pandas.io.common.EmptyDataError: No columns to parse from file
```

In addition to this error change, several others have been made as well:

- CParserError now sub-classes ValueError instead of just a Exception ([GH12551](#))
- A CParserError is now raised instead of a generic Exception in read\_csv when the c engine cannot parse a column ([GH12506](#))
- A ValueError is now raised instead of a generic Exception in read\_csv when the c engine encounters a NaN value in an integer column ([GH12506](#))
- A ValueError is now raised instead of a generic Exception in read\_csv when true\_values is specified, and the c engine encounters an element in a column containing unencodable bytes ([GH12506](#))
- pandas.parser.OverflowError exception has been removed and has been replaced with Python's built-in OverflowError exception ([GH12506](#))
- pd.read\_csv() no longer allows a combination of strings and integers for the usecols parameter ([GH12678](#))

### 1.13.3.5 to\_datetime error changes

Bugs in pd.to\_datetime() when passing a unit with convertible entries and errors='coerce' or non-convertible with errors='ignore'. Furthermore, an OutOfBoundsDatetime exception will be raised when an out-of-range value is encountered for that unit when errors='raise'. ([GH11758](#), [GH13052](#), [GH13059](#))

Previous behaviour:

```
In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long
```

New behaviour:

```
In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'
```

### 1.13.3.6 Other API changes

- `.swaplevel()` for `Series`, `DataFrame`, `Panel`, and `MultiIndex` now features defaults for its first two parameters `i` and `j` that swap the two innermost levels of the index. (GH12934)
- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with `numpy`'s `searchsorted` function (GH12238)
- `Period` and `PeriodIndex` now raises `IncompatibleFrequency` error which inherits `ValueError` rather than raw `ValueError` (GH12615)
- `Series.apply` for category dtype now applies the passed function to each of the `.categories` (and not the `.codes`), and returns a category dtype if possible (GH12473)
- `read_csv` will now raise a `TypeError` if `parse_dates` is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
- The default for `.query()/eval()` is now `engine=None`, which will use `numexpr` if it's installed; otherwise it will fallback to the `python` engine. This mimics the pre-0.18.1 behavior if `numexpr` is installed (and which, previously, if `numexpr` was not installed, `.query()/eval()` would raise). (GH12749)
- `pd.show_versions()` now includes `pandas_datareader` version (GH12740)
- Provide a proper `__name__` and `__qualname__` attributes for generic functions (GH12021)
- `pd.concat(ignore_index=True)` now uses `RangeIndex` as default (GH12695)
- `pd.merge()` and `DataFrame.join()` will show a `UserWarning` when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)
- Compat with `scipy > 0.17` for deprecated `piecewise_polynomial` interpolation method; support for the replacement `from_derivatives` method (GH12887)

### 1.13.3.7 Deprecations

- The method name `Index.sym_diff()` is deprecated and can be replaced by `Index.symmetric_difference()` (GH12591)
- The method name `Categorical.sort()` is deprecated in favor of `Categorical.sort_values()` (GH12882)

### 1.13.4 Performance Improvements

- Improved speed of SAS reader (GH12656, GH12961)
- Performance improvements in `.groupby(...).cumcount()` (GH11039)
- Improved memory usage in `pd.read_csv()` when using `skiprows=an_integer` (GH13005)
- Improved performance of `DataFrame.to_sql` when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
- Improved performance of `Period` construction and time series plotting (GH12903, GH11831).
- Improved performance of `.str.encode()` and `.str.decode()` methods (GH13008)
- Improved performance of `to_numeric` if input is numeric dtype (GH12777)
- Improved performance of sparse arithmetic with `IntIndex` (GH13036)

### 1.13.5 Bug Fixes

- `usecols` parameter in `pd.read_csv` is now respected even when the lines of a CSV file are not even ([GH12203](#))
- Bug in `groupby.transform(...)` when `axis=1` is specified with a non-monotonic ordered index ([GH12713](#))
- Bug in `Period` and `PeriodIndex` creation raises `KeyError` if `freq="Minute"` is specified. Note that “Minute” `freq` is deprecated in v0.17.0, and recommended to use `freq="T"` instead ([GH11854](#))
- Bug in `.resample(...).count()` with a `PeriodIndex` always raising a `TypeError` ([GH12774](#))
- Bug in `.resample(...)` with a `PeriodIndex` casting to a `DatetimeIndex` when empty ([GH12868](#))
- Bug in `.resample(...)` with a `PeriodIndex` when resampling to an existing frequency ([GH12770](#))
- Bug in printing data which contains `Period` with different `freq` raises `ValueError` ([GH12615](#))
- Bug in `Series` construction with `Categorical` and `dtype='category'` is specified ([GH12574](#))
- Bugs in concatenation with a coercible `dtype` was too aggressive, resulting in different `dtypes` in output formatting when an object was longer than `display.max_rows` ([GH12411](#), [GH12045](#), [GH11594](#), [GH10571](#), [GH12211](#))
- Bug in `float_format` option with option not being validated as a callable. ([GH12706](#))
- Bug in `GroupBy.filter` when `dropna=False` and no groups fulfilled the criteria ([GH12768](#))
- Bug in `__name__` of `.cum*` functions ([GH12021](#))
- Bug in `.astype()` of a `Float64Index/Int64Index` to an `Int64Index` ([GH12881](#))
- Bug in roundtripping an integer based index in `.to_json()/read_json()` when `orient='index'` (the default) ([GH12866](#))
- Bug in plotting `Categorical` `dtypes` cause error when attempting stacked bar plot ([GH13019](#))
- Compat with `>= numpy 1.11` for `NaT` comparisons ([GH12969](#))
- Bug in `.drop()` with a non-unique `MultiIndex`. ([GH12701](#))
- Bug in `.concat` of datetime tz-aware and naive `DataFrames` ([GH12467](#))
- Bug in correctly raising a `ValueError` in `.resample(...).fillna(...)` when passing a non-string ([GH12952](#))
- Bug fixes in various encoding and header processing issues in `pd.read_sas()` ([GH12659](#), [GH12654](#), [GH12647](#), [GH12809](#))
- Bug in `pd.crosstab()` where would silently ignore `aggfunc` if `values=None` ([GH12569](#)).
- Potential segfault in `DataFrame.to_json` when serialising `datetime.time` ([GH11473](#)).
- Potential segfault in `DataFrame.to_json` when attempting to serialise `0d` array ([GH11299](#)).
- Segfault in `to_json` when attempting to serialise a `DataFrame` or `Series` with non-ndarray values; now supports serialization of `category`, `sparse`, and `datetime64[ns, tz]` `dtypes` ([GH10778](#)).
- Bug in `DataFrame.to_json` with unsupported `dtype` not passed to default handler ([GH12554](#)).
- Bug in `.align` not returning the sub-class ([GH12983](#))
- Bug in aligning a `Series` with a `DataFrame` ([GH13037](#))
- Bug in `ABCPanel` in which `Panel4D` was not being considered as a valid instance of this generic type ([GH12810](#))

- Bug in consistency of `.name` on `.groupby(..).apply(..)` cases ([GH12363](#))
- Bug in `Timestamp.__repr__` that caused `pprint` to fail in nested structures ([GH12622](#))
- Bug in `Timedelta.min` and `Timedelta.max`, the properties now report the true minimum/maximum `timedeltas` as recognized by pandas. See the [documentation](#). ([GH12727](#))
- Bug in `.quantile()` with interpolation may coerce to `float` unexpectedly ([GH12772](#))
- Bug in `.quantile()` with empty `Series` may return scalar rather than empty `Series` ([GH12772](#))
- Bug in `.loc` with out-of-bounds in a large indexer would raise `IndexError` rather than `KeyError` ([GH12527](#))
- Bug in resampling when using a `TimedeltaIndex` and `.asfreq()`, would previously not include the final fencepost ([GH12926](#))
- Bug in equality testing with a `Categorical` in a `DataFrame` ([GH12564](#))
- Bug in `GroupBy.first()`, `.last()` returns incorrect row when `TimeGrouper` is used ([GH7453](#))
- Bug in `pd.read_csv()` with the `c` engine when specifying `skiprows` with newlines in quoted items ([GH10911](#), [GH12775](#))
- Bug in `DataFrame` `timezone` lost when assigning `tz-aware` `datetime` `Series` with `alignment` ([GH12981](#))
- Bug in `.value_counts()` when `normalize=True` and `dropna=True` where `nulls` still contributed to the normalized count ([GH12558](#))
- Bug in `Series.value_counts()` loses `name` if its `dtype` is `category` ([GH12835](#))
- Bug in `Series.value_counts()` loses `timezone` info ([GH12835](#))
- Bug in `Series.value_counts(normalize=True)` with `Categorical` raises `UnboundLocalError` ([GH12835](#))
- Bug in `Panel.fillna()` ignoring `inplace=True` ([GH12633](#))
- Bug in `pd.read_csv()` when specifying `names`, `usecols`, and `parse_dates` simultaneously with the `c` engine ([GH9755](#))
- Bug in `pd.read_csv()` when specifying `delim_whitespace=True` and `lineterminator` simultaneously with the `c` engine ([GH12912](#))
- Bug in `Series.rename`, `DataFrame.rename` and `DataFrame.rename_axis` not treating `Series` as mappings to relabel ([GH12623](#)).
- Clean in `.rolling.min` and `.rolling.max` to enhance `dtype` handling ([GH12373](#))
- Bug in `groupby` where complex types are coerced to `float` ([GH12902](#))
- Bug in `Series.map` raises `TypeError` if its `dtype` is `category` or `tz-aware` `datetime` ([GH12473](#))
- Bugs on 32bit platforms for some test comparisons ([GH12972](#))
- Bug in index coercion when falling back from `RangeIndex` construction ([GH12893](#))
- Better error message in window functions when invalid argument (e.g. a `float` window) is passed ([GH12669](#))
- Bug in slicing subclassed `DataFrame` defined to return subclassed `Series` may return normal `Series` ([GH11559](#))
- Bug in `.str` accessor methods may raise `ValueError` if input has `name` and the result is `DataFrame` or `MultiIndex` ([GH12617](#))
- Bug in `DataFrame.last_valid_index()` and `DataFrame.first_valid_index()` on empty frames ([GH12800](#))

- Bug in `CategoricalIndex.get_loc` returns different result from regular `Index` ([GH12531](#))
- Bug in `PeriodIndex.resample` where name not propagated ([GH12769](#))
- Bug in `date_range` closed keyword and timezones ([GH12684](#)).
- Bug in `pd.concat` raises `AttributeError` when input data contains tz-aware datetime and timedelta ([GH12620](#))
- Bug in `pd.concat` did not handle empty `Series` properly ([GH11082](#))
- Bug in `.plot.bar` alignment when width is specified with `int` ([GH12979](#))
- Bug in `fill_value` is ignored if the argument to a binary operator is a constant ([GH12723](#))
- Bug in `pd.read_html()` when using `bs4` flavor and parsing table with a header and only one column ([GH9178](#))
- Bug in `.pivot_table` when `margins=True` and `dropna=True` where nulls still contributed to margin count ([GH12577](#))
- Bug in `.pivot_table` when `dropna=False` where table index/column names disappear ([GH12133](#))
- Bug in `pd.crosstab()` when `margins=True` and `dropna=False` which raised ([GH12642](#))
- Bug in `Series.name` when name attribute can be a hashable type ([GH12610](#))
- Bug in `.describe()` resets categorical columns information ([GH11558](#))
- Bug where `loffset` argument was not applied when calling `resample().count()` on a timeseries ([GH12725](#))
- `pd.read_excel()` now accepts column names associated with keyword argument `names` ([GH12870](#))
- Bug in `pd.to_numeric()` with `Index` returns `np.ndarray`, rather than `Index` ([GH12777](#))
- Bug in `pd.to_numeric()` with datetime-like may raise `TypeError` ([GH12777](#))
- Bug in `pd.to_numeric()` with scalar raises `ValueError` ([GH12777](#))

## 1.14 v0.18.0 (March 13, 2016)

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 ([GH7718](#), [GH11273](#))

**Warning:** numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (>= 2.1 and >= 2.4.6). ([GH12489](#))

Highlights include:

- Moving and expanding window functions are now methods on `Series` and `DataFrame`, similar to `.groupby`, see [here](#).
- Adding support for a `RangeIndex` as a specialized form of the `Int64Index` for memory savings, see [here](#).

- API breaking change to the `.resample` method to make it more `.groupby` like, see [here](#).
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see [here](#).
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see [here](#).
- The `read_sas` function has been enhanced to read `sas7bdat` files, see [here](#).
- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available ([GH4327](#)).

Check the [API Changes](#) and [deprecations](#) before updating.

### What's new in v0.18.0

- *New features*
  - *Window functions are now methods*
  - *Changes to rename*
  - *Range Index*
  - *Changes to str.extract*
  - *Addition of str.extractall*
  - *Changes to str.cat*
  - *Datetimelike rounding*
  - *Formatting of Integers in FloatIndex*
  - *Changes to dtype assignment behaviors*
  - *to\_xarray*
  - *Latex Representation*
  - *pd.read\_sas() changes*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *NaT and Timedelta operations*
  - *Changes to msgpack*
  - *Signature change for .rank*
  - *Bug in QuarterBegin with n=0*
  - *Resample API*
    - \* *Downsampling*
    - \* *Upsampling*
    - \* *Previous API will work but with deprecations*
  - *Changes to eval*
  - *Other API Changes*
  - *Deprecations*

- *Removal of deprecated float indexers*
- *Removal of prior version deprecations/changes*
- *Performance Improvements*
- *Bug Fixes*

## 1.14.1 New features

### 1.14.1.1 Window functions are now methods

Window functions have been refactored to be methods on `Series/DataFrame` objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of `.groupby`. See the full documentation [here](#) (GH11603, GH12373)

```
In [1]: np.random.seed(1234)

In [2]: df = pd.DataFrame({'A' : range(10), 'B' : np.random.randn(10)})

In [3]: df
Out[3]:
```

	A	B
0	0	0.471435
1	1	-1.190976
2	2	1.432707
3	3	-0.312652
4	4	-0.720589
5	5	0.887163
6	6	0.859588
7	7	-0.636524
8	8	0.015696
9	9	-2.242685

Previous Behavior:

```
In [8]: pd.rolling_mean(df,window=3)
FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be
removed in a future version, replace with
DataFrame.rolling(window=3,center=False).mean()

Out[8]:
```

	A	B
0	NaN	NaN
1	NaN	NaN
2	1	0.237722
3	2	-0.023640
4	3	0.133155
5	4	-0.048693
6	5	0.342054
7	6	0.370076
8	7	0.079587
9	8	-0.954504

New Behavior:

```
In [4]: r = df.rolling(window=3)
```

These show a descriptive repr

```
In [5]: r
Out[5]: Rolling [window=3,center=False,axis=0]
```

with tab-completion of available methods and properties.

```
In [9]: r.
r.A          r.agg          r.apply          r.count          r.exclusions  r.max          r.
↳median      r.name          r.skew          r.sum
r.B          r.aggregate      r.corr          r.cov          r.kurt        r.mean        r.
↳min         r.quantile      r.std          r.var
```

The methods operate on the Rolling object itself

```
In [6]: r.mean()
Out[6]:
   A      B
0 NaN    NaN
1 NaN    NaN
2 1.0  0.237722
3 2.0 -0.023640
4 3.0  0.133155
5 4.0 -0.048693
6 5.0  0.342054
7 6.0  0.370076
8 7.0  0.079587
9 8.0 -0.954504
```

They provide getitem accessors

```
In [7]: r['A'].mean()
Out[7]:
0    NaN
1    NaN
2    1.0
3    2.0
4    3.0
5    4.0
6    5.0
7    6.0
8    7.0
9    8.0
Name: A, dtype: float64
```

And multiple aggregations

```
In [8]: r.agg({'A' : ['mean','std'],
...          'B' : ['mean','std']})
Out[8]:
   A      B
mean std mean std
0 NaN NaN NaN NaN
1 NaN NaN NaN NaN
2 1.0 1.0 0.237722 1.327364
3 2.0 1.0 -0.023640 1.335505
4 3.0 1.0 0.133155 1.143778
```

(continues on next page)

(continued from previous page)

```

5  4.0  1.0 -0.048693  0.835747
6  5.0  1.0  0.342054  0.920379
7  6.0  1.0  0.370076  0.871850
8  7.0  1.0  0.079587  0.750099
9  8.0  1.0 -0.954504  1.162285

```

### 1.14.1.2 Changes to rename

`Series.rename` and `NDFrame.rename_axis` can now take a scalar or list-like argument for altering the Series or axis *name*, in addition to their old behaviors of altering labels. ([GH9494](#), [GH11965](#))

```
In [9]: s = pd.Series(np.random.randn(5))
```

```
In [10]: s.rename('newname')
```

```
Out[10]:
```

```
0    1.150036
```

```
1    0.991946
```

```
2    0.953324
```

```
3   -2.021255
```

```
4   -0.334077
```

```
Name: newname, dtype: float64
```

```
In [11]: df = pd.DataFrame(np.random.randn(5, 2))
```

```
In [12]: (df.rename_axis("indexname")
```

```
.....:      .rename_axis("columns_name", axis="columns"))
```

```
.....:
```

```
Out[12]:
```

```
columns_name      0      1
```

```
indexname
```

```
0      0.002118  0.405453
```

```
1      0.289092  1.321158
```

```
2     -1.546906 -0.202646
```

```
3     -0.655969  0.193421
```

```
4      0.553439  1.318152
```

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a *label* to a new label. This continues to work as before for function or dict-like values.

### 1.14.1.3 Range Index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to `Int64Index` if needed.

This will now be the default constructed index for `NDFrame` objects, rather than previous an `Int64Index`. ([GH939](#), [GH12070](#), [GH12071](#), [GH12109](#), [GH12888](#))

Previous Behavior:

```
In [3]: s = pd.Series(range(1000))
```

```
In [4]: s.index
```

(continues on next page)

(continued from previous page)

```

Out [4]:
Int64Index([ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9,
            ...
            990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
            length=1000)

In [6]: s.index.nbytes
Out [6]: 8000

```

New Behavior:

```

In [13]: s = pd.Series(range(1000))

In [14]: s.index
Out [14]: RangeIndex(start=0, stop=1000, step=1)

In [15]: s.index.nbytes
Out [15]: 80

```

#### 1.14.1.4 Changes to str.extract

The `.str.extract` method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups ([GH11386](#)).

In v0.18.0, the `expand` argument was added to `extract`.

- `expand=False`: it returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- `expand=True`: it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user.

Currently the default is `expand=None` which gives a FutureWarning and uses `expand=False`. To avoid this warning, please explicitly specify `expand`.

```

In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/
↳ DataFrame)
but in a future version of pandas this will be changed to expand=True (return
↳ DataFrame)

Out [1]:
0      1
1      2
2     NaN
dtype: object

```

Extracting a regular expression with one group returns a Series if `expand=False`.

```

In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=False)
Out [16]:
0      1
1      2
2     NaN
dtype: object

```

It returns a DataFrame with one column if `expand=True`.

```
In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=True)
Out[17]:
      0
0     1
1     2
2  NaN
```

Calling on an Index with a regex with exactly one capture group returns an Index if `expand=False`.

```
In [18]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])

In [19]: s.index
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')

In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[20]: Index(['A', 'B', 'C'], dtype='object', name='letter')
```

It returns a DataFrame with one column if `expand=True`.

```
In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[21]:
  letter
0      A
1      B
2      C
```

Calling on an Index with a regex with more than one capture group raises `ValueError` if `expand=False`.

```
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index
```

It returns a DataFrame if `expand=True`.

```
In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[22]:
  letter  1
0      A  11
1      B  22
2      C  33
```

In summary, `extract(expand=True)` always returns a DataFrame with a row for every subject string, and a column for every capture group.

#### 1.14.1.5 Addition of `str.extractall`

The `.str.extractall` method was added (GH11386). Unlike `extract`, which returns only the first match.

```
In [23]: s = pd.Series(["a1a2", "b1", "c1"], ["A", "B", "C"])

In [24]: s
Out[24]:
A    a1a2
B      b1
C      c1
dtype: object
```

(continues on next page)

(continued from previous page)

```
In [25]: s.str.extract("(?P<letter>[ab])(?P<digit>\d)", expand=False)
Out[25]:
letter digit
A      a      1
B      b      1
C     NaN     NaN
```

The `extractall` method returns all matches.

```
In [26]: s.str.extractall("(?P<letter>[ab])(?P<digit>\d)")
Out[26]:
letter digit
match
A 0      a      1
  1      a      2
B 0      b      1
```

### 1.14.1.6 Changes to `str.cat`

The method `.str.cat()` concatenates the members of a `Series`. Before, if `NaN` values were present in the `Series`, calling `.str.cat()` on it would return `NaN`, unlike the rest of the `Series.str.*` API. This behavior has been amended to ignore `NaN` values by default. (GH11435).

A new, friendlier `ValueError` is added to protect against the mistake of supplying the `sep` as an arg, rather than as a kwarg. (GH11334).

```
In [27]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ')
Out[27]: 'a b c'

In [28]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(sep=' ', na_rep='?')
Out[28]: 'a b ? c'
```

```
In [2]: pd.Series(['a', 'b', np.nan, 'c']).str.cat(' ')
ValueError: Did you mean to supply a `sep` keyword?
```

### 1.14.1.7 Datetimelike rounding

`DatetimeIndex`, `Timestamp`, `TimedeltaIndex`, `Timedelta` have gained the `.round()`, `.floor()` and `.ceil()` method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```
In [29]: dr = pd.date_range('20130101 09:12:56.1234', periods=3)

In [30]: dr
Out[30]:
DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
              '2013-01-03 09:12:56.123400'],
              dtype='datetime64[ns]', freq='D')

In [31]: dr.round('s')
Out[31]:
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
              '2013-01-03 09:12:56'],
              dtype='datetime64[ns]', freq='D')
```

(continues on next page)

(continued from previous page)

[illegible]

Tz-aware are rounded, floored and ceiled in local times

```
In [34]: dr = dr.tz_localize('US/Eastern')

In [35]: dr
Out[35]:
DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
               '2013-01-02 09:12:56.123400-05:00',
               '2013-01-03 09:12:56.123400-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')

In [36]: dr.round('s')
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
               '2013-01-03 09:12:56-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq=None)
```

Timedeltas

[illegible]

In addition, `.round()`, `.floor()` and `.ceil()` will be available thru the `.dt` accessor of `Series`.

```
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

0, 1
1, 2
2, 3

```
Out[47]: Float64Index([0.0, 1.0, 2.0], dtype='float64')
```

(continued from previous page)

```
In [48]: print(s.to_csv(path=None))
```

```
////////////////////////////////////  
↪0,1  
1.0,2  
2.0,3
```

### 1.14.1.9 Changes to dtype assignment behaviors

When a DataFrame's slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous Behavior:

```
In [5]: df = pd.DataFrame({'a': [0, 1, 1],  
                           'b': pd.Series([100, 200, 300], dtype='uint32')})  
  
In [7]: df.dtypes  
Out[7]:  
a      int64  
b      uint32  
dtype: object  
  
In [8]: ix = df['a'] == 1  
  
In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']  
  
In [11]: df.dtypes  
Out[11]:  
a      int64  
b      int64  
dtype: object
```

New Behavior:

```
In [49]: df = pd.DataFrame({'a': [0, 1, 1],  
.....:                     'b': pd.Series([100, 200, 300], dtype='uint32')})  
.....:  
  
In [50]: df.dtypes  
Out[50]:  
a      int64  
b      uint32  
dtype: object  
  
In [51]: ix = df['a'] == 1  
  
In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']  
  
In [53]: df.dtypes  
Out[53]:  
a      int64  
b      uint32  
dtype: object
```

When a DataFrame's integer slice is partially updated with a new slice of floats that could potentially be downcasted to integer without losing precision, the dtype of the slice will be set to float instead of integer.

Previous Behavior:

```
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                          columns=list('abc'),
                          index=[[4,4,8], [8,10,12]])

In [5]: df
Out[5]:
```

	a	b	c
4 8	1	2	3
10	4	5	6
8 12	7	8	9

```
In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out[8]:
```

	a	b	c
4 8	1	2	0
10	4	5	1
8 12	7	8	9

New Behavior:

```
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
.....:                    columns=list('abc'),
.....:                    index=[[4,4,8], [8,10,12]])
.....:

In [55]: df
Out[55]:
```

	a	b	c
4 8	1	2	3
10	4	5	6
8 12	7	8	9

```
In [56]: df.loc[4, 'c'] = np.array([0., 1.])

In [57]: df
Out[57]:
```

	a	b	c
4 8	1	2	0.0
10	4	5	1.0
8 12	7	8	9.0

### 1.14.1.10 to\_xarray

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the `.to_xarray()` method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the [xarray full-documentation](#) here.

```
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))

In [2]: p.to_xarray()
Out[2]:
```

(continues on next page)

(continued from previous page)

```
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array([[[ 0,  1,  2,  3],
        [ 4,  5,  6,  7],
        [ 8,  9, 10, 11]],

       [[12, 13, 14, 15],
        [16, 17, 18, 19],
        [20, 21, 22, 23]]])
Coordinates:
  * items          (items) int64 0 1
  * major_axis     (major_axis) int64 0 1 2
  * minor_axis     (minor_axis) int64 0 1 2 3
```

### 1.14.1.11 Latex Representation

DataFrame has gained a `._repr_latex_()` method in order to allow for conversion to latex in a ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option `pd.display.latex.repr=True` (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement `pd.display.latex.repr=True` in the first cell to have the contained DataFrame output also stored as latex.

The options `display.latex.escape` and `display.latex.longtable` have also been added to the configuration and are used automatically by the `to_latex` method. See the [available options docs](#) for more info.

### 1.14.1.12 pd.read\_sas() changes

`read_sas` has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see [here](#). (GH4052)

### 1.14.1.13 Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in `Series.to_string` (GH11729)
- `read_excel` now supports s3 urls of the format `s3://bucketname/filename` (GH11447)
- add support for `AWS_S3_HOST` env variable when reading from s3 (GH12198)
- A simple version of `Panel.round()` is now implemented (GH11763)
- For Python 3.x, `round(DataFrame)`, `round(Series)`, `round(Panel)` will work (GH11763)
- `sys.getsizeof(obj)` returns the memory usage of a pandas object, including the values it contains (GH11597)
- `Series` gained an `is_unique` attribute (GH11946)
- `DataFrame.quantile` and `Series.quantile` now accept interpolation keyword (GH10174).
- Added `DataFrame.style.format` for more flexible formatting of cell values (GH11692)
- `DataFrame.select_dtypes` now allows the `np.float16` typecode (GH11990)
- `pivot_table()` now accepts most iterables for the `values` parameter (GH12017)

- Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see [here](#)
- HDFStore is now iterable: `for k in store` is equivalent to `for k in store.keys()` (GH12221).
- Add missing methods/fields to `.dt` for `Period` (GH8848)
- The entire codebase has been PEP-ified (GH12096)

### 1.14.2 Backwards incompatible API changes

- the leading whitespaces have been removed from the output of `.to_string(index=False)` method (GH11833)
- the `out` parameter has been removed from the `Series.round()` method. (GH11763)
- `DataFrame.round()` leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
- `DataFrame.head(0)` and `DataFrame.tail(0)` return empty frames, rather than `self`. (GH11937)
- `Series.head(0)` and `Series.tail(0)` return empty series, rather than `self`. (GH11937)
- `to_msgpack` and `read_msgpack` encoding now defaults to `'utf-8'`. (GH12170)
- the order of keyword arguments to text file parsing functions (`.read_csv()`, `.read_table()`, `.read_fwf()`) changed to group related arguments. (GH11555)
- `NaTType.isoformat` now returns the string `'NaT'` to allow the result to be passed to the constructor of `Timestamp`. (GH12300)

#### 1.14.2.1 NaT and Timedelta operations

`NaT` and `Timedelta` have expanded arithmetic operations, which are extended to `Series` arithmetic where applicable. Operations defined for `datetime64[ns]` or `timedelta64[ns]` are now also defined for `NaT` (GH11564).

`NaT` now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
\\Out[59]: NaT

In [60]: pd.NaT / 2
\\Out[60]: NaT

In [61]: pd.NaT * np.nan
\\Out[61]: NaT
```

`NaT` defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
\\Out[63]: nan
```

`NaT` may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```
In [64]: pd.NaT + pd.NaT
Out[64]: NaT

# same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to

```
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'
```

However, when wrapped in a Series whose dtype is `datetime64[ns]` or `timedelta64[ns]`, the dtype information is respected.

```
In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction,
but the operator [__add__] was passed
```

```
In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0      NaT
dtype: timedelta64[ns]
```

Timedelta division by floats now works.

```
In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')
```

Subtraction by Timedelta in a Series by a Timestamp works (GH11925)

```
In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out[69]:
0    1 days
1    2 days
2    3 days
dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0    2011-12-31
1    2011-12-30
2    2011-12-29
dtype: datetime64[ns]
```

`NaT.isoformat()` now returns `'NaT'`. This change allows `pd.Timestamp` to rehydrate any timestamp like object from its `isoformat` (GH12300).

### 1.14.2.2 Changes to msgpack

Forward incompatible changes in msgpack writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527)

Bugs in `to_msgpack` and `read_msgpack` introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

`Series.rank` and `DataFrame.rank` now have the same signature ([GH11759](#))

Previous signature

```
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                                ascending=True, pct=False)

Out[3]:
0    1
1    2
dtype: float64

In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                                   method='average', na_option='keep',
                                   ascending=True, pct=False)

Out[4]:
0
0  1
1  2
```

[illegible]

### 1.14.2.4 Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the `n` parameter was 0. (GH11406)

The general semantics of anchored offsets for `n=0` is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

```
In [73]: d = pd.Timestamp('2014-02-01')

In [74]: d
Out[74]: Timestamp('2014-02-01 00:00:00')

In [75]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[75]: Timestamp('2014-02-01 00:00:00')

In [76]: d + pd.offsets.QuarterBegin(n=0, startingMonth=1)
Out[76]: Timestamp('2014-04-01 00:00:00')
```

For the QuarterBegin offset in previous versions, the date would be rolled *backwards* if date was in the same month as the quarter start date.

```
In [3]: d = pd.Timestamp('2014-02-15')

In [4]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[4]: Timestamp('2014-02-01 00:00:00')
```

This behavior has been corrected in version 0.18.0, which is consistent with other anchored offsets like MonthBegin and YearBegin.

```
In [77]: d = pd.Timestamp('2014-02-15')

In [78]: d + pd.offsets.QuarterBegin(n=0, startingMonth=2)
Out[78]: Timestamp('2014-05-01 00:00:00')
```

### 1.14.2.5 Resample API

Like the change in the window functions API [above](#), `.resample(...)` is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).

```
In [79]: np.random.seed(1234)

In [80]: df = pd.DataFrame(np.random.rand(10,4),
.....:                    columns=list('ABCD'),
.....:                    index=pd.date_range('2010-01-01 09:00:00', periods=10,
.....:                    freq='s'))

In [81]: df
Out[81]:
```

	A	B	C	D
2010-01-01 09:00:00	0.191519	0.622109	0.437728	0.785359
2010-01-01 09:00:01	0.779976	0.272593	0.276464	0.801872
2010-01-01 09:00:02	0.958139	0.875933	0.357817	0.500995
2010-01-01 09:00:03	0.683463	0.712702	0.370251	0.561196

(continues on next page)

(continued from previous page)

2010-01-01 09:00:04	0.503083	0.013768	0.772827	0.882641
2010-01-01 09:00:05	0.364886	0.615396	0.075381	0.368824
2010-01-01 09:00:06	0.933140	0.651378	0.397203	0.788730
2010-01-01 09:00:07	0.316836	0.568099	0.869127	0.436173
2010-01-01 09:00:08	0.802148	0.143767	0.704261	0.704581
2010-01-01 09:00:09	0.218792	0.924868	0.442141	0.909316

**Previous API:**

You would write a resampling operation that immediately evaluates. If a how parameter was not provided, it would default to how='mean'.

```
In [6]: df.resample('2s')
```

```
Out [6]:
```

	A	B	C	D
2010-01-01 09:00:00	0.485748	0.447351	0.357096	0.793615
2010-01-01 09:00:02	0.820801	0.794317	0.364034	0.531096
2010-01-01 09:00:04	0.433985	0.314582	0.424104	0.625733
2010-01-01 09:00:06	0.624988	0.609738	0.633165	0.612452
2010-01-01 09:00:08	0.510470	0.534317	0.573201	0.806949

You could also specify a how directly

```
In [7]: df.resample('2s', how='sum')
```

```
Out [7]:
```

	A	B	C	D
2010-01-01 09:00:00	0.971495	0.894701	0.714192	1.587231
2010-01-01 09:00:02	1.641602	1.588635	0.728068	1.062191
2010-01-01 09:00:04	0.867969	0.629165	0.848208	1.251465
2010-01-01 09:00:06	1.249976	1.219477	1.266330	1.224904
2010-01-01 09:00:08	1.020940	1.068634	1.146402	1.613897

**New API:**

Now, you can write `.resample(...)` as a 2-stage operation like `.groupby(...)`, which yields a Resampler.

```
In [82]: r = df.resample('2s')
```

```
In [83]: r
```

```
Out [83]: DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, label=left, ↵
↪convention=start, base=0]
```

**Downsampling**

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```
In [84]: r.mean()
```

```
Out [84]:
```

	A	B	C	D
2010-01-01 09:00:00	0.485748	0.447351	0.357096	0.793615
2010-01-01 09:00:02	0.820801	0.794317	0.364034	0.531096
2010-01-01 09:00:04	0.433985	0.314582	0.424104	0.625733
2010-01-01 09:00:06	0.624988	0.609738	0.633165	0.612452
2010-01-01 09:00:08	0.510470	0.534317	0.573201	0.806949

```
In [85]: r.sum()
```

```
Out [85]:
```

	A	B	C	D
2010-01-01 09:00:00	0.971495	0.894701	0.714192	1.587231
2010-01-01 09:00:02	1.641602	1.588635	0.728068	1.062191
2010-01-01 09:00:04	0.867969	0.629165	0.848208	1.251465
2010-01-01 09:00:06	1.249976	1.219477	1.266330	1.224904
2010-01-01 09:00:08	1.020940	1.068634	1.146402	1.613897

Furthermore, `resample` now supports `getitem` operations to perform the resample on specific columns.

```
In [86]: r[['A', 'C']].mean()
```

```
Out [86]:
```

	A	C
2010-01-01 09:00:00	0.485748	0.357096
2010-01-01 09:00:02	0.820801	0.364034
2010-01-01 09:00:04	0.433985	0.424104
2010-01-01 09:00:06	0.624988	0.633165
2010-01-01 09:00:08	0.510470	0.573201

and `.aggregate` type operations.

```
In [87]: r.agg({'A' : 'mean', 'B' : 'sum'})
```

```
Out [87]:
```

	A	B
2010-01-01 09:00:00	0.485748	0.894701
2010-01-01 09:00:02	0.820801	1.588635
2010-01-01 09:00:04	0.433985	0.629165
2010-01-01 09:00:06	0.624988	1.219477
2010-01-01 09:00:08	0.510470	1.068634

These accessors can of course, be combined

```
In [88]: r[['A', 'B']].agg(['mean', 'sum'])
```

```
Out [88]:
```

	A		B	
	mean	sum	mean	sum
2010-01-01 09:00:00	0.485748	0.971495	0.447351	0.894701
2010-01-01 09:00:02	0.820801	1.641602	0.794317	1.588635
2010-01-01 09:00:04	0.433985	0.867969	0.314582	0.629165
2010-01-01 09:00:06	0.624988	1.249976	0.609738	1.219477
2010-01-01 09:00:08	0.510470	1.020940	0.534317	1.068634

## Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the `Resampler` objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```
In [89]: s = pd.Series(np.arange(5, dtype='int64'),
.....:                 index=date_range('2010-01-01', periods=5, freq='Q'))
.....:
```

```
In [90]: s
```

```
Out [90]:
2010-03-31    0
```

(continues on next page)

(continued from previous page)

```

2010-06-30    1
2010-09-30    2
2010-12-31    3
2011-03-31    4
Freq: Q-DEC, dtype: int64

```

### Previously

```

In [6]: s.resample('M', fill_method='ffill')
Out [6]:
2010-03-31    0
2010-04-30    0
2010-05-31    0
2010-06-30    1
2010-07-31    1
2010-08-31    1
2010-09-30    2
2010-10-31    2
2010-11-30    2
2010-12-31    3
2011-01-31    3
2011-02-28    3
2011-03-31    4
Freq: M, dtype: int64

```

### New API

```

In [91]: s.resample('M').ffill()
Out [91]:
2010-03-31    0
2010-04-30    0
2010-05-31    0
2010-06-30    1
2010-07-31    1
2010-08-31    1
2010-09-30    2
2010-10-31    2
2010-11-30    2
2010-12-31    3
2011-01-31    3
2011-02-28    3
2011-03-31    4
Freq: M, dtype: int64

```

**Note:** In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass an aggregator function (like `mean`) even though you were upsampling, providing a bit of confusion.

### Previous API will work but with deprecations

**Warning:** This new API for `resample` includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the `resample` operation returns a deferred object. We can intercept operations

and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```
In [4]: r = df.resample('2s')
```

```
In [6]: r*10
```

```
pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred_
→operation
use .resample(...).mean() instead of .resample(...)
```

```
Out [6]:
```

	A	B	C	D
2010-01-01 09:00:00	4.857476	4.473507	3.570960	7.936154
2010-01-01 09:00:02	8.208011	7.943173	3.640340	5.310957
2010-01-01 09:00:04	4.339846	3.145823	4.241039	6.257326
2010-01-01 09:00:06	6.249881	6.097384	6.331650	6.124518
2010-01-01 09:00:08	5.104699	5.343172	5.732009	8.069486

However, getting and assignment operations directly on a Resampler will raise a ValueError:

```
In [7]: r.iloc[0] = 5
```

```
ValueError: .resample() is now a deferred operation
use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the mean AND then take the min of those results.

```
In [4]: df.resample('2s').min()
```

```
Out [4]:
```

```
A    0.433985
B    0.314582
C    0.357096
D    0.531096
dtype: float64
```

The new API will:

```
In [92]: df.resample('2s').min()
```

```
Out [92]:
```

	A	B	C	D
2010-01-01 09:00:00	0.191519	0.272593	0.276464	0.785359
2010-01-01 09:00:02	0.683463	0.712702	0.357817	0.500995
2010-01-01 09:00:04	0.364886	0.013768	0.075381	0.368824
2010-01-01 09:00:06	0.316836	0.568099	0.397203	0.436173
2010-01-01 09:00:08	0.218792	0.143767	0.442141	0.704581

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation

```
In [93]: df.resample('2s').mean().min()
```

```
Out [93]:
```

```
A    0.433985
B    0.314582
C    0.357096
D    0.531096
dtype: float64
```

### 1.14.2.6 Changes to eval

In prior versions, new columns assignments in an `eval` expression resulted in an inplace change to the `DataFrame`. (GH9297, GH8664, GH10486)

```
In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})
```

```
In [95]: df
```

```
Out[95]:
```

	a	b
0	0.0	0
1	2.5	1
2	5.0	2
3	7.5	3
4	10.0	4

```
In [12]: df.eval('c = a + b')
```

FutureWarning: eval expressions containing an assignment currently default to `inplace=True`. This will change in a future version of pandas, use `inplace=False` to avoid this warning.

```
In [13]: df
```

```
Out[13]:
```

	a	b	c
0	0.0	0	0.0
1	2.5	1	3.5
2	5.0	2	7.0
3	7.5	3	10.5
4	10.0	4	14.0

In version 0.18.0, a new `inplace` keyword was added to choose whether the assignment should be done inplace or return a copy.

```
In [96]: df
```

```
Out[96]:
```

	a	b	c
0	0.0	0	0.0
1	2.5	1	3.5
2	5.0	2	7.0
3	7.5	3	10.5
4	10.0	4	14.0

```
In [97]: df.eval('d = c - b', inplace=False)
```

```
Out[97]:
```

	a	b	c	d
0	0.0	0	0.0	0.0
1	2.5	1	3.5	2.5
2	5.0	2	7.0	5.0
3	7.5	3	10.5	7.5
4	10.0	4	14.0	10.0

```
In [98]: df
```

```
Out[98]:
```

	a	b	c
0	0.0	0	0.0
1	2.5	1	3.5
2	5.0	2	7.0
3	7.5	3	10.5
4	10.0	4	14.0

(continues on next page)

(continued from previous page)

```

0    0.0  0    0.0
1    2.5  1    3.5
2    5.0  2    7.0
3    7.5  3   10.5
4   10.0  4   14.0

```

```
In [99]: df.eval('d = c - b', inplace=True)
```

```
In [100]: df
```

```
Out[100]:
```

	a	b	c	d
0	0.0	0	0.0	0.0
1	2.5	1	3.5	2.5
2	5.0	2	7.0	5.0
3	7.5	3	10.5	7.5
4	10.0	4	14.0	10.0

**Warning:** For backwards compatibility, `inplace` defaults to `True` if not specified. This will change in a future version of pandas. If your code depends on an inplace assignment you should update to explicitly set `inplace=True`

The `inplace` keyword parameter was also added the `query` method.

```
In [101]: df.query('a > 5')
```

```
Out[101]:
```

	a	b	c	d
3	7.5	3	10.5	7.5
4	10.0	4	14.0	10.0

```
In [102]: df.query('a > 5', inplace=True)
```

```
In [103]: df
```

```
Out[103]:
```

	a	b	c	d
3	7.5	3	10.5	7.5
4	10.0	4	14.0	10.0

**Warning:** Note that the default value for `inplace` in a `query` is `False`, which is consistent with prior versions.

`eval` has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.

```
In [104]: df
```

```
Out[104]:
```

	a	b	c	d
3	7.5	3	10.5	7.5
4	10.0	4	14.0	10.0

```
In [105]: df.eval("""
.....: e = d + a
.....: f = e - 22
.....: g = f / 2.0""", inplace=True)
```

(continues on next page)

(continued from previous page)

```
.....:
In [106]: df
Out[106]:
```

	a	b	c	d	e	f	g
3	7.5	3	10.5	7.5	15.0	-7.0	-3.5
4	10.0	4	14.0	10.0	20.0	-2.0	-1.0

### 1.14.2.7 Other API Changes

- `DataFrame.between_time` and `Series.between_time` now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError`. (GH11818)

```
In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H',
↳ periods=10))

In [108]: s.between_time("7:00am", "9:00am")
Out[108]:
2015-01-01 07:00:00    7
2015-01-01 08:00:00    8
2015-01-01 09:00:00    9
Freq: H, dtype: int64
```

This will now raise.

```
In [2]: s.between_time('20150101 07:00:00', '20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.
```

- `.memory_usage()` now includes values in the index, as does `memory_usage` in `.info()` (GH11597)
- `DataFrame.to_latex()` now supports non-ascii encodings (eg `utf-8`) in Python 2 with the parameter `encoding` (GH7061)
- `pandas.merge()` and `DataFrame.merge()` will show a specific error message when trying to merge with an object that is not of type `DataFrame` or a subclass (GH12081)
- `DataFrame.unstack` and `Series.unstack` now take `fill_value` keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting `DataFrame`. As an added benefit, specifying `fill_value` will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for *window functions* and *resampling*, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in *groupby*.
- Statistical functions for `NDFrame` objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for `**kwargs` (GH12301)
- `.to_latex` and `.to_html` gain a `decimal` parameter like `.to_csv`; the default is `'.'` (GH12031)
- More helpful error message when constructing a `DataFrame` with empty data but with indices (GH8020)
- `.describe()` will now properly handle `bool` dtype as a categorical (GH6625)
- More helpful error message with an invalid `.transform` with user defined input (GH10165)
- Exponentially weighted functions now allow specifying `alpha` directly (GH10789) and raise `ValueError` if parameters violate  $0 < \alpha \leq 1$  (GH12492)

### 1.14.2.8 Deprecations

- The functions `pd.rolling_*`, `pd.expanding_*`, and `pd.ewm*` are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) ([GH11603](#))

```
In [1]: s = pd.Series(range(3))

In [2]: pd.rolling_mean(s, window=2, min_periods=1)
FutureWarning: pd.rolling_mean is deprecated for Series and
will be removed in a future version, replace with
Series.rolling(min_periods=1, window=2, center=False).mean()

Out [2]:
0    0.0
1    0.5
2    1.5
dtype: float64

In [3]: pd.rolling_cov(s, s, window=2)
FutureWarning: pd.rolling_cov is deprecated for Series and
will be removed in a future version, replace with
Series.rolling(window=2).cov(other=<Series>)

Out [3]:
0    NaN
1    0.5
2    0.5
dtype: float64
```

- The `freq` and `how` arguments to the `.rolling`, `.expanding`, and `.ewm` (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. ([GH11603](#)).

For example, instead of `s.rolling(window=5, freq='D').max()` to get the max value on a rolling 5 Day window, one could use `s.resample('D').mean().rolling(window=5).max()`, which first resamples the data to daily data, then provides a rolling 5 day window.

- `pd.tseries.frequencies.get_offset_name` function is deprecated. Use `offset's .freqstr` property as alternative ([GH11192](#))
- `pandas.stats.fama_macbeth` routines are deprecated and will be removed in a future version ([GH6077](#))
- `pandas.stats.ols`, `pandas.stats.plm` and `pandas.stats.var` routines are deprecated and will be removed in a future version ([GH6077](#))
- show a `FutureWarning` rather than a `DeprecationWarning` on using long-time deprecated syntax in `HDFStore.select`, where the `where` clause is not a string-like ([GH12027](#))
- The `pandas.options.display.mpl_style` configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib's [style sheets](#) ([GH11783](#)).

### 1.14.2.9 Removal of deprecated float indexers

In [GH4892](#) indexing with floating point numbers on a non-`Float64Index` was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a `TypeError`. ([GH12165](#), [GH12333](#))

```
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])

In [110]: s
```

(continues on next page)

(continued from previous page)

```

Out[110]:
4      1
5      2
6      3
dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2
Out[112]:
a      1
b      2
c      3
dtype: int64

```

**Previous Behavior:**

```

# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[2]: 2

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[3]: 2

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not
↳floating point
Out[4]: 2

# .ix would coerce 1.0 to the positional 1, and index
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not
↳floating point

In [6]: s2
Out[6]:
a      1
b     10
c      3
dtype: int64

```

**New Behavior:**

For iloc, getting & setting via a float scalar will always raise.

```

In [3]: s.iloc[2.0]
TypeError: cannot do label indexing on <class 'pandas.indexes.numeric.Int64Index'>
↳with these indexers [2.0] of <type 'float'>

```

Other indexers will coerce to a like integer for both getting and setting. The FutureWarning has been dropped for .loc, .ix and [].

```
In [113]: s[5.0]
Out[113]: 2

In [114]: s.loc[5.0]
\\\\\\\\\\\\\\\\\\\\Out[114]: 2
```

and setting

```
In [115]: s_copy = s.copy()

In [116]: s_copy[5.0] = 10

In [117]: s_copy
Out[117]:
4      1
5     10
6      3
dtype: int64

In [118]: s_copy = s.copy()

In [119]: s_copy.loc[5.0] = 10

In [120]: s_copy
Out[120]:
4      1
5     10
6      3
dtype: int64
```

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

```
In [3]: s2.ix[1.0] = 10
In [4]: s2
Out[4]:
a      1
b      2
c      3
1.0    10
dtype: int64
```

Slicing will also coerce integer-like floats to integers for a non-Float64Index.

```
In [121]: s.loc[5.0:6]
Out[121]:
5      2
6      3
dtype: int64
```

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded

```
In [122]: s.loc[5.1:6]
Out[122]:
6      3
dtype: int64
```

Float indexing on a Float64Index is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))
In [124]: s[1.0]
Out[124]: 2
In [125]: s[1.0:2.5]
\\\\\\\\\\\\\\\\\\\\Out[125]:
1.0    2
2.0    3
dtype: int64
```

#### 1.14.2.10 Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `.rolling().corr(pairwise=True)` ([GH4950](#))
- Removal of `expanding_corr_pairwise` in favor of `.expanding().corr(pairwise=True)` ([GH4950](#))
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event ([GH12111](#))
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` ([GH6680](#))
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 ([GH6292](#)).
- Removal of the `order` keyword from `.factorize()` ([GH6930](#))

#### 1.14.3 Performance Improvements

- Improved performance of `andrews_curves` ([GH11534](#))
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`'s ops performance including `NaT` ([GH10277](#))
- Improved performance of `pandas.concat` ([GH11958](#))
- Improved performance of `StataReader` ([GH11591](#))
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` ([GH12077](#))
- Improved performance of ISO 8601 date parsing for dates without separators ([GH11899](#)), leading zeros ([GH11871](#)) and with whitespace preceding the time zone ([GH9714](#))

#### 1.14.4 Bug Fixes

- Bug in `GroupBy.size` when data-frame is empty. ([GH11699](#))
- Bug in `Period.end_time` when a multiple of time period is requested ([GH11738](#))
- Regression in `.clip` with tz-aware datetimes ([GH11838](#))
- Bug in `date_range` when the boundaries fell on the frequency ([GH11804](#), [GH12409](#))
- Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` ([GH9052](#))
- Accept unicode in `Timedelta` constructor ([GH11995](#))

- Bug in value label reading for `StataReader` when reading incrementally ([GH12014](#))
- Bug in vectorized `DateOffset` when `n` parameter is 0 ([GH11370](#))
- Compat for numpy 1.11 w.r.t. `NaT` comparison changes ([GH12049](#))
- Bug in `read_csv` when reading from a `StringIO` in threads ([GH11790](#))
- Bug in not treating `NaT` as a missing value in datetimelikes when factorizing & with `Categoricals` ([GH12077](#))
- Bug in `getitem` when the values of a `Series` were tz-aware ([GH12089](#))
- Bug in `Series.str.get_dummies` when one of the variables was 'name' ([GH12180](#))
- Bug in `pd.concat` while concatenating tz-aware `NaT` series. ([GH11693](#), [GH11755](#), [GH12217](#))
- Bug in `pd.read_stata` with version `<= 108` files ([GH12232](#))
- Bug in `Series.resample` using a frequency of `Nano` when the index is a `DatetimeIndex` and contains non-zero nanosecond parts ([GH12037](#))
- Bug in resampling with `.nunique` and a sparse index ([GH12352](#))
- Removed some compiler warnings ([GH12471](#))
- Work around compat issues with `boto` in python 3.5 ([GH11915](#))
- Bug in `NaT` subtraction from `Timestamp` or `DatetimeIndex` with timezones ([GH11718](#))
- Bug in subtraction of `Series` of a single tz-aware `Timestamp` ([GH12290](#))
- Use compat iterators in PY2 to support `.next()` ([GH12299](#))
- Bug in `Timedelta.round` with negative values ([GH11690](#))
- Bug in `.loc` against `CategoricalIndex` may result in normal `Index` ([GH11586](#))
- Bug in `DataFrame.info` when duplicated column names exist ([GH11761](#))
- Bug in `.copy` of datetime tz-aware objects ([GH11794](#))
- Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed ([GH11349](#))
- Bug in `DataFrame.set_index()` with tz-aware `Series` ([GH12358](#))
- Bug in subclasses of `DataFrame` where `AttributeError` did not propagate ([GH11808](#))
- Bug groupby on tz-aware data where selection not returning `Timestamp` ([GH11616](#))
- Bug in `pd.read_clipboard` and `pd.to_clipboard` functions not supporting Unicode; upgrade included `pyperclip` to v1.5.15 ([GH9263](#))
- Bug in `DataFrame.query` containing an assignment ([GH8664](#))
- Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. ([GH11880](#))
- Bug in `.resample` on categorical data with `TimedeltaIndex` ([GH12169](#))
- Bug in timezone info lost when broadcasting scalar datetime to `DataFrame` ([GH11682](#))
- Bug in `Index` creation from `Timestamp` with mixed tz coerces to UTC ([GH11488](#))
- Bug in `to_numeric` where it does not raise if input is more than one dimension ([GH11776](#))
- Bug in parsing timezone offset strings with non-zero minutes ([GH11708](#))
- Bug in `df.plot` using incorrect colors for bar plots under `matplotlib` 1.5+ ([GH11614](#))

- Bug in the `groupby` `plot` method when using keyword arguments (GH11805).
- Bug in `DataFrame.duplicated` and `drop_duplicates` causing spurious matches when setting `keep=False` (GH11864)
- Bug in `.loc` result with duplicated key may have `Index` with incorrect `dtype` (GH11497)
- Bug in `pd.rolling_median` where memory allocation failed even with sufficient memory (GH11696)
- Bug in `DataFrame.style` with spurious zeros (GH12134)
- Bug in `DataFrame.style` with integer columns not starting at 0 (GH12125)
- Bug in `.style.bar` may not rendered properly using specific browser (GH11678)
- Bug in rich comparison of `Timedelta` with a `numpy.array` of `Timedelta` that caused an infinite recursion (GH11835)
- Bug in `DataFrame.round` dropping column index name (GH11986)
- Bug in `df.replace` while replacing value in mixed dtype `Dataframe` (GH11698)
- Bug in `Index` prevents copying name of passed `Index`, when a new name is not provided (GH11193)
- Bug in `read_excel` failing to read any non-empty sheets when empty sheets exist and `sheetname=None` (GH11711)
- Bug in `read_excel` failing to raise `NotImplemented` error when keywords `parse_dates` and `date_parser` are provided (GH11544)
- Bug in `read_sql` with `pymysql` connections failing to return chunked data (GH11522)
- Bug in `.to_csv` ignoring formatting parameters `decimal`, `na_rep`, `float_format` for float indexes (GH11553)
- Bug in `Int64Index` and `Float64Index` preventing the use of the modulo operator (GH9244)
- Bug in `MultiIndex.drop` for not lexsorted multi-indexes (GH12078)
- Bug in `DataFrame` when masking an empty `DataFrame` (GH11859)
- Bug in `.plot` potentially modifying the `colors` input when the number of columns didn't match the number of series provided (GH12039).
- Bug in `Series.plot` failing when index has a `CustomBusinessDay` frequency (GH7222).
- Bug in `.to_sql` for `datetime.time` values with `sqlite` fallback (GH8341)
- Bug in `read_excel` failing to read data with one column when `squeeze=True` (GH12157)
- Bug in `read_excel` failing to read one empty column (GH12292, GH9002)
- Bug in `.groupby` where a `KeyError` was not raised for a wrong column if there was only one row in the dataframe (GH11741)
- Bug in `.read_csv` with `dtype` specified on empty data producing an error (GH12048)
- Bug in `.read_csv` where strings like `'2E'` are treated as valid floats (GH12237)
- Bug in building `pandas` with debugging symbols (GH12123)
- Removed `millisecond` property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
- Bug in `Series` constructor with read-only data (GH11502)
- Removed `pandas.util.testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)

- Bug in `.loc` setitem indexer preventing the use of a TZ-aware `DatetimeIndex` ([GH12050](#))
- Bug in `.style` indexes and multi-indexes not appearing ([GH11655](#))
- Bug in `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize `NaT` ([GH12307](#)).
- Bug in `.skew` and `.kurt` due to roundoff error for highly similar values ([GH11974](#))
- Bug in `Timestamp` constructor where microsecond resolution was lost if `HHMMSS` were not separated with `‘.’` ([GH10041](#))
- Bug in `buffer_rd_bytes` `src->buffer` could be freed more than once if reading failed, causing a segfault ([GH12098](#))
- Bug in `crosstab` where arguments with non-overlapping indexes would return a `KeyError` ([GH10291](#))
- Bug in `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a numpy dtype ([GH12244](#))
- Bug when initializing categorical series with a scalar value. ([GH12336](#))
- Bug when specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` ([GH11934](#))
- Bug when increasing the buffer size of CSV reader in `read_csv` ([GH12494](#))
- Bug when setting columns of a `DataFrame` with duplicate column names ([GH12344](#))

## 1.15 v0.17.1 (November 21, 2015)

---

**Note:** We are proud to announce that *pandas* has become a sponsored project of the ([NumFOCUS organization](#)). This will help ensure the success of development of *pandas* as a world-class open-source project.

---

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see [here](#)
- Releasing the GIL on the csv reader & other ops, see [here](#)
- Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values ([GH11376](#))

### What's new in v0.17.1

- *New features*
  - *Conditional HTML Formatting*
- *Enhancements*
- *API changes*
  - *Deprecations*
- *Performance Improvements*
- *Bug Fixes*

## 1.15.1 New features

### 1.15.1.1 Conditional HTML Formatting

**Warning:** This is a new feature and is under active development. We'll be adding features and possibly making breaking changes in future releases. Feedback is [welcome](#).

We've added *experimental* support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Accesses the styler class with the `pandas.DataFrame.style` attribute, an instance of `Styler` with your data attached.

Here's a quick example:

```
In [1]: np.random.seed(123)

In [2]: df = DataFrame(np.random.randn(10, 5), columns=list('abcde'))

In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)
```

We can render the HTML to get the following table.

`Styler` interacts nicely with the Jupyter Notebook. See the [documentation](#) for more.

## 1.15.2 Enhancements

- `DatetimeIndex` now supports conversion to strings with `astype(str)` (GH10442)
- Support for compression (gzip/bz2) in `pandas.DataFrame.to_csv()` (GH7615)
- `pd.read_*` functions can now also accept `pathlib.Path`, or `py._path.local.LocalPath` objects for the `filepath_or_buffer` argument. (GH11033) - The `DataFrame` and `Series` functions `.to_csv()`, `.to_html()` and `.to_latex()` can now handle paths beginning with tildes (e.g. `~/Documents/`) (GH11438)
- `DataFrame` now uses the fields of a `namedtuple` as columns, if columns are not supplied (GH11181)
- `DataFrame.itertuples()` now returns `namedtuple` objects, when possible. (GH11269, GH11625)
- Added `axvlines_kwds` to parallel coordinates plot (GH10709)
- Option to `.info()` and `.memory_usage()` to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```
In [4]: df = DataFrame({'A' : ['foo']*1000})

In [5]: df['B'] = df['A'].astype('category')

# shows the '+' as we have object dtypes
In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
A      1000 non-null object
B      1000 non-null category
dtypes: category(1), object(1)
memory usage: 9.0+ KB
```

(continues on next page)

- Index now has a `fillna` method ([GH10089](#))

- Series of type `category` now make `.str.<...>` and `.dt.<...>` accessor methods / properties available, if the categories are of that type. (GH10661)

(continues on next page)

(continued from previous page)

```

0      1
1      2
2      3
3      4
4      5
dtype: int64

```

- `pivot_table` now has a `margins_name` argument so you can use something other than the default of 'All' ([GH3335](#))
- Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store ([GH11411](#))
- Pretty printing sets (e.g. in `DataFrame` cells) now uses set literal syntax (`{x, y}`) instead of Legacy Python syntax (`set([x, y])`) ([GH11215](#))
- Improve the error message in `pandas.io.gbq.to_gbq()` when a streaming insert fails ([GH11285](#)) and when the `DataFrame` does not match the schema of the destination table ([GH11359](#))

### 1.15.3 API changes

- raise `NotImplementedError` in `Index.shift` for non-supported index types ([GH8038](#))
- `min` and `max` reductions on `datetime64` and `timedelta64` dtyped series now result in `NaT` and not `nan` ([GH11245](#)).
- Indexing with a null key will raise a `TypeError`, instead of a `ValueError` ([GH11356](#))
- `Series.ptp` will now ignore missing values by default ([GH11163](#))

#### 1.15.3.1 Deprecations

- The `pandas.io.ga` module which implements google-analytics support is deprecated and will be removed in a future version ([GH11308](#))
- Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version ([GH11274](#))

### 1.15.4 Performance Improvements

- Checking monotonic-ness before sorting on an index ([GH11080](#))
- `Series.dropna` performance improvement when its dtype can't contain `NaN` ([GH11159](#))
- Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` ([GH11263](#))
- Release the GIL on some rolling algos: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` ([GH11450](#))
- Release the GIL when reading and parsing text files in `read_csv`, `read_table` ([GH11272](#))
- Improved performance of `rolling_median` ([GH11450](#))
- Improved performance of `to_excel` ([GH11352](#))
- Performance bug in repr of Categorical categories, which was rendering the strings before chopping them for display ([GH11305](#))

- Performance improvement in `Categorical.remove_unused_categories`, ([GH11643](#)).
- Improved performance of `Series` constructor with no data and `DatetimeIndex` ([GH11433](#))
- Improved performance of `shift`, `cumprod`, and `cumsum` with `groupby` ([GH4095](#))

### 1.15.5 Bug Fixes

- `SparseArray.__iter__()` now does not cause `PendingDeprecationWarning` in Python 3.5 ([GH11622](#))
- Regression from 0.16.2 for output formatting of long floats/nan, restored in ([GH11302](#))
- `Series.sort_index()` now correctly handles the `inplace` option ([GH11402](#))
- Incorrectly distributed `.c` file in the build on PyPi when reading a csv of floats and passing `na_values=<a scalar>` would show an exception ([GH11374](#))
- Bug in `.to_latex()` output broken when the index has a name ([GH10660](#))
- Bug in `HDFStore.append` with strings whose encoded length exceeded the max unencoded length ([GH11234](#))
- Bug in merging `datetime64[ns, tz]` dtypes ([GH11405](#))
- Bug in `HDFStore.select` when comparing with a numpy scalar in a `where` clause ([GH11283](#))
- Bug in using `DataFrame.ix` with a multi-index indexer ([GH11372](#))
- Bug in `date_range` with ambiguous endpoints ([GH11626](#))
- Prevent adding new attributes to the accessors `.str`, `.dt` and `.cat`. Retrieving such a value was not possible, so error out on setting it. ([GH10673](#))
- Bug in tz-conversions with an ambiguous time and `.dt` accessors ([GH11295](#))
- Bug in output formatting when using an index of ambiguous times ([GH11619](#))
- Bug in comparisons of `Series` vs list-likes ([GH11339](#))
- Bug in `DataFrame.replace` with a `datetime64[ns, tz]` and a non-compatible `to_replace` ([GH11326](#), [GH11153](#))
- Bug in `isnull` where `numpy.datetime64('NaT')` in a `numpy.array` was not determined to be null ([GH11206](#))
- Bug in list-like indexing with a mixed-integer `Index` ([GH11320](#))
- Bug in `pivot_table` with `margins=True` when indexes are of `Categorical` dtype ([GH10993](#))
- Bug in `DataFrame.plot` cannot use hex strings colors ([GH10299](#))
- Regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values ([GH11376](#))
- Bug in `pd.eval` where unary ops in a list error ([GH11235](#))
- Bug in `squeeze()` with zero length arrays ([GH11230](#), [GH8999](#))
- Bug in `describe()` dropping column names for hierarchical indexes ([GH11517](#))
- Bug in `DataFrame.pct_change()` not propagating `axis` keyword on `.fillna` method ([GH11150](#))
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the `columns` parameter ([GH11637](#))
- Bug in indexing with a `range`, ([GH11652](#))

- Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving `UnicodeEncodeError` with (GH11431).
- Fix regression in setting of `xticks` in `plot` (GH11529).
- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when `header=False` (GH7124)
- Bug in `df.groupby(...).apply(func)` when a func returns a `Series` containing a new datetimelike column (GH11324)
- Bug in `pandas.json` when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of dtype `datetime64[ns, tz]` (GH11245).
- Bug in `read_excel` with multi-index containing integers (GH11317)
- Bug in `to_excel` with `openpyxl` 2.2+ and merging (GH11408)
- Bug in `DataFrame.to_dict()` produces a `np.datetime64` object instead of `Timestamp` when only datetime is present in data (GH11327)
- Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for `DataFrames` with boolean and not boolean columns (GH11560)
- Bug in the link-time error caused by `C inline` functions on FreeBSD 10+ (with `clang`) (GH10510)
- Bug in `DataFrame.to_csv` in passing through arguments for formatting `MultiIndexes`, including `date_format` (GH7791)
- Bug in `DataFrame.join()` with `how='right'` producing a `TypeError` (GH11519)
- Bug in `Series.quantile` with empty list results has `Index` with `object` dtype (GH11588)
- Bug in `pd.merge` results in empty `Int64Index` rather than `Index(dtype=object)` when the merge result is empty (GH11588)
- Bug in `Categorical.remove_unused_categories` when having `NaN` values (GH11599)
- Bug in `DataFrame.to_sparse()` loses column names for `MultiIndexes` (GH11600)
- Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
- Bug in `DataFrame.round()` with `decimals` being a non-unique indexed `Series` producing extra columns (GH11618)

## 1.16 v0.17.0 (October 9, 2015)

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)

**Warning:** The `pandas.io.data` package is deprecated and will be replaced by the `pandas-datareader` package. This will allow the data modules to be independently updated to your pandas installation. The API for `pandas-datareader v0.1.1` is exactly the same as in `pandas v0.17.0` (GH8961, GH10861).

After installing `pandas-datareader`, you can easily change your imports:

```
from pandas.io import data, wb
```

becomes

```
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see [here](#)
- Plotting methods are now available as attributes of the `.plot` accessor, see [here](#)
- The sorting API has been revamped to remove some long-time inconsistencies, see [here](#)
- Support for a `datetime64[ns]` with timezones as a first-class dtype, see [here](#)
- The default for `to_datetime` will now be to `raise` when presented with unparseable formats, previously this would return the original input. Also, date parse functions now return consistent results. See [here](#)
- The default for `dropna` in `HDFStore` has changed to `False`, to store by default all rows even if they are all `NaN`, see [here](#)
- Datetime accessor (`dt`) now supports `Series.dt.strftime` to generate formatted strings for datetime-likes, and `Series.dt.total_seconds` to generate each duration of the `timedelta` in seconds. See [here](#)
- `Period` and `PeriodIndex` can handle multiplied freq like `3D`, which corresponding to 3 days span. See [here](#)
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)
- Development support for benchmarking with the [Air Speed Velocity](#) library (GH8361)
- Support for reading SAS `xport` files, see [here](#)
- Documentation comparing SAS to *pandas*, see [here](#)
- Removal of the automatic `TimeSeries` broadcasting, deprecated since 0.8.0, see [here](#)
- Display format with plain text can optionally align with Unicode East Asian Width, see [here](#)
- Compatibility with Python 3.5 (GH11097)
- Compatibility with matplotlib 1.5.0 (GH11111)

Check the [API Changes](#) and [deprecations](#) before updating.

### What's new in v0.17.0

- *New features*
  - *Datetime with TZ*
  - *Releasing the GIL*
  - *Plot submethods*
  - *Additional methods for `dt` accessor*
    - \* *`strftime`*

- \* *total\_seconds*
  - *Period Frequency Enhancement*
  - *Support for SAS XPORT files*
  - *Support for Math Functions in .eval()*
  - *Changes to Excel with MultiIndex*
  - *Google BigQuery Enhancements*
  - *Display Alignment with Unicode East Asian Width*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes to sorting API*
  - *Changes to to\_datetime and to\_timedelta*
    - \* *Error handling*
    - \* *Consistent Parsing*
  - *Changes to Index Comparisons*
  - *Changes to Boolean Comparisons vs. None*
  - *HDFStore dropna behavior*
  - *Changes to display.precision option*
  - *Changes to Categorical.unique*
  - *Changes to bool passed as header in Parsers*
  - *Other API Changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance Improvements*
- *Bug Fixes*

## 1.16.1 New features

### 1.16.1.1 Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously *could* be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number rows. See the [docs](#) for more details. ([GH8260](#), [GH10763](#), [GH11034](#)).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```
In [1]: df = DataFrame({'A' : date_range('20130101', periods=3),
...:                  'B' : date_range('20130101', periods=3, tz='US/Eastern'),
...:                  'C' : date_range('20130101', periods=3, tz='CET')})
...:

In [2]: df
```

(continues on next page)

(continued from previous page)

```
Out [2]:
```

	A	B	C
0	2013-01-01 2013-01-01 00:00:00-05:00	2013-01-01 00:00:00+01:00	
1	2013-01-02 2013-01-02 00:00:00-05:00	2013-01-02 00:00:00+01:00	
2	2013-01-03 2013-01-03 00:00:00-05:00	2013-01-03 00:00:00+01:00	

```
In [3]: df.dtypes
```

```

////////////////////////////////////
↪
A          datetime64[ns]
B    datetime64[ns, US/Eastern]
C          datetime64[ns, CET]
dtype: object
```

```
In [4]: df.B
```

```
Out [4]:
```

0	2013-01-01 00:00:00-05:00
1	2013-01-02 00:00:00-05:00
2	2013-01-03 00:00:00-05:00

Name: B, dtype: datetime64[ns, US/Eastern]

```
In [5]: df.B.dt.tz_localize(None)
```

```

////////////////////////////////////
↪
0    2013-01-01
1    2013-01-02
2    2013-01-03
Name: B, dtype: datetime64[ns]
```

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin `datetime64[ns]`

```
In [6]: df['B'].dtype
```

```
Out [6]: datetime64[ns, US/Eastern]
```

```
In [7]: type(df['B'].dtype)
```

```
Out [7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

**Note:** There is a slightly different string repr for the underlying `DatetimeIndex` as a result of the dtype changes, but functionally these are the same.

Previous Behavior:

```
In [1]: pd.date_range('20130101', periods=3, tz='US/Eastern')
Out [1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
                        '2013-01-03 00:00:00-05:00'],
                        dtype='datetime64[ns]', freq='D', tz='US/Eastern')
```

```
In [2]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
```

```
Out [2]: dtype('<M8[ns]')
```

New Behavior:

```
In [8]: pd.date_range('20130101', periods=3, tz='US/Eastern')
```

```
Out [8]:
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
              '2013-01-03 00:00:00-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')
```

```
In [9]: pd.date_range('20130101', periods=3, tz='US/Eastern').dtype
```

```
dtype='datetime64[ns, US/Eastern]'
```

### 1.16.1.2 Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably `groupby`, `nsmallest`, `value_counts` and some indexing operations benefit from this. (GH8882)

For example the `groupby` expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame({'key' : np.random.randint(0, ngroups, size=N),
               'data' : np.random.randn(N) })
df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. [QT](#)), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the [dask](#) library.

### 1.16.1.3 Plot submethods

The `Series` and `DataFrame` `.plot()` method allows for customizing *plot types* by supplying the `kind` keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`:

```
In [10]: df = pd.DataFrame(np.random.rand(10, 2), columns=['a', 'b'])
```

```
In [11]: df.plot.bar()
```

As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB>
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist      df.plot.line
df.plot.scatter
df.plot.bar       df.plot.box       df.plot.hexbin   df.plot.kde       df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new [Plotting API](#) documentation.

#### 1.16.1.4 Additional methods for dt accessor

##### strftime

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
# DatetimeIndex
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))

In [14]: s
Out[14]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]

In [15]: s.dt.strftime('%Y/%m/%d')
Out[15]:
0    2013/01/01
```

(continues on next page)

(continued from previous page)

```

1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object

```

```

# PeriodIndex
In [16]: s = pd.Series(pd.period_range('20130101', periods=4))

In [17]: s
Out[17]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: object

In [18]: s.dt.strftime('%Y/%m/%d')
Out[18]:
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object

```

The string format is as the python standard library and details can be found [here](#)

### total\_seconds

`pd.Series` of type `timedelta64` has new method `.dt.total_seconds()` returning the duration of the `timedelta` in seconds ([GH10817](#))

```

# TimedeltaIndex
In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))

In [20]: s
Out[20]:
0    0 days 00:01:00
1    1 days 00:01:00
2    2 days 00:01:00
3    3 days 00:01:00
dtype: timedelta64[ns]

In [21]: s.dt.total_seconds()
Out[21]:
0         60.0
1    86460.0
2   172860.0
3   259260.0
dtype: float64

```

### 1.16.1.5 Period Frequency Enhancement

`Period`, `PeriodIndex` and `period_range` can now accept multiplied freq. Also, `Period.freq` and `PeriodIndex.freq` are now stored as a `DateOffset` instance like `DatetimeIndex`, and not as `str` (GH7811)

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```
In [22]: p = pd.Period('2015-08-01', freq='3D')

In [23]: p
Out[23]: Period('2015-08-01', '3D')

In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')

In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')

In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')

In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 00:00:00')
```

You can use the multiplied freq in `PeriodIndex` and `period_range`.

```
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')

In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype=
    <period[2D]', freq='2D')

In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype=
    <period[2D]', freq='2D')
```

### 1.16.1.6 Support for SAS XPORT files

`read_sas()` provides support for reading *SAS XPORT* format files. (GH4052).

```
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```
for df in pd.read_sas('sas_xport.xpt', chunksize=10000):
    do_something(df)
```

See the *docs* for more details.

### 1.16.1.7 Support for Math Functions in `.eval()`

`eval()` now supports calling math functions ([GH4893](#))

```
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are *sin*, *cos*, *exp*, *log*, *expm1*, *log1p*, *sqrt*, *sinh*, *cosh*, *tanh*, *arcsin*, *arccos*, *arctan*, *arccosh*, *arcsinh*, *arctanh*, *abs* and *arctan2*.

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

### 1.16.1.8 Changes to Excel with `MultiIndex`

In version 0.16.2 a `DataFrame` with `MultiIndex` columns could not be written to Excel via `to_excel`. That functionality has been added ([GH10564](#)), along with updating `read_excel` so that the data can be read back with, no loss of information, by specifying which columns/rows make up the `MultiIndex` in the `header` and `index_col` parameters ([GH4679](#))

See the [documentation](#) for more details.

```
In [31]: df = pd.DataFrame([[1,2,3,4], [5,6,7,8]],
.....:                    columns = pd.MultiIndex.from_product(['foo', 'bar'], ['a', 'b
↳ ']),
.....:                    names = ['col1', 'col2
↳ ']),
.....:                    index = pd.MultiIndex.from_product(['j'], ['l', 'k']),
.....:                    names = ['i1', 'i2']))

In [32]: df
Out[32]:
col1 foo    bar
col2  a  b   a  b
i1 i2
j  l    1  2   3  4
   k    5  6   7  8

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0,1], index_col=[0,1])

In [35]: df
Out[35]:
col1 foo    bar
col2  a  b   a  b
i1 i2
j  l    1  2   3  4
   k    5  6   7  8
```

Previously, it was necessary to specify the `has_index_names` argument in `read_excel`, if the serialized data had index names. For version 0.17.0 the output format of `to_excel` has been changed to make this keyword unnecessary - the change is shown below.

**Old**

	A	B	C	D	E	F
1		A	B	C	D	
2	idx_name					
3	2000-01-07 00:00:00	0.968129	0.906529	0.05343	0.02619	
4	2000-01-10 00:00:00	-0.16632	1.981993	1.833093	0.803685

6	2000-01-12 00:00:00	-1.70456	-0.73098	-0.38088	0.020946	
7	2000-01-13 00:00:00	-1.20024	1.907733	0.629318	1.507033	
8	2000-01-14 00:00:00	-0.66344	0.073188	1.583482	0.735205	
9	2000-01-17 00:00:00	0.716635	-2.07952	1.760536	0.970309	

New

	A	B	C	D	E	
1	idx_name	A	B	C	D	
2	2000-01-07 00:00:00	0.968129	0.906529	0.05343	0.02619	
3	2000-01-10 00:00:00	-0.16632	1.981993	1.833093	0.803685	
4	2000-01-11 00:00:00	0.121057	0.36946	-0.02888	1.683975	
5	2000-01-12 00:00:00	-1.70456	-0.73098	-0.38088	0.020946	
6	2000-01-13 00:00:00	-1.20024	1.907733	0.629318	1.507033	
7	2000-01-14 00:00:00	-0.66344	0.073188	1.583482	0.735205	
8	2000-01-17 00:00:00	0.716635	-2.07952	1.760536	0.970309	
9	2000-01-18 00:00:00	0.727628	2.22267	2.706276	0.681842	

**Warning:** Excel files saved in version 0.16.2 or prior that had index names will still be able to be read in, but the `has_index_names` argument must be specified to `True`.

### 1.16.1.9 Google BigQuery Enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the [docs](#) for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the `gbq` module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121).
- The `gbq` module will now support Python 3 (GH11094).

### 1.16.1.10 Display Alignment with Unicode East Asian Width

**Warning:** Enabling this option will affect the performance for printing of `DataFrame` and `Series` (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters its width is corresponding to 2 alphabets. If a `DataFrame` or `Series` contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```
In [36]: df = pd.DataFrame({'u': ['UK', u''], u': ['Alice', u'']})
```

```
In [37]: df;
```

```
>>> df = pd.DataFrame({'u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
      名前  国籍
0  Alice  UK
1  のぶ  日本
```

```
In [38]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [39]: df;
```

```
>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
      名前  国籍
0  Alice  UK
1  のぶ  日本
```

For further details, see [here](#)

### 1.16.1.11 Other enhancements

- Support for `openpyxl`  $\geq 2.2$ . The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

Observation Origin	<code>_merge</code> value
Merge key only in 'left' frame	<code>left_only</code>
Merge key only in 'right' frame	<code>right_only</code>
Merge key in both frames	<code>both</code>

```
In [40]: df1 = pd.DataFrame({'coll': [0, 1], 'col_left': ['a', 'b']})
```

(continues on next page)

(continued from previous page)

```
In [41]: df2 = pd.DataFrame({'coll': [1, 2, 2], 'col_right': [2, 2, 2]})

In [42]: pd.merge(df1, df2, on='coll', how='outer', indicator=True)
Out[42]:
```

	coll	col_left	col_right	_merge
0	0	a	NaN	left_only
1	1	b	2.0	both
2	2	NaN	2.0	right_only
3	2	NaN	2.0	right_only

For more, see the [updated docs](#)

- `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) ([GH11133](#))
- `pd.merge` will now allow duplicate column names if they are not merged upon ([GH10639](#)).
- `pd.pivot` will now allow passing index as `None` ([GH3962](#)).
- `pd.concat` will now use existing Series names if provided ([GH10698](#)).

```
In [43]: foo = pd.Series([1, 2], name='foo')

In [44]: bar = pd.Series([1, 2])

In [45]: baz = pd.Series([4, 5])
```

Previous Behavior:

```
In [1] pd.concat([foo, bar, baz], 1)
Out[1]:
```

	0	1	2
0	1	1	4
1	2	2	5

New Behavior:

```
In [46]: pd.concat([foo, bar, baz], 1)
Out[46]:
```

	foo	0	1
0	1	1	4
1	2	2	5

- `DataFrame` has gained the `nlargest` and `nsmallest` methods ([GH10393](#))
- Add a `limit_direction` keyword argument that works with `limit` to enable interpolate to fill NaN values forward, backward, or both ([GH9218](#), [GH10420](#), [GH11115](#))

```
In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])

In [48]: ser.interpolate(limit=1, limit_direction='both')
Out[48]:
```

0	NaN
1	5.0
2	5.0
3	7.0
4	NaN
5	11.0
6	13.0

dtype: float64

235

```

In [57]: df = pd.DataFrame({'x': range(5),
.....:                     't': pd.date_range('2000-01-01', periods=5)})
.....:

In [58]: df.reindex([0.1, 1.9, 3.5],
.....:               method='nearest',
.....:               tolerance=0.2)
.....:
Out[58]:
      x      t
0.1  0.0 2000-01-01
1.9  2.0 2000-01-03
3.5  NaN      NaT

```

When used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with a string:

```

In [59]: df = df.set_index('t')

In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
.....:               method='nearest',
.....:               tolerance='1 day')
.....:
Out[60]:
      x
1999-12-31  0

```

`tolerance` is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- Added functionality to use the `base` argument when resampling a `TimeDeltaIndex` (GH10530)
- `DatetimeIndex` can be instantiated using strings that contain `NaT` (GH7599)
- `to_datetime` can now accept the `yearfirst` keyword (GH7599)
- `pandas.tseries.offsets` larger than the `Day` offset can now be used with a `Series` for addition/subtraction (GH10699). See the *docs* for more details.
- `pd.Timedelta.total_seconds()` now returns `Timedelta` duration to ns precision (previously microsecond precision) (GH10939)
- `PeriodIndex` now supports arithmetic with `np.ndarray` (GH10638)
- Support pickling of `Period` objects (GH10439)
- `.as_blocks` will now take a `copy` optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
- `regex` argument to `DataFrame.filter` now handles numeric column names instead of raising `ValueError` (GH10384).
- Enable reading gzip compressed files via URL, either by explicitly setting the `compression` parameter or by inferring from the presence of the `HTTP Content-Encoding` header in the response (GH8685)
- Enable writing Excel files in *memory* using `StringIO/BytesIO` (GH7074)
- Enable serialization of lists and dicts to strings in `ExcelWriter` (GH8188)
- SQL io functions now accept a `SQLAlchemy` connectable. (GH7877)
- `pd.read_sql` and `to_sql` can accept database URI as `con` parameter (GH10214)
- `read_sql_table` will now allow reading from views (GH10750).

- Enable writing complex values to HDFStores when using the table format ([GH10447](#))
- Enable `pd.read_hdf` to be used without specifying a key when the HDF file contains a single dataset ([GH10443](#))
- `pd.read_stata` will now read Stata 118 type files. ([GH9882](#))
- `msgpack` submodule has been updated to 0.4.6 with backward compatibility ([GH10581](#))
- `DataFrame.to_dict` now accepts `orient='index'` keyword argument ([GH10844](#)).
- `DataFrame.apply` will return a Series of dicts if the passed function returns a dict and `reduce=True` ([GH8735](#)).
- Allow passing *kwargs* to the interpolation methods ([GH10378](#)).
- Improved error message when concatenating an empty iterable of Dataframe objects ([GH9157](#))
- `pd.read_csv` can now read bz2-compressed files incrementally, and the C parser can read bz2-compressed files from AWS S3 ([GH11070](#), [GH11072](#)).
- In `pd.read_csv`, recognize `s3n://` and `s3a://` URLs as designating S3 file storage ([GH11070](#), [GH11071](#)).
- Read CSV files from AWS S3 incrementally, instead of first downloading the entire file. (Full file download still required for compressed files in Python 2.) ([GH11070](#), [GH11073](#))
- `pd.read_csv` is now able to infer compression type for files read from AWS S3 storage ([GH11070](#), [GH11074](#)).

## 1.16.2 Backwards incompatible API changes

### 1.16.2.1 Changes to sorting API

The sorting API has had some longtime inconsistencies. ([GH9816](#), [GH8239](#)).

Here is a summary of the API **PRIOR** to 0.17.0:

- `Series.sort` is **INPLACE** while `DataFrame.sort` returns a new object.
- `Series.order` returns a new object
- It was possible to use `Series/DataFrame.sort_index` to sort by **values** by passing the `by` keyword.
- `Series/DataFrame.sortlevel` worked only on a `MultiIndex` for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of **values**.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A \* marks items that will show a `FutureWarning`.

To sort by the **values**:

Previous	Replacement
* Series.order()	Series.sort_values()
* Series.sort()	Series.sort_values(inplace=True)
* DataFrame.sort(columns=...)	DataFrame.sort_values(by=...)

To sort by the **index**:

Previous	Replacement
Series.sort_index()	Series.sort_index()
Series.sortlevel(level=...)	Series.sort_index(level=...)
DataFrame.sort_index()	DataFrame.sort_index()
DataFrame.sortlevel(level=...)	DataFrame.sort_index(level=...)
* DataFrame.sort()	DataFrame.sort_index()

We have also deprecated and changed similar methods in two Series-like classes, Index and Categorical.

Previous	Replacement
* Index.order()	Index.sort_values()
* Categorical.order()	Categorical.sort_values()

### 1.16.2.2 Changes to to\_datetime and to\_timedelta

#### Error handling

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather than return the original input as in previous versions. ([GH10636](#))

Previous Behavior:

```
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

New Behavior:

```
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format
```

Of course you can coerce this as well.

```
In [61]: to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```
In [62]: to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out[62]: array(['2009-07-31', 'asd'], dtype=object)
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise'|'ignore'|'coerce'`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`.

## Consistent Parsing

The string parsing of `to_datetime`, `Timestamp` and `DatetimeIndex` has been made consistent. ([GH7599](#))

Prior to v0.17.0, `Timestamp` and `to_datetime` may parse year-only datetime-string incorrectly using today's date, otherwise `DatetimeIndex` uses the beginning of the year. `Timestamp` and `to_datetime` may raise `ValueError` in some types of datetime-string which `DatetimeIndex` can parse, such as a quarterly string.

Previous Behavior:

```
In [1]: Timestamp('2012Q2')
Traceback
...
ValueError: Unable to parse 2012Q2

# Results in today's date.
In [2]: Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on `DatetimeIndex` also.

New Behavior:

```
In [63]: Timestamp('2012Q2')
Out [63]: Timestamp('2012-04-01 00:00:00')

In [64]: Timestamp('2014')
Out [64]: Timestamp('2014-01-01 00:00:00')

In [65]: DatetimeIndex(['2012Q2', '2014'])
Out [65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]', freq=None)
```

**Note:** If you want to perform calculations based on today's date, use `Timestamp.now()` and `pandas.tseries.offsets`.

```
In [66]: import pandas.tseries.offsets as offsets

In [67]: Timestamp.now()
Out [67]: Timestamp('2018-07-05 17:10:40.227744')

In [68]: Timestamp.now() + offsets.DateOffset(years=1)
Out [68]: Timestamp('2019-07-05 17:10:40.228803')
```

### 1.16.2.3 Changes to Index Comparisons

Operator equal on Index should behavior similarly to Series ([GH9947](#), [GH10637](#))

Starting in v0.17.0, comparing Index objects of different lengths will raise a `ValueError`. This is to be consistent with the behavior of Series.

Previous Behavior:

```
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False,  True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False
```

New Behavior:

```
In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare
```

Note that this is different from the numpy behavior where a comparison can be broadcast:

```
In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([ True, False, False], dtype=bool)
```

or it can return False if broadcasting can not be done:

```
In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False
```

#### 1.16.2.4 Changes to Boolean Comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with `np.nan`, rather than raise `TypeError`. (GH1079).

```
In [71]: s = Series(range(3))

In [72]: s.iloc[1] = None

In [73]: s
Out[73]:
0    0.0
1    NaN
2    2.0
dtype: float64
```

Previous Behavior:

```
In [5]: s==None
TypeError: Could not compare <type 'NoneType'> type with Series
```

New Behavior:

```
In [74]: s==None
Out[74]:
```

(continues on next page)

(continued from previous page)

```
0    False
1    False
2    False
dtype: bool
```

Usually you simply want to know which values are null.

```
In [75]: s.isnull()
Out[75]:
0    False
1     True
2    False
dtype: bool
```

**Warning:** You generally will want to use `isnull/notnull` for these types of comparisons, as `isnull/notnull` tells you which elements are null. One has to be mindful that `nan`'s don't compare equal, but `None`'s do. Note that Pandas/numpy uses the fact that `np.nan != np.nan`, and treats `None` like `np.nan`.

```
In [76]: None == None
Out[76]: True

In [77]: np.nan == np.nan
Out[77]: False
```

### 1.16.2.5 HDFStore dropna behavior

The default behavior for `HDFStore` write functions with `format='table'` is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the `dropna=True` option. (GH9382)

Previous Behavior:

```
In [78]: df_with_missing = pd.DataFrame({'col1':[0, np.nan, 2],
....:                                  'col2':[1, np.nan, np.nan]})
....:

In [79]: df_with_missing
Out[79]:
   col1  col2
0    0.0    1.0
1    NaN    NaN
2    2.0    NaN
```

```
In [27]: df_with_missing.to_hdf('file.h5',
...                             'df_with_missing',
...                             format='table',
...                             mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')

Out [28]:
   col1  col2
```

(continues on next page)

(continued from previous page)

0	0	1
2	2	NaN

New Behavior:

```
In [80]: df_with_missing.to_hdf('file.h5',
.....:                        'df_with_missing',
.....:                        format='table',
.....:                        mode='w')
.....:

In [81]: pd.read_hdf('file.h5', 'df_with_missing')
Out[81]:
   col1  col2
0    0.0    1.0
1   NaN   NaN
2    2.0   NaN
```

See the [docs](#) for more details.

### 1.16.2.6 Changes to `display.precision` option

The `display.precision` option has been clarified to refer to decimal places ([GH10451](#)).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```
In [1]: pd.set_option('display.precision', 2)

In [2]: pd.DataFrame({'x': [123.456789]})
Out[2]:
      x
0  123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```
In [82]: pd.set_option('display.precision', 2)

In [83]: pd.DataFrame({'x': [123.456789]})
Out[83]:
      x
0  123.46
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

### 1.16.2.7 Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with `categories` and `codes` that are unique, rather than returning `np.array` ([GH10508](#))

- `unordered` category: values and categories are sorted by appearance order.

- When constructing `DataFrame` with an array of `complex64` dtype previously meant the corresponding column was automatically promoted to the `complex128` dtype. Pandas will now preserve the itemsize of the input for complex data ([GH10952](#))
- some numeric reduction operators would return `ValueError`, rather than `TypeError` on object types that includes strings and numbers ([GH11131](#))
- Passing currently unsupported `chunksize` argument to `read_excel` or `ExcelFile.parse` will now raise `NotImplementedError` ([GH8011](#))
- Allow an `ExcelFile` object to be passed into `read_excel` ([GH11198](#))
- `DatetimeIndex.union` does not infer `freq` if self and the input have `None` as `freq` ([GH11086](#))
- `NaT`'s methods now either raise `ValueError`, or return `np.nan` or `NaT` ([GH9513](#))

Behavior	Methods
return <code>np.nan</code>	<code>weekday</code> , <code>isoweekday</code>
return <code>NaT</code>	<code>date</code> , <code>now</code> , <code>replace</code> , <code>to_datetime</code> , <code>today</code>
return <code>np.datetime64('NaT')</code>	<code>to_datetime64</code> (unchanged)
raise <code>ValueError</code>	All other public methods (names not beginning with underscores)

#### 1.16.2.10 Deprecations

- For `Series` the following indexing functions are deprecated ([GH10177](#)).

Deprecated Function	Replacement
<code>.irow(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>
<code>.iget(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>
<code>.iget_value(i)</code>	<code>.iloc[i]</code> or <code>.iat[i]</code>

- For `DataFrame` the following indexing functions are deprecated ([GH10177](#)).

Deprecated Function	Replacement
<code>.irow(i)</code>	<code>.iloc[i]</code>
<code>.iget_value(i, j)</code>	<code>.iloc[i, j]</code> or <code>.iat[i, j]</code>
<code>.icol(j)</code>	<code>.iloc[:, j]</code>

---

**Note:** These indexing function have been deprecated in the documentation since 0.11.0.

---

- `Categorical.name` was deprecated to make `Categorical` more `numpy.ndarray` like. Use `Series(cat, name="whatever")` instead ([GH10482](#)).
- Setting missing values (`NaN`) in a `Categorical`'s categories will issue a warning ([GH10748](#)). You can still have missing values in the values.
- `drop_duplicates` and `uplicated`'s `take_last` keyword was deprecated in favor of `keep`. ([GH6511](#), [GH8505](#))
- `Series.nsmallest` and `nlargest`'s `take_last` keyword was deprecated in favor of `keep`. ([GH10792](#))
- `DataFrame.combineAdd` and `DataFrame.combineMult` are deprecated. They can easily be replaced by using the `add` and `mul` methods: `DataFrame.add(other, fill_value=0)` and `DataFrame.mul(other, fill_value=1.)` ([GH10735](#)).

- `TimeSeries` deprecated in favor of `Series` (note that this has been an alias since 0.13.0), ([GH10890](#))
- `SparsePanel` deprecated and will be removed in a future version ([GH11157](#)).
- `Series.is_time_series` deprecated in favor of `Series.index.is_all_dates` ([GH11135](#))
- Legacy offsets (like `'A@JAN'`) are deprecated (note that this has been alias since 0.8.0) ([GH10878](#))
- `WidePanel` deprecated in favor of `Panel`, `LongPanel` in favor of `DataFrame` (note these have been aliases since < 0.11.0), ([GH10892](#))
- `DataFrame.convert_objects` has been deprecated in favor of type-specific functions `pd.to_datetime`, `pd.to_timestamp` and `pd.to_numeric` (new in 0.17.0) ([GH11133](#)).

#### 1.16.2.11 Removal of prior version deprecations/changes

- Removal of `na_last` parameters from `Series.order()` and `Series.sort()`, in favor of `na_position`. ([GH5231](#))
- Remove of `percentile_width` from `.describe()`, in favor of percentiles. ([GH7088](#))
- Removal of `colSpace` parameter from `DataFrame.to_string()`, in favor of `col_space`, circa 0.8.0 version.
- Removal of automatic time-series broadcasting ([GH2304](#))

```
In [90]: np.random.seed(1234)

In [91]: df = DataFrame(np.random.randn(5,2), columns=list('AB'), index=date_range(
↳ '20130101', periods=5))

In [92]: df
Out[92]:
```

	A	B

2013-01-05	0.031393	-2.226989

- Remove `table` keyword in `HDFStore.put/append`, in favor of using `format=` (GH4645)
- Remove `kind` in `read_excel/ExcelFile` as its unused (GH4712)
- Remove `infer_type` keyword from `pd.read_html` as its unused (GH4770, GH7032)
- Remove `offset` and `timeRule` keywords from `Series.tshift/shift`, in favor of `freq` (GH4853, GH4864)
- Remove `pd.load/pd.save` aliases in favor of `pd.to_pickle/pd.read_pickle` (GH3787)

### 1.16.3 Performance Improvements

- Development support for benchmarking with the `Air Speed Velocity` library (GH8361)
- Added `vbench` benchmarks for alternative `ExcelWriter` engines and reading Excel files (GH7171)
- Performance improvements in `Categorical.value_counts` (GH10804)
- Performance improvements in `SeriesGroupBy.nunique` and `SeriesGroupBy.value_counts` and `SeriesGroupBy.transform` (GH10820, GH11077)
- Performance improvements in `DataFrame.drop_duplicates` with integer dtypes (GH10917)
- Performance improvements in `DataFrame.duplicated` with wide frames. (GH10161, GH11180)
- 4x improvement in `timedelta` string parsing (GH6755, GH10426)
- 8x improvement in `timedelta64` and `datetime64` ops (GH6755)
- Significantly improved performance of indexing `MultiIndex` with slicers (GH10287)
- 8x improvement in `iloc` using list-like input (GH10791)
- Improved performance of `Series.isin` for `datetimelike/integer` Series (GH10287)
- 20x improvement in `concat` of `Categoricals` when categories are identical (GH10587)
- Improved performance of `to_datetime` when specified format string is ISO8601 (GH10178)
- 2x improvement of `Series.value_counts` for float dtype (GH10821)
- Enable `infer_datetime_format` in `to_datetime` when date components do not have 0 padding (GH11142)
- Regression from 0.16.1 in constructing `DataFrame` from nested dictionary (GH11084)
- Performance improvements in addition/subtraction operations for `DateOffset` with `Series` or `DatetimeIndex` (GH10744, GH11205)

### 1.16.4 Bug Fixes

- Bug in incorrection computation of `.mean()` on `timedelta64[ns]` because of overflow ([GH9442](#))
- Bug in `.isin` on older numpies ([GH11232](#))
- Bug in `DataFrame.to_html(index=False)` renders unnecessary name row ([GH10344](#))
- Bug in `DataFrame.to_latex()` the `column_format` argument could not be passed ([GH9402](#))
- Bug in `DatetimeIndex` when localizing with `NaT` ([GH10477](#))
- Bug in `Series.dt` ops in preserving meta-data ([GH10477](#))
- Bug in preserving `NaT` when passed in an otherwise invalid `to_datetime` construction ([GH10477](#))
- Bug in `DataFrame.apply` when function returns categorical series. ([GH9573](#))
- Bug in `to_datetime` with invalid dates and formats supplied ([GH10154](#))
- Bug in `Index.drop_duplicates` dropping name(s) ([GH10115](#))
- Bug in `Series.quantile` dropping name ([GH10881](#))
- Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. ([GH10193](#))
- Bug in `pd.Series.interpolate` with invalid order keyword values. ([GH10633](#))
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters ([GH10387](#))
- Bug in `Index` construction with a mixed list of tuples ([GH10697](#))
- Bug in `DataFrame.reset_index` when index contains `NaT`. ([GH10388](#))
- Bug in `ExcelReader` when worksheet is empty ([GH6403](#))
- Bug in `BinGrouper.group_info` where returned values are not compatible with base class ([GH10914](#))
- Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op ([GH10912](#))
- Bug in indexing with a mixed-integer `Index` causing an `ImportError` ([GH10610](#))
- Bug in `Series.count` when index has nulls ([GH10946](#))
- Bug in pickling of a non-regular freq `DatetimeIndex` ([GH11002](#))
- Bug causing `DataFrame.where` to not respect the `axis` parameter when the frame has a symmetric shape. ([GH9736](#))
- Bug in `Table.select_column` where name is not preserved ([GH10392](#))
- Bug in `offsets.generate_range` where start and end have finer precision than offset ([GH9907](#))
- Bug in `pd.rolling_*` where `Series.name` would be lost in the output ([GH10565](#))
- Bug in stack when index or columns are not unique. ([GH10417](#))
- Bug in setting a `Panel` when an axis has a multi-index ([GH10360](#))
- Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect ([GH10278](#) and [GH9760](#))
- Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` ([GH10738](#))
- Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. ([GH10738](#))

- Regression fixed in ([GH9311](#), [GH6620](#), [GH9345](#)), where groupby with a datetime-like converting to float with certain aggregators ([GH10979](#))
- Bug in `DataFrame.interpolate` with `axis=1` and `inplace=True` ([GH10395](#))
- Bug in `io.sql.get_schema` when specifying multiple columns as primary key ([GH10385](#)).
- Bug in `groupby(sort=False)` with datetime-like Categorical raises `ValueError` ([GH10505](#))
- Bug in `groupby(axis=1)` with `filter()` throws `IndexError` ([GH11041](#))
- Bug in `test_categorical` on big-endian builds ([GH10425](#))
- Bug in `Series.shift` and `DataFrame.shift` not supporting categorical data ([GH9416](#))
- Bug in `Series.map` using categorical Series raises `AttributeError` ([GH10324](#))
- Bug in `MultiIndex.get_level_values` including Categorical raises `AttributeError` ([GH10460](#))
- Bug in `pd.get_dummies` with `sparse=True` not returning `SparseDataFrame` ([GH10531](#))
- Bug in Index subtypes (such as `PeriodIndex`) not returning their own type for `.drop` and `.insert` methods ([GH10620](#))
- Bug in `algos.outer_join_indexer` when right array is empty ([GH10618](#))
- Bug in `filter` (regression from 0.16.0) and `transform` when grouping on multiple keys, one of which is datetime-like ([GH10114](#))
- Bug in `to_datetime` and `to_timedelta` causing Index name to be lost ([GH10875](#))
- Bug in `len(DataFrame.groupby)` causing `IndexError` when there's a column containing only NaNs ([GH11016](#))
- Bug that caused segfault when resampling an empty Series ([GH10228](#))
- Bug in `DatetimeIndex` and `PeriodIndex.value_counts` resets name from its result, but retains in result's Index. ([GH10150](#))
- Bug in `pd.eval` using `numexpr` engine coerces 1 element numpy array to scalar ([GH10546](#))
- Bug in `pd.concat` with `axis=0` when column is of dtype category ([GH10177](#))
- Bug in `read_msgpack` where input type is not always checked ([GH10369](#), [GH10630](#))
- Bug in `pd.read_csv` with kwargs `index_col=False`, `index_col=['a', 'b']` or dtype ([GH10413](#), [GH10467](#), [GH10577](#))
- Bug in `Series.from_csv` with header kwarg not setting the `Series.name` or the `Series.index.name` ([GH10483](#))
- Bug in `groupby.var` which caused variance to be inaccurate for small float values ([GH10448](#))
- Bug in `Series.plot(kind='hist')` Y Label not informative ([GH10485](#))
- Bug in `read_csv` when using a converter which generates a `uint8` type ([GH9266](#))
- Bug causes memory leak in time-series line and area plot ([GH9003](#))
- Bug when setting a Panel sliced along the major or minor axes when the right-hand side is a `DataFrame` ([GH11014](#))
- Bug that returns `None` and does not raise `NotImplementedError` when operator functions (e.g. `.add`) of Panel are not implemented ([GH7692](#))
- Bug in line and kde plot cannot accept multiple colors when `subplots=True` ([GH9894](#))

- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters ([GH10387](#))
- Bug in left and right align of `Series` with `MultiIndex` may be inverted ([GH10665](#))
- Bug in left and right join of with `MultiIndex` may be inverted ([GH10741](#))
- Bug in `read_stata` when reading a file with a different order set in columns ([GH10757](#))
- Bug in `Categorical` may not representing properly when category contains `tz` or `Period` ([GH10713](#))
- Bug in `Categorical.__iter__` may not returning correct `datetime` and `Period` ([GH10713](#))
- Bug in indexing with a `PeriodIndex` on an object with a `PeriodIndex` ([GH4125](#))
- Bug in `read_csv` with `engine='c'`: EOF preceded by a comment, blank line, etc. was not handled correctly ([GH10728](#), [GH10548](#))
- Reading “famafrench” data via `DataReader` results in HTTP 404 error because of the website url is changed ([GH10591](#)).
- Bug in `read_msgpack` where `DataFrame` to decode has duplicate column names ([GH9618](#))
- Bug in `io.common.get_filepath_or_buffer` which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission ([GH10604](#))
- Bug in vectorised setting of timestamp columns with `python datetime.date` and `numpy datetime64` ([GH10408](#), [GH10412](#))
- Bug in `Index.take` may add unnecessary `freq` attribute ([GH10791](#))
- Bug in merge with empty `DataFrame` may raise `IndexError` ([GH10824](#))
- Bug in `to_latex` where unexpected keyword argument for some documented arguments ([GH10888](#))
- Bug in indexing of large `DataFrame` where `IndexError` is uncaught ([GH10645](#) and [GH10692](#))
- Bug in `read_csv` when using the `nrows` or `chunksize` parameters if file contains only a header line ([GH9535](#))
- Bug in serialization of category types in HDF5 in presence of alternate encodings. ([GH10366](#))
- Bug in `pd.DataFrame` when constructing an empty `DataFrame` with a string dtype ([GH9428](#))
- Bug in `pd.DataFrame.diff` when `DataFrame` is not consolidated ([GH10907](#))
- Bug in `pd.unique` for arrays with the `datetime64` or `timedelta64` dtype that meant an array with object dtype was returned instead the original dtype ([GH9431](#))
- Bug in `Timedelta` raising error when slicing from 0s ([GH10583](#))
- Bug in `DatetimeIndex.take` and `TimedeltaIndex.take` may not raise `IndexError` against invalid index ([GH10295](#))
- Bug in `Series([np.nan]).astype('M8[ms]')`, which now returns `Series([pd.NaT])` ([GH10747](#))
- Bug in `PeriodIndex.order` reset `freq` ([GH10295](#))
- Bug in `date_range` when `freq` divides `end` as `nanos` ([GH10885](#))
- Bug in `iloc` allowing memory outside bounds of a `Series` to be accessed with negative integers ([GH10779](#))
- Bug in `read_msgpack` where encoding is not respected ([GH10581](#))
- Bug preventing access to the first index when using `iloc` with a list containing the appropriate negative integer ([GH10547](#), [GH10779](#))

- Bug in `TimedeltaIndex` formatter causing error while trying to save `DataFrame` with `TimedeltaIndex` using `to_csv` (GH10833)
- Bug in `DataFrame.where` when handling `Series` slicing (GH10218, GH9558)
- Bug where `pd.read_gbq` throws `ValueError` when Bigquery returns zero rows (GH10273)
- Bug in `to_json` which was causing segmentation fault when serializing 0-rank `ndarray` (GH9576)
- Bug in plotting functions may raise `IndexError` when plotted on `GridSpec` (GH10819)
- Bug in plot result may show unnecessary minor ticklabels (GH10657)
- Bug in `groupby` incorrect computation for aggregation on `DataFrame` with `NaT` (E.g `first`, `last`, `min`). (GH10590, GH11010)
- Bug when constructing `DataFrame` where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)
- Bug in `.var()` causing roundoff errors for highly similar values (GH10242)
- Bug in `DataFrame.plot(subplots=True)` with duplicated columns outputs incorrect result (GH10962)
- Bug in `Index` arithmetic may result in incorrect class (GH10638)
- Bug in `date_range` results in empty if `freq` is negative annually, quarterly and monthly (GH11018)
- Bug in `DatetimeIndex` cannot infer negative `freq` (GH11018)
- Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
- Bug in `Index` dtype may not applied properly (GH11017)
- Bug in `io.gbq` when testing for minimum google api client version (GH10652)
- Bug in `DataFrame` construction from nested dict with `timedelta` keys (GH11129)
- Bug in `.fillna` against may raise `TypeError` when data contains `datetime` dtype (GH7095, GH11153)
- Bug in `.groupby` when number of keys to group by is same as length of index (GH11185)
- Bug in `convert_objects` where converted values might not be returned if all null and `coerce` (GH9589)
- Bug in `convert_objects` where `copy` keyword was not respected (GH9589)

## 1.17 v0.16.2 (June 12, 2015)

This is a minor bug-fix release from 0.16.1 and includes a a large number of bug fixes along some new features (`pipe()` method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

- A new `pipe` method, see [here](#)
- Documentation on how to use `numba` with `pandas`, see [here](#)

### What's new in v0.16.2

- *New features*
  - *Pipe*

– *Other Enhancements*

- *API Changes*
- *Performance Improvements*
- *Bug Fixes*

## 1.17.1 New features

### 1.17.1.1 Pipe

We've introduced a new method `DataFrame.pipe()`. As suggested by the name, `pipe` should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3)
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```
(df.pipe(h)
    .pipe(g, arg1=1)
    .pipe(f, arg2=2, arg3=3)
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of `(function, keyword)` indicating where the `DataFrame` should flow. For example:

```
In [1]: import statsmodels.formula.api as sm

In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')

# sm.ols takes (formula, data)
In [3]: (bb.query('h > 0')
...:     .assign(ln_h = lambda df: np.log(df.h))
...:     .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
...:     .fit()
...:     .summary()
...: )
...:
Out[3]:
<class 'statsmodels.iolib.summary.Summary'>
"""

[2] The condition number is large, 1.49e+07. This might indicate that there are
    strong multicollinearity or other numerical problems.
"""

```

The pipe method is inspired by unix pipes, which stream text through processes. More recently `dplyr` and `magrittr` have introduced the popular `(%>%)` pipe operator for R.

See the [documentation](#) for more. (GH10129)

### 1.17.1.2 Other Enhancements

- Added `rsplit` to Index/Series StringMethods (GH10303)
- Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

Note that the notebook has a `toggle output scrolling` feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here [here](#).

- `axis` parameter of `DataFrame.quantile` now accepts also `index` and `column`. (GH9543)

## 1.17.2 API Changes

- `Holiday` now raises `NotImplementedError` if both `offset` and `observance` are used in the constructor instead of returning an incorrect result (GH10217).

## 1.17.3 Performance Improvements

- Improved `Series.resample` performance with `dtype=datetime64[ns]` (GH7754)
- Increase performance of `str.split` when `expand=True` (GH10081)

### 1.17.4 Bug Fixes

- Bug in `Series.hist` raises an error when a one row `Series` was given ([GH10214](#))
- Bug where `HDFStore.select` modifies the passed columns list ([GH7212](#))
- Bug in `Categorical` repr with `display.width` of `None` in Python 3 ([GH10087](#))
- Bug in `to_json` with certain `orients` and a `CategoricalIndex` would segfault ([GH10317](#))
- Bug where some of the nan funcs do not have consistent return dtypes ([GH10251](#))
- Bug in `DataFrame.quantile` on checking that a valid axis was passed ([GH9543](#))
- Bug in `groupby.apply` aggregation for `Categorical` not preserving categories ([GH10138](#))
- Bug in `to_csv` where `date_format` is ignored if the `datetime` is fractional ([GH10209](#))
- Bug in `DataFrame.to_json` with mixed data types ([GH10289](#))
- Bug in cache updating when consolidating ([GH10264](#))
- Bug in `mean()` where integer dtypes can overflow ([GH10172](#))
- Bug where `Panel.from_dict` does not set dtype when specified ([GH10058](#))
- Bug in `Index.union` raises `AttributeError` when passing array-likes. ([GH10149](#))
- Bug in `Timestamp`'s `microsecond`, `quarter`, `dayofyear`, `week` and `daysinmonth` properties return `np.int` type, not built-in `int`. ([GH10050](#))
- Bug in `NaT` raises `AttributeError` when accessing to `daysinmonth`, `dayofweek` properties. ([GH10096](#))
- Bug in `Index` repr when using the `max_seq_items=None` setting ([GH10182](#)).
- Bug in getting timezone data with `dateutil` on various platforms ( [GH9059](#), [GH8639](#), [GH9663](#), [GH10121](#))
- Bug in displaying datetimes with mixed frequencies; display 'ms' datetimes to the proper precision. ([GH10170](#))
- Bug in `setitem` where type promotion is applied to the entire block ([GH10280](#))
- Bug in `Series` arithmetic methods may incorrectly hold names ([GH10068](#))
- Bug in `GroupBy.get_group` when grouping on multiple keys, one of which is categorical. ([GH10132](#))
- Bug in `DatetimeIndex` and `TimedeltaIndex` names are lost after `timedelta` arithmetics ( [GH9926](#))
- Bug in `DataFrame` construction from nested dict with `datetime64` ([GH10160](#))
- Bug in `Series` construction from dict with `datetime64` keys ([GH9456](#))
- Bug in `Series.plot(label="LABEL")` not correctly setting the label ([GH10119](#))
- Bug in `plot` not defaulting to `matplotlib.axes.grid` setting ([GH9792](#))
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in `engine='python'` for the `read_csv` parser ([GH9565](#))
- Bug in `Series.align` resets name when `fill_value` is specified ([GH10067](#))
- Bug in `read_csv` causing index name not to be set on an empty `DataFrame` ([GH10184](#))
- Bug in `SparseSeries.abs` resets name ([GH10241](#))
- Bug in `TimedeltaIndex` slicing may reset freq ([GH10292](#))
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` ([GH6992](#))
- Bug in `SparseSeries` constructor ignores input data name ([GH10258](#))

- Bug in `Categorical.remove_categories` causing a `ValueError` when removing the `NaN` category if underlying dtype is floating-point ([GH10156](#))
- Bug where `infer_freq` infers timerule (WOM-5XXX) unsupported by `to_offset` ([GH9425](#))
- Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. ([GH9057](#))
- Bug to handle masking empty `DataFrame` ([GH10126](#)).
- Bug where MySQL interface could not handle numeric table/column names ([GH10255](#))
- Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than `[ns]` ([GH10245](#))
- Bug in `Panel.apply` when the result has `ndim=0` ([GH10332](#))
- Bug in `read_hdf` where `auto_close` could not be passed ([GH9327](#)).
- Bug in `read_hdf` where open stores could not be used ([GH10330](#)).
- Bug in adding empty `DataFrames`, now results in a `DataFrame` that `.equals` an empty `DataFrame` ([GH10181](#)).
- Bug in `to_hdf` and `HDFStore` which did not check that complib choices were valid ([GH4582](#), [GH8874](#)).

## 1.18 v0.16.1 (May 11, 2015)

This is a minor bug-fix release from 0.16.0 and includes a a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for a `CategoricalIndex`, a category based index, see [here](#)
- New section on how-to-contribute to *pandas*, see [here](#)
- Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see [here](#)
- New method `sample` for drawing random samples from Series, DataFrames and Panels. See [here](#)
- The default `Index` printing has changed to a more uniform format, see [here](#)
- `BusinessHour` datetime-offset is now supported, see [here](#)
- Further enhancement to the `.str` accessor to make string operations easier, see [here](#)

### What’s new in v0.16.1

- *Enhancements*
  - *CategoricalIndex*
  - *Sample*
  - *String Methods Enhancements*
  - *Other Enhancements*
- *API changes*
  - *Deprecations*

- *Index Representation*
- *Performance Improvements*
- *Bug Fixes*

**Warning:** In pandas 0.17.0, the sub-package `pandas.io.data` will be removed in favor of a separately installable package ([GH8961](#)).

## 1.18.1 Enhancements

### 1.18.1.1 CategoricalIndex

We introduce a `CategoricalIndex`, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a `Categorical` (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a `DataFrame`/`Series` with a `category` dtype would convert this to regular object-based `Index`.

```
In [1]: df = DataFrame({'A' : np.arange(6),
...:                   'B' : Series(list('aabbca')).astype('category',
...:                                                     categories=list('cab'))
...:                   })
...:

In [2]: df
Out[2]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [3]: df.dtypes
Out[3]:
A      int64
B    category
dtype: object

In [4]: df.B.cat.categories
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create a `CategoricalIndex`

```
In [5]: df2 = df.set_index('B')

In [6]: df2.index
Out[6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ ordered=False, name='B', dtype='category')
```

indexing with `__getitem__/.iloc/.loc/.ix` works similarly to an `Index` with duplicates. The indexers **MUST** be in the category or the operation will raise.

```
In [7]: df2.loc['a']
Out[7]:
A
B
a    0
a    1
a    5
```

and preserves the CategoricalIndex

```
In [8]: df2.loc['a'].index
Out[8]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

sorting will order by the order of the categories

```
In [9]: df2.sort_index()
Out[9]:
A
B
c    4
a    0
a    1
a    5
b    2
b    3
```

groupby operations on the index will preserve the index nature as well

```
In [10]: df2.groupby(level=0).sum()
Out[10]:
A
B
c    4
a    6
b    5

In [11]: df2.groupby(level=0).sum().index
Out[11]: CategoricalIndex(['c', 'a', 'b'], categories=['c', 'a', 'b'], ordered=False,
↳name='B', dtype='category')
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the PASSED Categorical dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```
In [12]: df2.reindex(['a', 'e'])
Out[12]:
A
B
a    0.0
a    1.0
a    5.0
e    NaN

In [13]: df2.reindex(['a', 'e']).index
Out[13]: Index(['a', 'a', 'a', 'e'], dtype='object', name='B')
```

(continues on next page)

(continued from previous page)

```

In [14]: df2.reindex(pd.Categorical(['a','e'],categories=list('abcde'))))
Out[14]:
      A
B
a    0.0
a    1.0
a    5.0
e    NaN

In [15]: df2.reindex(pd.Categorical(['a','e'],categories=list('abcde'))).index
Out[15]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'],
↳ordered=False, name='B', dtype='category')

```

See the [documentation](#) for more. ([GH7629](#), [GH10038](#), [GH10039](#))

### 1.18.1.2 Sample

Series, DataFrames, and Panels now have a new method: `sample()`. The method accepts a specific number of rows or columns to return, or a fraction of the total number of rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. ([GH2419](#))

```

In [1]: example_series = Series([0,1,2,3,4,5])

# When no arguments are passed, returns 1
In [2]: example_series.sample()
Out[2]:
3      3
dtype: int64

# One may specify either a number of rows:
In [3]: example_series.sample(n=3)
Out[3]:
5      5
1      1
4      4
dtype: int64

# Or a fraction of the rows:
In [4]: example_series.sample(frac=0.5)
Out[4]:
4      4
1      1
0      0
dtype: int64

# weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)
Out[6]:
2      2
3      3
5      5

```

(continues on next page)

(continued from previous page)

```
dtype: int64

# weights will also be normalized if they do not sum to one,
# and missing values will be treated as zeros.
In [7]: example_weights2 = [0.5, 0, 0, 0, None, np.nan]

In [8]: example_series.sample(n=1, weights=example_weights2)
Out[8]:
0      0
dtype: int64
```

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

```
In [9]: df = DataFrame({'col1':[9,8,7,6], 'weight_column':[0.5, 0.4, 0.1, 0]})

In [10]: df.sample(n=3, weights='weight_column')
Out[10]:
   col1  weight_column
0     9             0.5
1     8             0.4
2     7             0.1
```

### 1.18.1.3 String Methods Enhancements

*Continuing from v0.16.0*, the following enhancements make string operations easier and more consistent with standard python string operations.

- Added StringMethods (`.str` accessor) to Index ([GH9068](#))

The `.str` accessor is now available for both Series and Index.

```
In [11]: idx = Index([' jack', 'jill ', ' jesse ', 'frank'])

In [12]: idx.str.strip()
Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
```

One special case for the `.str` accessor on Index is that if a string method returns bool, the `.str` accessor will return a `np.array` instead of a boolean Index ([GH8875](#)). This enables the following expression to work naturally:

```
In [13]: idx = Index(['a1', 'a2', 'b1', 'b2'])

In [14]: s = Series(range(4), index=idx)

In [15]: s
Out[15]:
a1    0
a2    1
b1    2
b2    3
dtype: int64

In [16]: idx.str.startswith('a')
Out[16]: array([ True,  True, False, False], dtype=bool)
```

(continues on next page)

```
In [17]: s[s.index.str.startswith('a')]
\\
a1      0
a2      1
dtype: int64
```

```

In [24]: from pandas.tseries.offsets import BusinessHour

In [25]: Timestamp('2014-08-01 09:00') + BusinessHour()
Out[25]: Timestamp('2014-08-01 10:00:00')

In [26]: Timestamp('2014-08-01 07:00') + BusinessHour()
Out[26]: Timestamp('2014-08-01 10:00:00')

In [27]: Timestamp('2014-08-01 16:30') + BusinessHour()
Out[27]: Timestamp('2014-08-04 09:30:00')

```

- `DataFrame.diff` now takes an `axis` parameter that determines the direction of differencing ([GH9727](#))
- Allow `clip`, `clip_lower`, and `clip_upper` to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an `axis` parameter which determines how the Series or DataFrame will be aligned with the threshold(s). ([GH6966](#))
- `DataFrame.mask()` and `Series.mask()` now support same keywords as `where` ([GH8801](#))
- `drop` function can now accept `errors` keyword to suppress `ValueError` raised when any of label does not exist in the target data. ([GH6736](#))

```

In [28]: df = DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])

In [29]: df.drop(['A', 'X'], axis=1, errors='ignore')
Out[29]:
      B      C
0  1.058969 -0.397840
1  1.047579  1.045938
2 -0.122092  0.124713

```

- Add support for separating years and quarters using dashes, for example 2014-Q1. ([GH9688](#))
- Allow conversion of values with dtype `datetime64` or `timedelta64` to strings using `astype(str)` ([GH9757](#))
- `get_dummies` function now accepts `sparse` keyword. If set to `True`, the return DataFrame is sparse, e.g. `SparseDataFrame`. ([GH8823](#))
- `Period` now accepts `datetime64` as value input. ([GH9054](#))
- Allow `timedelta` string conversion when leading zero is missing from time definition, ie `0:00:00` vs `00:00:00`. ([GH9570](#))
- Allow `Panel.shift` with `axis='items'` ([GH9890](#))
- Trying to write an excel file now raises `NotImplementedError` if the DataFrame has a `MultiIndex` instead of writing a broken Excel file. ([GH9794](#))
- Allow `Categorical.add_categories` to accept `Series` or `np.array`. ([GH9927](#))
- Add/delete `str/dt/cat` accessors dynamically from `__dir__`. ([GH9910](#))
- Add `normalize` as a `dt` accessor method. ([GH10047](#))
- `DataFrame` and `Series` now have `_constructor_expanddim` property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see [here](#)
- `pd.lib.infer_dtype` now returns `'bytes'` in Python 3 where appropriate. ([GH10032](#))

## 1.18.2 API changes

- When passing in an `ax` to `df.plot(..., ax=ax)`, the `sharex` kwarg will now default to `False`. The result is that the visibility of `xlabels` and `xticklabels` will not anymore be changed. You have to do that by yourself for the right axes in your figure or set `sharex=True` explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in `ax` kwarg), then the default is still `sharex=True` and the visibility changes are applied.
- `assign()` now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)
- By default, `read_csv` and `read_table` will now try to infer the compression type based on the file extension. Set `compression=None` to restore the previous behavior (no decompression). (GH9770)

### 1.18.2.1 Deprecations

- `Series.str.split`'s `return_type` keyword was removed in favor of `expand` (GH9847)

## 1.18.3 Index Representation

The string representation of `Index` and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than `display.max_seq_items`; if lots of items (`> display.max_seq_items`) will show a truncated display (the head and tail of the data). The formatting for `MultiIndex` is unchanged (a multi-line wrapped display). The display width responds to the option `display.max_seq_items`, which is defaulted to 100. (GH6482)

Previous Behavior

```
In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18,
↳19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39,
↳40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60,
↳61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81,
↳82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype=
↳'int64')

In [4]: pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')
Out[4]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern

In [5]: pd.date_range('20130101', periods=104, name='foo', tz='US/Eastern')
Out[5]:
<class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-04-14 00:00:00-04:00]
Length: 104, Freq: D, Timezone: US/Eastern
```

New Behavior

```
In [30]: pd.set_option('display.width', 80)

In [31]: pd.Index(range(4), name='foo')
Out[31]: RangeIndex(start=0, stop=4, step=1, name='foo')
```

(continues on next page)

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
              '2013-01-03 00:00:00-05:00', '2013-01-04 00:00:00-05:00',
              '2013-01-05 00:00:00-05:00', '2013-01-06 00:00:00-05:00',
              '2013-01-07 00:00:00-05:00', '2013-01-08 00:00:00-05:00',
              '2013-01-09 00:00:00-05:00', '2013-01-10 00:00:00-05:00',
              ...,
              '2013-04-05 00:00:00-04:00', '2013-04-06 00:00:00-04:00',
              '2013-04-07 00:00:00-04:00', '2013-04-08 00:00:00-04:00',
              '2013-04-09 00:00:00-04:00', '2013-04-10 00:00:00-04:00',
              '2013-04-11 00:00:00-04:00', '2013-04-12 00:00:00-04:00',
              '2013-04-13 00:00:00-04:00', '2013-04-14 00:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', name='foo', length=104, freq='D')
```

### 1.18.4 Performance Improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x ([GH9940](#))
- Improved csv write performance generally by 2x ([GH9940](#))
- Improved the performance of `pd.lib.max_len_string_array` by 5-7x ([GH10024](#))

### 1.18.5 Bug Fixes

- Bug where labels did not appear properly in the legend of `DataFrame.plot()`, passing `label=` arguments works, and Series indices are no longer mutated. ([GH9542](#))
- Bug in json serialization causing a segfault when a frame had zero length. ([GH9805](#))
- Bug in `read_csv` where missing trailing delimiters would cause segfault. ([GH5664](#))
- Bug in retaining index name on appending ([GH9862](#))
- Bug in `scatter_matrix` draws unexpected axis ticklabels ([GH5662](#))
- Fixed bug in `StataWriter` resulting in changes to input `DataFrame` upon save ([GH9795](#)).
- Bug in `transform` causing length mismatch when null entries were present and a fast aggregator was being used ([GH9697](#))
- Bug in `equals` causing false negatives when block order differed ([GH9330](#))
- Bug in grouping with multiple `pd.Grouper` where one is non-time based ([GH10063](#))
- Bug in `read_sql_table` error when reading postgres table with timezone ([GH7139](#))
- Bug in `DataFrame` slicing may not retain metadata ([GH9776](#))
- Bug where `TimedeltaIndex` were not properly serialized in fixed `HDFStore` ([GH9635](#))
- Bug with `TimedeltaIndex` constructor ignoring name when given another `TimedeltaIndex` as data ([GH10025](#)).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index ([GH7856](#))
- Bug in `.loc` with a read-only ndarray data source ([GH10043](#))
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only `None` (for all input). ([GH9685](#))

- Always use temporary files in pytables tests ([GH9992](#))
- Bug in plotting continuously using `secondary_y` may not show legend properly. ([GH9610](#), [GH9779](#))
- Bug in `DataFrame.plot(kind="hist")` results in `TypeError` when `DataFrame` contains non-numeric columns ([GH9853](#))
- Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise `TypeError` ([GH9852](#))
- Bug in `setup.py` that would allow an incompat cython version to build ([GH9827](#))
- Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. ([GH9861](#))
- Bug in `Series.quantile` on empty `Series` of type `Datetime` or `Timedelta` ([GH9675](#))
- Bug in `where` causing incorrect results when upcasting was required ([GH9731](#))
- Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given `display.precision` ([GH9764](#))
- Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the style strings ([GH9671](#))
- Not showing a `DeprecationWarning` on combining list-likes with an `Index` ([GH10083](#))
- Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. ([GH9832](#))
- Bug in `read_csv()` interprets `index_col=True` as 1 ([GH9798](#))
- Bug in index equality comparisons using `==` failing on `Index/MultiIndex` type incompatibility ([GH9785](#))
- Bug in which `SparseDataFrame` could not take `nan` as a column name ([GH8822](#))
- Bug in `to_msgpack` and `read_msgpack` `zlib` and `blosc` compression support ([GH9783](#))
- Bug `GroupBy.size` doesn’t attach index name properly if grouped by `TimeGrouper` ([GH9925](#))
- Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results ([GH9995](#))
- Bug in `csv` parser causing lines with initial whitespace plus one non-space character to be skipped. ([GH9710](#))
- Bug in `C` `csv` parser causing spurious NaNs when data started with newline followed by whitespace. ([GH10022](#))
- Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` ([GH9603](#))
- Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes ([GH9964](#))
- Bug in invalid attribute access on a `TimedeltaIndex` incorrectly raised `ValueError` instead of `AttributeError` ([GH9680](#))
- Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. `Series(Categorical(list("abc")), ordered=True) > "d"`. This returned `False` for all elements, but now raises a `TypeError`. Equality comparisons also now return `False` for `==` and `True` for `!=`. ([GH9848](#))
- Bug in `DataFrame.__setitem__` when right hand side is a dictionary ([GH9874](#))
- Bug in `where` when `dtype` is `datetime64/timedelta64`, but `dtype` of other is not ([GH9804](#))
- Bug in `MultiIndex.sortlevel()` results in unicode level name breaks ([GH9856](#))
- Bug in which `groupby.transform` incorrectly enforced output dtypes to match input dtypes. ([GH9807](#))
- Bug in `DataFrame` constructor when `columns` parameter is set, and `data` is an empty list ([GH9939](#))

- Bug in bar plot with `log=True` raises `TypeError` if all values are less than 1 (GH9905)
- Bug in horizontal bar plot ignores `log=True` (GH9905)
- Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)
- Bug where dividing a dataframe containing values of type `Decimal` by another `Decimal` would raise. (GH9787)
- Bug where using DataFrames `asfreq` would remove the name of the index. (GH9885)
- Bug causing extra index point when `resample` BM/BQ (GH9756)
- Changed caching in `AbstractHolidayCalendar` to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
- Fixed latex output for multi-indexed dataframes (GH9778)
- Bug causing an exception when setting an empty range using `DataFrame.loc` (GH9596)
- Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
- Bug in `transform` and `filter` when grouping on a categorical variable (GH9921)
- Bug in `transform` when groups are equal in number and dtype to the input index (GH9700)
- Google BigQuery connector now imports dependencies on a per-method basis. (GH9713)
- Updated BigQuery connector to no longer use deprecated `oauth2client.tools.run()` (GH8327)
- Bug in subclassed `DataFrame`. It may not return the correct class, when slicing or subsetting it. (GH9632)
- Bug in `.median()` where non-float null values are not handled correctly (GH10040)
- Bug in `Series.fillna()` where it raises if a numerically convertible string is given (GH10092)

## 1.19 v0.16.0 (March 22, 2015)

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- `DataFrame.assign` method, see [here](#)
- `Series.to_coo/from_coo` methods to interact with `scipy.sparse`, see [here](#)
- Backwards incompatible change to `Timedelta` to conform the `.seconds` attribute with `datetime.timedelta`, see [here](#)
- Changes to the `.loc` slicing API to conform with the behavior of `.ix` see [here](#)
- Changes to the default for ordering in the `Categorical` constructor, see [here](#)
- Enhancement to the `.str` accessor to make string operations easier, see [here](#)
- The `pandas.tools.rplot`, `pandas.sandbox.qtpandas` and `pandas.rpy` modules are deprecated. We refer users to external packages like [seaborn](#), [pandas-qt](#) and [rpy2](#) for similar or equivalent functionality, see [here](#)

Check the [API Changes](#) and [deprecations](#) before updating.

**What's new in v0.16.0**

- *New features*
  - *DataFrame Assign*
  - *Interaction with scipy.sparse*
  - *String Methods Enhancements*
  - *Other enhancements*
- *Backwards incompatible API changes*
  - *Changes in Timedelta*
  - *Indexing Changes*
  - *Categorical Changes*
  - *Other API Changes*
  - *Deprecations*
  - *Removal of prior version deprecations/changes*
- *Performance Improvements*
- *Bug Fixes*

**1.19.1 New features****1.19.1.1 DataFrame Assign**

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or `NumPy` array), or a function of one argument to be called on the `DataFrame`. The new values are inserted, and the entire `DataFrame` (with all original and new columns) is returned.

```
In [1]: iris = read_csv('data/iris.data')
```

```
In [2]: iris.head()
```

```
Out[2]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name
0	5.1	3.5	1.4	0.2	Iris-setosa
1	4.9	3.0	1.4	0.2	Iris-setosa
2	4.7	3.2	1.3	0.2	Iris-setosa
3	4.6	3.1	1.5	0.2	Iris-setosa
4	5.0	3.6	1.4	0.2	Iris-setosa

```
In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
```

```

////////////////////////////////////
↪

```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```
In [4]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] /
...:                                         x['SepalLength'])).head()
Out[4]:
```

	SepalLength	SepalWidth	PetalLength	PetalWidth	Name	sepal_ratio
0	5.1	3.5	1.4	0.2	Iris-setosa	0.686275
1	4.9	3.0	1.4	0.2	Iris-setosa	0.612245
2	4.7	3.2	1.3	0.2	Iris-setosa	0.680851
3	4.6	3.1	1.5	0.2	Iris-setosa	0.673913
4	5.0	3.6	1.4	0.2	Iris-setosa	0.720000

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```
In [5]: (iris.query('SepalLength > 5')
...:      .assign(SepalRatio = lambda x: x.SepalWidth / x.SepalLength,
...:              PetalRatio = lambda x: x.PetalWidth / x.PetalLength)
...:      .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x1c41df41d0>
```

See the [documentation](#) for more. (GH9229)

### 1.19.1.2 Interaction with `scipy.sparse`

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods (GH8048) for converting to and from `scipy.sparse.coo_matrix` instances (see [here](#)). For example, given a `SparseSeries` with `MultiIndex` we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```
In [6]: from numpy import nan

In [7]: s = Series([3.0, nan, 1.0, 3.0, nan, nan])

In [8]: s.index = MultiIndex.from_tuples([(1, 2, 'a', 0),
...:                                     (1, 2, 'a', 1),
...:                                     (1, 1, 'b', 0),
...:                                     (1, 1, 'b', 1),
...:                                     (2, 1, 'b', 0),
```

(continues on next page)

(continued from previous page)

[illegible]

The `from_coo` method is a convenience method for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`:

[illegible]

### 1.19.1.3 String Methods Enhancements

- Following new methods are accessible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. ([GH9282](#), [GH9352](#), [GH9386](#), [GH9387](#), [GH9439](#))

		Methods		
isalnum()	isalpha()	isdigit()	isdigit()	isspace()
islower()	isupper()	istitle()	isnumeric()	isdecimal()
find()	rfind()	ljust()	rjust()	zfill()

```
In [23]: s = Series(['abcd', '3456', 'EFGH'])

In [24]: s.str.isalpha()
Out[24]:
0      True
1     False
2      True
dtype: bool

In [25]: s.str.find('ab')
Out[25]:
0      0
```

(continues on next page)

(continued from previous page)

```
1    -1
2    -1
dtype: int64
```

- `Series.str.pad()` and `Series.str.center()` now accept `fillchar` option to specify filling character (GH9352)

```
In [26]: s = Series(['12', '300', '25'])

In [27]: s.str.pad(5, fillchar='_')
Out[27]:
0    ____12
1    __300
2    ____25
dtype: object
```

- Added `Series.str.slice_replace()`, which previously raised `NotImplementedError` (GH8888)

```
In [28]: s = Series(['ABCD', 'EFGH', 'IJK'])

In [29]: s.str.slice_replace(1, 3, 'X')
Out[29]:
0    AXD
1    EXH
2     IX
dtype: object

# replaced with empty char
In [30]: s.str.slice_replace(0, 1)
Out[30]:
0    BCD
1    FGH
2     JK
dtype: object
```

### 1.19.1.4 Other enhancements

- Reindex now supports `method='nearest'` for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [31]: df = pd.DataFrame({'x': range(5)})

In [32]: df.reindex([0.2, 1.8, 3.5], method='nearest')
Out[32]:
      x
0.2  0
1.8  2
3.5  4
```

This method is also exposed by the lower level `Index.get_indexer` and `Index.get_loc` methods.

- The `read_excel()` function's `sheetname` argument now accepts a list and `None`, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```

- Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs [here](#) (GH9493:).
- Paths beginning with ~ will now be expanded to begin with the user's home directory (GH9066)
- Added time interval selection in `get_data_yahoo` (GH9071)
- Added `Timestamp.to_datetime64()` to complement `Timedelta.to_timedelta64()` (GH9255)
- `tsseries.frequencies.to_offset()` now accepts `Timedelta` as input (GH9064)
- Lag parameter was added to the autocorrelation method of `Series`, defaults to lag-1 autocorrelation (GH9192)
- `Timedelta` will now accept `nanoseconds` keyword in constructor (GH9273)
- SQL code now safely escapes table and column names (GH8986)
- Added auto-complete for `Series.str.<tab>`, `Series.dt.<tab>` and `Series.cat.<tab>` (GH9322)
- `Index.get_indexer` now supports `method='pad'` and `method='backfill'` even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
- `Index.asof` now works on all index types (GH9258).
- A `verbose` argument has been augmented in `io.read_excel()`, defaults to `False`. Set to `True` to print sheet names as they are parsed. (GH9450)
- Added `days_in_month` (compatibility alias `daysinmonth`) property to `Timestamp`, `DatetimeIndex`, `Period`, `PeriodIndex`, and `Series.dt` (GH9572)
- Added `decimal` option in `to_csv` to provide formatting for non-',' decimal separators (GH781)
- Added `normalize` option for `Timestamp` to normalized to midnight (GH8794)
- Added example for `DataFrame` import to R using HDF5 file and `rhdf5` library. See the [documentation](#) for more (GH9636).

## 1.19.2 Backwards incompatible API changes

### 1.19.2.1 Changes in Timedelta

In v0.15.0 a new scalar type `Timedelta` was introduced, that is a sub-class of `datetime.timedelta`. Mentioned [here](#) was a notice of an API change w.r.t. the `.seconds` accessor. The intent was to provide a user-friendly set of accessors that give the 'natural' value for that unit, e.g. if you had a `Timedelta('1 day, 10:11:12')`, then `.seconds` would return 12. However, this is at odds with the definition of `datetime.timedelta`, which defines `.seconds` as `10 * 3600 + 11 * 60 + 12 == 36672`.

So in v0.16.0, we are restoring the API to match that of `datetime.timedelta`. Further, the component values are still available through the `.components` accessor. This affects the `.seconds` and `.microseconds` accessors, and removes the `.hours`, `.minutes`, `.milliseconds` accessors. These changes affect `TimedeltaIndex` and the `Series .dt` accessor as well. (GH9185, GH9139)

Previous Behavior

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [3]: t.days
Out[3]: 1
```

(continues on next page)

(continued from previous page)

```
In [4]: t.seconds
Out[4]: 12

In [5]: t.microseconds
Out[5]: 123
```

### New Behavior

```
In [33]: t = pd.Timedelta('1 day, 10:11:12.100123')

In [34]: t.days
Out[34]: 1

In [35]: t.seconds
Out[35]: 36672

In [36]: t.microseconds
Out[36]: 100123
```

Using `.components` allows the full component access

```
In [37]: t.components
Out[37]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100,
↳ microseconds=123, nanoseconds=0)

In [38]: t.components.seconds
Out[38]: 12
```

### 1.19.2.2 Indexing Changes

The behavior of a small sub-set of edge cases for using `.loc` have changed ([GH8613](#)). Furthermore we have improved the content of the error messages that are raised:

- Slicing with `.loc` where the start and/or stop bound is not found in the index is now allowed; this previously would raise a `KeyError`. This makes the behavior the same as `.ix` in this case. This change is only for slicing, not when indexing with a single label.

```
In [39]: df = DataFrame(np.random.randn(5,4),
.....:                  columns=list('ABCD'),
.....:                  index=date_range('20130101', periods=5))
.....:

In [40]: df
Out[40]:
```

	A	B	C	D
2013-01-01	-0.322795	0.841675	2.390961	0.076200
2013-01-02	-0.566446	0.036142	-2.074978	0.247792
2013-01-03	-0.897157	-0.136795	0.018289	0.755414
2013-01-04	0.215269	0.841009	-1.445810	-1.401973
2013-01-05	-0.100918	-0.548242	-0.144620	0.354020

```
In [41]: s = Series(range(5), [-2, -1, 1, 2, 3])

In [42]: s
```

(continues on next page)

(continued from previous page)

```
Out[42]:
-2      0
-1      1
 1      2
 2      3
 3      4
dtype: int64
```

## Previous Behavior

```
In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'
```

```
In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'
```

### New Behavior

```
In [43]: df.loc['2013-01-02':'2013-01-10']
Out[43]:
```

	A	B	C	D
2013-01-02	-0.566446	0.036142	-2.074978	0.247792
2013-01-03	-0.897157	-0.136795	0.018289	0.755414
2013-01-04	0.215269	0.841009	-1.445810	-1.401973
2013-01-05	-0.100918	-0.548242	-0.144620	0.354020

```
In [44]: s.loc[-10:3]
//////////
↵
-2      0
-1      1
1       2
2       3
3       4
dtype: int64
```

- Allow slicing with float-like values on an integer index for `.ix`. Previously this was only enabled for `.loc`:

## Previous Behavior

```
In [8]: s.ix[-1.0:2]
TypeError: the slice start value [-1.0] is not a proper indexer for this index_
↪type (Int64Index)
```

## New Behavior

```
In [2]: s.ix[-1.0:2]
Out[2]:
-1      1
 1      2
 2      3
dtype: int64
```

- Provide a useful exception for indexing with an invalid type for that index when using `.loc`. For example trying to use `.loc` on an index of type `DatetimeIndex` or `PeriodIndex` or `TimedeltaIndex`, with an integer (or a float).

## Previous Behavior

```
In [4]: df.loc[2:3]
KeyError: 'start bound [2] is not the [index]'
```

#### New Behavior

```
In [4]: df.loc[2:3]
TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'
↳> with <type 'int'> keys
```

### 1.19.2.3 Categorical Changes

In prior versions, `Categoricals` that had an unspecified ordering (meaning no `ordered` keyword was passed) were defaulted as ordered `Categoricals`. Going forward, the `ordered` keyword in the `Categorical` constructor will default to `False`. Ordering must now be explicit.

Furthermore, previously you *could* change the `ordered` attribute of a `Categorical` by just setting the attribute, e.g. `cat.ordered=True`; This is now deprecated and you should use `cat.as_ordered()` or `cat.as_unordered()`. These will by default return a **new** object and not modify the existing object. (GH9347, GH9190)

#### Previous Behavior

```
In [3]: s = Series([0,1,2], dtype='category')

In [4]: s
Out[4]:
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [5]: s.cat.ordered
Out[5]: True

In [6]: s.cat.ordered = False

In [7]: s
Out[7]:
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0, 1, 2]
```

#### New Behavior

```
In [45]: s = Series([0,1,2], dtype='category')

In [46]: s
Out[46]:
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0, 1, 2]
```

(continues on next page)

(continued from previous page)

```

In [47]: s.cat.ordered
\\Out [47]:
↪False

In [48]: s = s.cat.as_ordered()

In [49]: s
Out[49]:
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [50]: s.cat.ordered
\\Out [50]:
↪True

# you can set in the constructor of the Categorical
In [51]: s = Series(Categorical([0,1,2],ordered=True))

In [52]: s
Out[52]:
0    0
1    1
2    2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [53]: s.cat.ordered
\\Out [53]:
↪True

```

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling `.astype()`. These are passed directly to the constructor.

```

In [54]: s = Series(["a", "b", "c", "a"]).astype('category', ordered=True)

In [55]: s
Out[55]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = Series(["a", "b", "c", "a"]).astype('category', categories=list('abcdef'),
↪ordered=False)

In [57]: s
Out[57]:
0    a
1    b
2    c

```

(continues on next page)

(continued from previous page)

```
3      a
dtype: category
Categories (6, object): [a, b, c, d, e, f]
```

### 1.19.2.4 Other API Changes

- `Index.duplicated` now returns `np.array(dtype=bool)` rather than `Index(dtype=object)` containing `bool` values. (GH8875)
- `DataFrame.to_json` now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out [2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'
```

Now each column is serialised using its correct dtype:

```
In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
Out [2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'
```

- `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex.summary` now output the same format. (GH9116)
- `TimedeltaIndex.freqstr` now output the same string format as `DatetimeIndex`. (GH9116)
- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib's `axhline` or `axvline` methods (GH9088).
- Series accessors `.dt`, `.cat` and `.str` now raise `AttributeError` instead of `TypeError` if the series does not contain the appropriate type of data (GH9617). This follows Python's built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.
- Series now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to `bool`.

Previous Behavior

```
In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
Out [2]:
a      True
b      True
c      True
d      True
dtype: bool
```

New Behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

```
In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
Out [2]:
a      4
b      5
c      6
```

(continues on next page)

```
d      7
dtype: int64
```

- ## Previous Behavior

```
0      inf
1      inf
dtype: float64
```

```
0      NaN
1      inf
dtype: float64
```

- Old behavior:

```
Out[4]: Timestamp('2000-01-31 00:00:00')
```

```
Out[57]: Timestamp('2000-02-28 00:00:00')
```

To reproduce the old behavior, simply add more precision to the label (e.g., use 2000-02-01 instead of 2000-02).

### 1.19.2.5 Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality ([GH3445](#)). The documentation includes some examples how to convert your existing code using `rplot` to `seaborn`: [rplot docs](#).
- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt`. ([GH9615](#))
- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed thru the `rpy2` project ([GH9602](#))
- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. ([GH9094](#))
- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. ([GH9094](#))

### 1.19.2.6 Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s `rows` and `cols` keyword arguments were removed in favor of `index` and `columns` ([GH6581](#))
- `DataFrame.to_excel` and `DataFrame.to_csv` `cols` keyword argument was removed in favor of `columns` ([GH6581](#))
- Removed `convert_dummies` in favor of `get_dummies` ([GH6581](#))
- Removed `value_range` in favor of `describe` ([GH6581](#))

## 1.19.3 Performance Improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like ([GH9126](#)).
- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. ([GH9037](#))
- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values ([GH9125](#))
- Improved the speed of `nunique` by calling `unique` instead of `value_counts` ([GH9129](#), [GH7771](#))
- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately ([GH9136](#))
- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument ([GH9163](#))
- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds ([GH9151](#))
- Performance improvements in multi-key `groupby` ([GH9429](#))
- Performance improvements in `MultiIndex.sortlevel` ([GH9445](#))
- Performance and memory usage improvements in `DataFrame.duplicated` ([GH9398](#))

- Cythonized Period ([GH9440](#))
- Decreased memory usage on `to_hdf` ([GH9648](#))

### 1.19.4 Bug Fixes

- Changed `.to_html` to remove leading/trailing spaces in table body ([GH4987](#))
- Fixed issue using `read_csv` on s3 with Python 3 ([GH9452](#))
- Fixed compatibility issue in `DatetimeIndex` affecting architectures where `numpy.int_` defaults to `numpy.int32` ([GH8943](#))
- Bug in Panel indexing with an object-like ([GH9140](#))
- Bug in the returned `Series.dt.components` index was reset to the default index ([GH9247](#))
- Bug in `Categorical.__getitem__`/`__setitem__` with listlike input getting incorrect results from indexer coercion ([GH9469](#))
- Bug in partial setting with a `DatetimeIndex` ([GH9478](#))
- Bug in groupby for integer and `datetime64` columns when applying an aggregator that caused the value to be changed when the number was sufficiently large ([GH9311](#), [GH6620](#))
- Fixed bug in `to_sql` when mapping a `Timestamp` object column (datetime column with timezone info) to the appropriate sqlalchemy type ([GH9085](#)).
- Fixed bug in `to_sql` `dtype` argument not accepting an instantiated `SQLAlchemy` type ([GH9083](#)).
- Bug in `.loc` partial setting with a `np.datetime64` ([GH9516](#))
- Incorrect dtypes inferred on datetimelike looking `Series` & on `.xs` slices ([GH9477](#))
- Items in `Categorical.unique()` (and `s.unique()` if `s` is of dtype `category`) now appear in the order in which they are originally found, not in sorted order ([GH9331](#)). This is now consistent with the behavior for other dtypes in pandas.
- Fixed bug on big endian platforms which produced incorrect results in `StataReader` ([GH8688](#)).
- Bug in `MultiIndex.has_duplicates` when having many levels causes an indexer overflow ([GH9075](#), [GH5873](#))
- Bug in `pivot` and `unstack` where nan values would break index alignment ([GH4862](#), [GH7401](#), [GH7403](#), [GH7405](#), [GH7466](#), [GH9497](#))
- Bug in `left join` on multi-index with `sort=True` or null values ([GH9210](#)).
- Bug in `MultiIndex` where inserting new keys would fail ([GH9250](#)).
- Bug in groupby when key space exceeds `int64` bounds ([GH9096](#)).
- Bug in `unstack` with `TimedeltaIndex` or `DatetimeIndex` and nulls ([GH9491](#)).
- Bug in `rank` where comparing floats with tolerance will cause inconsistent behaviour ([GH8365](#)).
- Fixed character encoding bug in `read_stata` and `StataReader` when loading data from a URL ([GH9231](#)).
- Bug in adding `offsets.Nano` to other offsets raises `TypeError` ([GH9284](#))
- Bug in `DatetimeIndex` iteration, related to ([GH8890](#)), fixed in ([GH9100](#))
- Bugs in `resample` around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. ([GH5172](#), [GH8744](#), [GH8653](#), [GH9173](#), [GH9468](#)).
- Bug in binary operator method (eg `.mul()`) alignment with integer levels ([GH9463](#)).

- Bug in boxplot, scatter and hexbin plot may show an unnecessary warning ([GH8877](#))
- Bug in subplot with `layout` kw may show unnecessary warning ([GH9464](#))
- Bug in using grouper functions that need passed thru arguments (e.g. `axis`), when using wrapped function (e.g. `fillna`), ([GH9221](#))
- `DataFrame` now properly supports simultaneous `copy` and `dtype` arguments in constructor ([GH9099](#))
- Bug in `read_csv` when using `skiprows` on a file with CR line endings with the `c` engine. ([GH9079](#))
- `isnull` now detects `NaT` in `PeriodIndex` ([GH9129](#))
- Bug in `groupby .nth()` with a multiple column `groupby` ([GH8979](#))
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly ([GH9280](#))
- Bug in `DataFrame.where` and `Series.where` raise `ValueError` when string list-like is passed. ([GH9280](#))
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results ([GH9184](#))
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing ([GH9512](#))
- Fixed division by zero error for `Series.kurt()` when all values are equal ([GH9197](#))
- Fixed issue in the `xlsxwriter` engine where it added a default 'General' format to cells if no other format was applied. This prevented other row or column formatting being applied. ([GH9167](#))
- Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. ([GH9082](#))
- Bug where `wide_to_long` would modify the input stubnames list ([GH9204](#))
- Bug in `to_sql` not storing float64 values using double precision. ([GH9009](#))
- `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) ([GH9272](#)).
- Regression in merging `Categorical` and object dtypes ([GH9426](#))
- Bug in `read_csv` with buffer overflows with certain malformed input files ([GH9205](#))
- Bug in `groupby MultiIndex` with missing pair ([GH9049](#), [GH9344](#))
- Fixed bug in `Series.groupby` where grouping on `MultiIndex` levels would ignore the sort argument ([GH9444](#))
- Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of `Categorical` columns. ([GH8868](#))
- Fixed bug with reading CSV files from Amazon S3 on python 3 raising a `TypeError` ([GH9452](#))
- Bug in the Google BigQuery reader where the 'jobComplete' key may be present but False in the query results ([GH8728](#))
- Bug in `Series.values_counts` with excluding NaN for categorical type Series with `dropna=True` ([GH9443](#))
- Fixed missing `numeric_only` option for `DataFrame.std/var/sem` ([GH9201](#))
- Support constructing `Panel` or `Panel4D` with scalar data ([GH8285](#))
- `Series` text representation disconnected from `max_rows/max_columns` ([GH7508](#)).

- Series number formatting inconsistent when truncated ([GH8532](#)).

#### Previous Behavior

```
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0      1
1      1
2      1
...
127    0.9999
128    1.0000
129    1.0000
Length: 130, dtype: float64
```

#### New Behavior

```
0      1.0000
1      1.0000
2      1.0000
3      1.0000
4      1.0000
...
125    1.0000
126    1.0000
127    0.9999
128    1.0000
129    1.0000
dtype: float64
```

- A Spurious SettingWithCopy Warning was generated when setting a new item in a frame in some cases ([GH8730](#))

The following would previously report a SettingWithCopy Warning.

```
In [1]: df1 = DataFrame({'x': Series(['a', 'b', 'c']), 'y': Series(['d', 'e', 'f'])})
In [2]: df2 = df1[['x']]
In [3]: df2['y'] = ['g', 'h', 'i']
```

## 1.20 v0.15.2 (December 12, 2014)

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Bug Fixes*

### 1.20.1 API changes

- Indexing in `MultiIndex` beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
...:                        'joe':['x', 'x', 'z', 'y'],
...:                        'jolie':np.random.rand(4)}).set_index(['jim', 'joe'])
...:
```

```
In [2]: df
```

Out [2]:

		jolie
jim	joe	
0	x	0.123943
	x	0.119381
1	z	0.738523
	y	0.587304

```
In [3]: df.index.lexsort_depth
```

```
# in prior versions this would raise a KeyError
# will now show a PerformanceWarning
```

```
In [4]: df.loc[(1, 'z')]
```

	jolie
jim joe	
1 z	0.738523

```
# lexically sorting
```

```
In [5]: df2 = df.sort_index()
```

```
In [6]: df2
```

Out [6]:

```
jim joe      jolie
0    x      0.123943
      x      0.119381
1    y      0.587304
      z      0.738523
```

```
In [7]: df2.index.lexsort_depth
```

```
In [8]: df2.loc[(1, 'z')]
```

```
jim      jodie
jim joe
1      z      0.738523
```

- Bug in `unique` of Series with `category` dtype, which returned all categories regardless whether they were “used” or not (see [GH8559](#) for the discussion). Previous behaviour was to return all categories:

```
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [4]: cat
Out[4]:
[a, b, a]
Categories (3, object): [a < b < c]

In [5]: cat.unique()
Out[5]: array(['a', 'b', 'c'], dtype=object)
```

Now, only the categories that do effectively occur in the array are returned:

```
In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [10]: cat.unique()
Out[10]:
[a, b]
Categories (2, object): [a, b]
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters. `Series.all`, `Series.any`, `Index.all`, and `Index.any` no longer support the `out` and `keepdims` parameters, which existed for compatibility with `ndarray`. Various index types no longer support the `all` and `any` aggregation functions and will now raise `TypeError`. (GH8302).
- Allow equality comparisons of `Series` with a categorical dtype and object dtype; previously these would raise `TypeError` (GH8938)
- Bug in `NDFrame`: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named `y` existed, `data.y` would return the attribute, while `data.y = z` would update the column (GH8994)

```
In [11]: data = pd.DataFrame({'x': [1, 2, 3]})

In [12]: data.y = 2

In [13]: data['y'] = [2, 4, 6]

In [14]: data
Out[14]:
   x  y
0  1  2
1  2  4
2  3  6

# this assignment was inconsistent
In [15]: data.y = 5
```

Old behavior:

```
In [6]: data.y
Out[6]: 2

In [7]: data['y'].values
Out[7]: array([5, 5, 5])
```

New behavior:

```
In [16]: data.y
Out[16]: 5

In [17]: data['y'].values
Out[17]: array([2, 4, 6])
```

- `Timestamp('now')` is now equivalent to `Timestamp.now()` in that it returns the local time rather than UTC. Also, `Timestamp('today')` is now equivalent to `Timestamp.today()` and both have `tz` as a possible argument. (GH9000)
- Fix negative step support for label-based slices (GH8753)

Old behavior:

```
In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
Out[1]:
a    0
b    1
c    2
dtype: int64

In [2]: s.loc['c':'a':-1]
Out[2]:
c    2
dtype: int64
```

New behavior:

```
In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])

In [19]: s.loc['c':'a':-1]
Out[19]:
c    2
b    1
a    0
dtype: int64
```

## 1.20.2 Enhancements

Categorical enhancements:

- Added ability to export Categorical data to Stata (GH8633). See [here](#) for limitations of categorical variables exported to Stata data files.
- Added flag `order_categoricals` to `StataReader` and `read_stata` to select whether to order imported categorical data (GH8836). See [here](#) for more information on importing categorical variables from Stata data files.
- Added ability to export Categorical data to to/from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See [here](#) for an example and caveats w.r.t. prior versions of pandas.
- Added support for `searchsorted()` on *Categorical* class (GH8420).

Other enhancements:

- Added the ability to specify the SQL type of columns when writing a `DataFrame` to a database (GH8778). For example, specifying to use the sqlalchemy `String` type instead of the default `Text` type for string columns:

```
from sqlalchemy.types import String
data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

- `Series.all` and `Series.any` now support the `level` and `skipna` parameters (GH8302):

```
In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])

In [21]: s.any(level=0)
Out[21]:
0      True
1     False
dtype: bool
```

- `Panel` now supports the `all` and `any` aggregation functions. (GH8302):

```
In [22]: p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)

In [23]: p.all()
Out[23]:
      0      1      2      3
0  True  True  True  True
1  True  True  False True
2  True  True  True  True
3  True  True  False True
4  True  True  True  True
```

- Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on `Timestamp` class (GH5351).
- Added Google Analytics (*pandas.io.ga*) basic documentation (GH8835). See [here](#).
- `Timedelta` arithmetic returns `NotImplemented` in unknown cases, allowing extensions by custom classes (GH8813).
- `Timedelta` now supports arithmetic with `numpy.ndarray` objects of the appropriate dtype (numpy 1.8 or newer only) (GH8884).
- Added `Timedelta.to_timedelta64()` method to the public API (GH8884).
- Added `gbq.generate_bq_schema()` function to the `gbq` module (GH8325).
- `Series` now works with `map` objects the same way as generators (GH8909).
- Added context manager to `HDFStore` for automatic closing (GH8791).
- `to_datetime` gains an `exact` keyword to allow for a format to not require an exact match for a provided format string (if its `False`). `exact` defaults to `True` (meaning that exact matching is still the default) (GH8904)
- Added `axvlines` boolean option to `parallel_coordinates` plot function, determines whether vertical lines will be printed, default is `True`
- Added ability to read table footers to `read_html` (GH8552)
- `to_sql` now infers datatypes of non-NA values for columns that contain NA values and have dtype object (GH8778).

### 1.20.3 Performance

- Reduce memory usage when `skiprows` is an integer in `read_csv` (GH8681)

- Performance boost for `to_datetime` conversions with a passed `format=`, and the `exact=False` (GH8904)

## 1.20.4 Bug Fixes

- Bug in concat of Series with `category` dtype which were coercing to object. (GH8641)
- Bug in Timestamp-Timestamp not returning a Timedelta type and datelike-datelike ops with timezones (GH8865)
- Made consistent a timezone mismatch exception (either tz operated with None or incompatible timezone), will now return `TypeError` rather than `ValueError` (a couple of edge cases only), (GH8865)
- Bug in using a `pd.Grouper(key=...)` with no level/axis or level only (GH8795, GH8866)
- Report a `TypeError` when invalid/no parameters are passed in a groupby (GH8015)
- Bug in packaging pandas with py2app/cx\_Freeze (GH8602, GH8831)
- Bug in groupby signatures that didn't include `*args` or `**kwargs` (GH8733).
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)
- Bug in slicing a multi-index with an empty list and at least one boolean indexer (GH8781)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo (GH8761).
- `Timedelta` kwargs may now be numpy ints and floats (GH8757).
- Fixed several outstanding bugs for `Timedelta` arithmetic and comparisons (GH8813, GH5963, GH5436).
- `sql_schema` now generates dialect appropriate `CREATE TABLE` statements (GH8697)
- `slice` string method now takes step into account (GH8754)
- Bug in `BlockManager` where setting values with different type would break block integrity (GH8850)
- Bug in `DatetimeIndex` when using time object as key (GH8667)
- Bug in merge where `how='left'` and `sort=False` would not preserve left frame order (GH7331)
- Bug in `MultiIndex.reindex` where reindexing at level would not reorder labels (GH4088)
- Bug in certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)
- Regression in `DatetimeIndex` iteration with a Fixed/Local offset timezone (GH8890)
- Bug in `to_datetime` when parsing a nanoseconds using the `%f` format (GH8989)
- `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).
- Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)
- Fixed division by 0 when reading big csv files in python 3 (GH8621)
- Bug in outputting a Multindex with `to_html, index=False` which would add an extra column (GH8452)
- Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).
- Defined `.size` attribute across `NDFrame` objects to provide compat with numpy `>= 1.9.1`; buggy with `np.array_split` (GH8846)

- Skip testing of histogram plots for matplotlib  $\leq 1.2$  (GH8648).
- Bug where `get_data_google` returned object dtypes (GH3995)
- Bug in `DataFrame.stack(..., dropna=False)` when the `DataFrame`'s columns is a `MultiIndex` whose labels do not reference all its levels. (GH8844)
- Bug in that `Option` context applied on `__enter__` (GH8514)
- Bug in `resample` that causes a `ValueError` when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- Bug where `DataFrame.plot(kind='scatter')` fails when checking if an `np.array` is in the `DataFrame` (GH8852)
- Bug in `pd.infer_freq/DataFrame.inferred_freq` that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- Bug where index name was still used when plotting a series with `use_index=False` (GH8558).
- Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- Bug in `MultiIndex` where `__contains__` returns wrong result if index is not lexically sorted or unique (GH7724)
- BUG CSV: fix problem with trailing whitespace in skipped rows, (GH8679), (GH8661), (GH8983)
- Regression in `Timestamp` does not parse 'Z' zone designator for UTC (GH8771)
- Bug in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed `ValueError` raised by `cummin/cummax` when `datetime64` Series contains `NaT`. (GH8965)
- Bug in `Datareader` returns object dtype if there are missing values (GH8980)
- Bug in plotting if `sharex` was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
- Bug where passing a unit to the `TimedeltaIndex` constructor applied the to nano-second conversion twice. (GH9011).
- Bug in plotting of a period-like array (GH9012)

## 1.21 v0.15.1 (November 9, 2014)

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- *Enhancements*
- *API Changes*
- *Bug Fixes*

### 1.21.1 API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously -1), (GH8689)

```
In [1]: s = Series(date_range('20130101', periods=5, freq='D'))

In [2]: s.iloc[2] = np.nan

In [3]: s
Out[3]:
0    2013-01-01
1    2013-01-02
2             NaT
3    2013-01-04
4    2013-01-05
dtype: datetime64[ns]
```

previous behavior:

```
In [6]: s.dt.hour
Out[6]:
0      0
1      0
2     -1
3      0
4      0
dtype: int64
```

current behavior:

```
In [4]: s.dt.hour
Out[4]:
0      0.0
1      0.0
2      NaN
3      0.0
4      0.0
dtype: float64
```

- `groupby` with `as_index=False` will not add erroneous extra columns to result (GH8582):

```
In [5]: np.random.seed(2718281)

In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)),
...:                      columns=['jim', 'joe'])
...:

In [7]: df.head()
Out[7]:
   jim  joe
0    61   81
1    96   49
2    55   65
3    72   51
4    77   12

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))
```

previous behavior:

```
In [4]: df.groupby(ts, as_index=False).max()
Out[4]:
```

	NaN	jim	joe
0	0	72	83
1	5	77	84
2	10	96	65

current behavior:

```
In [9]: df.groupby(ts, as_index=False).max()
Out[9]:
```

	jim	joe
0	72	83
1	77	84
2	96	65

- groupby will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

```
In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})
In [11]: df
Out[11]:
```

	jim	joe
0	0	5
1	1	6
2	2	7
3	3	8
4	4	9

```
In [12]: gr = df.groupby(df['jim'] < 2)
```

previous behavior (excludes 1st column from output):

```
In [4]: gr.apply(sum)
Out[4]:
```

	joe
jim	
False	24
True	11

current behavior:

```
In [13]: gr.apply(sum)
Out[13]:
```

	jim	joe
jim		
False	9	24
True	1	11

- Support for slicing with monotonic decreasing indexes, even if start or stop is not found in the index (GH7860):

```
In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])
In [15]: s
Out[15]:
```

	a
4	a

(continues on next page)

(continued from previous page)

```
3    b
2    c
1    d
dtype: object
```

previous behavior:

```
In [8]: s.loc[3.5:1.5]
KeyError: 3.5
```

current behavior:

```
In [16]: s.loc[3.5:1.5]
Out[16]:
3    b
2    c
dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page ([GH8612](#)), ([GH8741](#))

**Note:** As a result of a change in Yahoo's option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsSMMYY` and `putsSMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```
In [17]: from pandas.io.data import Options

In [18]: aapl = Options('aapl', 'yahoo')

In [19]: aapl.get_call_data().iloc[0:5,0:1]
Out[19]:
```

Strike	Expiry	Type	Symbol	Last
80	2014-11-14	call	AAPL141114C00080000	29.05
84	2014-11-14	call	AAPL141114C00084000	24.80
85	2014-11-14	call	AAPL141114C00085000	24.05
86	2014-11-14	call	AAPL141114C00086000	22.76
87	2014-11-14	call	AAPL141114C00087000	21.74

```
In [20]: aapl.expiry_dates
Out[20]:
[datetime.date(2014, 11, 14),
```

(continues on next page)

(continued from previous page)

```

datetime.date(2014, 11, 22),
datetime.date(2014, 11, 28),
datetime.date(2014, 12, 5),
datetime.date(2014, 12, 12),
datetime.date(2014, 12, 20),
datetime.date(2015, 1, 17),
datetime.date(2015, 2, 20),
datetime.date(2015, 4, 17),
datetime.date(2015, 7, 17),
datetime.date(2016, 1, 15),
datetime.date(2017, 1, 20)]

```

```
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5,0:1]
```

```
Out [21]:
```

	Strike	Expiry	Type	Symbol	Last
109		2014-11-22	call	AAPL141122C00109000	1.48
		2014-11-28	call	AAPL141128C00109000	1.79
110		2014-11-14	call	AAPL141114C00110000	0.55
		2014-11-22	call	AAPL141122C00110000	1.02
		2014-11-28	call	AAPL141128C00110000	1.32

- pandas now also registers the `datetime64` dtype in matplotlib's units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` ([GH8614](#)).

## 1.21.2 Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter ([GH8645](#)):

```
In [17]: from collections import deque
```

```
In [18]: df1 = pd.DataFrame([1, 2, 3])
```

```
In [19]: df2 = pd.DataFrame([4, 5, 6])
```

previous behavior:

```
In [7]: pd.concat(deque((df1, df2)))
```

```
TypeError: first argument must be a list-like of pandas objects, you passed an_
↪object of type "deque"
```

current behavior:

```
In [20]: pd.concat(deque((df1, df2)))
```

```
Out [20]:
```

```

0
0 1
1 2
2 3
0 4
1 5
2 6

```

- Represent `MultiIndex` labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the *reported* memory usage was incorrect as it didn't show the usage for the memory occupied by the underlying data array. (GH8456)

```
In [21]: dfi = DataFrame(1, index=pd.MultiIndex.from_product(['a'], range(1000)),
↳ columns=['A'])
```

previous behavior:

```
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out [1]:
Index      8000 # took about 24008 bytes in < 0.15.1
A          8000
dtype: int64
```

current behavior:

```
In [22]: dfi.memory_usage(index=True)
Out [22]:
Index      52080
A          8000
dtype: int64
```

- Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).
- Added option to select columns when importing Stata files (GH7935)
- Qualify memory usage in `DataFrame.info()` by adding + if it is a lower bound (GH8578)
- Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).
- Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)
- World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank's JSON response. In prior versions, the error messages didn't look at the World Bank's JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
- Added option to `Series.str.split()` to return a `DataFrame` rather than a `Series` (GH8428)
- Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)

### 1.21.3 Bug Fixes

- Bug in unpickling of a `CustomBusinessDay` object (GH8591)
- Bug in coercing `Categorical` to a records array, e.g. `df.to_records()` (GH8626)
- Bug in `Categorical` not created properly with `Series.to_frame()` (GH8626)
- Bug in coercing in `astype` of a `Categorical` of a passed `pd.Categorical` (this now raises `TypeError` correctly), (GH8626)
- Bug in `cut/qcut` when using `Series` and `retbins=True` (GH8589)
- Bug in writing `Categorical` columns to an SQL database with `to_sql` (GH8624).

- Bug in comparing `Categorical` of datetime raising when being compared to a scalar datetime (GH8687)
- Bug in selecting from a `Categorical` with `.iloc` (GH8623)
- Bug in groupby-transform with a `Categorical` (GH8623)
- Bug in duplicated/drop\_duplicates with a `Categorical` (GH8623)
- Bug in `Categorical` reflected comparison operator raising if the first argument was a numpy array scalar (e.g. `np.int64`) (GH8658)
- Bug in Panel indexing with a list-like (GH8710)
- Compat issue is `DataFrame.dtypes` when `options.mode.use_inf_as_null` is `True` (GH8722)
- Bug in `read_csv`, `dialect` parameter would not take a string (GH8703)
- Bug in slicing a multi-index level with an empty-list (GH8737)
- Bug in numeric index operations of add/sub with `Float/Int Index` with numpy arrays (GH8608)
- Bug in `setitem` with empty indexer and unwanted coercion of dtypes (GH8669)
- Bug in `ix/loc` block splitting on `setitem` (manifests with integer-like dtypes, e.g. `datetime64`) (GH8607)
- Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
- Bug when indexing a `Float64Index` with `np.nan` on numpy 1.7 (GH8980).
- Fix `shape` attribute for `MultiIndex` (GH8609)
- Bug in `GroupBy` where a name conflict between the grouper and columns would break groupby operations (GH7115, GH8112)
- Fixed a bug where plotting a column `y` and specifying a label would mutate the index name of the original `DataFrame` (GH8494)
- Fix regression in plotting of a `DatetimeIndex` directly with `matplotlib` (GH8614).
- Bug in `date_range` where partially-specified dates would incorporate current date (GH6961)
- Bug in Setting by indexer to a scalar value with a mixed-dtype `Panel4d` was failing (GH8702)
- Bug where `DataReader`'s would fail if one of the symbols passed was invalid. Now returns data for valid symbols and `np.nan` for invalid (GH8494)
- Bug in `get_quote_yahoo` that wouldn't allow non-float return values (GH5229).

## 1.22 v0.15.0 (October 18, 2014)

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.15.0 will no longer support compatibility with NumPy versions < 1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy >= 1.7.0 (GH7711)

- Highlights include:
  - The `Categorical` type was integrated as a first-class pandas type, see [here](#)
  - New scalar type `Timedelta`, and a new index type `TimedeltaIndex`, see [here](#)

- New datetimelike properties accessor `.dt` for Series, see [Datetimelike Properties](#)
  - New DataFrame default display for `df.info()` to include memory usage, see [Memory Usage](#)
  - `read_csv` will now by default ignore blank lines when parsing, see [here](#)
  - API change in using Indexes in set operations, see [here](#)
  - Enhancements in the handling of timezones, see [here](#)
  - A lot of improvements to the rolling and expanding moment functions, see [here](#)
  - Internal refactoring of the `Index` class to no longer sub-class `ndarray`, see [Internal Refactoring](#)
  - dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)
  - Split indexing documentation into [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#)
  - Split out string methods documentation into [Working with Text Data](#)
- Check the [API Changes](#) and [deprecations](#) before updating
  - [Other Enhancements](#)
  - [Performance Improvements](#)
  - [Bug Fixes](#)

**Warning:** In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the [Internal Refactoring](#))

**Warning:** The refactorings in [Categorical](#) changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use [Categorical](#) directly, please audit your code before updating to this pandas version and change it to use the `from_codes()` constructor. See more on [Categorical](#) [here](#)

## 1.22.1 New features

### 1.22.1.1 Categoricals in Series/DataFrame

[Categorical](#) can now be included in *Series* and *DataFrames* and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the [categorical introduction](#) and the [API documentation](#).

```
In [1]: df = DataFrame({"id": [1, 2, 3, 4, 5, 6], "raw_grade": ['a', 'b', 'b', 'a', 'a', 'e']})
In [2]: df["grade"] = df["raw_grade"].astype("category")
In [3]: df["grade"]
Out[3]:
0    a
1    b
```

(continues on next page)

(continued from previous page)

```

2     b
3     a
4     a
5     e
Name: grade, dtype: category
Categories (3, object): [a, b, e]

# Rename the categories
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

# Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",
↳ "good", "very good"])

In [6]: df["grade"]
Out[6]:
0     very good
1         good
2         good
3     very good
4     very good
5     very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

In [7]: df.sort_values("grade")
////////////////////////////////////
↳
   id raw_grade  grade
5   6         e  very bad
1   2         b    good
2   3         b    good
0   1         a  very good
3   4         a  very good
4   5         a  very good

In [8]: df.groupby("grade").size()
////////////////////////////////////
↳
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64

```

- `pandas.core.groupby` and `pandas.core.factor_agg` were removed. As an alternative, construct a dataframe and use `df.groupby(<group>).agg(<func>)`.
- Supplying “codes/labels and levels” to the *Categorical* constructor is not supported anymore. Supplying two arguments to the constructor is now interpreted as “values and levels (now called ‘categories’)”. Please change your code to use the *from\_codes()* constructor.
- The `Categorical.labels` attribute was renamed to `Categorical.codes` and is read only. If you want to manipulate codes, please use one of the *API methods on Categoricals*.
- The `Categorical.levels` attribute is renamed to `Categorical.categories`.

### 1.22.1.2 TimedeltaIndex/Scalar

We introduce a new scalar type `Timedelta`, which is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes. This type is very similar to how `Timestamp` works for datetimes. It is a nice-API box for the type. See the *docs*. ([GH3009](#), [GH4533](#), [GH8209](#), [GH8187](#), [GH8190](#), [GH7869](#), [GH7661](#), [GH8345](#), [GH8471](#))

**Warning:** `Timedelta` scalars (and `TimedeltaIndex`) component fields are *not the same* as the component fields on a `datetime.timedelta` object. For example, `.seconds` on a `datetime.timedelta` object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas `Timedelta` breaks out hours, minutes, microseconds and nanoseconds separately.

```
# Timedelta accessor
In [9]: tds = Timedelta('31 days 5 min 3 sec')

In [10]: tds.minutes
Out[10]: 5L

In [11]: tds.seconds
Out[11]: 3L

# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
```

**Note:** this is no longer true starting from v0.16.0, where full compatibility with `datetime.timedelta` is introduced. See the [0.16.0 whatsnew entry](#)

**Warning:** Prior to 0.15.0 `pd.to_timedelta` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

The arguments to `pd.to_timedelta` are now `(arg, unit='ns', box=True, coerce=False)`, previously were `(arg, box=True, unit='ns')` as these are more logical.

Construct a scalar

```
In [9]: Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: Timedelta('15.5us')
\\Out[10]: Timedelta('0 days 00:00:00.000015
↪')

In [11]: Timedelta('1 hour 15.5us')
\\Out[11]:
↪Timedelta('0 days 01:00:00.000015')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: Timedelta('-1us')
\\
↪Timedelta('-1 days +23:59:59.999999')
```

(continues on next page)

(continued from previous page)

```
# a NaT
In [13]: Timedelta('nan')
////////////////////////////////////
↪NaT
```

## Access fields for a Timedelta

```
In [14]: td = Timedelta('1 hour 3m 15.5us')
```

```
In [15]: td.seconds
```

Out[15]: 3780

```
In [16]: td.microseconds
```

```
Out[16]: 16
```

```
In [17]: td.nanoseconds
```

```
Out[17]: 500
```

## Construct a TimedeltaIndex

```
In [18]: TimedeltaIndex(['1 days', '1 days, 00:00:05',
.....:                  np.timedelta64(2, 'D'), timedelta(days=2, seconds=2)])
.....:
```

Out [18] :

```
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
               '2 days 00:00:02'],
              dtype='timedelta64[ns]', freq=None)
```

## Constructing a TimedeltaIndex with a regular range

```
In [19]: timedelta_range('1 days', periods=5, freq='D')
```

```
Out[19]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
→ 'timedelta64[ns]', freq='D')
```

```
In [20]: timedelta_range(start='1 days', end='2 days', freq='30T')
```

```
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='30T')
```

You can now use a `TimedeltaIndex` as the index of a pandas object

```
In [21]: s = Series(np.arange(5),
.....:             index=timedelta_range('1 days', periods=5, freq='s'))
.....:

In [22]: s
Out[22]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
1 days 00:00:03    3
1 days 00:00:04    4
Freq: S, dtype: int64
```

You can select with partial string selections

```
In [23]: s['1 day 00:00:02']
Out[23]: 2

In [24]: s['1 day':'1 day 00:00:02']
Out[24]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
Freq: S, dtype: int64
```

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```
In [25]: tdi = TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [27]: dti = date_range('20130101', periods=3)

In [28]: dti.tolist()
Out[28]: [Timestamp('2013-01-01 00:00:00', freq='D'),
Timestamp('2013-01-02 00:00:00', freq='D'),
Timestamp('2013-01-03 00:00:00', freq='D')]

In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

- iteration of a Series e.g. `list(Series(...))` of `timedelta64[ns]` would prior to v0.15.0 return `np.timedelta64` for each element. These will now be wrapped in `Timedelta`.

### 1.22.1.3 Memory Usage

Implemented methods to find memory usage of a `DataFrame`. See the [FAQ](#) for more. ([GH6852](#)).

A new display option `display.memory_usage` (see [Options and Settings](#)) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
.....:           'complex128', 'object', 'bool']
.....:

In [32]: n = 5000

In [33]: data = dict([ (t, np.random.randint(100, size=n).astype(t))
.....:                  for t in dtypes])
.....:

In [34]: df = DataFrame(data)

In [35]: df['categorical'] = df['object'].astype('category')

In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64          5000 non-null int64
float64        5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128     5000 non-null complex128
object         5000 non-null object
bool          5000 non-null bool
categorical    5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
↳ object(1), timedelta64[ns](1)
memory usage: 289.1+ KB
```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```
In [37]: df.memory_usage(index=True)
Out[37]:
Index          80
int64         40000
float64       40000
datetime64[ns] 40000
timedelta64[ns] 40000
complex128    80000
object        40000
bool          5000
categorical   10920
dtype: int64
```

#### 1.22.1.4 .dt accessor

`Series` has gained an accessor to succinctly return datetime like properties for the *values* of the `Series`, if its a datetime/period like `Series`. (GH7207) This will return a `Series`, indexed like the existing `Series`. See the [docs](#)

```
# datetime
In [38]: s = Series(date_range('20130101 09:10:12', periods=4))
```

(continues on next page)

(continued from previous page)

```
In [39]: s
Out[39]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
dtype: datetime64[ns]
```

```
In [40]: s.dt.hour
```

```

////////////////////////////////////
↪
0     9
1     9
2     9
3     9
dtype: int64
```

```
In [41]: s.dt.second
```

```

////////////////////////////////////
↪
0    12
1    12
2    12
3    12
dtype: int64
```

```
In [42]: s.dt.day
```

```

////////////////////////////////////
↪
0     1
1     2
2     3
3     4
dtype: int64
```

```
In [43]: s.dt.freq
```

```

////////////////////////////////////
↪ 'D'
```

This enables nice expressions like this:

```
In [44]: s[s.dt.day==2]
Out[44]:
1    2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produce tz aware transformations:

```
In [45]: stz = s.dt.tz_localize('US/Eastern')

In [46]: stz
Out[46]:
0    2013-01-01 09:10:12-05:00
1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
```

(continues on next page)

(continued from previous page)

dtype: timedelta64[ns]

**In [55]:** s.dt.days

```

////////////////////////////////////
↪
0    1
1    1
2    1
3    1
dtype: int64

```

**In [56]:** s.dt.seconds

```

////////////////////////////////////
↪
0    5
1    6
2    7
3    8
dtype: int64

```

**In [57]:** s.dt.components

```

////////////////////////////////////
↪
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0      1      0         0         5              0              0              0
1      1      0         0         6              0              0              0
2      1      0         0         7              0              0              0
3      1      0         0         8              0              0              0

```

### 1.22.1.5 Timezone handling improvements

- `tz_localize(None)` for `tz`-aware `Timestamp` and `DatetimeIndex` now removes timezone holding local time, previously this resulted in `Exception` or `TypeError` ([GH7812](#))

**In [58]:** ts = Timestamp('2014-08-01 09:00', tz='US/Eastern')**In [59]:** ts**Out [59]:** Timestamp('2014-08-01 09:00:00-0400', tz='US/Eastern')**In [60]:** ts.tz\_localize(None)

```

////////////////////////////////////Out [60]: ↪
↪Timestamp('2014-08-01 09:00:00')

```

**In [61]:** didx = DatetimeIndex(start='2014-08-01 09:00', freq='H', periods=10, tz='US/Eastern')

**In [62]:** didx**Out [62]:**

```

DatetimeIndex(['2014-08-01 09:00:00-04:00', '2014-08-01 10:00:00-04:00',
              '2014-08-01 11:00:00-04:00', '2014-08-01 12:00:00-04:00',
              '2014-08-01 13:00:00-04:00', '2014-08-01 14:00:00-04:00',
              '2014-08-01 15:00:00-04:00', '2014-08-01 16:00:00-04:00',
              '2014-08-01 17:00:00-04:00', '2014-08-01 18:00:00-04:00'],
              dtype='datetime64[ns, US/Eastern]', freq='H')

```

(continues on next page)

(continued from previous page)

```
In [63]: didx.tz_localize(None)
////////////////////////////////////
↪
DatetimeIndex(['2014-08-01 09:00:00', '2014-08-01 10:00:00',
              '2014-08-01 11:00:00', '2014-08-01 12:00:00',
              '2014-08-01 13:00:00', '2014-08-01 14:00:00',
              '2014-08-01 15:00:00', '2014-08-01 16:00:00',
              '2014-08-01 17:00:00', '2014-08-01 18:00:00'],
              dtype='datetime64[ns]', freq='H')
```

- `tz_localize` now accepts the ambiguous keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, 'NaT' for setting transition times to NaT, 'infer' for inferring DST/non-DST, and 'raise' (default) for an `AmbiguousTimeError` to be raised. See [the docs](#) for more details ([GH7943](#))
- `DataFrame.tz_localize` and `DataFrame.tz_convert` now accepts an optional `level` argument for localizing a specific level of a `MultiIndex` ([GH7846](#))
- `Timestamp.tz_localize` and `Timestamp.tz_convert` now raise `TypeError` in error cases, rather than `Exception` ([GH8025](#))
- a timeseries/index localized to UTC when inserted into a `Series/DataFrame` will preserve the UTC timezone (rather than being a naive `datetime64[ns]`) as object `dtype` ([GH8411](#))
- `Timestamp.__repr__` displays `dateutil.tz.tzoffset` info ([GH7907](#))

### 1.22.1.6 Rolling/Expanding Moments improvements

- `rolling_min()`, `rolling_max()`, `rolling_cov()`, and `rolling_corr()` now return objects with all NaN when `len(arg) < min_periods <= window` rather than raising. (This makes all rolling functions consistent in this behavior). ([GH7766](#))

Prior to 0.15.0

```
In [64]: s = Series([10, 11, 12, 13])
```

```
In [15]: rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)
```

New behavior

```
In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out[4]:
0    NaN
1    NaN
2    NaN
3    NaN
dtype: float64
```

- `rolling_max()`, `rolling_min()`, `rolling_sum()`, `rolling_mean()`, `rolling_median()`, `rolling_std()`, `rolling_var()`, `rolling_skew()`, `rolling_kurt()`, `rolling_quantile()`, `rolling_cov()`, `rolling_corr()`, `rolling_corr_pairwise()`, `rolling_window()`, and `rolling_apply()` with `center=True` previously would return a result of the same structure as the input `arg` with NaN in the final  $(window-1)/2$  entries.

Now the final  $(window-1)/2$  entries of the result are calculated as if the input `arg` were followed by  $(window-1)/2$  NaN values (or with shrinking windows, in the case of `rolling_apply()`). ([GH7925](#), [GH8269](#))

Prior behavior (note final value is NaN):

```
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out [7]:
0      1
1      3
2      6
3     NaN
dtype: float64
```

New behavior (note final value is 5 = sum([2, 3, NaN])):

```
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
Out [7]:
0      1
1      3
2      6
3      5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode (`mean=True`) so that the calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated without weighting (i.e. ‘boxcar’). See [the note on normalization](#) for further details. (GH7618)

```
In [65]: s = Series([10.5, 8.8, 11.4, 9.7, 9.3])
```

Behavior prior to 0.15.0:

```
In [39]: rolling_window(s, window=3, win_type='triang', center=True)
Out [39]:
0      NaN
1    6.583333
2    6.883333
3    6.683333
4      NaN
dtype: float64
```

New behavior

```
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
Out [10]:
0      NaN
1    9.875
2   10.325
3   10.025
4      NaN
dtype: float64
```

- Removed `center` argument from all `expanding_` functions (see [list](#)), as the results produced when `center=True` did not make much sense. (GH7925)
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. (GH8279)
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and `rolling_std()`. These functions’ support of a `ddof` argument (with a default value of 1) was previously undocumented. (GH8064)

- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*`() and `expanding_*`() functions do: a given result entry will be NaN if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to NaN the `min_periods` entries starting with the first non- NaN value. (GH7977)

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```
In [66]: s = Series([1, None, None, None, 2, 3])
```

```
In [51]: ewma(s, com=3., min_periods=2)
```

```
Out [51]:
0      NaN
1      NaN
2    1.000000
3    1.000000
4    1.571429
5    2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```
In [2]: pd.ewma(s, com=3., min_periods=2)
```

```
Out [2]:
0      NaN
1      NaN
2      NaN
3      NaN
4    1.759644
5    2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See *Exponentially weighted moment functions* for details. (GH7911)
- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```
In [7]: pd.ewma(Series([None, 1., 8.]), com=2.)
```

```
Out [7]:
0      NaN
1     1.0
2     5.2
dtype: float64
```

```
In [8]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=True) # pre-0.15.0
↪behavior
```

```
Out [8]:
0     1.0
1     1.0
2     5.2
dtype: float64
```

```
In [9]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=False) # new default
```

(continues on next page)

(continued from previous page)

```
Out [9]:
0      1.000000
1      1.000000
2      5.846154
dtype: float64
```

**Warning:** By default (`ignore_na=False`) the `ewm*()` functions' weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly `ignore_na=True`.

- Bug in `expanding_cov()`, `expanding_corr()`, `rolling_cov()`, `rolling_cor()`, `ewmcov()`, and `ewmcorr()` returning results with columns sorted by name and producing an error for non-unique columns; now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with `pairwise=False`, where behavior is unchanged) (GH7542)
- Bug in `rolling_count()` and `expanding_*()` functions unnecessarily producing error message for zero-length data (GH8056)
- Bug in `rolling_apply()` and `expanding_apply()` interpreting `min_periods=0` as `min_periods=1` (GH8080)
- Bug in `expanding_std()` and `expanding_var()` for a single value producing a confusing error message (GH7900)
- Bug in `rolling_std()` and `rolling_var()` for a single value producing 0 rather than NaN (GH7900)
- Bug in `ewmstd()`, `ewmvol()`, `ewmvar()`, and `ewmcov()` calculation of de-biasing factors when `bias=False` (the default). Previously an incorrect constant factor was used, based on `adjust=True`, `ignore_na=True`, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual  $N/(N-1)$  factor). In particular, for a single point a value of NaN is returned when `bias=False`, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for `ewmvar(..., bias=False)`, and the corresponding debiasing factors:

```
In [67]: s = Series([1., 2., 0., 4.])
```

```
In [89]: ewmvar(s, com=2., bias=False)
```

```
Out [89]:
0      -2.775558e-16
1       3.000000e-01
2       9.556787e-01
3       3.585799e+00
dtype: float64
```

```
In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
```

```
Out [90]:
0       1.25
1       1.25
2       1.25
3       1.25
dtype: float64
```

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):

```

In [14]: pd.ewmvar(s, com=2., bias=False)
Out[14]:
0      NaN
1    0.500000
2    1.210526
3    4.089069
dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out[15]:
0      NaN
1    2.083333
2    1.583333
3    1.425439
dtype: float64

```

See *Exponentially weighted moment functions* for details. (GH7912)

### 1.22.1.7 Improvements in the sql io module

- Added support for a `chunksize` parameter to `to_sql` function. This allows `DataFrame` to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a `schema` to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

```

df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')

```

- Added support for writing `NaN` values with `to_sql` (GH2754).
- Added support for writing `datetime64` columns with `to_sql` for all database flavors (GH7103).

## 1.22.2 Backwards incompatible API changes

### 1.22.2.1 Breaking changes

API changes related to `Categorical` (see [here](#) for more details):

- The `Categorical` constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

An old function call like (prior to 0.15.0):

```
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:

```
In [2]: pd.Categorical.from_codes([0,1,0,2,1], categories=['a', 'b', 'c'])
Out[2]:
[a, b, a, c, b]
Categories (3, object): [a, b, c]
```

API changes related to the introduction of the Timedelta scalar (see [above](#) for more details):

- Prior to 0.15.0 `to_timedelta()` would return a `Series` for list-like/`Series` input, and a `np.timedelta64` for scalar input. It will now return a `TimedeltaIndex` for list-like input, `Series` for `Series` input, and `Timedelta` for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview [above](#).

Other notable API changes:

- Consistency when indexing with `.loc` and a list-like indexer when no values are found.

```
In [68]: df = DataFrame(['a'], ['b'], index=[1,2])

In [69]: df
Out[69]:
0
1  a
2  b
```

In prior versions there was a difference in these two constructs:

- `df.loc[[3]]` would return a frame reindexed by 3 (with all `np.nan` values)
- `df.loc[[3],:]` would raise `KeyError`.

Both will now raise a `KeyError`. The rule is that *at least 1* indexer must be found when using a list-like and `.loc` ([GH7999](#))

Furthermore in prior versions these were also different:

- `df.loc[[1,3]]` would return a frame reindexed by [1,3]
- `df.loc[[1,3],:]` would raise `KeyError`.

Both will now return a frame reindex by [1,3]. E.g.

```
In [3]: df.loc[[1,3]]
Out[3]:
0
1  a
3 NaN

In [4]: df.loc[[1,3],:]
Out[4]:
0
1  a
3 NaN
```

This can also be seen in multi-axis indexing with a `Panel`.

```
In [70]: p = Panel(np.arange(2*3*4).reshape(2,3,4),
.....:             items=['ItemA', 'ItemB'],
.....:             major_axis=[1,2,3],
.....:             minor_axis=['A', 'B', 'C', 'D'])
.....:
```

(continues on next page)

(continued from previous page)

```
In [71]: p
Out[71]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D
```

The following would raise `KeyError` prior to 0.15.0:

```
In [5]:
Out[5]:
```

	ItemA	ItemD
1	3	NaN
2	7	NaN
3	11	NaN

Furthermore, `.loc` will raise `KeyError` if no values are found in a multi-index with a list-like indexer:

[illegible]

- Assigning values to `None` now considers the dtype when choosing an ‘empty’ value ([GH7941](#)).

Previously, assigning to `None` in numeric containers changed the dtype to object (or errored, depending on the call). It now uses `NaN`:

```
In [75]: s = Series([1, 2, 3])

In [76]: s.loc[0] = None

In [77]: s
Out[77]:
0      NaN
1      2.0
2      3.0
dtype: float64
```

NaT is now used similarly for datetime containers.

For object containers, we now preserve `None` values (previously these were converted to NaN values).

```
In [78]: s = Series(["a", "b", "c"])

In [79]: s.loc[0] = None

In [80]: s
Out[80]:
0      None
1         b
2         c
dtype: object
```

To insert a NaN, you must explicitly use `np.nan`. See the [docs](#).

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [81]: s = Series([1, 2, 3])

In [82]: s2 = s

In [83]: s += 1.5
```

Behavior prior to v0.15.0

```
# the original object
In [5]: s
Out[5]:
0      2.5
1      3.5
2      4.5
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0      1
1      2
2      3
dtype: int64
```

This is now the correct behavior

```
# the original object
In [84]: s
Out[84]:
0      2.5
1      3.5
2      4.5
dtype: float64

# a reference to the original object
In [85]: s2
Out[85]:
0      2.5
```

(continues on next page)

(continued from previous page)

```
1    3.5
2    4.5
dtype: float64
```

- Made both the C-based and Python engines for `read_csv` and `read_table` ignore empty lines in input as well as whitespace-filled lines, as long as `sep` is not whitespace. This is an API change that can be controlled by the keyword parameter `skip_blank_lines`. See [the docs](#) (GH4466)
- A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as `object` dtype rather than being converted to a naive `datetime64[ns]` (GH8411).
- Bug in passing a `DatetimeIndex` with a timezone that was not being retained in DataFrame construction from a dict (GH7822)

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of `object` dtype:

```
In [86]: i = date_range('1/1/2011', periods=3, freq='10s', tz = 'US/Eastern')

In [87]: i
Out[87]:
DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
              '2011-01-01 00:00:20-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='10S')

In [88]: df = DataFrame( {'a' : i } )

In [89]: df
Out[89]:
           a
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00

In [90]: df.dtypes
//////////
↪
a    datetime64[ns, US/Eastern]
dtype: object
```

Previously this would have yielded a column of `datetime64` dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as `df['a'] = i` remains unchanged (this already returned an `object` column with a timezone).

- When passing multiple levels to `stack()`, it will now raise a `ValueError` when the levels aren't all level names or all level numbers (GH7660). See [Reshaping by stacking and unstacking](#).
- Raise a `ValueError` in `df.to_hdf` with 'fixed' format, if `df` has non-unique columns as the resulting file will be broken (GH7761)
- `SettingWithCopy` raise/warnings (according to the option `mode.chained_assignment`) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)

```
In [1]: df = DataFrame(np.arange(0,9), columns=['count'])

In [2]: df['group'] = 'b'
```

(continues on next page)

(continued from previous page)

```
In [3]: df.iloc[0:5]['group'] = 'a'
/usr/local/bin/ipython:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame.
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: http://pandas.pydata.org/pandas-docs/stable/
↪indexing.html#indexing-view-versus-copy
```

- `merge`, `DataFrame.merge`, and `ordered_merge` now return the same type as the left argument (GH7737).
- Previously an enlargement with a mixed-dtype frame would act unlike `.append` which will preserve dtypes (related GH2578, GH8176):

```
In [91]: df = DataFrame([[True, 1], [False, 2]],
.....:                  columns=["female", "fitness"])
.....:

In [92]: df
Out[92]:
   female  fitness
0    True         1
1   False         2

In [93]: df.dtypes
Out[93]:
female      bool
fitness    int64
dtype: object

# dtypes are now preserved
In [94]: df.loc[2] = df.loc[1]

In [95]: df
Out[95]:
   female  fitness
0    True         1
1   False         2
2   False         2

In [96]: df.dtypes
Out[96]:
female      bool
fitness    int64
dtype: object
```

- `Series.to_csv()` now returns a string when `path=None`, matching the behaviour of `DataFrame.to_csv()` (GH8215).
- `read_hdf` now raises `IOError` when a file that doesn't exist is passed in. Previously, a new, empty file was created, and a `KeyError` raised (GH7715).
- `DataFrame.info()` now ends its output with a newline character (GH8114)
- Concatenating no objects will now raise a `ValueError` rather than a bare `Exception`.
- Merge errors will now be sub-classes of `ValueError` rather than raw `Exception` (GH8501)

- `DataFrame.plot` and `Series.plot` keywords are now have consistent orders (GH8037)

### 1.22.2.2 Internal Refactoring

In 0.15.0 `Index` has internally been refactored to no longer sub-class `ndarray` but instead subclass `PandasObject`, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (GH5080, GH7439, GH7796, GH8024, GH8367, GH7997, GH8522):

- you may need to unpickle pandas version < 0.15.0 pickles using `pd.read_pickle` rather than `pickle.load`. See [pickle docs](#)
- when plotting with a `PeriodIndex`, the matplotlib internal axes will now be arrays of `Period` rather than a `PeriodIndex` (this is similar to how a `DatetimeIndex` passes arrays of datetimes now)
- `MultiIndexes` will now raise similarly to other pandas objects w.r.t. truth testing, see [here](#) (GH7897).
- When plotting a `DatetimeIndex` directly with matplotlib's `plot` function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a `datetime64`). **UPDATE** This is fixed in 0.15.1, see [here](#).

### 1.22.2.3 Deprecations

- The attributes `Categorical.labels` and `levels` attributes are deprecated and renamed to `codes` and `categories`.
- The `outtype` argument to `pd.DataFrame.to_dict` has been deprecated in favor of `orient`. (GH7840)
- The `convert_dummies` method has been deprecated in favor of `get_dummies` (GH8140)
- The `infer_dst` argument in `tz_localize` will be deprecated in favor of `ambiguous` to allow for more flexibility in dealing with DST transitions. Replace `infer_dst=True` with `ambiguous='infer'` for the same behavior (GH7943). See [the docs](#) for more details.
- The top-level `pd.value_range` has been deprecated and can be replaced by `.describe()` (GH8481)
- The `Index` set operations `+` and `-` were deprecated in order to provide these for numeric type operations on certain index types. `+` can be replaced by `.union()` or `|`, and `-` by `.difference()`. Further the method name `Index.diff()` is deprecated and can be replaced by `Index.difference()` (GH8226)

```
# +
Index(['a', 'b', 'c']) + Index(['b', 'c', 'd'])

# should be replaced by
Index(['a', 'b', 'c']).union(Index(['b', 'c', 'd']))
```

```
# -
Index(['a', 'b', 'c']) - Index(['b', 'c', 'd'])

# should be replaced by
Index(['a', 'b', 'c']).difference(Index(['b', 'c', 'd']))
```

- The `infer_types` argument to `read_html()` now has no effect and is deprecated (GH7762, GH7032).

### 1.22.2.4 Removal of prior version deprecations/changes

- Remove `DataFrame.delevel` method in favor of `DataFrame.reset_index`

- Added support for bool, uint8, uint16 and uint32 datatypes in `to_stata` ([GH7097](#), [GH7365](#))
- Added conversion option when importing Stata files ([GH8527](#))
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError`. ([GH7858](#))
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to `True`. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have object data type. ([GH8045](#))

- Added layout keyword to `DataFrame.plot`. You can pass a tuple of (rows, columns), one of which can be -1 to automatically infer ([GH6667](#), [GH8071](#)).
- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` ([GH5353](#), [GH6970](#), [GH7069](#))
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` ([GH7780](#))
- Histogram from `DataFrame.plot` with `kind='hist'` ([GH7809](#)), See [the docs](#).
- Boxplot from `DataFrame.plot` with `kind='box'` ([GH7998](#)), See [the docs](#).

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see [here](#) (GH8002, GH8044)
- Added `searchsorted` method to `Series` objects (GH7447)
- `describe()` on mixed-types `DataFrames` is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See the [docs](#) (GH8164).

```

      catA catB      numC
count    24   24  24.000000
unique     2    4         NaN
top      foo   a         NaN
freq     16    6         NaN

```

## Chapter 1. What's New

(continued from previous page)

mean	NaN	NaN	11.500000
std	NaN	NaN	7.071068
min	NaN	NaN	0.000000
25%	NaN	NaN	5.750000
50%	NaN	NaN	11.500000
75%	NaN	NaN	17.250000
max	NaN	NaN	23.000000

Requesting all columns is possible with the shorthand 'all'

```
In [100]: df.describe(include='all')
Out[100]:
```

	catA	catB	numC	numD
count	24	24	24.000000	24.000000
unique	2	4	NaN	NaN
top	foo	a	NaN	NaN
freq	16	6	NaN	NaN
mean	NaN	NaN	11.500000	12.000000
std	NaN	NaN	7.071068	7.071068
min	NaN	NaN	0.000000	0.500000
25%	NaN	NaN	5.750000	6.250000
50%	NaN	NaN	11.500000	12.000000
75%	NaN	NaN	17.250000	17.750000
max	NaN	NaN	23.000000	23.500000

Without those arguments, describe will behave as before, including only numerical columns or, if none are, only categorical columns. See also the [docs](#)

- Added split as an option to the orient argument in `pd.DataFrame.to_dict`. ([GH7840](#))
- The `get_dummies` method can now be used on DataFrames. By default only catagorical columns are encoded as 0's and 1's, while other columns are left untouched.

```
In [101]: df = DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                  'C': [1, 2, 3]})
.....:

In [102]: pd.get_dummies(df)
Out[102]:
```

	C	A_a	A_b	B_b	B_c
0	1	1	0	0	1
1	2	0	1	0	1
2	3	1	0	1	0

- `PeriodIndex` supports resolution as the same as `DatetimeIndex` ([GH7708](#))
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays ([GH7070](#))
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 ([GH7070](#))
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter ([GH7070](#))
- `GroupBy.nth()` now supports selecting multiple nth values ([GH7910](#))

```
In [103]: business_dates = date_range(start='4/1/2014', end='6/30/2014', freq='B')

In [104]: df = DataFrame(1, index=business_dates, columns=['a', 'b'])
```

(continues on next page)

(continued from previous page)

```
# get the first, 4th, and last date index for each month
In [105]: df.groupby((df.index.year, df.index.month)).nth([0, 3, -1])
Out[105]:
```

	a	b
2014 4	1	1
4	1	1
4	1	1
5	1	1
5	1	1
5	1	1
6	1	1
6	1	1
6	1	1

- Period and PeriodIndex supports addition/subtraction with timedelta-like (GH7966)

If Period freq is D, H, T, S, L, U, N, Timedelta-like can be added if the result can have same freq. Otherwise, only the same offsets can be added.

```
In [106]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
In [107]: idx
Out[107]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

In [108]: idx + pd.offsets.Hour(2)
↪
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [109]: idx + Timedelta('120m')
↪
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
            '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [110]: idx = pd.period_range('2014-07', periods=5, freq='M')
In [111]: idx
Out[111]: PeriodIndex(['2014-07', '2014-08', '2014-09', '2014-10', '2014-11'],
↪ dtype='period[M]', freq='M')

In [112]: idx + pd.offsets.MonthEnd(3)
↪
PeriodIndex(['2014-10', '2014-11', '2014-12', '2015-01', '2015-02'], dtype=
↪ 'period[M]', freq='M')
```

- Added experimental compatibility with openpyxl for versions >= 2.0. The DataFrame.to\_excel method engine keyword now recognizes openpyxl1 and openpyxl2 which will explicitly require openpyxl v1 and v2 respectively, failing if the requested version is not available. The openpyxl engine is now a meta-engine that automatically uses whichever version of openpyxl is installed. (GH7177)

- `DataFrame.fillna` can now accept a `DataFrame` as a fill value ([GH8377](#))
- Passing multiple levels to `stack()` will now work when multiple level numbers are passed ([GH7660](#)). See *Reshaping by stacking and unstacking*.
- `set_names()`, `set_labels()`, and `set_levels()` methods now take an optional `level` keyword argument to all modification of specific level(s) of a `MultiIndex`. Additionally `set_names()` now accepts a scalar string value when operating on an `Index` or on a specific level of a `MultiIndex` ([GH7792](#))

```
In [113]: idx = MultiIndex.from_product(['a'], range(3), list("pqr")), names=[
↳ 'foo', 'bar', 'baz'])

In [114]: idx.set_names('qux', level=0)
Out[114]:
MultiIndex(levels=[['a'], [0, 1, 2], ['p', 'q', 'r']],
            labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0,
↳ 1, 2, 0, 1, 2, 0, 1, 2]],
            names=['qux', 'bar', 'baz'])

In [115]: idx.set_names(['qux', 'corge'], level=[0,1])
↳
MultiIndex(levels=[['a'], [0, 1, 2], ['p', 'q', 'r']],
            labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0,
↳ 1, 2, 0, 1, 2, 0, 1, 2]],
            names=['qux', 'corge', 'baz'])

In [116]: idx.set_levels(['a', 'b', 'c'], level='bar')
↳
MultiIndex(levels=[['a'], ['a', 'b', 'c'], ['p', 'q', 'r']],
            labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0,
↳ 1, 2, 0, 1, 2, 0, 1, 2]],
            names=['foo', 'bar', 'baz'])

In [117]: idx.set_levels(['a', 'b', 'c'], [1,2,3], level=[1,2])
↳
MultiIndex(levels=[['a'], ['a', 'b', 'c'], [1, 2, 3]],
            labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0,
↳ 1, 2, 0, 1, 2, 0, 1, 2]],
            names=['foo', 'bar', 'baz'])
```

- `Index.isin` now supports a `level` argument to specify which index level to use for membership tests ([GH7892](#), [GH7890](#))

```
In [1]: idx = MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [2]: idx.values
Out[2]: array([(0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
↳ dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]: array([ True, False,  True,  True, False,  True], dtype=bool)
```

- `Index` now supports duplicated and `drop_duplicates`. ([GH4060](#))

```
In [118]: idx = Index([1, 2, 3, 4, 1, 2])
```

(continues on next page)

(continued from previous page)

```

In [119]: idx
Out[119]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [120]: idx.duplicated()
Out[120]: array([False,  1
↪False, False, False,  True,  True], dtype=bool)

In [121]: idx.drop_duplicates()
Out[121]: Int64Index([1, 2, 3, 4], dtype='int64')

```

- add `copy=True` argument to `pd.concat` to enable pass thru of complete blocks (GH8252)
- Added support for numpy 1.8+ data types (`bool_`, `int_`, `float_`, `string_`) for conversion to R dataframe (GH8400)

## 1.22.4 Performance

- Performance improvements in `DatetimeIndex.__iter__` to allow faster iteration (GH7683)
- Performance improvements in `Period` creation (and `PeriodIndex.setitem`) (GH5155)
- Improvements in `Series.transform` for significant performance gains (revised) (GH6496)
- Performance improvements in `StataReader` when reading large files (GH8040, GH8073)
- Performance improvements in `StataWriter` when writing large files (GH8079)
- Performance and memory usage improvements in multi-key `groupby` (GH8128)
- Performance improvements in `groupby.agg` and `groupby.apply` where builtins `max/min` were not mapped to numpy/cythonized versions (GH7722)
- Performance improvement in writing to sql (`to_sql`) of up to 50% (GH8208).
- Performance benchmarking of `groupby` for large value of `ngroups` (GH6787)
- Performance improvement in `CustomBusinessDay`, `CustomBusinessMonth` (GH8236)
- Performance improvement for `MultiIndex.values` for multi-level indexes containing datetimes (GH8543)

## 1.22.5 Bug Fixes

- Bug in `pivot_table`, when using margins and a dict `aggfunc` (GH8349)
- Bug in `read_csv` where `squeeze=True` would return a view (GH8217)
- Bug in checking of table name in `read_sql` in certain cases (GH7826).
- Bug in `DataFrame.groupby` where `Grouper` does not recognize level when frequency is specified (GH7885)
- Bug in multiindexes dtypes getting mixed up when `DataFrame` is saved to SQL table (GH8021)
- Bug in `Series` 0-division with a float and integer operand dtypes (GH7785)
- Bug in `Series.astype("unicode")` not calling `unicode` on the values correctly (GH7758)
- Bug in `DataFrame.as_matrix()` with mixed `datetime64[ns]` and `timedelta64[ns]` dtypes (GH7778)

- Bug in `HDFStore.select_column()` not preserving UTC timezone info when selecting a `DatetimeIndex` (GH7777)
- Bug in `to_datetime` when `format='%Y%m%d'` and `coerce=True` are specified, where previously an object array was returned (rather than a coerced time-series with `NaT`), (GH7930)
- Bug in `DatetimeIndex` and `PeriodIndex` in-place addition and subtraction cause different result from normal one (GH6527)
- Bug in adding and subtracting `PeriodIndex` with `PeriodIndex` raise `TypeError` (GH7741)
- Bug in `combine_first` with `PeriodIndex` data raises `TypeError` (GH3367)
- Bug in multi-index slicing with missing indexers (GH7866)
- Bug in multi-index slicing with various edge cases (GH8132)
- Regression in multi-index indexing with a non-scalar type object (GH7914)
- Bug in Timestamp comparisons with `==` and `int64` dtype (GH8058)
- Bug in pickles contains `DateOffset` may raise `AttributeError` when `normalize` attribute is referred internally (GH7748)
- Bug in Panel when using `major_xs` and `copy=False` is passed (deprecation warning fails because of missing warnings) (GH8152).
- Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there's only one block there's no ambiguity (GH7794)
- Bug in putting a `PeriodIndex` into a `Series` would convert to `int64` dtype, rather than object of `Periods` (GH7932)
- Bug in `HDFStore` iteration when passing a `where` (GH8014)
- Bug in `DataFrameGroupby.transform` when transforming with a passed non-sorted key (GH8046, GH8430)
- Bug in repeated timeseries line and area plot may result in `ValueError` or incorrect kind (GH7733)
- Bug in inference in a `MultiIndex` with `datetime.date` inputs (GH7888)
- Bug in `get` where an `IndexError` would not cause the default value to be returned (GH7725)
- Bug in `offsets.apply`, `rollforward` and `rollback` may reset nanosecond (GH7697)
- Bug in `offsets.apply`, `rollforward` and `rollback` may raise `AttributeError` if `Timestamp` has `dateutil.tzinfo` (GH7697)
- Bug in sorting a multi-index frame with a `Float64Index` (GH8017)
- Bug in inconsistent panel setitem with a rhs of a `DataFrame` for alignment (GH7763)
- Bug in `is_superperiod` and `is_subperiod` cannot handle higher frequencies than `S` (GH7760, GH7772, GH7803)
- Bug in 32-bit platforms with `Series.shift` (GH8129)
- Bug in `PeriodIndex.unique` returns `int64 np.ndarray` (GH7540)
- Bug in `groupby.apply` with a non-affecting mutation in the function (GH8467)
- Bug in `DataFrame.reset_index` which has `MultiIndex` contains `PeriodIndex` or `DatetimeIndex` with `tz` raises `ValueError` (GH7746, GH7793)
- Bug in `DataFrame.plot` with `subplots=True` may draw unnecessary minor xticks and yticks (GH7801)

- Bug in `StataReader` which did not read variable labels in 117 files due to difference between Stata documentation and implementation ([GH7816](#))
- Bug in `StataReader` where strings were always converted to 244 characters-fixed width irrespective of underlying string size ([GH7858](#))
- Bug in `DataFrame.plot` and `Series.plot` may ignore `rot` and `fontsize` keywords ([GH7844](#))
- Bug in `DatetimeIndex.value_counts` doesn't preserve `tz` ([GH7735](#))
- Bug in `PeriodIndex.value_counts` results in `Int64Index` ([GH7735](#))
- Bug in `DataFrame.join` when doing left join on index and there are multiple matches ([GH5391](#))
- Bug in `GroupBy.transform()` where int groups with a transform that didn't preserve the index were incorrectly truncated ([GH7972](#)).
- Bug in `groupby` where callable objects without name attributes would take the wrong path, and produce a `DataFrame` instead of a `Series` ([GH7929](#))
- Bug in `groupby` error message when a `DataFrame` grouping column is duplicated ([GH7511](#))
- Bug in `read_html` where the `infer_types` argument forced coercion of date-likes incorrectly ([GH7762](#), [GH7032](#)).
- Bug in `Series.str.cat` with an index which was filtered as to not include the first item ([GH7857](#))
- Bug in `Timestamp` cannot parse nanosecond from string ([GH7878](#))
- Bug in `Timestamp` with string offset and `tz` results incorrect ([GH7833](#))
- Bug in `tslib.tz_convert` and `tslib.tz_convert_single` may return different results ([GH7798](#))
- Bug in `DatetimeIndex.intersection` of non-overlapping timestamps with `tz` raises `IndexError` ([GH7880](#))
- Bug in alignment with `TimeOps` and non-unique indexes ([GH8363](#))
- Bug in `GroupBy.filter()` where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn't ([GH7870](#)).
- Bug in `date_range()/DatetimeIndex()` when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries ([GH7835](#), [GH7901](#)).
- Bug in `to_excel()` where a negative sign was being prepended to positive infinity and was absent for negative infinity ([GH7949](#))
- Bug in area plot draws legend with incorrect `alpha` when `stacked=True` ([GH8027](#))
- `Period` and `PeriodIndex` addition/subtraction with `np.timedelta64` results in incorrect internal representations ([GH7740](#))
- Bug in `Holiday` with no offset or observance ([GH7987](#))
- Bug in `DataFrame.to_latex` formatting when columns or index is a `MultiIndex` ([GH7982](#)).
- Bug in `DateOffset` around Daylight Savings Time produces unexpected results ([GH5175](#)).
- Bug in `DataFrame.shift` where empty columns would throw `ZeroDivisionError` on numpy 1.7 ([GH8019](#))
- Bug in installation where `html_encoding/*.html` wasn't installed and therefore some tests were not running correctly ([GH7927](#)).
- Bug in `read_html` where bytes objects were not tested for in `_read` ([GH7927](#)).
- Bug in `DataFrame.stack()` when one of the column levels was a datelike ([GH8039](#))

- Bug in broadcasting numpy scalars with DataFrame ([GH8116](#))
- Bug in pivot\_table performed with nameless index and columns raises KeyError ([GH8103](#))
- Bug in DataFrame.plot(kind='scatter') draws points and errorbars with different colors when the color is specified by c keyword ([GH8081](#))
- Bug in Float64Index where iat and at were not testing and were failing ([GH8092](#)).
- Bug in DataFrame.boxplot() where y-limits were not set correctly when producing multiple axes ([GH7528](#), [GH5517](#)).
- Bug in read\_csv where line comments were not handled correctly given a custom line terminator or delim\_whitespace=True ([GH8122](#)).
- Bug in read\_html where empty tables caused a StopIteration ([GH7575](#))
- Bug in casting when setting a column in a same-dtype block ([GH7704](#))
- Bug in accessing groups from a GroupBy when the original grouper was a tuple ([GH8121](#)).
- Bug in .at that would accept integer indexers on a non-integer index and do fallback ([GH7814](#))
- Bug with kde plot and NaNs ([GH8182](#))
- Bug in GroupBy.count with float32 data type where nan values were not excluded ([GH8169](#)).
- Bug with stacked barplots and NaNs ([GH8175](#)).
- Bug in resample with non evenly divisible offsets (e.g. '7s') ([GH8371](#))
- Bug in interpolation methods with the limit keyword when no values needed interpolating ([GH7173](#)).
- Bug where col\_space was ignored in DataFrame.to\_string() when header=False ([GH8230](#)).
- Bug with DatetimeIndex.asof incorrectly matching partial strings and returning the wrong date ([GH8245](#)).
- Bug in plotting methods modifying the global matplotlib rcParams ([GH8242](#)).
- Bug in DataFrame.\_\_setitem\_\_ that caused errors when setting a dataframe column to a sparse array ([GH8131](#))
- Bug where Dataframe.boxplot() failed when entire column was empty ([GH8181](#)).
- Bug with messed variables in radviz visualization ([GH8199](#)).
- Bug in interpolation methods with the limit keyword when no values needed interpolating ([GH7173](#)).
- Bug where col\_space was ignored in DataFrame.to\_string() when header=False ([GH8230](#)).
- Bug in to\_clipboard that would clip long column data ([GH8305](#))
- Bug in DataFrame terminal display: Setting max\_column/max\_rows to zero did not trigger auto-resizing of dfs to fit terminal width/height ([GH7180](#)).
- Bug in OLS where running with "cluster" and "nw\_lags" parameters did not work correctly, but also did not throw an error ([GH5884](#)).
- Bug in DataFrame.dropna that interpreted non-existent columns in the subset argument as the 'last column' ([GH8303](#))
- Bug in Index.intersection on non-monotonic non-unique indexes ([GH8362](#)).
- Bug in masked series assignment where mismatching types would break alignment ([GH8387](#))
- Bug in NDFrame.equals gives false negatives with dtype=object ([GH8437](#))
- Bug in assignment with indexer where type diversity would break alignment ([GH8258](#))

- Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray ([GH6552](#))
- Regression in `NDFrame.loc` indexing when rows/columns were converted to `Float64Index` if target was an empty list/ndarray ([GH7774](#))
- Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted ([GH8444](#))
- Bug in item assignment of a `DataFrame` with multi-index columns where right-hand-side columns were not aligned ([GH7655](#))
- Suppress `FutureWarning` generated by NumPy when comparing object arrays containing NaN for equality ([GH7065](#))
- Bug in `DataFrame.eval()` where the dtype of the `not` operator (`~`) was not correctly inferred as `bool`.

## 1.23 v0.14.1 (July 11, 2014)

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  - Support for dateutil timezones (see [docs](#)).
  - Support for ignoring full line comments in the `read_csv()` text parser.
  - New documentation section on *Options and Settings*.
  - Lots of bug fixes.
- *Enhancements*
- *API Changes*
- *Performance Improvements*
- *Experimental Changes*
- *Bug Fixes*

### 1.23.1 API changes

- Openpyxl now raises a `ValueError` on construction of the openpyxl writer instead of warning on pandas import ([GH7284](#)).
- For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` ([GH7242](#))
- `Period` objects no longer raise a `TypeError` when compared using `==` with another object that *isn't* a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn't a `Period` `False` is returned. ([GH7376](#))

- Previously, the behaviour on resetting the time or not in `offsets.apply`, `rollforward` and `rollback` operations differed between offsets. With the support of the `normalize` keyword for all offsets (see below) with a default value of `False` (preserve time), the behaviour changed for certain offsets (`BusinessMonthBegin`, `MonthEnd`, `BusinessMonthEnd`, `CustomBusinessMonthEnd`, `BusinessYearBegin`, `LastWeekOfMonth`, `FY5253Quarter`, `LastWeekOfMonth`, `Easter`):

```
In [6]: from pandas.tseries import offsets

In [7]: d = pd.Timestamp('2014-01-01 09:00')

# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: Timestamp('2014-01-31 00:00:00')
```

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with `normalize=True`

```
# new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')

In [2]: d + offsets.MonthEnd(normalize=True)
Out[2]: Timestamp('2014-01-31 00:00:00')
```

Note that for the other offsets the default behaviour did not change.

- Add back `#N/A` `N/A` as a default NA value in text parsing, (regression from 0.12) (GH5521)
- Raise a `TypeError` on inplace-setting with a `.where` and a non `np.nan` value as this is inconsistent with a set-item expression like `df[mask] = None` (GH7656)

## 1.23.2 Enhancements

- Add `dropna` argument to `value_counts` and `nunique` (GH5569).
- Add `select_dtypes()` method to allow selection of columns based on dtype (GH7316). See *the docs*.
- All offsets supports the `normalize` keyword to specify whether `offsets.apply`, `rollforward` and `rollback` resets the time (hour, minute, etc) or not (default `False`, preserves time) (GH7156):

```
In [3]: import pandas.tseries.offsets as offsets

In [4]: day = offsets.Day()

In [5]: day.apply(Timestamp('2014-01-01 09:00'))
Out[5]: Timestamp('2014-01-02 09:00:00')

In [6]: day = offsets.Day(normalize=True)

In [7]: day.apply(Timestamp('2014-01-01 09:00'))
Out[7]: Timestamp('2014-01-02 00:00:00')
```

- `PeriodIndex` is represented as the same format as `DatetimeIndex` (GH7601)
- `StringMethods` now work on empty Series (GH7242)
- The file parsers `read_csv` and `read_table` now ignore line comments provided by the parameter `comment`, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)

- Add `NotImplementedError` for simultaneous use of `chunksize` and `nrows` for `read_csv()` (GH6774).
- Tests for basic reading of public S3 buckets now exist (GH7281).
- `read_html` now sports an `encoding` argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).
- `read_excel` now supports reading from URLs in the same way that `read_csv` does. (GH6809)
- Support for `dateutil` timezones, which can now be used in the same way as `pytz` timezones across pandas. (GH4688)

```
In [8]: rng = date_range('3/6/2012 00:00', periods=10, freq='D',
...:                    tz='dateutil/Europe/London')
...:
In [9]: rng.tz
Out[9]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See *the docs*.

- Implemented `sem` (standard error of the mean) operation for `Series`, `DataFrame`, `Panel`, and `Groupby` (GH6897)
- Add `nlargest` and `nsmallest` to the `Series` `groupby` whitelist, which means you can now use these methods on a `SeriesGroupBy` object (GH7053).
- All offsets apply, `rollforward` and `rollback` can now handle `np.datetime64`, previously results in `ApplyTypeError` (GH7452)
- `Period` and `PeriodIndex` can contain `NaT` in its values (GH7485)
- Support pickling `Series`, `DataFrame` and `Panel` objects with non-unique labels along *item* axis (`index`, `columns` and `items` respectively) (GH7370).
- Improved inference of `datetime/timedelta` with mixed null objects. Regression from 0.13.1 in interpretation of an object `Index` with all null elements (GH7431)

### 1.23.3 Performance

- Improvements in dtype inference for numeric operations involving yielding performance gains for dtypes: `int64`, `timedelta64`, `datetime64` (GH7223)
- Improvements in `Series.transform` for significant performance gains (GH6496)
- Improvements in `DataFrame.transform` with `ufuncs` and built-in grouper functions for significant performance gains (GH7383)
- Regression in `groupby` aggregation of `datetime64` dtypes (GH7555)
- Improvements in `MultiIndex.from_product` for large iterables (GH7627)

### 1.23.4 Experimental

- `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a multi-indexed `DataFrame` (GH5602)
- `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google `bq.py` command line client. This submodule now uses `httplib2` and the Google `apiclient` and `oauth2client` API client libraries which should be more stable and, therefore, reliable than `bq.py`. See *the docs*. (GH6937).

### 1.23.5 Bug Fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a `DataFrame` (GH7506)
- Bug in Panel indexing with a multi-index axis (GH7516)
- Regression in datetimelike slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in `setitem` with list-of-lists and single vs mixed types (GH7551:)
- Bug in `timeops` with non-aligned Series (GH7500)
- Bug in `timedelta` inference when assigning an incomplete Series (GH7592)
- Bug in `groupby.nth` with a Series and integer-like column name (GH7559)
- Bug in `Series.get` with a boolean accessor (GH7407)
- Bug in `value_counts` where `NaT` did not qualify as missing (`NaN`) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted 'm/h' (GH7611, GH6423)
- Bug in line plot doesn't set correct `xlim` if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot`, `hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by` kw raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in subplots displays `ticklabels` and `labels` in different rule (GH5897)
- Bug in `Panel.apply` with a multi-index as an axis (GH7469)
- Bug in `DatetimeIndex.insert` doesn't preserve `name` and `tz` (GH7299)
- Bug in `DatetimeIndex.asobject` doesn't preserve `name` (GH7299)
- Bug in multi-index slicing with datetimelike ranges (strings and Timestamps), (GH7429)
- Bug in `Index.min` and `max` doesn't handle `nan` and `NaT` properly (GH7261)
- Bug in `PeriodIndex.min/max` results in `int` (GH7609)
- Bug in `resample` where `fill_method` was ignored if you passed `how` (GH2073)
- Bug in `TimeGrouper` doesn't exclude column specified by `key` (GH7227)
- Bug in `DataFrame` and `Series` `bar` and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `DataFrame.hist` raises `TypeError` when it contains non numeric column (GH7277)
- Bug in `Index.delete` does not preserve `name` and `freq` attributes (GH7302)
- Bug in `DataFrame.query()/eval` where local string variables with the `@` sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in `Float64Index` which didn't allow duplicates (GH7149).
- Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
- Bug in `StringMethods.extract()` where a single match group Series would use the matcher's name instead of the group name (GH7313).
- Bug in `isnull()` when `mode.use_inf_as_null == True` where `isnull` wouldn't test `True` when it encountered an `inf/-inf` (GH7315).

- Bug in `inferred_freq` results in `None` for eastern hemisphere timezones (GH7310)
- Bug in `Easter` returns incorrect date when offset is negative (GH7195)
- Bug in broadcasting with `.div`, integer dtypes and divide-by-zero (GH7325)
- Bug in `CustomBusinessDay.apply` raises `NameError` when `np.datetime64` object is passed (GH7196)
- Bug in `MultiIndex.append`, `concat` and `pivot_table` don't preserve timezone (GH6606)
- Bug in `.loc` with a list of indexers on a single-multi index level (that is not nested) (GH7349)
- Bug in `Series.map` when mapping a dict with tuple keys of different lengths (GH7333)
- Bug all `StringMethods` now work on empty `Series` (GH7242)
- Fix delegation of `read_sql` to `read_sql_query` when query does not contain 'select' (GH7324).
- Bug where a string column name assignment to a `DataFrame` with a `Float64Index` raised a `TypeError` during a call to `np.isnan` (GH7366).
- Bug where `NDFrame.replace()` didn't correctly replace objects with `Period` values (GH7379).
- Bug in `.ix` `getitem` should always return a `Series` (GH7150)
- Bug in multi-index slicing with incomplete indexers (GH7399)
- Bug in multi-index slicing with a step in a sliced level (GH7400)
- Bug where negative indexers in `DatetimeIndex` were not correctly sliced (GH7408)
- Bug where `NaT` wasn't repr'd correctly in a `MultiIndex` (GH7406, GH7409).
- Bug where bool objects were converted to `nan` in `convert_objects` (GH7416).
- Bug in `quantile` ignoring the `axis` keyword argument (GH7306)
- Bug where `nanops._maybe_null_out` doesn't work with complex numbers (GH7353)
- Bug in several `nanops` functions when `axis==0` for 1-dimensional `nan` arrays (GH7354)
- Bug where `nanops.nanmedian` doesn't work when `axis==None` (GH7352)
- Bug where `nanops._has_infs` doesn't work with many dtypes (GH7357)
- Bug in `StataReader.data` where reading a 0-observation dta failed (GH7369)
- Bug in `StataReader` when reading Stata 13 (117) files containing fixed width strings (GH7360)
- Bug in `StataWriter` where encoding was ignored (GH7286)
- Bug in `DatetimeIndex` comparison doesn't handle `NaT` properly (GH7529)
- Bug in passing input with `tzinfo` to some offsets `apply`, `rollforward` or `rollback` resets `tzinfo` or raises `ValueError` (GH7465)
- Bug in `DatetimeIndex.to_period`, `PeriodIndex.asobject`, `PeriodIndex.to_timestamp` doesn't preserve name (GH7485)
- Bug in `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` handle `NaT` incorrectly (GH7228)
- Bug in `offsets.apply`, `rollforward` and `rollback` may return normal datetime (GH7502)
- Bug in `resample` raises `ValueError` when target contains `NaT` (GH7227)
- Bug in `Timestamp.tz_localize` resets nanosecond info (GH7534)
- Bug in `DatetimeIndex.asobject` raises `ValueError` when it contains `NaT` (GH7539)

- Bug in `Timestamp.__new__` doesn't preserve nanosecond properly ([GH7610](#))
- Bug in `Index.astype(float)` where it would return an object dtype Index ([GH7464](#)).
- Bug in `DataFrame.reset_index` loses tz ([GH3950](#))
- Bug in `DatetimeIndex.freqstr` raises `AttributeError` when `freq` is `None` ([GH7606](#))
- Bug in `GroupBy.size` created by `TimeGrouper` raises `AttributeError` ([GH7453](#))
- Bug in single column bar plot is misaligned ([GH7498](#)).
- Bug in area plot with tz-aware time series raises `ValueError` ([GH7471](#))
- Bug in non-monotonic `Index.union` may preserve name incorrectly ([GH7458](#))
- Bug in `DatetimeIndex.intersection` doesn't preserve timezone ([GH4690](#))
- Bug in `rolling_var` where a window larger than the array would raise an error([GH7297](#))
- Bug with last plotted timeseries dictating `xlim` ([GH2960](#))
- Bug with `secondary_y` axis not being considered for timeseries `xlim` ([GH3490](#))
- Bug in `Float64Index` assignment with a non scalar indexer ([GH7586](#))
- Bug in `pandas.core.strings.str_contains` does not properly match in a case insensitive fashion when `regex=False` and `case=False` ([GH7505](#))
- Bug in `expanding_cov`, `expanding_corr`, `rolling_cov`, and `rolling_corr` for two arguments with mismatched index ([GH7512](#))
- Bug in `to_sql` taking the boolean column as text column ([GH7678](#))
- Bug in grouped `hist` doesn't handle `rot` kw and `sharex` kw properly ([GH7234](#))
- Bug in `.loc` performing fallback integer indexing with object dtype indices ([GH7496](#))
- Bug (regression) in `PeriodIndex` constructor when passed `Series` objects ([GH7701](#)).

## 1.24 v0.14.0 (May 31 , 2014)

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Highlights include:
  - Officially support Python 3.4
  - SQL interfaces updated to use `sqlalchemy`, See [Here](#).
  - Display interface changes, See [Here](#)
  - MultiIndexing Using Slicers, See [Here](#).
  - Ability to join a singly-indexed `DataFrame` with a multi-indexed `DataFrame`, see [Here](#)
  - More consistency in groupby results and more flexible groupby specifications, See [Here](#)
  - Holiday calendars are now supported in `CustomBusinessDay`, see [Here](#)
  - Several improvements in plotting functions, including: hexbin, area and pie plots, see [Here](#).
  - Performance doc section on I/O operations, See [Here](#)
- *Other Enhancements*

- *API Changes*
- *Text Parsing API Changes*
- *Groupby API Changes*
- *Performance Improvements*
- *Prior Deprecations*
- *Deprecations*
- *Known Issues*
- *Bug Fixes*

**Warning:** In 0.14.0 all NDFrame based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container's labels. This should not have any visible user/API behavior changes ([GH6745](#))

## 1.24.1 API changes

- `read_excel` uses 0 as the default sheet ([GH6573](#))
- `iloc` will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise `IndexError` ([GH6296](#), [GH6299](#)). This could result in an empty axis (e.g. an empty `DataFrame` being returned)

```
In [1]: df1 = DataFrame(np.random.randn(5,2), columns=list('AB'))
```

```
In [2]: df1
```

```
Out [2]:
```

```
      A      B
0  1.583584 -0.438313
1 -0.402537 -0.780572
2 -0.141685  0.542241
3  0.370966 -0.251642
4  0.787484  1.666563
```

```
In [3]: df1.iloc[:,2:3]
```

```

////////////////////////////////////
↪
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]
```

```
In [4]: df1.iloc[:,1:3]
```

```

////////////////////////////////////
↪
      B
0 -0.438313
1 -0.780572
2  0.542241
3 -0.251642
4  1.666563
```

(continues on next page)

(continued from previous page)

```
In [5]: df1.iloc[4:6]
//////////
↪
      A      B
4  0.787484  1.666563
```

These are out-of-bounds selections

```
df1.iloc[[4,5,6]]
IndexError: positional indexers are out-of-bounds

df1.iloc[:,4]
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values handles corner cases better (GH6531):
  - `df.iloc[: -len(df)]` is now empty
  - `df.iloc[len(df) : -1]` now enumerates all elements in reverse
- The `DataFrame.interpolate()` keyword `downcast` default has been changed from `infer` to `None`. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).
- When converting a dataframe to HTML it used to return *Empty DataFrame*. This special case has been removed, instead a header with the column names is returned (GH6062).
- `Series` and `Index` now internally share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on `Index` types as well. The `Series.weekday` property from is removed from `Series` for API consistency. Using a `DatetimeIndex/PeriodIndex` method on a `Series` will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).
- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DatetimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DatetimeIndex / Timestamp` (GH4565, GH6998)
- Local variable usage has changed in `pandas.eval()`/`DataFrame.eval()`/`DataFrame.query()` (GH5987). For the *DataFrame* methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is *not* a column you must still refer to it with the '@' prefix.
  - You can have an expression like `df.query('@a < a')` with no complaints from pandas about ambiguity of the name `a`.
  - The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn't necessary anymore.
- Define and document the order of column vs index names in `query/eval` (GH6676)
- `concat` will now concatenate mixed `Series` and `DataFrames` using the `Series` name or numbering columns as needed (GH2385). See *the docs*
- Slicing and advanced/boolean indexing operations on `Index` classes as well as `Index.delete()` and `Index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)

```
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])

In [7]: i[[0,1,2]]
Out[7]: Index([1, 2, 3], dtype='object')

In [8]: i.drop(['a', 'b', 'c'])
Out[8]: Index([1, 2, 3], dtype='object')
```

Previously, the above operation would return `Int64Index`. If you'd like to do this manually, use `Index.astype()`

```
In [9]: i[[0,1,2]].astype(np.int_)
Out[9]: Int64Index([1, 2, 3], dtype='int64')
```

- `set_index` no longer converts `MultiIndex`s to an `Index` of tuples. For example, the old behavior returned an `Index` in this case ([GH6459](#)):

```
# Old behavior, casted MultiIndex to an Index
In [10]: tuple_ind
Out[10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')

In [11]: df_multi.set_index(tuple_ind)
Out[11]:
      0      1
(a, c) 0.471435 -1.190976
(a, d) 1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588 -0.636524

# New behavior
In [12]: mi
Out[12]:
MultiIndex(levels=[['a', 'b'], ['c', 'd']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]])

In [13]: df_multi.set_index(mi)
Out[13]:
      0      1
a c  0.471435 -1.190976
  d  1.432707 -0.312652
b c -0.720589  0.887163
  d  0.859588 -0.636524
```

This also applies when passing multiple indices to `set_index`:

```
# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out[14]:
      0      1
(a, c) (a, c) 0.471435 -1.190976
(a, d) (a, d) 1.432707 -0.312652
(b, c) (b, c) -0.720589  0.887163
(b, d) (b, d)  0.859588 -0.636524
```

(continues on next page)

(continued from previous page)

```
# New output, 4-level MultiIndex
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out [15]:
```

		0	1
a	c a c	0.471435	-1.190976
	d a d	1.432707	-0.312652
b	c b c	-0.720589	0.887163
	d b d	0.859588	-0.636524

- `pairwise` keyword was added to the statistical moment functions `rolling_cov`, `rolling_corr`, `ewmcov`, `ewmcorr`, `expanding_cov`, `expanding_corr` to allow the calculation of moving window covariance and correlation matrices (GH4950). See *Computing rolling pairwise covariances and correlations* in the docs.

```
In [1]: df = DataFrame(np.random.randn(10,4), columns=list('ABCD'))

In [4]: covs = pd.rolling_cov(df[['A','B','C']], df[['B','C','D']], 5,
↳ pairwise=True)

In [5]: covs[df.index[-1]]
Out [5]:
```

	B	C	D
A	0.035310	0.326593	-0.505430
B	0.137748	-0.006888	-0.005383
C	-0.006888	0.861040	0.020762

- `Series.iteritems()` is now lazy (returns an iterator rather than a list). This was the documented behavior prior to 0.14. (GH6760)
- Added `nunique` and `value_counts` functions to `Index` for counting unique elements. (GH6734)
- `stack` and `unstack` now raise a `ValueError` when the `level` keyword refers to a non-unique item in the `Index` (previously raised a `KeyError`). (GH6738)
- drop unused `order` argument from `Series.sort`; args now are in the same order as `Series.order`; add `na_position` arg to conform to `Series.order` (GH6847)
- default sorting algorithm for `Series.order` is now `quicksort`, to conform with `Series.sort` (and `numpy` defaults)
- add `inplace` keyword to `Series.order/sort` to make them inverses (GH6859)
- `DataFrame.sort` now places NaNs at the beginning or end of the sort according to the `na_position` parameter. (GH3917)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583), this was a regression from 0.13.1
- Added `factorize` functions to `Index` and `Series` to get indexer and unique values (GH7090)
- `describe` on a `DataFrame` with a mix of `Timestamp` and string like objects returns a different `Index` (GH7088). Previously the index was unintentionally sorted.
- Arithmetic operations with **only** `bool` dtypes now give a warning indicating that they are evaluated in Python space for `+`, `-`, and `*` operations and raise for all others (GH7011, GH6762, GH7015, GH7210)

```
x = pd.Series(np.random.rand(10) > 0.5)
y = True
x + y # warning generated: should do x | y instead
```

(continues on next page)

(continued from previous page)

```
x / y # this raises because it doesn't make sense  
NotImplementedError: operator '/' not implemented for bool dtypes
```

- In `HDFStore`, `select_as_multiple` will always raise a `KeyError`, when a key or the selector is not found (GH6177)
- `df['col'] = value` and `df.loc[:, 'col'] = value` are now completely equivalent; previously the `.loc` would not necessarily coerce the dtype of the resultant series (GH6149)
- `dtypes` and `ftypes` now return a series with `dtype=object` on empty containers (GH5740)
- `df.to_csv` will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- `pd.infer_freq()` will now raise a `TypeError` if given an invalid `Series/Index` type (GH6407, GH6463)
- A tuple passed to `DataFrame.sort_index` will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- all offset operations now return `Timestamp` types (rather than `datetime`), `Business/Week` frequencies were incorrect (GH4069)
- `to_excel` now converts `np.inf` into a string representation, customizable by the `inf_rep` keyword argument (Excel has no native inf representation) (GH6782)
- Replace `pandas.compat.scipy.scoreatpercentile` with `numpy.percentile` (GH6810)
- `.quantile` on a `datetime[ns]` series now returns `Timestamp` instead of `np.datetime64` objects (GH6810)
- change `AssertionError` to `TypeError` for invalid types passed to `concat` (GH6583)
- Raise a `TypeError` when `DataFrame` is passed an iterator as the `data` argument (GH5357)

### 1.24.2 Display Changes

- The default way of printing large `DataFrames` has changed. `DataFrames` exceeding `max_rows` and/or `max_columns` are now displayed in a centrally truncated view, consistent with the printing of a `pandas.Series` (GH5603).

In previous versions, a `DataFrame` was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.

```

In [1]: import pandas as pd

In [2]: import numpy as np

In [3]: pd.options.display.max_rows = 6

In [4]: pd.options.display.max_columns = 6

In [5]: index = pd.DatetimeIndex(start='20010101', freq='D', periods=10)

In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
Out[6]:
      0  1  2  3  4  5 ...
2001-01-01  0  1  2  3  4  5 ...
2001-01-02 10 11 12 13 14 15 ...
2001-01-03 20 21 22 23 24 25 ...
2001-01-04 30 31 32 33 34 35 ...
2001-01-05 40 41 42 43 44 45 ...
2001-01-06 50 51 52 53 54 55 ...
... ..
[10 rows x 10 columns]

```

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

```

In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
Out[24]:
      0  1  2 ...  7  8  9
2001-01-01  0  1  2 ...  7  8  9
2001-01-02 10 11 12 ... 17 18 19
2001-01-03 20 21 22 ... 27 28 29
... ..
2001-01-08 70 71 72 ... 77 78 79
2001-01-09 80 81 82 ... 87 88 89
2001-01-10 90 91 92 ... 97 98 99
[10 rows x 10 columns]

```

- allow option 'truncate' for `display.show_dimensions` to only show the dimensions if the frame is truncated (GH6547).

The default for `display.show_dimensions` will now be `truncate`. This is consistent with how Series display length.

```

In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1,5), index=[0,1,2,3,4],
↳ columns=[0,1,2,3,4])

# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
.....:                          'display.show_dimensions', 'truncate'):
.....:     print(dfd)
.....:

```

(continues on next page)

(continued from previous page)

```
[5 rows x 5 columns]
```

```
# will not show dimensions since it is not truncated
```

```
In [18]: with pd.option_context('display.max_rows', 10, 'display.max_columns', 40,
```

```
.....:                               'display.show_dimensions', 'truncate'):
```

```
.....:     print(dfd)
```

```
.....:
```

```
↪ 0  1  2  3  4
```

```
0  0  1  2  3  4
```

```
1  5  6  7  8  9
```

```
2 10 11 12 13 14
```

```
3 15 16 17 18 19
```

```
4 20 21 22 23 24
```

- Regression in the display of a MultiIndexed Series with `display.max_rows` is less than the length of the series ([GH7101](#))
- Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' ([GH7105](#))
- The `verbose` keyword in `DataFrame.info()`, which controls whether to shorten the `info` representation, is now `None` by default. This will follow the global setting in `display.max_info_columns`. The global setting can be overridden with `verbose=True` or `verbose=False`.
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting ([GH6939](#))
- Offset/freq info now in `Timestamp.__repr__` ([GH4553](#))

### 1.24.3 Text Parsing API Changes

`read_csv()/read_table()` will now be noisier w.r.t invalid options rather than falling back to the `PythonParser`.

- Raise `ValueError` when `sep` specified with `delim_whitespace=True` in `read_csv()/read_table()` ([GH6607](#))
- Raise `ValueError` when `engine='c'` specified with unsupported options in `read_csv()/read_table()` ([GH6607](#))
- Raise `ValueError` when fallback to python parser causes options to be ignored ([GH6607](#))
- Produce `ParserWarning` on fallback to python parser when no options are ignored ([GH6607](#))
- Translate `sep='\s+'` to `delim_whitespace=True` in `read_csv()/read_table()` if no other C-unsupported options specified ([GH6607](#))

### 1.24.4 Groupby API Changes

More consistent behaviour for some groupby methods:

- `groupby head` and `tail` now act more like `filter` rather than an aggregation:

```
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])

In [20]: g = df.groupby('A')

In [21]: g.head(1)  # filters DataFrame
Out[21]:
   A  B
0  1  2
2  5  6

In [22]: g.apply(lambda x: x.head(1))  # used to simply fall-through
Out[22]:
   A  B
A
1  0  1  2
5  2  5  6
```

- groupby head and tail respect column selection:

```
In [23]: g[['B']].head(1)
Out[23]:
   B
0  2
2  6
```

- groupby nth now reduces by default; filtering can be achieved by passing `as_index=False`. With an optional `dropna` argument to ignore NaN. See [the docs](#).

#### Reducing

```
In [24]: df = DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [25]: g = df.groupby('A')

In [26]: g.nth(0)
Out[26]:
   B
A
1 NaN
5 6.0

# this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
   B
A
1 4.0
5 6.0

# this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
   B
A
1 4.0
5 6.0
```

## Filtering

```
In [29]: gf = df.groupby('A',as_index=False)

In [30]: gf.nth(0)
Out[30]:
   A    B
0  1  NaN
2  5  6.0

In [31]: gf.nth(0, dropna='any')
Out[31]:
   A    B
1  1  4.0
5  5  6.0
```

- `groupby` will now not return the grouped column for non-cython functions ([GH5610](#), [GH5614](#), [GH6732](#)), as its already the index

```
In [32]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])

In [33]: g = df.groupby('A')

In [34]: g.count()
Out[34]:
   B
A
1  1
5  2

In [35]: g.describe()
Out[35]:
   B
count mean      std min 25% 50% 75% max
A
1  1.0  4.0      NaN  4.0  4.0  4.0  4.0  4.0
5  2.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0
```

- passing `as_index` will leave the grouped column in-place (this is not change in 0.14.0)

```
In [36]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])

In [37]: g = df.groupby('A',as_index=False)

In [38]: g.count()
Out[38]:
   A  B
0  1  1
1  5  2

In [39]: g.describe()
Out[39]:
   A      B
count mean      std min 25% 50% 75% max count mean      std min 25% 50% 75% max
A
1  1.0  4.0      NaN  4.0  4.0  4.0  4.0  4.0  1.0  4.0      NaN  4.0  4.0  4.0  4.0
5  2.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0  1.0  7.0  1.414214  6.0  6.5  7.0  7.5  8.0
```

(continues on next page)

(continued from previous page)

```

1    2.0  5.0  0.0  5.0  5.0  5.0  5.0  5.0  2.0  7.0  1.414214  6.0  6.5  7.0  7.
↪5    8.0

```

- Allow specification of a more complex groupby via `pd.Grouper`, such as grouping by a Time and a string field simultaneously. See [the docs](#). (GH3794)
- Better propagation/preservation of Series names when performing groupby operations:
  - `SeriesGroupBy.agg` will ensure that the name attribute of the original series is propagated to the result (GH6265).
  - If the function provided to `GroupBy.apply` returns a named series, the name of the series will be kept as the name of the column index of the DataFrame returned by `GroupBy.apply` (GH6124). This facilitates `DataFrame.stack` operations where the name of the column index is used as the name of the inserted column containing the pivoted data.

### 1.24.5 SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on [included dialects](#)).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```

In [40]: from sqlalchemy import create_engine

# Create your connection.
In [41]: engine = create_engine('sqlite:///memory:')

```

This engine can then be used to write or read data to/from this database:

```

In [42]: df = pd.DataFrame({'A': [1,2,3], 'B': ['a', 'b', 'c']})

In [43]: df.to_sql('db_table', engine, index=False)

```

You can read data from a database by specifying the table name:

```

In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A  B
0  1  a
1  2  b
2  3  c

```

or by specifying a sql query:

```
In [45]: pd.read_sql_query('SELECT * FROM db_table', engine)
Out[45]:
```

	A	B
0	1	a
1	2	b
2	3	c

Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is `True`).
- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

**Warning:** The support for the ‘mysql’ flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).

## 1.24.6 MultiIndexing Using Slicers

In 0.14.0 we added a new way to slice multi-indexed objects. You can slice a multi-index by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see *Selection by Label*, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See *the docs* See also issues ([GH6134](#), [GH4036](#), [GH3057](#), [GH2598](#), [GH5641](#), [GH7106](#))

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the MultiIndex for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), .....), :]
```

rather than this:

```
df.loc[(slice('A1', 'A3'), .....)]
```

**Warning:** You will need to make sure that the selection axes are fully lexsorted!

```

In [46]: def mklbl(prefix,n):
.....:     return ["%s%s" % (prefix,i) for i in range(n)]
.....:

## 1.24.7 Plotting

- Hexagonal bin plots from `DataFrame.plot` with `kind='hexbin'` ([GH5478](#)), See [the docs](#).
- `DataFrame.plot` and `Series.plot` now supports area plot with specifying `kind='area'` ([GH6656](#)), See [the docs](#)
- Pie plots from `Series.plot` and `DataFrame.plot` with `kind='pie'` ([GH6976](#)), See [the docs](#).
- Plotting with Error Bars is now supported in the `.plot` method of `DataFrame` and `Series` objects ([GH3796](#), [GH6834](#)), See [the docs](#).
- `DataFrame.plot` and `Series.plot` now support a `table` keyword for plotting `matplotlib.Table`, See [the docs](#). The `table` keyword can receive the following values.
  - `False`: Do nothing (default).
  - `True`: Draw a table using the `DataFrame` or `Series` called `plot` method. Data will be transposed to meet `matplotlib`'s default layout.
  - `DataFrame` or `Series`: Draw `matplotlib.table` using the passed data. The data will be drawn as displayed in `print` method (not transposed automatically). Also, helper function `pandas.tools.plotting.table` is added to create a table from `DataFrame` and `Series`, and add it to an `matplotlib.Axes`.
- `plot(legend='reverse')` will now reverse the order of legend labels for most plot kinds. ([GH6014](#))
- Line plot and area plot can be stacked by `stacked=True` ([GH6656](#))
- Following keywords are now acceptable for `DataFrame.plot()` with `kind='bar'` and `kind='barh'`:
  - `width`: Specify the bar width. In previous versions, static value 0.5 was passed to `matplotlib` and it cannot be overwritten. ([GH6604](#))
  - `align`: Specify the bar alignment. Default is `center` (different from `matplotlib`). In previous versions, `pandas` passes `align='edge'` to `matplotlib` and adjust the location to `center` by itself, and it results `align` keyword is not applied as expected. ([GH4525](#))
  - `position`: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). ([GH6604](#))

Because of the default `align` value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using `set_xlim`, `set_ylim`, etc. In this cases, please modify your script to meet with new coordinates.

- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. ([GH6956](#))

- `DataFrame.boxplot()` now supports `layout` keyword (GH6769)
- `DataFrame.boxplot()` has a new keyword argument, `return_type`. It accepts `'dict'`, `'axes'`, or `'both'`, in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

### 1.24.8 Prior Version Deprecations/Changes

There are prior version deprecations that are taking effect as of 0.14.0.

- Remove `DateRange` in favor of `DatetimeIndex` (GH6816)
- Remove `column` keyword from `DataFrame.sort` (GH4370)
- Remove `precision` keyword from `set_eng_float_format()` (GH395)
- Remove `force_unicode` keyword from `DataFrame.to_string()`, `DataFrame.to_latex()`, and `DataFrame.to_html()`; these function encode in unicode by default (GH2224, GH2225)
- Remove `nanRep` keyword from `DataFrame.to_csv()` and `DataFrame.to_string()` (GH275)
- Remove `unique` keyword from `HDFStore.select_column()` (GH3256)
- Remove `inferTimeRule` keyword from `Timestamp.offset()` (GH391)
- Remove `name` keyword from `get_data_yahoo()` and `get_data_google()` (commit b921d1a)
- Remove `offset` keyword from `DatetimeIndex` constructor (commit 3136390)
- Remove `time_rule` from several rolling-moment statistical functions, such as `rolling_sum()` (GH1042)
- Removed `neg` – boolean operations on numpy arrays in favor of `inv ~`, as this is going to be deprecated in numpy 1.9 (GH6960)

### 1.24.9 Deprecations

- The `pivot_table()/DataFrame.pivot_table()` and `crosstab()` functions now take arguments `index` and `columns` instead of `rows` and `cols`. A `FutureWarning` is raised to alert that the old `rows` and `cols` arguments will not be supported in a future release (GH5505)
- The `DataFrame.drop_duplicates()` and `DataFrame.duplicated()` methods now take argument `subset` instead of `cols` to better align with `DataFrame.dropna()`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6680)
- The `DataFrame.to_csv()` and `DataFrame.to_excel()` functions now takes argument `columns` instead of `cols`. A `FutureWarning` is raised to alert that the old `cols` arguments will not be supported in a future release (GH6645)
- Indexers will warn `FutureWarning` when used with a scalar indexer and a non-floating point `Index` (GH4892, GH6960)

```
# non-floating point indexes can only be indexed by integers / labels
In [1]: Series(1,np.arange(5))[3.0]
        pandas/core/index.py:469: FutureWarning: scalar indexers for index type_
        ↪Int64Index should be integers and not floating point
Out [1]: 1

In [2]: Series(1,np.arange(5)).iloc[3.0]
        pandas/core/index.py:469: FutureWarning: scalar indexers for index type_
        ↪Int64Index should be integers and not floating point
Out [2]: 1
```

(continues on next page)

(continued from previous page)

```

In [3]: Series(1,np.arange(5)).iloc[3.0:4]
pandas/core/index.py:527: FutureWarning: slice indexers when using iloc_
↪ should be integers and not floating point
Out[3]:
      3      1
dtype: int64

# these are Float64Indexes, so integer or floating point is acceptable
In [4]: Series(1,np.arange(5.))[3]
Out[4]: 1

In [5]: Series(1,np.arange(5.))[3.0]
Out[6]: 1

```

- Numpy 1.9 compat w.r.t. deprecation warnings ([GH6960](#))
- `Panel.shift()` now has a function signature that matches `DataFrame.shift()`. The old positional argument `lags` has been changed to a keyword argument `periods` with a default value of 1. A `FutureWarning` is raised if the old argument `lags` is used by name. ([GH6910](#))
- The order keyword argument of `factorize()` will be removed. ([GH6926](#)).
- Remove the `copy` keyword from `DataFrame.xs()`, `Panel.major_xs()`, `Panel.minor_xs()`. A view will be returned if possible, otherwise a copy will be made. Previously the user could think that `copy=False` would ALWAYS return a view. ([GH6894](#))
- The `parallel_coordinates()` function now takes argument `color` instead of `colors`. A `FutureWarning` is raised to alert that the old `colors` argument will not be supported in a future release. ([GH6956](#))
- The `parallel_coordinates()` and `andrews_curves()` functions now take positional argument `frame` instead of `data`. A `FutureWarning` is raised if the old `data` argument is used by name. ([GH6956](#))
- The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines ([GH6900](#)).
- The following `io.sql` functions have been deprecated: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.
- The `percentile_width` keyword argument in `describe()` has been deprecated. Use the `percentiles` keyword instead, which takes a list of percentiles to display. The default output is unchanged.
- The default return type of `boxplot()` will change from a dict to a matplotlib Axes in a future release. You can use the future behavior now by passing `return_type='axes'` to `boxplot`.

## 1.24.10 Known Issues

- OpenPyXL 2.0.0 breaks backwards compatibility ([GH7169](#))

## 1.24.11 Enhancements

- `DataFrame` and `Series` will create a `MultiIndex` object if passed a tuples dict, See *the docs* ([GH3323](#))

```
In [65]: Series({'a': 1, ('a', 'a'): 0,
.....:          ('a', 'c'): 2, ('b', 'a'): 3, ('b', 'b'): 4})
.....:

Out[65]:
a b    1
a    0
c    2
b a    3
b    4
dtype: int64

In [66]: DataFrame({'a': {'A': 1, ('A', 'C'): 2,
.....:                    ('a', 'a'): 3, ('A', 'B'): 4,
.....:                    ('a', 'c'): 5, ('A', 'C'): 6,
.....:                    ('b', 'a'): 7, ('A', 'B'): 8,
.....:                    ('b', 'b'): 9, ('A', 'B'): 10}})
.....:

Out[66]:
      a      b
A B  1.0  4.0  5.0  8.0 10.0
C   2.0  3.0  6.0  7.0  NaN
D   NaN  NaN  NaN  NaN  9.0
```

- Added the `sym_diff` method to `Index` ([GH5543](#))
- `DataFrame.to_latex` now takes a `longtable` keyword, which if `True` will return a table in a `longtable` environment. ([GH6617](#))
- Add option to turn off escaping in `DataFrame.to_latex` ([GH6472](#))
- `pd.read_clipboard` will, if the keyword `sep` is unspecified, try to detect data copied from a spreadsheet and parse accordingly. ([GH6223](#))
- Joining a singly-indexed `DataFrame` with a multi-indexed `DataFrame` ([GH3662](#))

See [the docs](#). Joining multi-index DataFrames on both the left and right is not yet supported ATM.

```
In [67]: household = DataFrame(dict(household_id = [1,2,3],
.....:                               male = [0,1,0],
.....:                               wealth = [196087.3,316478.7,294750]),
.....:                               columns = ['household_id', 'male', 'wealth']
.....:                               ).set_index('household_id'))

In [68]: household
Out[68]:
```

	male	wealth
household_id		
1	0	196087.3
2	1	316478.7
3	0	294750.0

```
In [69]: portfolio = DataFrame(dict(household_id = [1,2,2,3,3,3,4],

- `quotechar`, `doublequote`, and `escapechar` can now be specified when using `DataFrame.to_csv` (GH5414, GH4528)
- Partially sort by only the specified levels of a MultiIndex with the `sort_remaining` boolean kwarg. (GH3984)
- Added `to_julian_date` to `TimeStamp` and `DatetimeIndex`. The Julian Date is used primarily in astronomy and represents the number of days from noon, January 1, 4713 BC. Because nanoseconds are used to define the time in pandas the actual range of dates that you can use is 1678 AD to 2262 AD. (GH4041)
- `DataFrame.to_stata` will now check data for compatibility with Stata data types and will upcast when needed. When it is not possible to losslessly upcast, a warning is issued (GH6327)
- `DataFrame.to_stata` and `StataWriter` will accept keyword arguments `time_stamp` and `data_label` which allow the time stamp and dataset label to be set when creating a file. (GH6545)
- `pandas.io.gbq` now handles reading unicode strings properly. (GH5940)
- *Holidays Calendars* are now available and can be used with the `CustomBusinessDay` offset (GH6719)
- `Float64Index` is now backed by a `float64` dtype ndarray instead of an object dtype array (GH6471).
- Implemented `Panel.pct_change` (GH6904)
- Added `how` option to rolling-moment functions to dictate how to handle resampling; `rolling_max()` defaults to max, `rolling_min()` defaults to min, and all others default to mean (GH6297)
- `CustomBuisnessMonthBegin` and `CustomBusinessMonthEnd` are now available (GH6866)

- `Series.quantile()` and `DataFrame.quantile()` now accept an array of quantiles.
- `describe()` now accepts an array of percentiles to include in the summary statistics ([GH4196](#))
- `pivot_table` can now accept `Groupby` by `index` and `columns` keywords ([GH6913](#))

```

- `read_excel` can now read milliseconds in Excel dates and times with `xlrd >= 0.9.3`. (GH5945)
- `pd.stats.moments.rolling_var` now uses Welford's method for increased numerical stability (GH6817)
- `pd.expanding_apply` and `pd.rolling_apply` now take args and kwargs that are passed on to the func (GH6289)
- `DataFrame.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` now has a percentage rank option (GH5971)
- `Series.rank()` and `DataFrame.rank()` now accept `method='dense'` for ranks without gaps (GH6514)
- Support passing encoding with `xlwt` (GH3710)
- Refactor Block classes removing `Block.items` attributes to avoid duplication in item handling (GH6745, GH6988).
- Testing statements updated to use specialized asserts (GH6175)

### 1.24.12 Performance

- Performance improvement when converting `DatetimeIndex` to floating ordinals using `DatetimeConverter` (GH6636)
- Performance improvement for `DataFrame.shift` (GH5609)
- Performance improvement in indexing into a multi-indexed `Series` (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of `DataFrame` construction with certain offsets, by removing faulty caching (e.g. `MonthEnd`, `BusinessMonthEnd`), (GH6479)
- Improve performance of `CustomBusinessDay` (GH6584)
- improve performance of slice indexing on `Series` with string keys (GH6341, GH6372)
- Performance improvement for `DataFrame.from_records` when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in timedelta conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing `take_2d` (GH6749)
- `GroupBy.count()` is now implemented in Cython and is much faster for large numbers of groups (GH7016).

### 1.24.13 Experimental

There are no experimental changes in 0.14.0

### 1.24.14 Bug Fixes

- Bug in `Series ValueError` when index doesn't match data (GH6532)
- Prevent segfault due to `MultiIndex` not being supported in `HDFStore` table format (GH1848)
- Bug in `pd.DataFrame.sort_index` where mergesort wasn't stable when `ascending=False` (GH6399)
- Bug in `pd.tseries.frequencies.to_offset` when argument has leading zeroes (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing `Timestamp` / `to_datetime` for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)
- Bug in `.xs` with a `Series` multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a `DatetimeIndex` with a specified frequency (GH6273, GH6274)
- Bug in `eval` where type-promotion failed for large expressions (GH6205)
- Bug in `interpolate` with `inplace=True` (GH6281)
- `HDFStore.remove` now handles start and stop (GH6177)
- `HDFStore.select_as_multiple` handles start and stop the same way as `select` (GH6177)
- `HDFStore.select_as_coordinates` and `select_column` works with a `where` clause that results in filters (GH6177)

- Regression in join of non\_unique\_indexes (GH6329)
- Issue with groupby agg with a single function and a mixed-type frame (GH6337)
- Bug in DataFrame.replace() when passing a non-bool to\_replace argument (GH6332)
- Raise when trying to align on different levels of a multi-index assignment (GH3738)
- Bug in setting complex dtypes via boolean indexing (GH6345)
- Bug in TimeGrouper/resample when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
- Bug in index name propagation in TimeGrouper/resample (GH4161)
- TimeGrouper has a more compatible API to the rest of the groupers (e.g. groups was missing) (GH3881)
- Bug in multiple grouping with a TimeGrouper depending on target column order (GH6764)
- Bug in pd.eval when parsing strings with possible tokens like ' & ' (GH6351)
- Bug correctly handle placements of -inf in Panels when dividing by integer 0 (GH6178)
- DataFrame.shift with axis=1 was raising (GH6371)
- Disabled clipboard tests until release time (run locally with nosetests -A disabled) (GH6048).
- Bug in DataFrame.replace() when passing a nested dict that contained keys not in the values to be replaced (GH6342)
- str.match ignored the na flag (GH6609).
- Bug in take with duplicate columns that were not consolidated (GH6240)
- Bug in interpolate changing dtypes (GH6290)
- Bug in Series.get, was using a buggy access method (GH6383)
- Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313)
- Bug in DataFrame.dropna with duplicate indices (GH6355)
- Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394)
- Float64Index with nans not comparing correctly (GH6401)
- eval/query expressions with strings containing the @ character will now work (GH6366).
- Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418)
- Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
- Perf issue in concatting with empty objects (GH3259)
- Clarify sorting of sym\_diff on Index objects with NaN values (GH6444)
- Regression in MultiIndex.from\_product with a DatetimeIndex as input (GH6439)
- Bug in str.extract when passed a non-default index (GH6348)
- Bug in str.split when passed pat=None and n=1 (GH6466)
- Bug in io.data.DataReader when passed "F-F\_Momentum\_Factor" and data\_source="famafrench" (GH6460)
- Bug in sum of a timedelta64[ns] series (GH6462)

- Bug in `resample` with a timezone and certain offsets (GH6397)
- Bug in `iat/iloc` with duplicate indices on a Series (GH6493)
- Bug in `read_html` where nan's were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
- Bug in `read_html` tests where redirected invalid URLs would make one test fail (GH6445).
- Bug in multi-axis indexing using `.loc` on non-unique indices (GH6504)
- Bug that caused `_ref_locs` corruption when slice indexing across columns axis of a DataFrame (GH6525)
- Regression from 0.13 in the treatment of numpy `datetime64` non-ns dtypes in Series creation (GH6529)
- `.names` attribute of MultiIndexes passed to `set_index` are now preserved (GH6459).
- Bug in `setitem` with a duplicate index and an alignable rhs (GH6541)
- Bug in `setitem` with `.loc` on mixed integer Indexes (GH6546)
- Bug in `pd.read_stata` which would use the wrong data types and missing values (GH6327)
- Bug in `DataFrame.to_stata` that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
- `StataWriter` replaces missing values in string columns by empty string (GH6802)
- Inconsistent types in Timestamp addition/subtraction (GH6543)
- Bug in preserving frequency across Timestamp addition/subtraction (GH4547)
- Bug in empty list lookup caused `IndexError` exceptions (GH6536, GH6551)
- `Series.quantile` raising on an object dtype (GH6555)
- Bug in `.xs` with a nan in level when dropped (GH6574)
- Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` dtype (GH6587)
- Bug in sql writing with mixed dtypes possibly leading to data loss (GH6509)
- Bug in `Series.pop` (GH6600)
- Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no re-ordering happened (GH6612)
- Bug in `fillna` with `limit` and `value` specified
- Bug in `DataFrame.to_stata` when columns have non-string names (GH4558)
- Bug in `compat` with `np.compress`, surfaced in (GH6658)
- Bug in binary operations with a rhs of a Series not aligning (GH6681)
- Bug in `DataFrame.to_stata` which incorrectly handles nan values and ignores `with_index` keyword argument (GH6685)
- Bug in `resample` with extra bins when using an evenly divisible frequency (GH4076)
- Bug in consistency of groupby aggregation when passing a custom function (GH6715)
- Bug in `resample` when `how=None` resample freq is the same as the axis frequency (GH5955)
- Bug in downcasting inference with empty arrays (GH6733)
- Bug in `obj.blocks` on sparse containers dropping all but the last items of same for dtype (GH6748)
- Bug in unpickling `NaT` (`NaTType`) (GH4606)

- Bug in `DataFrame.replace()` where regex metacharacters were being treated as regexs even when `regex=False` ([GH6777](#)).
- Bug in timedelta ops on 32-bit platforms ([GH6808](#))
- Bug in setting a tz-aware index directly via `.index` ([GH6785](#))
- Bug in `expressions.py` where `numexpr` would try to evaluate arithmetic ops ([GH6762](#)).
- Bug in Makefile where it didn't remove Cython generated C files with `make clean` ([GH6768](#))
- Bug with numpy < 1.7.2 when reading long strings from `HDFStore` ([GH6166](#))
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. ([GH6806](#))
- Regression from 0.13 with `fillna` and a Series on datetime-like ([GH6344](#))
- Bug in adding `np.timedelta64` to `DatetimeIndex` with timezone outputs incorrect results ([GH6818](#))
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value ([GH6689](#))
- Better error message when passing a frequency of 'MS' in `Period` construction ([GH5332](#))
- Bug in `Series.__unicode__` when `max_rows=None` and the Series has more than 1000 rows. ([GH6863](#))
- Bug in `groupby.get_group` where a datetlike wasn't always accepted ([GH5267](#))
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` ([GH6914](#))
- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting NaT incorrectly ([GH5546](#))
- Bug in arithmetic operations affecting NaT ([GH6873](#))
- Bug in `Series.str.extract` where the resulting Series from a single group match wasn't renamed to the group name
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the header kwarg ([GH6186](#))
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly ([GH6678](#))
- Internal tests for patching `__finalize__` / bug in merge not finalizing ([GH6923](#), [GH6927](#))
- accept `TextFileReader` in `concat`, which was affecting a common user idiom ([GH6583](#))
- Bug in C parser with leading whitespace ([GH3374](#))
- Bug in C parser with `delim_whitespace=True` and `\r`-delimited lines
- Bug in python parser with explicit multi-index in row following column header ([GH6893](#))
- Bug in `Series.rank` and `DataFrame.rank` that caused small floats (<1e-13) to all receive the same rank ([GH6886](#))
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result ([GH6952](#))
- Bug in sum/mean on 32-bit platforms on overflows ([GH6915](#))
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. ([GH6959](#))
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` ([GH6951](#))
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` ([GH6951](#))

- Bug in `read_csv` from a filesystem with non-utf-8 encoding ([GH6807](#))
- Bug in `iloc` when setting / aligning ([GH6766](#))
- Bug causing `UnicodeEncodeError` when `get_dummies` called with unicode values and a prefix ([GH6885](#))
- Bug in `timeseries-with-frequency` plot cursor display ([GH5453](#))
- Bug surfaced in `groupby.plot` when using a `Float64Index` ([GH7025](#))
- Stopped tests from failing if options data isn't able to be downloaded from Yahoo ([GH7034](#))
- Bug in `parallel_coordinates` and `radviz` where reordering of class column caused possible color/class mismatch ([GH6956](#))
- Bug in `radviz` and `andrews_curves` where multiple values of 'color' were being passed to plotting method ([GH6956](#))
- Bug in `Float64Index.isin()` where containing `nan`s would make indices claim that they contained all the things ([GH7066](#)).
- Bug in `DataFrame.boxplot` where it failed to use the axis passed as the `ax` argument ([GH3578](#))
- Bug in the `XlsxWriter` and `XlwtWriter` implementations that resulted in datetime columns being formatted without the time ([GH7075](#)) were being passed to plotting method
- `read_fwf()` treats `None` in `colspec` like regular python slices. It now reads from the beginning or until the end of the line when `colspec` contains a `None` (previously raised a `TypeError`)
- Bug in cache coherence with chained indexing and slicing; add `_is_view` property to `NDFrame` to correctly predict views; mark `is_copy` on `xs` only if its an actual copy (and not a view) ([GH7084](#))
- Bug in `DatetimeIndex` creation from string ndarray with `dayfirst=True` ([GH5917](#))
- Bug in `MultiIndex.from_arrays` created from `DatetimeIndex` doesn't preserve `freq` and `tz` ([GH7090](#))
- Bug in `unstack` raises `ValueError` when `MultiIndex` contains `PeriodIndex` ([GH4342](#))
- Bug in `boxplot` and `hist` draws unnecessary axes ([GH6769](#))
- Regression in `groupby.nth()` for out-of-bounds indexers ([GH6621](#))
- Bug in `quantile` with datetime values ([GH6965](#))
- Bug in `Dataframe.set_index`, `reindex` and `pivot` don't preserve `DatetimeIndex` and `PeriodIndex` attributes ([GH3950](#), [GH5878](#), [GH6631](#))
- Bug in `MultiIndex.get_level_values` doesn't preserve `DatetimeIndex` and `PeriodIndex` attributes ([GH7092](#))
- Bug in `Groupby` doesn't preserve `tz` ([GH3950](#))
- Bug in `PeriodIndex` partial string slicing ([GH6716](#))
- Bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the `large_repr` set to 'info' ([GH7105](#))
- Bug in `DatetimeIndex` specifying `freq` raises `ValueError` when passed value is too short ([GH7098](#))
- Fixed a bug with the `info` repr not honoring the `display.max_info_columns` setting ([GH6939](#))
- Bug `PeriodIndex` string slicing with out of bounds values ([GH5407](#))
- Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables ([GH7157](#))
- Bug in `isnull` when applied to 0-dimensional object arrays ([GH7176](#))

- Bug in `query/eval` where global constants were not looked up correctly ([GH7178](#))
- Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer ([GH7189](#))
- Bug in `setitem` with a single value, multi-index and integer indices ([GH7190](#), [GH7218](#))
- Bug in expressions evaluation with reversed ops, showing in series-dataframe ops ([GH7198](#), [GH7192](#))
- Bug in multi-axis indexing with  $> 2$  ndim and a multi-index ([GH7199](#))
- Fix a bug where invalid eval/query operations would blow the stack ([GH5198](#))

## 1.25 v0.13.1 (February 3, 2014)

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
- Will intelligently limit display precision for datetime/timedelta formats.
- Enhanced Panel `apply()` method.
- Suggested tutorials in new *Tutorials* section.
- Our pandas ecosystem is growing, We now feature related projects in a new *Pandas Ecosystem* section.
- Much work has been taking place on improving the docs, and a new *Contributing* section has been added.
- Even though it may only be of interest to devs, we <3 our new CI status page: [ScatterCI](#).

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having numpy  $< 1.8$ , and doing chained assignment on a string-like array. Please review [the docs](#), chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = DataFrame(dict(A = np.array(['foo', 'bar', 'bah', 'foo', 'bar'])))
In [2]: df['A'].iloc[0] = np.nan
In [3]: df
Out[3]:
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

The recommended way to do this type of assignment is:

```
In [4]: df = DataFrame(dict(A = np.array(['foo', 'bar', 'bah', 'foo', 'bar'])))

In [5]: df.loc[0, 'A'] = np.nan

In [6]: df
Out[6]:
   A
0 NaN
1 bar
2 bah
3 foo
4 bar
```

### 1.25.1 Output Formatting Enhancements

- `df.info()` view now display dtype info per column ([GH5682](#))
- `df.info()` now honors the option `max_info_rows`, to disable null counts for large frames ([GH5974](#))

```
In [7]: max_info_rows = pd.get_option('max_info_rows')

In [8]: df = DataFrame(dict(A = np.random.randn(10),
...:                        B = np.random.randn(10),
...:                        C = date_range('20130101', periods=10)))
...:

In [9]: df.iloc[3:6, [0, 2]] = np.nan
```

```
# set to not display the null counts
In [10]: pd.set_option('max_info_rows', 0)

In [11]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A      float64
B      float64
C      datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0 bytes
```

```
# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows', max_info_rows)

In [13]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A      7 non-null float64
B      10 non-null float64
C      7 non-null datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0 bytes
```

- Add `show_dimensions` display option for the new `DataFrame` repr to control whether the dimensions print.

```

In [14]: df = DataFrame([[1, 2], [3, 4]])

In [15]: pd.set_option('show_dimensions', False)

In [16]: df
Out[16]:
   0  1
0  1  2
1  3  4

In [17]: pd.set_option('show_dimensions', True)

In [18]: df
Out[18]:
   0  1
0  1  2
1  3  4

[2 rows x 2 columns]

```

- The `ArrayFormatter` for datetime and `timedelta64` now intelligently limit precision based on the values in the array ([GH3401](#))

Previously output might look like:

```

   age                today      diff
0 2001-01-01 00:00:00 2013-04-19 00:00:00 4491 days, 00:00:00
1 2004-06-01 00:00:00 2013-04-19 00:00:00 3244 days, 00:00:00

```

Now the output looks like:

```

In [19]: df = DataFrame([ Timestamp('20010101'),
   ....:                  Timestamp('20040601') ], columns=['age'])
   ....:

In [20]: df['today'] = Timestamp('20130419')

In [21]: df['diff'] = df['today']-df['age']

In [22]: df
Out[22]:
   age      today      diff
0 2001-01-01 2013-04-19 4491 days
1 2004-06-01 2013-04-19 3244 days

[2 rows x 3 columns]

```

## 1.25.2 API changes

- Add `-NaN` and `-nan` to the default set of NA values ([GH5952](#)). See *NA Values*.
- Added `Series.str.get_dummies` vectorized string method ([GH6021](#)), to extract dummy/indicator variables for separated string columns:

```

In [23]: s = Series(['a', 'a|b', np.nan, 'a|c'])

```

(continues on next page)

(continued from previous page)

```
b    NaN
Length: 2, dtype: float64
```

Now, when `apply` is called on an empty `DataFrame`: if the `reduce` argument is `True` a `Series` will be returned, if it is `False` a `DataFrame` will be returned, and if it is `None` (the default) the function being applied will be called with an empty series to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a    NaN
b    NaN
Length: 2, dtype: float64

In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []

[0 rows x 2 columns]
```

### 1.25.3 Prior Version Deprecations/Changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

### 1.25.4 Deprecations

There are no deprecations of prior behavior in 0.13.1

### 1.25.5 Enhancements

- `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexual for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

```
# Try to infer the format for the index column
df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                 infer_datetime_format=True)
```

- `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)
- `MultiIndex.from_product` convenience function for creating a `MultiIndex` from the cartesian product of a set of iterables (GH6055):

```
In [32]: shades = ['light', 'dark']

In [33]: colors = ['red', 'green', 'blue']
```

(continues on next page)

(continued from previous page)

```
In [34]: MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[34]:
MultiIndex(levels=[['dark', 'light'], ['blue', 'green', 'red']],
            labels=[[1, 1, 1, 0, 0, 0], [2, 1, 0, 2, 1, 0]],
            names=['shade', 'color'])
```

- Panel `apply()` will work on non-ufuncs. See *the docs*.

```
In [35]: import pandas.util.testing as tm

In [36]: panel = tm.makePanel(5)

In [37]: panel
Out[37]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [38]: panel['ItemA']
\\repeated slashes\\
↪
      A      B      C      D

2000-01-04  0.678630  0.639633  1.210384  1.176812
2000-01-05  0.239556 -0.962029  0.797435 -0.524336
2000-01-06  0.151227 -2.085266 -0.379811  0.700908
2000-01-07  0.816127  1.930247  0.702562  0.984188

[5 rows x 4 columns]
```

### Specifying an `apply` that operates on a Series (to return a single element)

```
In [39]: panel.apply(lambda x: x.dtype, axis='items')
Out[39]:
```

	A	B	C	D
2000-01-03	float64	float64	float64	float64
2000-01-04	float64	float64	float64	float64
2000-01-05	float64	float64	float64	float64
2000-01-06	float64	float64	float64	float64
2000-01-07	float64	float64	float64	float64

```
[5 rows x 4 columns]
```

A similar reduction type operation

```
In [40]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[40]:
```

	ItemA	ItemB	ItemC
A	2.579643	3.062757	0.379252
B	1.416120	-1.960855	0.923558
C	0.595222	-1.079772	-3.118269
D	1.487226	-0.734611	-1.979310

```
[4 rows x 3 columns]
```

This is equivalent to

```
In [41]: panel.sum('major_axis')
Out[41]:
```

	ItemA	ItemB	ItemC
A	2.579643	3.062757	0.379252
B	1.416120	-1.960855	0.923558
C	0.595222	-1.079772	-3.118269
D	1.487226	-0.734611	-1.979310

```
[4 rows x 3 columns]
```

A transformation operation that returns a Panel, but is computing the z-score across the major\_axis

```
In [42]: result = panel.apply(
.....:     lambda x: (x-x.mean())/x.std(),
.....:     axis='major_axis')
.....:

In [43]: result
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [44]: result['ItemA']
////////////////////////////////////
```

	A	B	C	D
2000-01-03	0.595800	0.907552	-1.556260	-1.244875

## 1.25.6 Performance

Performance improvements for 0.13.1

- Series datetime/timedelta binary operations ([GH5801](#))
- DataFrame count/dropna for axis=1
- Series.str.contains now has a *regex=False* keyword which can be faster for plain (non-regex) string patterns. ([GH5879](#))
- Series.str.extract ([GH5944](#))
- dtypes/ftypes methods ([GH5968](#))
- indexing with object dtypes ([GH5968](#))
- DataFrame.apply ([GH6013](#))
- Regression in JSON IO ([GH5765](#))
- Index construction from Series ([GH6150](#))

## 1.25.7 Experimental

There are no experimental changes in 0.13.1

## 1.25.8 Bug Fixes

See [V0.13.1 Bug Fixes](#) for an extensive list of bugs that have been fixed in 0.13.1.

See the [full release notes](#) or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

## 1.26 v0.13.0 (January 3, 2014)

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type `Float64Index`, and other Indexing enhancements
- `HDFStore` has a new string based syntax for query specification
- support for new methods of interpolation
- updated `timedelta` operations
- a new string manipulation method `extract`
- Nanosecond support for Offsets
- `isin` for DataFrames

Several experimental features are added, including:

- new `eval/query` methods for expression evaluation
- support for `msgpack` serialization
- an i/o interface to Google's `BigQuery`

There are several new or updated docs sections including:

- [Comparison with SQL](#), which should be useful for those familiar with SQL but still learning pandas.
- [Comparison with R](#), idiom translations from R to pandas.
- [Enhancing Performance](#), ways to enhance pandas performance with `eval/query`.

**Warning:** In 0.13.0 `Series` has internally been refactored to no longer sub-class `ndarray` but instead subclass `NDFrame`, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See [Internal Refactoring](#)

### 1.26.1 API changes

- `read_excel` now supports an integer in its `sheetname` argument giving the index of the sheet to read in (GH4301).

- Text parser now treats anything that reads like inf (“inf”, “Inf”, “-Inf”, “iNf”, etc.) as infinity. (GH4220, GH4219), affecting `read_table`, `read_csv`, etc.
- pandas now is Python 2/3 compatible without the need for 2to3 thanks to @jtratrner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s `six` library into `compat`. (GH4384, GH4375, GH4372)
- `pandas.util.compat` and `pandas.util.py3compat` have been merged into `pandas.compat`. `pandas.compat` now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of `range`, `filter`, `map` and `zip`, plus other necessary elements for Python 3 compatibility. `lmap`, `lzip`, `lrange` and `lfilter` all produce lists instead of iterators, for compatibility with `numpy`, subscripting and pandas constructors. (GH4384, GH4375, GH4372)
- `Series.get` with negative indexers now returns the same as `[]` (GH4390)
- Changes to how `Index` and `MultiIndex` handle metadata (`levels`, `labels`, and `names`) (GH4039):

```
# previously, you would have set levels or labels directly
index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
index = index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

# similarly, for names, you can rename the object
# but setting names is not deprecated
index = index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
index.set_names(["bob", "cranberry"], inplace=True)
```

- All division with `NDFrame` objects is now *truedivision*, regardless of the future import. This means that operating on pandas objects will by default use *floating point* division, and return a floating point dtype. You can use `//` and `floordiv` to do integer division.

#### Integer division

```
In [3]: arr = np.array([1, 2, 3, 4])

In [4]: arr2 = np.array([5, 3, 2, 1])

In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])

In [6]: Series(arr) // Series(arr2)
Out[6]:
0    0
1    0
2    1
3    4
dtype: int64
```

#### True Division

```
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
0    0.200000
1    0.666667
2    1.500000
```

(continues on next page)

(continued from previous page)

```
3      4.000000
dtype: float64
```

- Infer and downcast dtype if `downcast='infer'` is passed to `fillna/ffill/bfill` ([GH4604](#))
- `__nonzero__` for all `NDFrame` objects, will now raise a `ValueError`, this reverts back to ([GH1073](#), [GH4633](#)) behavior. See [gotchas](#) for a more detailed discussion.

This prevents doing boolean comparison on *entire* pandas objects, which is inherently ambiguous. These all will raise a `ValueError`.

```
if df:
    ....
df1 and df2
s1 and s2
```

Added the `.bool()` method to `NDFrame` objects to facilitate evaluating of single-element boolean Series:

```
In [1]: Series([True]).bool()
Out[1]: True

In [2]: Series([False]).bool()
Out[2]: False

In [3]: DataFrame([True]).bool()
Out[3]: True

In [4]: DataFrame([False]).bool()
Out[4]: False
```

- All non-Index `NDFrames` (`Series`, `DataFrame`, `Panel`, `Panel4D`, `SparsePanel`, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (`add`, `sub`, `mul`, etc.). `SparsePanel` does not support `pow` or `mod` with non-scalars. ([GH3765](#))
- `Series` and `DataFrame` now have a `mode()` method to calculate the statistical mode(s) by axis/Series. ([GH5367](#))
- Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option `mode.chained_assignment`, allowed options are `raise/warn/None`. See [the docs](#).

```
In [5]: dfc = DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
...
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.

```
In [8]: dfc.loc[0, 'A'] = 11

In [9]: dfc
Out[9]:
```

	A	B
0	11	1
1	bbb	2
2	ccc	3

```
[3 rows x 2 columns]
```

- **Panel.reindex** has the following call signature `Panel.reindex(items=None, major_axis=None, minor_axis=None)` to conform with other NDFrame objects. See *Internal Refactoring* for more information.
- **Series.argmax** and **Series.argmin** are now aliased to **Series.idxmax** and **Series.idxmin**. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

### 1.26.2 Prior Version Deprecations/Changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated `Factor` (GH3650)
- Remove deprecated `set_printoptions/reset_printoptions` (GH3046)
- Remove deprecated `_verbose_info` (GH3215)
- Remove deprecated `read_clipboard/to_clipboard/ExcelFile/ExcelWriter` from `pandas.io.parsers` (GH3717) These are available as functions in the main pandas namespace (e.g. `pd.read_clipboard`)
- default for `tupleize_cols` is now `False` for both `to_csv` and `read_csv`. Fair warning in 0.12 (GH3604)
- default for `display.max_seq_len` is now 100 rather than `None`. This activates truncated display (“...”) of long sequences in various places. (GH3391)

### 1.26.3 Deprecations

Deprecated in 0.13.0

- deprecated `iterkv`, which will be removed in a future release (this was an alias of `iteritems` used to bypass 2to3’s changes). (GH4384, GH4375, GH4372)
- deprecated the string method `match`, whose role is now performed more idiomatically by `extract`. In a future release, the default behavior of `match` will change to become analogous to `contains`, which returns a boolean indexer. (Their distinction is strictness: `match` relies on `re.match` while `contains` relies on `re.search`.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument `as_indexer=True`.

### 1.26.4 Indexing API Changes

Prior to 0.13, it was impossible to use a label indexer (`.loc/.ix`) to set a value that was not contained in the index of a particular axis. (GH2578). See *the docs*

In the `Series` case this is effectively an appending operation

```
In [10]: s = Series([1,2,3])
```

```
In [11]: s
```

```
Out[11]:
```

```
0    1
```

```
1    2
```

```
2    3
```

```
Length: 3, dtype: int64
```

```
In [12]: s[5] = 5.
```

```
In [13]: s
```

```
Out[13]:
```

```
0    1.0
```

```
1    2.0
```

```
2    3.0
```

```
5    5.0
```

```
Length: 4, dtype: float64
```

```
In [14]: dfi = DataFrame(np.arange(6).reshape(3,2),
.....:                  columns=['A', 'B'])
.....:
```

```
In [15]: dfi
```

```
Out[15]:
```

```
   A  B
```

```
0  0  1
```

```
1  2  3
```

```
2  4  5
```

```
[3 rows x 2 columns]
```

This would previously `KeyError`

```
In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

```
In [17]: dfi
```

```
Out[17]:
```

```
   A  B  C
```

```
0  0  1  0
```

```
1  2  3  2
```

```
2  4  5  4
```

```
[3 rows x 3 columns]
```

This is like an `append` operation.

```
In [18]: dfi.loc[3] = 5
```

```
In [19]: dfi
```

```
Out[19]:
```

```
   A  B  C
```

```
0  0  1  0
```

```
1  2  3  2
```

```
2  4  5  4
```

```
3  5  5  5
```

(continues on next page)

(continued from previous page)

[4 rows x 3 columns]

A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2,4,2),
.....:               items=['Item1','Item2'],
.....:               major_axis=pd.date_range('2001/1/12',periods=4),
.....:               minor_axis=['A','B'],dtype='float64')
.....:
```

```
In [21]: p
```

```
Out[21]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:, :, 'C'] = Series([30,32],index=p.items)
```

```
In [23]: p
```

```
Out[23]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C
```

```
In [24]: p.loc[:, :, 'C']
```

```
////////////////////////////////////
↪
      Item1  Item2
2001-01-12   30.0   32.0
2001-01-13   30.0   32.0
2001-01-14   30.0   32.0
2001-01-15   30.0   32.0

[4 rows x 2 columns]
```

### 1.26.5 Float64Index API Change

- Added a new index type, `Float64Index`. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `ix`, `loc` for scalar indexing and slicing work exactly the same. See [the docs](#), (GH263)

Construction is by default for floating type values.

```
In [25]: index = Index([1.5, 2, 3, 4.5, 5])
```

```
In [26]: index
```

```
Out[26]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
```

```
In [27]: s = Series(range(5),index=index)
```

```
In [28]: s
```

(continues on next page)

(continued from previous page)

```
Out [28]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
Length: 5, dtype: int64
```

Scalar selection for `[]`, `.ix`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

```
In [29]: s[3]
Out[29]: 2

In [30]: s.loc[3]
Out[30]: 2
```

The only positional indexing is via `iloc`

```
In [31]: s.iloc[3]
Out[31]: 3
```

A scalar index that is not found will raise `KeyError`

Slicing is ALWAYS on the values of the index, for `[]`, `ix`, `loc` and ALWAYS positional with `iloc`

```
In [32]: s[2:4]
Out[32]:
2.0    1
3.0    2
Length: 2, dtype: int64

In [33]: s.loc[2:4]
Out[33]:
2.0    1
3.0    2
Length: 2, dtype: int64

In [34]: s.iloc[2:4]
Out[34]:
3.0    2
4.5    3
Length: 2, dtype: int64
```

In float indexes, slicing using floats are allowed

```
In [35]: s[2.1:4.6]
Out[35]:
3.0    2
4.5    3
Length: 2, dtype: int64

In [36]: s.loc[2.1:4.6]
Out[36]:
3.0    2
```

(continues on next page)

(continued from previous page)

```
4.5      3
Length: 2, dtype: int64
```

- Indexing on other index types are preserved (and positional fallback for `[]`, `ix`), with the exception, that floating point slicing on indexes on non `Float64Index` will now raise a `TypeError`.

```
In [1]: Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type
↳ (Int64Index)

In [1]: Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
↳ (Int64Index)
```

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

```
In [3]: Series(range(5))[3.0]
Out[3]: 3
```

## 1.26.6 HDFStore API Changes

- Query Format Changes. A much more string-like query format is now supported. See [the docs](#).

```
In [37]: path = 'test.h5'

In [38]: dfq = DataFrame(randn(10,4),
.....:                  columns=list('ABCD'),
.....:                  index=date_range('20130101', periods=10))
.....:

In [39]: dfq.to_hdf(path, 'dfq', format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [40]: read_hdf(path, 'dfq',
.....:             where="index>Timestamp('20130104') & columns=['A', 'B']")
.....:
Out[40]:
```

	A	B
2013-01-05	1.057633	-0.791489
2013-01-06	1.910759	0.787965
2013-01-07	1.043945	2.107785
2013-01-08	0.749185	-0.675521
2013-01-09	-0.276646	1.924533
2013-01-10	0.226363	-2.078618

[6 rows x 2 columns]

Use an inline column reference

```
In [41]: read_hdf(path, 'dfq',
.....:             where="A>0 or C>0")
.....:
Out[41]:
```

	A	B	C	D
--	---	---	---	---

(continues on next page)

(continued from previous page)

```

2013-01-01 -0.414505 -1.425795  0.209395 -0.592886
2013-01-02 -1.473116 -0.896581  1.104352 -0.431550
2013-01-03 -0.161137  0.889157  0.288377 -1.051539

2013-01-10  0.226363 -2.078618 -0.387886 -0.087107

[10 rows x 4 columns]

```

- the format keyword now replaces the table keyword; allowed values are fixed(f) or table(t) the same defaults as prior < 0.13.0 remain, e.g. put implies fixed format and append implies table format. This default format can be set as an option by setting `io.hdf.default_format`.

```

In [42]: path = 'test.h5'

In [43]: df = pd.DataFrame(np.random.randn(10,2))

In [44]: df.to_hdf(path, 'df_table', format='table')

In [45]: df.to_hdf(path, 'df_table2', append=True)

In [46]: df.to_hdf(path, 'df_fixed')

In [47]: with pd.HDFStore(path) as store:
.....:     print(store)
.....:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

```

- Significant table writing performance improvements
- handle a passed Series in table format ([GH4330](#))
- can now serialize a `timedelta64[ns]` dtype in a table ([GH3577](#)), See *the docs*.
- added an `is_open` property to indicate if the underlying file handle is `is_open`; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) ([GH4409](#))
- a close of a `HDFStore` now will close that instance of the `HDFStore` but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of `HDFStore` referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise `ClosedFileError`

```

In [48]: path = 'test.h5'

In [49]: df = DataFrame(randn(10,2))

In [50]: store1 = HDFStore(path)

In [51]: store2 = HDFStore(path)

In [52]: store1.append('df', df)

```

(continues on next page)

(continued from previous page)

```

In [53]: store2.append('df2',df)

In [54]: store1
Out[54]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [55]: store2
Out[55]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [56]: store1.close()

In [57]: store2
Out[57]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [58]: store2.close()

In [59]: store2
Out[59]:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

```

- removed the `_quiet` attribute, replace by a `DuplicateWarning` if retrieving duplicate rows from a table ([GH4367](#))
- removed the `warn` argument from `open`. Instead a `PossibleDataLossError` exception will be raised if you try to use `mode='w'` with an OPEN file handle ([GH4367](#))
- allow a passed locations array or mask as a `where` condition ([GH4467](#)). See [the docs](#) for an example.
- add the keyword `dropna=True` to `append` to change whether ALL nan rows are not written to the store (default is `True`, ALL nan rows are NOT written), also settable via the option `io.hdf.dropna_table` ([GH4625](#))
- pass thru store creation arguments; can be used to support in-memory stores

### 1.26.7 DataFrame repr Changes

The HTML and plain text representations of `DataFrame` now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view ([GH4886](#), [GH5550](#)). This makes the representation more consistent as small `DataFrames` get larger.

<b>2010-03-29</b>	13.70	13.88	13.39	13.57	158225000	12.98
<b>2010-03-30</b>	13.55	13.64	13.18	13.28	142055200	12.70
	...	...	...	...	...	...

771 rows x 6 columns

To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

### 1.26.8 Enhancements

- `df.to_clipboard()` learned a new `excel` keyword that let's you paste df data directly into excel (enabled by default). (GH5070).
- `read_html` now raises a `URLError` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes `records` as a possible outtype. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handling in `get_dummies` (GH4446) with `dummy_na`

```
# previously, nan was erroneously counted as 2 here
# now it is not counted at all
In [60]: get_dummies([1, 2, np.nan])
Out[60]:
   1.0  2.0
0    1    0
1    0    1
2    0    0

[3 rows x 2 columns]

# unless requested
In [61]: get_dummies([1, 2, np.nan], dummy_na=True)
Out[61]:
   1.0  2.0  NaN
0    1    0    0
1    0    1    0
2    0    0    1

[3 rows x 3 columns]
```

- `timedelta64[ns]` operations. See [the docs](#).

**Warning:** Most of these operations require `numpy >= 1.7`

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard `timedelta` format (produced by `to_csv`) into a `timedelta` type (`np.timedelta64` in nanoseconds).

```
In [62]: to_timedelta('1 days 06:05:01.00003')
Out[62]: Timedelta('1 days 06:05:01.000030')

In [63]: to_timedelta('15.5us')
Out[63]: Timedelta('0 days 00:00:00.000015')

In [64]: to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[64]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT], dtype='timedelta64[ns]', freq=None)

In [65]: to_timedelta(np.arange(5), unit='s')
Out[65]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'], dtype='timedelta64[ns]', freq=None)

In [66]: to_timedelta(np.arange(5), unit='d')
Out[66]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)
```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` typed Series. This is frequency conversion. See [the docs](#) for the docs.

```
In [67]: from datetime import timedelta

In [68]: td = Series(date_range('20130101', periods=4)) - Series(date_range('20121201', periods=4))

In [69]: td[2] += np.timedelta64(timedelta(minutes=5, seconds=3))

In [70]: td[3] = np.nan

In [71]: td
Out[71]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3                NaT
Length: 4, dtype: timedelta64[ns]

# to days
In [72]: td / np.timedelta64(1, 'D')
Out[72]:
0    31.000000
1    31.000000
2    31.003507
3           NaN
Length: 4, dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [73]: td.astype('timedelta64[D]')
```

```

////////////////////////////////////
↪
0      31.0
1      31.0
2      31.0
3       NaN
Length: 4, dtype: float64
```

```
# to seconds
```

```
In [74]: td / np.timedelta64(1, 's')
```

```

////////////////////////////////////
↪
0      2678400.0
1      2678400.0
2      2678703.0
3           NaN
Length: 4, dtype: float64
```

```
In [75]: td.astype('timedelta64[s]')
```

```

////////////////////////////////////
↪
0      2678400.0
1      2678400.0
2      2678703.0
3           NaN
Length: 4, dtype: float64
```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```
In [76]: td * -1
```

```
Out[76]:
```

```

0      -31 days +00:00:00
1      -31 days +00:00:00
2      -32 days +23:54:57
3                NaT
Length: 4, dtype: timedelta64[ns]
```

```
In [77]: td * Series([1,2,3,4])
```

```

////////////////////////////////////
↪
0      31 days 00:00:00
1      62 days 00:00:00
2      93 days 00:15:09
3                NaT
Length: 4, dtype: timedelta64[ns]
```

Absolute `DateOffset` objects can act equivalently to `timedeltas`

```
In [78]: from pandas import offsets
```

```
In [79]: td + offsets.Minute(5) + offsets.Milli(5)
```

```
Out[79]:
```

```

0      31 days 00:05:00.005000
1      31 days 00:05:00.005000
2      31 days 00:10:03.005000
```

(continues on next page)

(continued from previous page)

```
3          NaT
Length: 4, dtype: timedelta64[ns]
```

Fillna is now supported for timedeltas

```
In [80]: td.fillna(0)
Out[80]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     0 days 00:00:00
Length: 4, dtype: timedelta64[ns]

In [81]: td.fillna(timedelta(days=1,seconds=5))
Out[81]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     1 days 00:00:05
Length: 4, dtype: timedelta64[ns]
```

You can do numeric reduction operations on timedeltas.

```
In [82]: td.mean()
Out[82]: Timedelta('31 days 00:01:41')

In [83]: td.quantile(.1)
Out[83]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for `scipy >= 0.11.0`) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See [scipy docs](#). ([GH4298](#))
- `DataFrame` constructor now accepts a numpy masked record array ([GH3478](#))
- The new vectorized string method `extract` return regular expression matches more conveniently.

```
In [84]: Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out[84]:
0    1
1    2
2   NaN
[3 rows x 1 columns]
```

Elements that do not match return NaN. Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [85]: Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)')
Out[85]:
0    a    1
1    b    2
2   NaN  NaN
```

(continues on next page)

(continued from previous page)

```
[3 rows x 2 columns]
```

Elements that do not match return a row of NaN. Thus, a Series of messy strings can be *converted* into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects.

Named groups like

```
In [86]: Series(['a1', 'b2', 'c3']).str.extract(
.....:         '(?P<letter>[ab])(?P<digit>\d)')
.....:
Out [86]:
   letter digit
0      a      1
1      b      2
2    NaN    NaN

[3 rows x 2 columns]
```

and optional groups can also be used.

```
In [87]: Series(['a1', 'b2', '3']).str.extract(
.....:         '(?P<letter>[ab])?(?P<digit>\d)')
.....:
Out [87]:
   letter digit
0      a      1
1      b      2
2    NaN      3

[3 rows x 2 columns]
```

- `read_stata` now accepts Stata 13 format ([GH4291](#))
- `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function ([GH4488](#)).
- support for nanosecond times as an offset

**Warning:** These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```
In [88]: date_range('2013-01-01', periods=5, freq='5N')
Out [88]:
DatetimeIndex([
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
              dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset

```
In [90]: t = Timestamp('20130101 09:01:02')

In [91]: t + pd.tseries.offsets.Nano(123)
Out[91]: Timestamp('2013-01-01 09:01:02.000000123')
```

- To get the rows where any of the conditions are met:

```
In [92]: dfi = DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})

In [93]: dfi
Out[93]:
   A  B
0  1  a
1  2  b
2  3  f
3  4  n

[4 rows x 2 columns]

In [94]: other = DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})

In [95]: mask = dfi.isin(other)

In [96]: mask
Out[96]:
      A      B
0  True  False
1  False False
2  True   True
3  False False

[4 rows x 2 columns]

In [97]: dfi[mask.any(1)]
////////////////////////////////////
↪
   A  B
0  1  a
2  3  f

[2 rows x 2 columns]
```

- `Series` now supports a `to_frame` method to convert it to a single-column `DataFrame` (GH5164)
- All R datasets listed here <http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html> can now be

loaded into Pandas objects

```
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see [the docs](#)
- `DatetimeIndex` is now in the API documentation, see [the docs](#)
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See [the docs](#) (GH1067)
- Added PySide support for the `qt pandas DataFrameModel` and `DataFrameWidget`.
- Python csv parser now supports `usecols` (GH4335)
- Frequencies gained several new offsets:
  - `LastWeekOfMonth` (GH4637)
  - `FY5253`, and `FY5253Quarter` (GH4511)
- `DataFrame` has a new `interpolate` method, similar to `Series` (GH4434, GH1892)

```
In [98]: df = DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                  'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
.....:

In [99]: df.interpolate()
Out[99]:
```

	A	B
0	1.0	0.25
1	2.1	1.50
2	3.4	2.75
3	4.7	4.00
4	5.6	12.20
5	6.8	14.40

```
[6 rows x 2 columns]
```

Additionally, the method argument to `interpolate` has been expanded to include `'nearest'`, `'zero'`, `'slinear'`, `'quadratic'`, `'cubic'`, `'barycentric'`, `'krogh'`, `'piecewise_polynomial'`, `'pchip'`, `'polynomial'`, `'spline'`. The new methods require `scipy`. Consult the [Scipy reference guide](#) and [documentation](#) for more information about when the various methods are appropriate. See [the docs](#).

`Interpolate` now also accepts a `limit` keyword argument. This works similar to `fillna`'s `limit`:

```
In [100]: ser = Series([1, 3, np.nan, np.nan, np.nan, 11])

In [101]: ser.interpolate(limit=2)
Out[101]:
```

0	1.0
1	3.0
2	5.0
3	7.0
4	NaN
5	11.0

```
Length: 6, dtype: float64
```

- Added `wide_to_long` panel data convenience function. See *the docs*.

```
In [102]: np.random.seed(123)

In [103]: df = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
.....:                      "A1980" : {0 : "d", 1 : "e", 2 : "f"},
.....:                      "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
.....:                      "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
.....:                      "X"      : dict(zip(range(3), np.random.randn(3)))
.....:                      })

In [104]: df["id"] = df.index

In [105]: df
Out[105]:
```

	A1970	A1980	B1970	B1980	X	id
0	a	d	2.5	3.2	-1.085631	0
1	b	e	1.2	1.3	0.997345	1
2	c	f	0.7	0.1	0.282978	2

```
[3 rows x 6 columns]

In [106]: wide_to_long(df, ["A", "B"], i="id", j="year")
////////////////////////////////////
```

		X	A	B
id	year			
0	1970	-1.085631	a	2.5
1	1970	0.997345	b	1.2
2	1970	0.282978	c	0.7
0	1980	-1.085631	d	3.2
1	1980	0.997345	e	1.3
2	1980	0.282978	f	0.1

```
[6 rows x 3 columns]
```

- `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. ([GH4313](#))
- `DataFrame.plot` will scatter plot x versus y by passing `kind='scatter'` ([GH2215](#))
- Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. ([GH5271](#))

### 1.26.9 Experimental

- The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,

```
In [107]: nrows, ncols = 20000, 100
In [108]: df1, df2, df3, df4 = [DataFrame(randn(nrows, ncols))
.....:                             for _ in range(4)]
.....:
```

```
# eval with NumExpr backend
In [109]: %timeit pd.eval('df1 + df2 + df3 + df4')
8.07 ms +- 212 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```
# pure Python evaluation
In [110]: %timeit df1 + df2 + df3 + df4
11.4 ms +- 752 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the [the docs](#)

- Similar to `pandas.eval`, `DataFrame` has a new `DataFrame.eval` method that evaluates an expression in the context of the `DataFrame`. For example,

```
In [111]: df = DataFrame(randn(10, 2), columns=['a', 'b'])

In [112]: df.eval('a + b')
Out[112]:
0    -0.685204
1     1.589745
2     0.325441
3    -1.784153
4    -0.432893
5     0.171850
6     1.895919
7     3.065587
8    -0.092759
9     1.391365
Length: 10, dtype: float64
```

- `query()` method has been added that allows you to select elements of a `DataFrame` using a natural query syntax nearly identical to Python syntax. For example,

```
In [113]: n = 20

In [114]: df = DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c
↪'])

In [115]: df.query('a < b < c')
Out[115]:
   a  b  c
11  1  5  8
15  8 16 19

[2 rows x 3 columns]
```

selects all the rows of `df` where `a < b < c` evaluates to `True`. For more details see the [the docs](#).

- `pd.read_msgpack()` and `pd.to_msgpack()` are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See [the docs](#)

**Warning:** Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```
In [116]: df = DataFrame(np.random.rand(5, 2), columns=list('AB'))
```

(continues on next page)

(continued from previous page)

```

In [117]: df.to_msgpack('foo.msg')

In [118]: pd.read_msgpack('foo.msg')
Out[118]:
      A      B
0  0.251082  0.017357
1  0.347915  0.929879
2  0.546233  0.203368
3  0.064942  0.031722
4  0.355309  0.524575

[5 rows x 2 columns]

In [119]: s = Series(np.random.rand(5), index=date_range('20130101', periods=5))

In [120]: pd.to_msgpack('foo.msg', df, s)

In [121]: pd.read_msgpack('foo.msg')
Out[121]:
[
      A      B
0  0.251082  0.017357
1  0.347915  0.929879
2  0.546233  0.203368
3  0.064942  0.031722
4  0.355309  0.524575

[5 rows x 2 columns], 2013-01-01    0.022321
2013-01-02    0.227025
2013-01-03    0.383282
2013-01-04    0.193225
2013-01-05    0.110977
Freq: D, Length: 5, dtype: float64]

```

You can pass `iterator=True` to iterator over the unpacked results

```

In [122]: for o in pd.read_msgpack('foo.msg', iterator=True):
.....:     print(o)
.....:
      A      B
0  0.251082  0.017357
1  0.347915  0.929879
2  0.546233  0.203368
3  0.064942  0.031722
4  0.355309  0.524575

[5 rows x 2 columns]
2013-01-01    0.022321
2013-01-02    0.227025
2013-01-03    0.383282
2013-01-04    0.193225
2013-01-05    0.110977
Freq: D, Length: 5, dtype: float64

```

- `pandas.io.gbq` provides a simple way to extract from, and load data into, Google's BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. *See the docs*

```

from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicdata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.

query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC"""

# Fetch the result set for this query

# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = xxxxxxxxx;

df = gbq.read_gbq(query, project_id = projectid)

# Use pandas to process and reshape the dataset

df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pandas.concat([df2.min(), df2.mean(), df2.max()],
                    axis=1,keys=["Min Tem", "Mean Temp", "Max Temp"])

```

The resulting DataFrame is:

```

> df3
      Min Tem  Mean Temp  Max Temp
MONTH
1    -53.336667  39.827892  89.770968
2    -49.837500  43.685219  93.437932
3    -77.926087  48.708355  96.099998
4    -82.892858  55.070087  97.317240
5    -92.378261  61.428117  102.042856
6    -77.703334  65.858888  102.900000
7    -87.821428  68.169663  106.510714
8    -89.431999  68.614215  105.500000
9    -86.611112  63.436935  107.142856
10   -78.209677  56.880838  92.103333
11   -50.125000  48.861228  94.996428
12   -50.332258  42.286879  94.396774

```

**Warning:** To use this module, you will need a BigQuery account. See <<https://cloud.google.com/products/big-query>> for details.

As of 10/10/13, there is a bug in Google's API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.

### 1.26.10 Internal Refactoring

In 0.13.0 there is a major refactor primarily to subclass `Series` from `NDFrame`, which is the base class currently for `DataFrame` and `Panel`, to unify methods and behaviors. `Series` formerly subclassed directly from `ndarray`. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a Series if passed a Series as an argument. This seems only to affect `np.ones_like`, `np.empty_like`, `np.diff` and `np.where`. These now return `ndarrays`.

```
In [123]: s = Series([1, 2, 3, 4])
```

## Numpy Usage

[illegible]

## Pandonic Usage

```
In [127]: Series(1, index=s.index)
Out[127]:
0    1
1    1
2    1
3    1
Length: 4, dtype: int64

In [128]: s.diff()
Out[128]:
0    NaN
1    1.0
2    1.0
3    1.0
Length: 4, dtype: float64

In [129]: s.where(s>1)
Out[129]:
0    NaN
1    2.0
2    3.0
3    4.0
Length: 4, dtype: float64
```

- Passing a `Series` directly to a cython function expecting an `ndarray` type will no longer work directly, you must pass `Series.values`, See [Enhancing Performance](#)
- `Series(0.5)` would previously return the scalar `0.5`, instead this will return a 1-element `Series`
- This change breaks `rpy2<=2.3.8`. An Issue has been opened against `rpy2` and a workaround is detailed in [GH5698](#). Thanks @JanSchulz.

- Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with `pd.read_pickle`, see [Pickling](#).
- Refactor of `series.py/frame.py/panel.py` to move common code to `generic.py`
  - added `__setup_axes` to created generic NDFrame structures
  - moved methods
    - \* `from_axes, __wrap_array, axes, ix, loc, iloc, shape, empty, swapaxes, transpose, pop`
    - \* `__iter__, keys, __contains__, __len__, __neg__, __invert__`
    - \* `convert_objects, as_blocks, as_matrix, values`
    - \* `__getstate__, __setstate__` (compat remains in frame/panel)
    - \* `__getattr__, __setattr__`
    - \* `_indexed_same, reindex_like, align, where, mask`
    - \* `fillna, replace` (Series `replace` is now consistent with DataFrame)
    - \* `filter` (also added axis argument to selectively filter on a different axis)
    - \* `reindex, reindex_axis, take`
    - \* `truncate` (moved to become part of NDFrame)
- These are API changes which make Panel more consistent with DataFrame
  - `swapaxes` on a Panel with the same axes specified now return a copy
  - support attribute access for setting
  - `filter` supports the same API as the original DataFrame filter
- Reindex called with no arguments will now return a copy of the input object
- `TimeSeries` is now an alias for `Series`. the property `is_time_series` can be used to distinguish (if desired)
- Refactor of Sparse objects to use BlockManager
  - Created a new block type in internals, `SparseBlock`, which can hold multi-dtypes and is non-consolidatable. `SparseSeries` and `SparseDataFrame` now inherit more methods from there hierarchy (Series/DataFrame), and no longer inherit from `SparseArray` (which instead is the object of the `SparseBlock`)
  - Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  - Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  - enable `setitem` on `SparseSeries` for boolean/integer/slices
  - `SparsePanels` implementation is unchanged (e.g. not using BlockManager, needs work)
- added `ftypes` method to Series/DataFrame, similar to `dtypes`, but indicates if the underlying is sparse/dense (as well as the dtype)
- All NDFrame objects can now use `__finalize__()` to specify various values to propagate to new objects from an existing one (e.g. name in Series will follow more automatically now)
- Internal type checking is now done via a suite of generated classes, allowing `isinstance(value, klass)` without having to directly import the klass, courtesy of @jtratrner

- Bug in Series update where the parent frame is not updating its cache based on changes ([GH4080](#)) or types ([GH3217](#)), fillna ([GH3386](#))
- Indexing with dtype conversions fixed ([GH4463](#), [GH4204](#))
- Refactor Series.reindex to core/generic.py ([GH4604](#), [GH4618](#)), allow method= in reindexing on a Series to work
- Series.copy no longer accepts the order parameter and is now consistent with NDFrame copy
- Refactor rename methods to core/generic.py; fixes Series.rename for ([GH4605](#)), and adds rename with the same signature for Panel
- Refactor clip methods to core/generic.py ([GH4798](#))
- Refactor of \_get\_numeric\_data/\_get\_bool\_data to core/generic.py, allowing Series/Panel functionality
- Series (for index) / Panel (for items) now allow attribute access to its elements ([GH1903](#))

```
In [130]: s = Series([1,2,3],index=list('abc'))

In [131]: s.b
Out[131]: 2

In [132]: s.a = 5

In [133]: s
Out[133]:
a    5
b    2
c    3
Length: 3, dtype: int64
```

### 1.26.11 Bug Fixes

See *V0.13.0 Bug Fixes* for an extensive list of bugs that have been fixed in 0.13.0.

See the *full release notes* or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

## 1.27 v0.12.0 (July 24, 2013)

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write multi-indexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via `filter`, and a revamped `replace` routine that accepts regular expressions.

### 1.27.1 API changes

- The I/O API is now much more consistent with a set of top level reader functions accessed like `pd.read_csv()` that generally return a pandas object.
  - `read_csv`

```

- read_excel
- read_hdf
- read_sql
- read_json
- read_html
- read_stata
- read_clipboard

```

The corresponding writer functions are object methods that are accessed like `df.to_csv()`

```

- to_csv
- to_excel
- to_hdf
- to_sql
- to_json
- to_html
- to_stata
- to_clipboard

```

- Fix modulo and integer division on Series, DataFrames to act similarly to float dtypes to return `np.nan` or `np.inf` as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes differently.

```
In [1]: p = DataFrame({ 'first' : [4,5,8], 'second' : [0,0,3] })
```

```
In [2]: p % 0
```

```
Out[2]:
```

```

      first  second
0      NaN      NaN
1      NaN      NaN
2      NaN      NaN

[3 rows x 2 columns]

```

```
In [3]: p % p
```

```

////////////////////////////////////
↪
      first  second
0      0.0      NaN
1      0.0      NaN
2      0.0      0.0

[3 rows x 2 columns]

```

```
In [4]: p / p
```

```

////////////////////////////////////
↪
      first  second
0      1.0      NaN
1      1.0      NaN
2      1.0      1.0

```

(continues on next page)

(continued from previous page)

[3 rows x 2 columns]

**In [5]:** p / 0

```

////////////////////////////////////

```

```

↪
   first  second
0    inf    NaN
1    inf    NaN
2    inf    inf

```

[3 rows x 2 columns]

- Add `squeeze` keyword to `groupby` to allow reduction from `DataFrame` -> `Series` if groups are unique. This is a Regression from 0.10.1. We are reverting back to the prior behavior. This means `groupby` will return the same shaped objects whether the groups are unique or not. Revert this issue ([GH2893](#)) with ([GH3596](#)).

```

In [6]: df2 = DataFrame([{"val1": 1, "val2": 20}, {"val1":1, "val2": 19},
...:                      {"val1":1, "val2": 27}, {"val1":1, "val2": 12}])
...:

```

```

In [7]: def func(dataf):
...:     return dataf["val2"] - dataf["val2"].mean()
...:

```

```

# squeezing the result frame to a series (because we have unique groups)

```

```

In [8]: df2.groupby("val1", squeeze=True).apply(func)

```

**Out [8]:**

```

0    0.5
1   -0.5
2    7.5
3   -7.5

```

```

Name: 1, Length: 4, dtype: float64

```

```

# no squeezing (the default, and behavior in 0.10.1)

```

```

In [9]: df2.groupby("val1").apply(func)

```

```

////////////////////////////////////Out [9]:

```

```

↪
val2    0    1    2    3
val1
1      0.5 -0.5  7.5 -7.5

```

[1 rows x 4 columns]

- Raise on `iloc` when boolean indexing with a label based indexer mask e.g. a boolean `Series`, even with integer labels, will raise. Since `iloc` is purely positional based, the labels on the `Series` are not alignable ([GH3631](#))

This case is rarely used, and there are plenty of alternatives. This preserves the `iloc` API to be *purely* positional based.

```

In [10]: df = DataFrame(lrange(5), list('ABCDE'), columns=['a'])

```

```

In [11]: mask = (df.a%2 == 0)

```

```

In [12]: mask

```

**Out [12]:**

```

A      True

```

(continues on next page)

(continued from previous page)

```

B    False
C     True
D    False
E     True
Name: a, Length: 5, dtype: bool

```

```
# this is what you should use
```

```
In [13]: df.loc[mask]
```

```

=====
↪
a
A  0
C  2
E  4

```

```
[3 rows x 1 columns]
```

```
# this will work as well
```

```
In [14]: df.iloc[mask.values]
```

```

=====
↪
a
A  0
C  2
E  4

```

```
[3 rows x 1 columns]
```

`df.iloc[mask]` will raise a `ValueError`

- The `raise_on_error` argument to plotting functions is removed. Instead, plotting functions raise a `TypeError` when the dtype of the object is object to remind you to avoid object arrays whenever possible and thus you should cast to an appropriate numeric dtype if you need to plot something.
- Add `colormap` keyword to `DataFrame` plotting methods. Accepts either a matplotlib colormap object (ie, `matplotlib.cm.jet`) or a string name of such an object (ie, `'jet'`). The colormap is sampled to select the color for each column. Please see [Colormaps](#) for more information. (GH3860)
- `DataFrame.interpolate()` is now deprecated. Please use `DataFrame.fillna()` and `DataFrame.replace()` instead. (GH3582, GH3675, GH3676)
- the method and axis arguments of `DataFrame.replace()` are deprecated
- `DataFrame.replace` 's `infer_types` parameter is removed and now performs conversion by default. (GH3907)
- Add the keyword `allow_duplicates` to `DataFrame.insert` to allow a duplicate column to be inserted if True, default is False (same as prior to 0.12) (GH3679)
- Implement `__nonzero__` for `NDFrame` objects (GH3691, GH3696)
- IO api
  - added top-level function `read_excel` to replace the following, The original API is deprecated and will be removed in a future version

```

from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])

```

With

```
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

- added top-level function `read_sql` that is equivalent to the following

```
from pandas.io.sql import read_frame
read_frame(...)
```

- `DataFrame.to_html` and `DataFrame.to_latex` now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to object, and `timedelta64[ns]` to object/int (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a `Series` and return an *empty* `Series` when performed on a `DataFrame` similar to performing these operations on, for example, a `DataFrame` of slice objects:
  - `sum`, `prod`, `mean`, `std`, `var`, `skew`, `kurt`, `corr`, and `cov`
- `read_html` now defaults to `None` when reading, and falls back on `bs4` + `html5lib` when `lxml` fails to parse. a list of parsers to try until success is also valid
- The internal pandas class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the baseclass for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

### 1.27.2 I/O Enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return `DataFrames`, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a *single* parser backend: `BeautifulSoup4` + `html5lib` *See the docs*

You can use `pd.read_html()` to read the output from `DataFrame.to_html()` like so

```
In [15]: df = DataFrame({'a': range(3), 'b': list('abc')})

In [16]: print(df)
   a  b
0  0  a
1  1  b
2  2  c

[3 rows x 2 columns]

In [17]: html = df.to_html()

In [18]: alist = pd.read_html(html, index_col=0)

In [19]: print(df == alist[0])
   a  b
```

(continues on next page)

(continued from previous page)

```

0  True  True
1  True  True
2  True  True

[3 rows x 2 columns]
```

Note that `alist` here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

- `pd.read_html()` no longer performs hard conversion of date strings ([GH3656](#)).

**Warning:** You may have to install an older version of BeautifulSoup4, [See the installation docs](#)

- Added module for reading and writing Stata files: `pandas.io.stata` ([GH1512](#)) accessible via `read_stata` top-level function for reading, and `to_stata` `DataFrame` method for writing, [See the docs](#)
- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` `DataFrame` method for writing, [See the docs](#) various issues ([GH1226](#), [GH3804](#), [GH3876](#), [GH3867](#), [GH1305](#))
- `MultiIndex` column support for reading and writing csv format files
  - The header option in `read_csv` now accepts a list of the rows from which to read the index.
  - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading `MultiIndex` columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a `MultiIndex` column.

Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default to write and read `MultiIndex` columns will be in the new format. ([GH3571](#), [GH1651](#), [GH3141](#))

- If an `index_col` is not specified (e.g. you don't have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be *lost*.

```

In [20]: from pandas.util.testing import makeCustomDataframe as mkdf

In [21]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [22]: df.to_csv('mi.csv')

[5 rows x 3 columns]

```

- Support for HDFStore (via PyTables 3.0.0) on Python3
- Iterator support via `read_hdf` that automatically opens and closes the store when iteration is finished. This is only for *tables*

```

In [25]: path = 'store_iterator.h5'

In [26]: DataFrame(randn(10,2)).to_hdf(path, 'df', table=True)

In [27]: for df in read_hdf(path, 'df', chunksize=3):
....:     print df
....:
      0      1
0  0.713216 -0.778461
1 -0.661062  0.862877
2  0.344342  0.149565
      0      1
3 -0.626968 -0.875772
4 -0.930687 -0.218983
5  0.949965 -0.442354
      0      1
6 -0.402985  1.111358
7 -0.241527 -0.670477
8  0.049355  0.632633
      0      1
9 -1.502767 -1.225492

```

- `read_csv` will now throw a more informative error message when a file contains no columns, e.g., all newline characters

### 1.27.3 Other Enhancements

- `DataFrame.replace()` now allows regular expressions on contained `Series` with object dtype. See the examples section in the regular docs [Replacing via String Expression](#)

For example you can do

```

In [25]: df = DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})

In [26]: df.replace(regex=r'\s*\.\s*', value=np.nan)
Out[26]:
   a  b
0  a  1
1  b  2

```

(continues on next page)

(continued from previous page)

```
2 NaN 3
3 NaN 4

[4 rows x 2 columns]
```

to replace all occurrences of the string ' .' with zero or more instances of surrounding whitespace with NaN.

Regular string replacement still works as expected. For example, you can do

```
In [27]: df.replace(' .', np.nan)
Out[27]:
   a  b
0  a  1
1  b  2
2 NaN 3
3 NaN 4

[4 rows x 2 columns]
```

to replace all occurrences of the string ' .' with NaN.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame.
- `pd.set_option()` now allows N option, value pairs ([GH3667](#)).

Let's say that we had an option 'a.b' and another option 'b.c'. We can set them at the same time:

```
In [28]: pd.get_option('a.b')
Out[28]: 2

In [29]: pd.get_option('b.c')
Out[29]: 3

In [30]: pd.set_option('a.b', 1, 'b.c', 4)

In [31]: pd.get_option('a.b')
Out[31]: 1

In [32]: pd.get_option('b.c')
Out[32]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [33]: sf = Series([1, 1, 2, 3, 3, 3])

In [34]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[34]:
3    3
4    3
5    3
Length: 3, dtype: int64
```

The argument of `filter` must a function that, applied to the group as a whole, returns True or False.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [35]: dff = DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})

In [36]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[36]:
```

	A	B
2	2	b
3	3	b
4	4	b
5	5	b

```
[4 rows x 2 columns]
```

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [37]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[37]:
```

	A	B
0	NaN	NaN
1	NaN	NaN
2	2.0	b
3	3.0	b
4	4.0	b
5	5.0	b
6	NaN	NaN
7	NaN	NaN

```
[8 rows x 2 columns]
```

- Series and DataFrame hist methods now take a `figsize` argument ([GH3834](#))
- DatetimeIndexes no longer try to convert mixed-integer indexes during join operations ([GH3877](#))
- Timestamp.min and Timestamp.max now represent valid Timestamp instances instead of the default date-time.min and datetime.max (respectively), thanks @SleepingPills
- `read_html` now raises when no tables are found and BeautifulSoup==4.2.0 is detected ([GH4214](#))

## 1.27.4 Experimental Features

- Added experimental `CustomBusinessDay` class to support `DateOffsets` with custom holiday calendars and custom weekmasks. ([GH2301](#))

---

**Note:** This uses the `numpy.busdaycalendar` API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.

---

```
In [38]: from pandas.tseries.offsets import CustomBusinessDay

In [39]: from datetime import datetime

# As an interesting example, let's look at Egypt where
# a Friday-Saturday weekend is observed.
In [40]: weekmask_egypt = 'Sun Mon Tue Wed Thu'

# They also observe International Workers' Day so let's
```

(continues on next page)

(continued from previous page)

```
# add that for a couple of years
In [41]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01
↳')]

In [42]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_
↳egypt)

In [43]: dt = datetime(2013, 4, 30)

In [44]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [45]: dts = date_range(dt, periods=5, freq=bday_egypt)

In [46]: print(Series(dts.weekday, dts).map(Series('Mon Tue Wed Thu Fri Sat Sun'.
↳split()))))
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, Length: 5, dtype: object
```

### 1.27.5 Bug Fixes

- Plotting functions now raise a `TypeError` before trying to plot anything if the associated objects have a `dtype` of `object` (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.
- `fillna` methods now raise a `TypeError` if the `value` parameter is a list or tuple.
- `Series.str` now supports iteration (GH3638). You can iterate over the individual elements of each string in the `Series`. Each iteration yields a `Series` with either a single character at each index of the original `Series` or `NaN`. For example,

```
In [47]: strs = 'go', 'bow', 'joe', 'slow'

In [48]: ds = Series(strs)

In [49]: for s in ds.str:
.....:     print(s)
.....:
0    g
1    b
2    j
3    s
Length: 4, dtype: object
0    o
1    o
2    o
3    l
Length: 4, dtype: object
0    NaN
1    w
```

(continues on next page)

(continued from previous page)

```

2      e
3      o
Length: 4, dtype: object
0      NaN
1      NaN
2      NaN
3      w
Length: 4, dtype: object

```

```
In [50]: s
```

```

////////////////////////////////////
↪
0      NaN
1      NaN
2      NaN
3      w
Length: 4, dtype: object

```

```
In [51]: s.dropna().values.item() == 'w'
```

```

////////////////////////////////////
↪ True

```

The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since `'slow'` is the longest string and there are no other strings with the same length `'w'` is the only non-null string in the yielded `Series`.

- `HDFStore`
  - will retain index attributes (`freq,tz,name`) on recreation ([GH3499](#))
  - will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
  - support datelike columns with a timezone as `data_columns` ([GH2852](#))
- Non-unique index support clarified ([GH3468](#)).
  - Fix assigning a new index to a duplicate index in a `DataFrame` would fail ([GH3468](#))
  - Fix construction of a `DataFrame` with a duplicate index
  - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) ([GH2194](#))
  - `applymap` on a `DataFrame` with a non-unique index now works (removed warning) ([GH2786](#)), and fix ([GH3230](#))
  - Fix `to_csv` to handle non-unique columns ([GH3495](#))
  - Duplicate indexes with `getitem` will return items in the correct order ([GH3455](#), [GH3457](#)) and handle missing elements like unique indices ([GH3561](#))
  - Duplicate indexes with an empty `DataFrame.from_records` will return a correct frame ([GH3562](#))
  - Concat to produce a non-unique columns when duplicates are across dtypes is fixed ([GH3602](#))
  - Allow insert/delete to non-unique columns ([GH3679](#))
  - Non-unique indexing with a slice via `loc` and friends fixed ([GH3659](#))
  - Allow insert/delete to non-unique columns ([GH3679](#))

- Extend `reindex` to correctly deal with non-unique indices (GH3679)
- `DataFrame.itertuples()` now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via `iloc` (GH4017); added `takeable` argument to `reindex` for location-based taking
- Allow non-unique indexing in series via `.ix/.loc` and `__getitem__` (GH4246)
- Fixed non-unique indexing memory allocation issue with `.ix/.loc` (GH4280)
- `DataFrame.from_records` did not accept empty recarrays (GH3682)
- `read_html` now correctly skips tests (GH3741)
- Fixed a bug where `DataFrame.replace` with a compiled regular expression in the `to_replace` argument wasn't working (GH3907)
- Improved `network` test decorator to catch `IOError` (and therefore `URLError` as well). Added `with_connectivity_check` decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new `optional_args` decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets were open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in `test_yahoo`, `test_google` where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- `Series.hist` will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN `DataFrame` would barf on a 1xN mask (GH4071)
- Fixed running of `tox` under python3 where the `pickle` import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where `sharex` and `sharey` were not being passed to `grouped_hist` (GH4089)
- Fixed bug in `DataFrame.replace` where a nested dict wasn't being iterated over when `regex=False` (GH4115)
- Fixed bug in the parsing of microseconds when using the `format` argument in `to_datetime` (GH4152)
- Fixed bug in `PandasAutoDateLocator` where `invert_xaxis` triggered incorrectly `MilliSecondLocator` (GH3990)
- Fixed bug in plotting that wasn't raising on invalid colormap for matplotlib 1.1.1 (GH4215)
- Fixed the legend displaying in `DataFrame.plot(kind='kde')` (GH4216)
- Fixed bug where Index slices weren't carrying the name attribute (GH4226)
- Fixed bug in initializing `DatetimeIndex` with an array of strings in a certain time zone (GH4229)
- Fixed bug where `html5lib` wasn't being properly skipped (GH4265)
- Fixed bug where `get_data_famafrench` wasn't using the correct file edges (GH4281)

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 1.28 v0.11.0 (April 22, 2013)

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.

There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

## 1.28.1 Selection Choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is strictly label based, will raise `KeyError` when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']
  - A slice object with labels 'a': 'f', (note that contrary to usual python slices, **both** the start and the stop are included!)
  - A boolean array

See more at *Selection by Label*

- `.iloc` is strictly integer position based (from 0 to `length-1` of the axis), will raise `IndexError` when the requested indicies are out of bounds. Allowed inputs are:
  - An integer e.g. 5
  - A list or array of integers [4, 3, 0]
  - A slice object with ints 1:7
  - A boolean array

See more at *Selection by Position*

- `.ix` supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. `.ix` is the most general and will support any of the inputs to `.loc` and `.iloc`, as well as support for floating point label schemes. `.ix` is especially useful when dealing with mixed positional and label based hierarchial indexes.

As using integer slices with `.ix` have different behavior depending on whether the slice is interpreted as position based or label based, it's usually better to be explicit and use `.iloc` or `.loc`.

See more at *Advanced Indexing* and *Advanced Hierarchical*.

## 1.28.2 Selection Deprecations

Starting in version 0.11.0, these methods *may* be deprecated in future versions.

- `irow`
- `icol`
- `iget_value`

See the section *Selection by Position* for substitutes.

### 1.28.3 Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [1]: df1 = DataFrame(randn(8, 1), columns = ['A'], dtype = 'float32')
```

```
In [2]: df1
```

```
Out[2]:
      A
0  1.392665
1 -0.123497
2 -0.402761
3 -0.246604
4 -0.288433
5 -0.763434
6  2.069526
7 -1.203569

[8 rows x 1 columns]
```

```
In [3]: df1.dtypes
```

```

////////////////////////////////////
↪
A      float32
Length: 1, dtype: object
```

```
In [4]: df2 = DataFrame(dict( A = Series(randn(8), dtype='float16'),
...:                          B = Series(randn(8)),
...:                          C = Series(randn(8), dtype='uint8') ))
...:
```

```
In [5]: df2
```

```
Out[5]:
      A      B      C
0  0.591797 -0.038605    0
1  0.841309 -0.460478    1
2 -0.500977 -0.310458    0
3 -0.816406  0.866493  254
4 -0.207031  0.245972    0
5 -0.664062  0.319442    1
6  0.580566  1.378512    1
7 -0.965820  0.292502  255

[8 rows x 3 columns]
```

```
In [6]: df2.dtypes
```

```

////////////////////////////////////
↪
A      float16
B      float64
C        uint8
Length: 3, dtype: object
```

```
# here you get some upcasting
```

```
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```

(continues on next page)

(continued from previous page)

```
In [8]: df3
Out[8]:
```

	A	B	C
0	1.984462	-0.038605	0.0
1	0.717812	-0.460478	1.0
2	-0.903737	-0.310458	0.0
3	-1.063011	0.866493	254.0
4	-0.495465	0.245972	0.0
5	-1.427497	0.319442	1.0
6	2.650092	1.378512	1.0
7	-2.169390	0.292502	255.0

```
[8 rows x 3 columns]
```

```
In [9]: df3.dtypes
```

```

A    float32
B    float64
C    float64
Length: 3, dtype: object
```

## 1.28.4 Dtype Conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

```
In [10]: df3.values.dtype
Out[10]: dtype('float64')
```

### Conversion

```
In [11]: df3.astype('float32').dtypes
Out[11]:
```

A	float32
B	float32
C	float32

```
Length: 3, dtype: object
```

### Mixed Conversion

```
In [12]: df3['D'] = '1.'
In [13]: df3['E'] = '1'
In [14]: df3.convert_objects(convert_numeric=True).dtypes
Out[14]:
```

A	float32
B	float64
C	float64
D	float64
E	int64

```
Length: 5, dtype: object

# same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')
```

(continues on next page)

(continued from previous page)

```
In [16]: df3['E'] = df3['E'].astype('int32')
```

```
In [17]: df3.dtypes
```

Out [17] :

A	float32
---	---------

B	float64
---	---------

C	float64
---	---------

D	float16
---	---------

E	int32
---	-------

```
Length: 5, dtype: object
```

### Forcing Date coercion (and setting NaT when not datelike)

```
In [18]: from datetime import datetime
```

```
In [19]: s = Series([datetime(2001,1,1,0,0), 'foo', 1.0, 1,
.....:               Timestamp('20010104'), '20010105'], dtype='O')
.....:
.....:
```

```
In [20]: s.convert_objects(convert_dates='coerce')
```

Out [20] :

0	2001-01-01
---	------------

1	NaT
---	-----

2	NaT
---	-----

3	NaT
---	-----

4	2001-01-04
---	------------

5	2001-01-05
---	------------

```
Length: 6, dtype: datetime64[ns]
```

### 1.28.5 Dtype Gotchas

## Platform Gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of `int64` and `float64`, *regardless of platform*. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they *WILL* be respected, however ([GH2837](#))

The following will all result in `int64` dtypes

```
In [21]: DataFrame([1,2],columns=['a']).dtypes
```

Out [21] :

```
a      int64
```

```
Length: 1, dtype: object
```

```
In [22]: DataFrame({'a' : [1,2] }).dtypes
```

```
Out[22]:
```

```
a    int64
```

```
Length: 1, dtype: object
```

```
In [23]: DataFrame({'a' : 1 }, index=range(2)).dtypes
```

```
a      int64
```

```
Length: 1, dtype: object
```

Keep in mind that `DataFrame(np.array([1, 2]))` **WILL** result in `int32` on 32-bit platforms!

### Upcasting Gotchas

Performing indexing operations on integer type data can easily upcast the data. The dtype of the input data will be preserved in cases where nans are not introduced.

```
In [24]: dfi = df3.astype('int32')
```

```
In [25]: dfi['D'] = dfi['D'].astype('int64')
```

```
In [26]: dfi
```

```
Out[26]:
```

	A	B	C	D	E
0	1	0	0	1	1
1	0	0	1	1	1
2	0	0	0	1	1
3	-1	0	254	1	1
4	0	0	0	1	1
5	-1	0	1	1	1
6	2	1	1	1	1
7	-2	0	255	1	1

```
[8 rows x 5 columns]
```

```
In [27]: dfi.dtypes
```

```

////////////////////////////////////
↪
A      int32
B      int32
C      int32
D      int64
E      int32
Length: 5, dtype: object
```

```
In [28]: casted = dfi[dfi>0]
```

```
In [29]: casted
```

```
Out[29]:
```

	A	B	C	D	E
0	1.0	NaN	NaN	1	1
1	NaN	NaN	1.0	1	1
2	NaN	NaN	NaN	1	1
3	NaN	NaN	254.0	1	1
4	NaN	NaN	NaN	1	1

E         int32
Length: 5, dtype: object
```

## 1.28.6 Datetimes Conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of `np.nan` to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore datetime64[ns] columns are created by default, when passed datetimelike objects (*this change was introduced in 0.10.1*) (GH2809, GH2810)

```
In [37]: df = DataFrame(randn(6,2),date_range('20010102',periods=6),columns=['A','B'])

In [38]: df['timestamp'] = Timestamp('20010103')

In [39]: df
```

(continues on next page)

(continued from previous page)

Out [39]:

	A	B	timestamp
2001-01-02	1.023958	0.660103	2001-01-03
2001-01-03	1.236475	-2.170629	2001-01-03
2001-01-04	-0.270630	-1.685677	2001-01-03
2001-01-05	-0.440747	-0.115070	2001-01-03
2001-01-06	-0.632102	-0.585977	2001-01-03
2001-01-07	-1.444787	-0.201135	2001-01-03

[6 rows x 3 columns]

# datetime64[ns] out of the box

In [40]: df.get\_dtype\_counts()

```

////////////////////////////////////

```

↪

float64 2

datetime64[ns] 1

Length: 2, dtype: int64

# use the traditional nan, which is mapped to NaT internally

In [41]: df.loc[df.index[2:4], ['A', 'timestamp']] = np.nan

In [42]: df

Out [42]:

	A	B	timestamp
2001-01-02	1.023958	0.660103	2001-01-03
2001-01-03	1.236475	-2.170629	2001-01-03
2001-01-04	NaN	-1.685677	NaT
2001-01-05	NaN	-0.115070	NaT
2001-01-06	-0.632102	-0.585977	2001-01-03

```

- In `pd.io.data.Options`,

- Fix bug when trying to fetch data for the current month when already past expiry.
- Now using lxml to scrape html instead of BeautifulSoup (lxml was faster).
- New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply `calls` and `puts`. Also works for future expiry months and save the instance variable as `callsMMYY` or `putsMMYY`, where `MMYY` are, respectively, the month and year of the option’s expiry.
- `Options.get_near_stock_price` now allows the user to specify the month for which to get relevant options data.
- `Options.get_forward_data` now has optional kwargs `near` and `above_below`. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from `Options.get_near_stock_price` instead of `Options.get_xxx_data()` (GH2758).
- Cursor coordinate information is now displayed in time-series plots.
- added option `display.max_seq_items` to control the number of elements printed per sequence pprinting it. (GH2979)
- added option `display.chop_threshold` to control display of small numerical values. (GH2739)
- added option `display.max_info_rows` to prevent verbose\_info from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
- `value_counts()` now accepts a “normalize” argument, for normalized histograms. (GH2710).
- `DataFrame.from_records` now accepts not only dicts but any instance of the collections.Mapping ABC.
- added option `display.mpl_style` providing a sleeker visual style for plots. Based on <https://gist.github.com/huyng/816622> (GH3075).
- Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
- `to_html()` now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes `&`, in addition to `<` and `>`. (GH2919)

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 1.29 v0.10.1 (January 22, 2013)

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the `inplace` option has been reverted and deprecation warnings added.

### 1.29.1 API changes

- Functions taking an `inplace` option return the calling object as before. A deprecation message has been added
- Groupby aggregations Max/Min no longer exclude non-numeric data (GH2700)
- Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception (GH2640)
- The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
- `DatetimeIndex.unique` now returns a `DatetimeIndex` with the same name and

- timezone instead of an array ([GH2563](#))

### 1.29.2 New features

- MySQL support for database (contribution from Dan Allan)

### 1.29.3 HDFStore

You may need to upgrade your existing data files. Please visit the **compatibility** section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to `data_columns`

```
In [1]: store = HDFStore('store.h5')

In [2]: df = DataFrame(randn(8, 3), index=date_range('1/1/2000', periods=8),
....:                  columns=['A', 'B', 'C'])
....:

In [3]: df['string'] = 'foo'

In [4]: df.loc[df.index[4:6], 'string'] = np.nan

In [5]: df.loc[df.index[7:9], 'string'] = 'bar'

In [6]: df['string2'] = 'cool'

In [7]: df
Out[7]:
```

	A	B	C	string	string2
2000-01-01	1.885136	-0.183873	2.550850	foo	cool
2000-01-02	0.180759	-1.117089	0.061462	foo	cool
2000-01-03	-0.294467	-0.591411	-0.876691	foo	cool
2000-01-04	3.127110	1.451130	0.045152	foo	cool
2000-01-05	-0.242846	1.195819	1.533294	NaN	cool
2000-01-06	0.820521	-0.281201	1.651561	NaN	cool
2000-01-07	-0.034086	0.252394	-0.498772	foo	cool
2000-01-08	-2.290958	-1.601262	-0.256718	bar	cool

```
[8 rows x 5 columns]

# on-disk operations
In [8]: store.append('df', df, data_columns = ['B','C','string','string2'])

In [9]: store.select('df', "B>0 and string=='foo'")
Out[9]:
```

	A	B	C	string	string2
2000-01-04	3.127110	1.451130	0.045152	foo	cool
2000-01-07	-0.034086	0.252394	-0.498772	foo	cool

```
[2 rows x 5 columns]

# this is in-memory version of this type of selection
In [10]: df[(df.B > 0) & (df.string == 'foo')]
////////////////////////////////////
```

(continues on next page)

(continued from previous page)

```

      A      B      C string string2
2000-01-04 3.127110 1.451130 0.045152    foo    cool
2000-01-07 -0.034086 0.252394 -0.498772    foo    cool

[2 rows x 5 columns]
```

Retrieving unique values in an indexable or data column.

```
# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df', 'index').unique()
store.unique('df', 'index')
store.unique('df', 'string')
```

You can now store `datetime64` in data columns

```
In [11]: df_mixed = df_mixed.copy()

In [12]: df_mixed['datetime64'] = Timestamp('20010102')

In [13]: df_mixed.loc[df_mixed.index[3:4], ['A', 'B']] = np.nan

In [14]: store.append('df_mixed', df_mixed)

In [15]: df_mixed1 = store.select('df_mixed')

In [16]: df_mixed1
Out[16]:
```

	A	B	C	string	string2	datetime64
2000-01-01	1.885136	-0.183873	2.550850	foo	cool	2001-01-02
2000-01-02	0.180759	-1.117089	0.061462	foo	cool	2001-01-02

## Enhancements

- `HDFStore` now can read native PyTables table format tables
- You can pass `nan_rep = 'my_nan_rep'` to `append`, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.
- You can pass `index` to `append`. This defaults to `True`. This will automatically create indices on the *indexables* and *data columns* of the table
- You can pass `chunksize=an integer` to `append`, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=an integer` to the first `append`, to set the TOTAL number of expected rows that PyTables will expect. This will optimize read/write performance.
- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers ([GH2698](#))
- Allow `DataFrame.merge` to handle combinatorial sizes too large for 64-bit integer ([GH2690](#))
- `Series` now has unary negation (`-series`) and inversion (`~series`) operators ([GH2686](#))
- `DataFrame.plot` now includes a `logx` parameter to change the x-axis to log scale ([GH2327](#))
- `Series` arithmetic operators can now handle constant and `ndarray` input ([GH2574](#))
- `ExcelFile` now takes a `kind` argument to specify the file type ([GH2613](#))
- A faster implementation for `Series.str` methods ([GH2602](#))

## Bug Fixes

- `HDFStore` tables can now store `float32` types correctly (cannot be mixed with `float64` however)
- Fixed Google Analytics prefix when specifying request segment ([GH2713](#)).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets ([GH2687](#)).
- Fixed `groupby` bug resulting in segfault when passing in `MultiIndex` ([GH2706](#))
- Fixed bug where passing a `Series` with `datetime64` values into `to_datetime` results in bogus output values ([GH2699](#))
- Fixed bug in `pattern` in `HDFStore` expressions when `pattern` is not a valid regex ([GH2694](#))
- Fixed performance issues while aggregating boolean data ([GH2692](#))

- When given a boolean mask key and a Series of new values, Series `__setitem__` will now align the incoming values with the original Series ([GH2686](#))
- Fixed MemoryError caused by performing counting sort on sorting MultiIndex levels with a very large number of combinatorial values ([GH2684](#))
- Fixed bug that causes plotting to fail when the index is a DatetimeIndex with a fixed-offset timezone ([GH2683](#))
- Corrected businessday subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend ([GH2680](#))
- Fixed C file parser behavior when the file has more columns than data ([GH2668](#))
- Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified *usecols* value
- DataFrames with numerical or datetime indices are now sorted prior to plotting ([GH2609](#))
- Fixed DataFrame.from\_records error when passed columns, index, but empty records ([GH2633](#))
- Several bug fixed for Series operations when dtype is datetime64 ([GH2689](#), [GH2629](#), [GH2626](#))

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 1.30 v0.10.0 (December 17, 2012)

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

### 1.30.1 File parsing new features

The delimited file parsing engine (the guts of `read_csv` and `read_table`) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the `encoding` option.
- Column filtering (`usecols`)
- Dtype specification (`dtype` argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (`as_recarray`)
- High performance `delim_whitespace` option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: `escapechar`, `lineterminator`, `quotechar`, etc.
- More robust handling of many exceptional kinds of files observed in the wild

### 1.30.2 API changes

## Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame's columns and broadcast down the rows, **except** in the special case that the DataFrame contains time series. Since there are now method for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (*Zen of Python: Special cases aren't special enough to break the rules*). Here's what I'm talking about:

```
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4),
...:                      index=pd.date_range('1/1/2000', periods=6))
...:
```

```
In [3]: df
```

```
Out[3]:
```

[6 rows x 4 columns]

```

You will get a deprecation warning in the 0.10.x series, and the deprecated functionality will be removed in 0.11 or later.

### Altered resample default behavior

The default time series `resample` binning behavior of daily `D` and *higher* frequencies has been changed to `closed='left', label='left'`. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
```

```
In [2]: series = Series(np.arange(len(dates)), index=dates)
```

```
In [3]: series
```

```

2000-01-04     93
2000-01-05    129
Freq: D, dtype: int64

```

- Infinity and negative infinity are no longer treated as NA by `isnull` and `notnull`. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the `mode.use_inf_as_null` option:

```

In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])

In [7]: pd.isnull(s)
Out[7]:
0    False
1    False
2    False
3    False
Length: 4, dtype: bool

In [8]: s.fillna(0)
Out[8]:
0    1.500000
1         inf
2    3.400000
3        -inf
Length: 4, dtype: float64

In [9]: pd.set_option('use_inf_as_null', True)

In [10]: pd.isnull(s)
Out[10]:
0    False
1     True
2    False
3     True
Length: 4, dtype: bool

In [11]: s.fillna(0)
Out[11]:
0    1.5
1    0.0
2    3.4
3    0.0
Length: 4, dtype: float64

In [12]: pd.reset_option('use_inf_as_null')

```

- Methods with the `inplace` option now all return `None` instead of the calling object. E.g. code written like `df = df.fillna(0, inplace=True)` may stop working. To fix, simply delete the unnecessary variable assignment.
- `pandas.merge` no longer sorts the group keys (`sort=False`) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unne-

essary.

- The default column names for a file with no header have been changed to the integers 0 through  $N - 1$ . This is to create consistency with the DataFrame constructor with no columns specified. The v0.9.0 behavior (names X0, X1, ...) can be reproduced by specifying `prefix='X'`:

```
In [6]: data= 'a,b,c\n1,Yes,2\n3,No,4'

In [7]: print(data)
a,b,c
1,Yes,2
3,No,4

In [8]: pd.read_csv(StringIO(data), header=None)
\\Out[8]:
   0  1  2
0  a  b  c
1  1  Yes 2
2  3  No  4

[3 rows x 3 columns]

In [9]: pd.read_csv(StringIO(data), header=None, prefix='X')
\\Out[9]:
↪
   X0  X1 X2
0  a   b  c
1  1  Yes 2
2  3  No  4

[3 rows x 3 columns]
```

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```
In [10]: print(data)
a,b,c
1,Yes,2
3,No,4

In [11]: pd.read_csv(StringIO(data))
\\Out[11]:
   a  b  c
0  1  Yes 2
1  3  No  4

[2 rows x 3 columns]

In [12]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
\\Out[12]:
↪
   a  b  c
0  1  True 2
1  3  False 4

[2 rows x 3 columns]
```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It's better to do post-processing using the `replace` function instead.

- Calling `fillna` on `Series` or `DataFrame` with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```
In [13]: s = Series([np.nan, 1., 2., np.nan, 4])

In [14]: s
Out[14]:
0      NaN
1      1.0
2      2.0
3      NaN
4      4.0
Length: 5, dtype: float64

In [15]: s.fillna(0)
Out[15]:
0      0.0
1      1.0
2      2.0
3      0.0
4      4.0
Length: 5, dtype: float64

In [16]: s.fillna(method='pad')
Out[16]:
0      NaN
1      1.0
2      2.0
3      2.0
4      4.0
Length: 5, dtype: float64
```

Convenience methods `ffill` and `bfill` have been added:

```
In [17]: s.fffll()
Out[17]:
0      NaN
1      1.0
2      2.0
3      2.0
4      4.0
Length: 5, dtype: float64
```

- `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a `DataFrame`

```
In [18]: def f(x):
.....:     return Series([ x, x**2 ], index = ['x', 'x^2'])
.....:

In [19]: s = Series(np.random.rand(5))

In [20]: s
Out[20]:
0      0.717478
1      0.815199
```

(continues on next page)

(continued from previous page)

```

2    0.452478
3    0.848385
4    0.235477
Length: 5, dtype: float64

```

```
In [21]: s.apply(f)
```

```

////////////////////////////////////
↪
      x      x^2
0  0.717478  0.514775
1  0.815199  0.664550
2  0.452478  0.204737
3  0.848385  0.719757
4  0.235477  0.055449

[5 rows x 2 columns]

```

- New API functions for working with pandas options ([GH2097](#)):

- `get_option` / `set_option` - get/set the value of an option. Partial names are accepted.
- `reset_option` - reset one or more options to their default value. Partial names are accepted.
- `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions` / `reset_printoptions` are now deprecated (but functioning), the print options now live under “`display.XYZ`”. For example:

```
In [22]: get_option("display.max_rows")
Out [22]: 15
```

- `to_string()` methods now always return unicode strings ([GH2224](#)).

### 1.30.3 New features

#### 1.30.4 Wide DataFrame Printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

```
In [23]: wide_frame = DataFrame(randn(5, 16))
```

```
In [24]: wide_frame
```

```

Out [24]:
      0         1         2         3         4         ...         11         12
↪  13         14         15
0 -0.681624  0.191356  1.180274 -0.834179  0.703043  ... -0.941235  0.863067 -0.
↪ 336232 -0.976847  0.033862
1  0.441522 -0.316864 -0.017062  1.570114 -0.360875  ... -0.906840  1.014601 -0.
↪ 475108 -0.358944  1.262942
2 -0.412451 -0.462580  0.422194  0.288403 -0.487393  ...  0.246354 -0.727728 -0.
↪ 094414 -0.276854  0.158399
3 -0.277255  1.331263  0.585174 -0.568825 -0.719412  ... -1.425911 -0.548829  0.
↪ 774225  0.740501  1.510263
4 -1.642511  0.432560  1.218080 -0.564705 -0.581790  ... -0.471786  0.314510 -0.
↪ 059986 -2.069319 -1.115104

```

(continues on next page)

(continued from previous page)

[5 rows x 16 columns]

The old behavior of printing out summary information can be achieved via the ‘expand\_frame\_repr’ print option:

```
In [25]: pd.set_option('expand_frame_repr', False)
```

```
In [26]: wide_frame
```

```
Out[26]:
```

```

      0         1         2         3         4         5         6         7
→  8      9      10      11      12      13      14      15
0 -0.681624  0.191356  1.180274 -0.834179  0.703043  0.166568 -0.583599 -1.201796 -1.

2000-01-07	-2.036047	0.000830	-0.955697	string	1
2000-01-08	-0.898872	-0.725411	0.059904	string	1

```
[8 rows x 5 columns]

In [57]: df1.get_dtype_counts()
//////////
```

(continues on next page)

(continued from previous page)

```
float64    3
object     1
int64      1
Length: 3, dtype: int64
```

- performance improvements on table writing
- support for arbitrarily indexed dimensions
- `SparseSeries` now has a density property ([GH2384](#))
- enable `Series.str.strip/lstrip/rstrip` methods to take an input argument to strip arbitrary characters ([GH2411](#))
- implement `value_vars` in `melt` to limit values to certain columns and add `melt` to pandas namespace ([GH2412](#))

### Bug Fixes

- added `Term` method of specifying where conditions ([GH1996](#)).
- `del store['df']` now call `store.remove('df')` for store deletion
- deleting of consecutive rows is much faster than before
- `min_itemsize` parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
- indexing support via `create_table_index` (requires `PyTables >= 2.3`) ([GH698](#)).
- appending on a store would fail if the table was not first created via `put`
- fixed issue with missing attributes after loading a pickled dataframe ([GH2431](#))
- minor change to `select` and `remove`: require a table ONLY if where is also provided (and not `None`)

### Compatibility

0.10 of `HDFStore` is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

## 1.30.6 N Dimensional Panels (Experimental)

Adding experimental support for `Panel4D` and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```
In [58]: p4d = Panel4D(randn(2, 2, 5, 4),
....:      labels=['Label1', 'Label2'],
....:      items=['Item1', 'Item2'],
....:      major_axis=date_range('1/1/2000', periods=5),
....:      minor_axis=['A', 'B', 'C', 'D'])
....:

In [59]: p4d
Out[59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
```

(continues on next page)

(continued from previous page)

```
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

See the *full release notes* or issue tracker on GitHub for a complete list.

## 1.31 v0.9.1 (November 14, 2012)

This is a bugfix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

### 1.31.1 New features

- `Series.sort`, `DataFrame.sort`, and `DataFrame.sort_index` can now be specified in a per-column manner to support multiple sort orders ([GH928](#))

```
In [2]: df = DataFrame(np.random.randint(0, 2, (6, 3)), columns=['A', 'B', 'C'])
In [3]: df.sort(['A', 'B'], ascending=[1, 0])

Out[3]:
```

	A	B	C
3	0	1	1
4	0	1	1
2	0	0	1
0	1	0	0
1	1	0	0
5	1	0	0

- `DataFrame.rank` now supports additional argument values for the `na_option` parameter so missing values can be assigned either the largest or the smallest rank ([GH1508](#), [GH2159](#))

```
In [1]: df = DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])

In [2]: df.loc[2:4] = np.nan

In [3]: df.rank()
Out[3]:
```

	A	B	C
0	3.0	1.0	3.0
1	1.0	3.0	2.0
2	NaN	NaN	NaN
3	NaN	NaN	NaN
4	NaN	NaN	NaN
5	2.0	2.0	1.0

```
[6 rows x 3 columns]

In [4]: df.rank(na_option='top')
```

```
////////////////////////////////////
```

```
↪
```

	A	B	C
0	6.0	4.0	6.0

(continues on next page)

(continued from previous page)

```

1  4.0  6.0  5.0
2  2.0  2.0  2.0
3  2.0  2.0  2.0
4  2.0  2.0  2.0
5  5.0  5.0  4.0

```

```
[6 rows x 3 columns]
```

```
In [5]: df.rank(na_option='bottom')
```

```

////////////////////////////////////

4  5.0  5.0  5.0
5  2.0  2.0  1.0

```

```
[6 rows x 3 columns]
```

- DataFrame has new *where* and *mask* methods to select values according to a given boolean mask ([GH2109](#), [GH2151](#))

DataFrame currently supports slicing via a boolean vector the same length as the DataFrame (inside the `[]`). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

```
In [6]: df = DataFrame(np.random.randn(5, 3), columns = ['A', 'B', 'C'])
```

```
In [7]: df
```

```
Out[7]:
      A      B      C
0 -1.101581 -1.187831  0.630693
1  2.369983  0.333769 -0.870464
2  1.118760 -0.224382  0.642489
3  0.961751 -1.848369  0.440883
4  1.235390  1.615529 -0.303272

```

```
[5 rows x 3 columns]
```

```
In [8]: df[df['A'] > 0]
```

```

////////////////////////////////////
↪
      A      B      C
1  2.369983  0.333769 -0.870464
2  1.118760 -0.224382  0.642489
3  0.961751 -1.848369  0.440883
4  1.235390  1.615529 -0.303272

```

```
[4 rows x 3 columns]
```

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as *NaN*. This is accomplished via the new method *DataFrame.where*. In addition, *where* takes an optional *other* argument for replacement.

```
In [9]: df[df>0]
```

```
Out[9]:
```

	A	B	C
0	NaN	NaN	0.630693
1	2.369983	0.333769	NaN
2	1.118760	NaN	0.642489
3	0.961751	NaN	0.440883
4	1.235390	1.615529	NaN

```
[5 rows x 3 columns]
```

```
In [10]: df.where(df>0)
```

```

////////////////////////////////////
↪
      A      B      C
0    NaN    NaN  0.630693
1  2.369983  0.333769    NaN
2  1.118760    NaN  0.642489
3  0.961751    NaN  0.440883
4  1.235390  1.615529    NaN

```

```
[5 rows x 3 columns]
```

```
In [11]: df.where(df>0,-df)
```

```

////////////////////////////////////
↪
      A      B      C
0  1.101581  1.187831  0.630693
1  2.369983  0.333769  0.870464
2  1.118760  0.224382  0.642489
3  0.961751  1.848369  0.440883
4  1.235390  1.615529  0.303272

```

```
[5 rows x 3 columns]
```

Furthermore, *where* now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via *.ix* (but on the contents rather than the axis labels)

```
In [12]: df2 = df.copy()
```

```
In [13]: df2[ df2[1:4] > 0 ] = 3
```

```
In [14]: df2
```

```
Out[14]:
```

	A	B	C
0	-1.101581	-1.187831	0.630693
1	3.000000	3.000000	-0.870464
2	3.000000	-0.224382	3.000000
3	3.000000	-1.848369	3.000000
4	1.235390	1.615529	-0.303272

```
[5 rows x 3 columns]
```

*DataFrame.mask* is the inverse boolean operation of *where*.

```
In [15]: df.mask(df<=0)
```

(continues on next page)

(continued from previous page)

```
Out [15]:
```

	A	B	C
0	NaN	NaN	0.630693
1	2.369983	0.333769	NaN
2	1.118760	NaN	0.642489
3	0.961751	NaN	0.440883
4	1.235390	1.615529	NaN

```
[5 rows x 3 columns]
```

- Enable referencing of Excel columns by their column names ([GH1936](#))

```
In [16]: xl = ExcelFile('data/test.xls')

In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True,
.....:           parse_cols='A:D')
.....:
Out [17]:
```

	A	B	C	D
2000-01-03	0.980269	3.685731	-0.364217	-1.159738
2000-01-04	1.047916	-0.041232	-0.161812	0.212549
2000-01-05	0.498581	0.731168	-0.537677	1.346270
2000-01-06	1.120202	1.567621	0.003641	0.675253
2000-01-07	-0.487094	0.571455	-1.611639	0.103469
2000-01-10	0.836649	0.246462	0.588543	1.062782
2000-01-11	-0.157161	1.340307	1.195778	-1.097007

```
[7 rows x 4 columns]
```

- Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` ([GH2205](#))
- Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame ([GH2149](#))
- DataFrame.dot can now accept ndarrays ([GH2042](#))
- DataFrame.drop now supports non-unique indexes ([GH2101](#))
- Panel.shift now supports negative periods ([GH2164](#))
- DataFrame now support unary `~` operator ([GH2110](#))

### 1.31.2 API changes

- Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```
In [1]: prng = period_range('2012Q1', periods=2, freq='Q')

In [2]: s = Series(np.random.randn(len(prng)), prng)

In [4]: s.resample('M')
Out [4]:
```

2012-01	-1.471992
2012-02	NaN
2012-03	NaN
2012-04	-0.493593

(continues on next page)

(continued from previous page)

```

2012-05      NaN
2012-06      NaN
Freq: M, dtype: float64

```

- `Period.end_time` now returns the last nanosecond in the time interval ([GH2124](#), [GH2125](#), [GH1764](#))

```

In [18]: p = Period('2012')

In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')

```

- File parsers no longer coerce to float or bool for columns that have custom converters specified ([GH2184](#))

```

In [20]: data = 'A,B,C\n00001,001,5\n00002,002,6'

In [21]: read_csv(StringIO(data), converters={'A' : lambda x: x.strip()})
Out[21]:
   A  B  C
0  00001  1  5
1  00002  2  6

[2 rows x 3 columns]

```

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 1.32 v0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for `Series.str`, `to_latex` method to `DataFrame`, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

### 1.32.1 New features

- Add `encode` and `decode` for unicode handling to *vectorized string processing methods* in `Series.str` ([GH1706](#))
- Add `DataFrame.to_latex` method ([GH1735](#))
- Add convenient expanding window equivalents of all `rolling_*` ops ([GH1785](#))
- Add `Options` class to `pandas.io.data` for fetching options data from Yahoo! Finance ([GH1748](#), [GH1739](#))
- More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) ([GH1691](#), [GH1295](#))
- Add `level` parameter to `Series.reset_index`
- `TimeSeries.between_time` can now select times across midnight ([GH1871](#))
- `Series` constructor can now handle generator as input ([GH1679](#))
- `DataFrame.dropna` can now take multiple axes (tuple/list) as input ([GH924](#))
- Enable `skip_footer` parameter in `ExcelFile.parse` ([GH1843](#))

### 1.32.2 API changes

- The default column names when `header=None` and no columns names passed to functions like `read_csv` has changed to be more Pythonic and amenable to attribute access:

```
In [1]: data = '0,0,1\n1,1,0\n0,1,0'

In [2]: df = read_csv(StringIO(data), header=None)

In [3]: df
Out[3]:
```

	0	1	2
0	0	0	1
1	1	1	0
2	0	1	0

```
[3 rows x 3 columns]
```

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

```
In [4]: s1 = Series([1, 2, 3])

In [5]: s1
Out[5]:
```

0	1
1	2
2	3

```
Length: 3, dtype: int64

In [6]: s2 = Series(s1, index=['foo', 'bar', 'baz'])

In [7]: s2
Out[7]:
```

foo	NaN
bar	NaN
baz	NaN

```
Length: 3, dtype: float64
```

- Deprecated `day_of_year` API removed from `PeriodIndex`, use `dayofyear` ([GH1723](#))
- Don't modify NumPy suppress printoption to True at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by `HDFStore` ([GH1834](#), [GH1824](#))
- Legacy cruft removed: `pandas.stats.misc.quantileTS`
- Use ISO8601 format for Period repr: monthly, daily, and on down ([GH1776](#))
- Empty DataFrame columns are now created as object dtype. This will prevent a class of `TypeError`s that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) ([GH1783](#))
- Setting parts of DataFrame/Panel using `ix` now aligns input Series/DataFrame ([GH1630](#))
- `first` and `last` methods in `GroupBy` no longer drop non-numeric columns ([GH1809](#))

- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type dict no longer override default NAs unless `keep_default_na` is set to false explicitly (GH1657)
- `DataFrame.dot` will not do data alignment, and also work with Series (GH1915)

See the [full release notes](#) or issue tracker on GitHub for a complete list.

## 1.33 v0.8.1 (July 22, 2012)

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

### 1.33.1 New features

- Add *vectorized string processing methods* accessible via `Series.str` (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- *Radviz plot* (GH1566)
- *Parallel coordinates plot*
- *Bootstrap plot*
- Per column styles and secondary y-axis plotting (GH1559)
- New datetime converters millisecond plotting (GH1599)
- Add option to disable “sparse” display of hierarchical indexes (GH1538)
- Series/DataFrame’s `set_index` method can *append levels* to an existing Index/MultiIndex (GH1569, GH1577)

### 1.33.2 Performance improvements

- Improved implementation of rolling min and max (thanks to Bottleneck !)
- Add accelerated 'median' GroupBy option (GH1358)
- Significantly improve the performance of parsing ISO8601-format date strings with `DatetimeIndex` or `to_datetime` (GH1571)
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

## 1.34 v0.8.0 (June 29, 2012)

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy `datetime64` dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the [full release notes](#) or issue tracker on GitHub for a complete list.

### 1.34.1 Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)

### 1.34.2 NumPy datetime64 dtype and 1.6 dependency

Time series data are now represented using NumPy's datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6's datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy codebases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

### 1.34.3 Time series changes and improvements

---

**Note:** With this release, legacy `scikits.timeseries` users should be able to port their code to use pandas.

---

---

**Note:** See [documentation](#) for overview of pandas timeseries API.

---

- New datetime64 representation **speeds up join operations and data alignment, reduces memory usage**, and improve serialization / deserialization performance significantly over `datetime.datetime`
- High performance and flexible **resample** method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.
- Revamp of *frequency aliases* and support for **frequency shortcuts** like ‘15min’, or ‘1h30min’
- New *DatetimeIndex class* supports both fixed frequency and irregular time series. Replaces now deprecated `DateRange` class
- New `PeriodIndex` and `Period` classes for representing *time spans* and performing **calendar logic**, including the *12 fiscal quarterly frequencies* `<timeseries.quarterly>`. This is a partial port of, and a substantial enhancement to, elements of the `scikits.timeseries` codebase. Support for conversion between `PeriodIndex` and `DatetimeIndex`
- New Timestamp data type subclasses *datetime.datetime*, providing the same interface while enabling working with nanosecond-resolution data. Also provides *easy time zone conversions*.
- Enhanced support for *time zones*. Add `tz_convert` and `tz_localize` methods to `TimeSeries` and `DataFrame`. All timestamps are stored as UTC; Timestamps from `DatetimeIndex` objects with time zone set will be localized to localtime. Time zone conversions are therefore essentially free. User needs to know very little about `pytz` library now; only time zone names as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.
- Time series **string indexing conveniences** / shortcuts: slice years, year and month, and index values with strings

- Enhanced time series **plotting**; adaptation of scikits.timeseries matplotlib-based plotting code
- New `date_range`, `bdate_range`, and `period_range` *factory functions*
- Robust **frequency inference** function `infer_freq` and `inferred_freq` property of `DatetimeIndex`, with option to infer frequency on construction of `DatetimeIndex`
- `to_datetime` function efficiently **parses array of strings** to `DatetimeIndex`. `DatetimeIndex` will parse array or list of strings to `datetime64`
- **Optimized** support for `datetime64-dtype` data in `Series` and `DataFrame` columns
- New `NaT` (Not-a-Time) type to represent **NA** in timestamp arrays
- Optimize `Series.asof` for looking up “as of” values for arrays of timestamps
- Milli, Micro, Nano date offset objects
- Can index time series with `datetime.time` objects to select all data at particular **time of day** (`TimeSeries.at_time`) or **between two times** (`TimeSeries.between_time`)
- Add *tshift* method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using `shift`

#### 1.34.4 Other new features

- New *cut* and `qcut` functions (like R’s `cut` function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins
- Rename `Factor` to `Categorical` and add a number of usability features
- Add *limit* argument to `fillna/reindex`
- More flexible multiple function application in `GroupBy`, and can pass list (name, function) tuples to get result in particular order with given names
- Add flexible *replace* method for efficiently substituting values
- Enhanced *read\_csv/read\_table* for reading time series data and converting multiple columns to dates
- Add *comments* option to parser functions: `read_csv`, etc.
- Add *dayfirst* option to parser functions for parsing international DD/MM/YYYY dates
- Allow the user to specify the CSV reader *dialect* to control quoting etc.
- Handling *thousands* separators in `read_csv` to improve integer parsing.
- Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)
- Move to `klib`-based hash tables for indexing; better performance and less memory usage than Python’s `dict`
- Add `first`, `last`, `min`, `max`, and `prod` optimized `GroupBy` functions
- New *ordered\_merge* function
- Add flexible *comparison* instance methods `eq`, `ne`, `lt`, `gt`, etc. to `DataFrame`, `Series`
- Improve *scatter\_matrix* plotting function and add histogram or kernel density estimates to diagonal
- Add ‘*kde*’ plot option for density plots
- Support for converting `DataFrame` to R `data.frame` through `rpy2`
- Improved support for complex numbers in `Series` and `DataFrame`

- Add *pct\_change* method to all data structures
- Add *max\_colwidth* configuration option for DataFrame console output
- *Interpolate* Series values using index values
- Can select multiple columns from GroupBy
- Add *update* methods to Series/DataFrame for updating values in place
- Add *any* and *all* method to DataFrame

### 1.34.5 New plotting methods

Series.plot now supports a *secondary\_y* option:

```
In [1]: plt.figure()
Out[1]: <Figure size 640x480 with 0 Axes>

In [2]: fx['FR'].plot(style='g')
Out[2]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c376acfd0>

In [3]: fx['IT'].plot(style='k--', secondary_y=True)
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3781cb38>
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```
In [4]: s = Series(np.concatenate((np.random.randn(1000),
...                               np.random.randn(1000) * 0.5 + 3)))

In [5]: plt.figure()
Out[5]: <Figure size 640x480 with 0 Axes>

In [6]: s.hist(normed=True, alpha=0.2)
Out[6]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c37c3a588>

In [7]: s.plot(kind='kde')
Out[7]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37c3a588>
```

See [the plotting page](#) for much more.

### 1.34.6 Other API changes

- Deprecation of *offset*, *time\_rule*, and *timeRule* arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

### 1.34.7 Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's *datetime64* data type instead of *dtype=object* arrays of Python's built-in *datetime.datetime* objects. *DateRange* has been

(continued from previous page)

```

datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)

In [20]: dt_array[5]
//////////
→datetime.datetime(2000, 1, 6, 0, 0)

```

matplotlib knows how to handle `datetime.datetime` but not `Timestamp` objects. While I recommend that you plot time series using `TimeSeries.plot`, you can either use `to_pydatetime` or register a converter for the `Timestamp` type. See [matplotlib documentation](#) for more on this.

**Warning:** There are bugs in the user-facing API with the nanosecond `datetime64` unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to `dtype=object` is similarly broken.

```

In [21]: rng = date_range('1/1/2000', periods=10)

In [22]: rng
Out [22]:
DatetimeIndex(['2000-01-01', '2000-01-02', '2000-01-03', '2000-01-04',
               '2000-01-05', '2000-01-06', '2000-01-07', '2000-01-08',
               '2000-01-09', '2000-01-10'],
              dtype='datetime64[ns]', freq='D')

In [23]: np.asarray(rng)
//////////
→
array(['2000-01-01T00:00:00.000000000', '2000-01-02T00:00:00.000000000',

→'datetime64[ns]')

In [24]: converted = np.asarray(rng, dtype=object)

In [25]: converted[5]
Out [25]: 947116800000000000

```

**Trust me: don't panic.** If you are using NumPy 1.6 and restrict your interaction with `datetime64` values to pandas's API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you **do not work directly with `datetime64` arrays in NumPy 1.6** and only use the pandas API.

**Support for non-unique indexes:** In the latter case, you may have code inside a `try:... catch:` block that failed due to the index not being unique. In many cases it will no longer fail (some method like `append` still check for uniqueness unless disabled). However, all is not lost: you can inspect `index.is_unique` and raise an exception explicitly if it is `False` or go to a different code branch.

## 1.35 v.0.7.3 (April 12, 2012)

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the [full release notes](#) or issue tracker on GitHub for a complete list.

### 1.35.1 New features

- New *fixed width file reader*, `read_fwf`
- New *scatter\_matrix* function for making a scatter plot matrix

```
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2)
```

- Add `stacked` argument to `Series` and `DataFrame`'s `plot` method for *stacked bar plots*.

```
df.plot(kind='bar', stacked=True)
```

```
df.plot(kind='barh', stacked=True)
```

- Add log x and y *scaling options* to `DataFrame.plot` and `Series.plot`
- Add kurt methods to `Series` and `DataFrame` for computing kurtosis

### 1.35.2 NA Boolean Comparison API Change

Reverted some changes to how NA values (represented typically as `NaN` or `None`) are handled in non-numeric `Series`:

```
In [1]: series = Series(['Steve', np.nan, 'Joe'])
In [2]: series == 'Steve'
Out[2]:
0      True
1     False
```

(continues on next page)

(continued from previous page)

```

2    False
Length: 3, dtype: bool

In [3]: series != 'Steve'
Out[3]:
0    False
1     True
2     True
Length: 3, dtype: bool

```

In comparisons, NA / NaN will always come through as `False` except with `!=` which is `True`. *Be very careful* with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```

In [4]: mask = series == 'Steve'

In [5]: series[mask & series.notnull()]
Out[5]:
0    Steve
Length: 1, dtype: object

```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

### 1.35.3 Other API Changes

When calling `apply` on a grouped Series, the return value will also be a Series, to be more consistent with the groupby behavior with DataFrame:

```

In [6]: df = DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...:                          'foo', 'bar', 'foo', 'foo'],
...:                   'B' : ['one', 'one', 'two', 'three',
...:                          'two', 'two', 'one', 'three'],
...:                   'C' : np.random.randn(8), 'D' : np.random.randn(8)})

In [7]: df
Out[7]:
   A    B         C         D
0  foo  one -0.841015  0.459840
1  bar  one  0.114219 -0.253040
2  foo  two -0.405617 -0.261128
3  bar three  1.240678  0.406604
4  foo  two -0.122828 -1.022256
5  bar  two  1.525196 -0.882785
6  foo  one  0.520047  1.793331
7  foo three  0.163834 -0.429688

[8 rows x 4 columns]

In [8]: grouped = df.groupby('A')['C']

In [9]: grouped.describe()

```

(continues on next page)

(continued from previous page)

```

Out [9]:
   count    mean    std    min    25%    50%    75%    max
A
bar     3.0  0.960031  0.746181  0.114219  0.677448  1.240678  1.525196
foo     5.0 -0.137116  0.522064 -0.841015 -0.405617 -0.122828  0.163834  0.520047

[2 rows x 8 columns]

In [10]: grouped.apply(lambda x: x.sort_values()[-2:]) # top 2 values
\
↪
A
bar  3    1.240678
     5    1.525196
foo  7    0.163834
     6    0.520047
Name: C, Length: 4, dtype: float64

```

## 1.36 v.0.7.2 (March 16, 2012)

This release targets bugs in 0.7.1, and adds a few minor features.

### 1.36.1 New features

- Add additional tie-breaking methods in `DataFrame.rank` (GH874)
- Add ascending parameter to rank in Series, DataFrame (GH875)
- Add `coerce_float` option to `DataFrame.from_records` (GH893)
- Add `sort_columns` parameter to allow unsorted plots (GH918)
- Enable column access via attributes on `GroupBy` (GH882)
- Can pass dict of values to `DataFrame.fillna` (GH661)
- Can select multiple hierarchical groups by passing list of values in `.ix` (GH134)
- Add `axis` option to `DataFrame.fillna` (GH174)
- Add `level` keyword to `drop` for dropping values from a level (GH159)

### 1.36.2 Performance improvements

- Use khash for `Series.value_counts`, add raw function to `algorithms.py` (GH861)
- Intercept `__builtin__.sum` in `groupby` (GH885)

## 1.37 v.0.7.1 (February 29, 2012)

This release includes a few new features and addresses over a dozen bugs in 0.7.0.

### 1.37.1 New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard ([GH774](#))
- Add `itertuples` method to `DataFrame` for iterating through the rows of a dataframe as tuples ([GH818](#))
- Add ability to pass `fill_value` and method to `DataFrame` and `Series` align method ([GH806](#), [GH807](#))
- Add `fill_value` option to `reindex`, align methods ([GH784](#))
- Enable `concat` to produce `DataFrame` from `Series` ([GH787](#))
- Add `between` method to `Series` ([GH802](#))
- Add HTML representation hook to `DataFrame` for the IPython HTML notebook ([GH773](#))
- Support for reading Excel 2007 XML documents using `openpyxl`

### 1.37.2 Performance improvements

- Improve performance and memory usage of `fillna` on `DataFrame`
- Can concatenate a list of `Series` along `axis=1` to obtain a `DataFrame` ([GH787](#))

## 1.38 v.0.7.0 (February 9, 2012)

### 1.38.1 New features

- New unified *merge function* for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains ([GH220](#), [GH249](#), [GH267](#))
- New *unified concatenation function* for concatenating `Series`, `DataFrame` or `Panel` objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` ([GH468](#), [GH479](#), [GH273](#))
- *Can* pass multiple `DataFrames` to `DataFrame.append` to concatenate (stack) and multiple `Series` to `Series.append` too
- *Can* pass list of dicts (e.g., a list of JSON objects) to `DataFrame` constructor ([GH526](#))
- You can now *set multiple columns* in a `DataFrame` via `__getitem__`, useful for transformation ([GH342](#))
- Handle differently-indexed output values in `DataFrame.apply` ([GH498](#))

```
In [1]: df = DataFrame(randn(10, 4))

In [2]: df.apply(lambda x: x.describe())
Out[2]:
```

	0	1	2	3
count	10.000000	10.000000	10.000000	10.000000
mean	0.424980	0.115056	0.452000	-0.103829
std	0.898046	0.712034	0.867316	0.830197
min	-1.337024	-0.779344	-1.206466	-1.022360
25%	-0.000996	-0.344789	-0.120217	-0.744313
50%	0.860419	0.098422	0.540168	-0.387554
75%	1.094236	0.375137	1.076331	0.674952
max	1.207725	1.601703	1.663859	1.096187

(continues on next page)

(continued from previous page)

[8 rows x 4 columns]

- *Add* `reorder_levels` method to `Series` and `DataFrame` (GH534)
- *Add* dict-like `get` function to `DataFrame` and `Panel` (GH521)
- *Add* `DataFrame.iterrows` method for efficiently iterating through the rows of a `DataFrame`
- *Add* `DataFrame.to_panel` with code adapted from `LongPanel.to_long`
- *Add* `reindex_axis` method added to `DataFrame`
- *Add* `level` option to binary arithmetic functions on `DataFrame` and `Series`
- *Add* `level` option to the `reindex` and `align` methods on `Series` and `DataFrame` for broadcasting values across a level (GH542, GH552, others)
- *Add* attribute-based item access to `Panel` and add IPython completion (GH563)
- *Add* `logy` option to `Series.plot` for log-scaling on the Y axis
- *Add* `index` and `header` options to `DataFrame.to_string`
- *Can* pass multiple `DataFrames` to `DataFrame.join` to join on index (GH115)
- *Can* pass multiple `Panels` to `Panel.join` (GH115)
- *Added* `justify` argument to `DataFrame.to_string` to allow different alignment of column headers
- *Add* `sort` option to `GroupBy` to allow disabling sorting of the group keys for potential speedups (GH595)
- *Can* pass `MaskedArray` to `Series` constructor (GH563)
- *Add* `Panel` item access via attributes and IPython completion (GH554)
- Implement `DataFrame.lookup`, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
- Can pass a *list of functions* to aggregate with `groupby` on a `DataFrame`, yielding an aggregated result with hierarchical columns (GH166)
- Can call `cummin` and `cummax` on `Series` and `DataFrame` to get cumulative minimum and maximum, respectively (GH647)
- `value_range` added as utility function to get min and max of a dataframe (GH288)
- Added `encoding` argument to `read_csv`, `read_table`, `to_csv` and `from_csv` for non-ascii text (GH717)
- *Added* `abs` method to pandas objects
- *Added* `crosstab` function for easily computing frequency tables
- *Added* `isin` method to index objects
- *Added* `level` argument to `xs` method of `DataFrame`.

### 1.38.2 API Changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how **integer indexes** are handled with regard to label-based indexing. Here is an example:

```
In [3]: s = Series(randn(10), index=range(0, 20, 2))
```

In [4]: s

Out [4] :

```
0      0.446246
2     -0.500268
4      0.814725
6     -0.312744
8      1.098892
10     1.306330
12    -0.366970
14    -0.030890
16     1.608095
18    -0.023287
Length: 10, dtype: float64
```

```
In [5]: s[0]
```

0.44624598505731339

```
In [6]: s[2]
```

$\rightarrow -0.500268093241102$

```
In [7]: s[4]
```

0.8147247587659604

This is all exactly identical to the behavior before. However, if you ask for a key **not** contained in the Series, in versions 0.6.1 and prior, Series would *fall back* on a location-based lookup. This now raises a `KeyError`:

```
In [2]: s[1]
```

```
KeyError: 1
```

This change also has the same impact on DataFrame:

```
In [3]: df = DataFrame(randn(8, 4), index=range(0, 16, 2))
```

```
In [4]: df
```

	0	1	2	3
0	0.88427	0.3363	-0.1787	0.03162
2	0.14451	-0.1415	0.2504	0.58374
4	-1.44779	-0.9186	-1.4996	0.27163
6	-0.26598	-2.4184	-0.2658	0.11503
8	-0.58776	0.3144	-0.8566	0.61941
10	0.10940	-0.7175	-1.0108	0.47990
12	-1.16919	-0.3087	-0.6049	-0.43544
14	-0.07337	0.3410	0.0424	-0.16037

```
In [5]: df.ix[3]
```

```
KeyError: 3
```

In order to support purely integer-based indexing, the following methods have been added:

Method	Description
<code>Series.iat_value(i)</code>	Retrieve value stored at location <i>i</i>
<code>Series.iat(i)</code>	Alias for <code>iat_value</code>
<code>DataFrame.irow(i)</code>	Retrieve the <i>i</i> -th row
<code>DataFrame.icol(j)</code>	Retrieve the <i>j</i> -th column
<code>DataFrame.iat_value(i, j)</code>	Retrieve the value at row <i>i</i> and column <i>j</i>

### 1.38.3 API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```
In [1]: s = Series(randn(6), index=list('gmkaec'))

In [2]: s
Out[2]:
g   -1.182230
m   -0.276183
k   -0.243550
a    1.628992
e    0.073308
c   -0.539890
dtype: float64
```

Then this is OK:

```
In [3]: s.ix['k':'e']
Out[3]:
k   -0.243550
a    1.628992
e    0.073308
dtype: float64
```

But this is not:

```
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```
In [4]: s2 = s.sort_index()

In [5]: s2
Out[5]:
a    1.628992
c   -0.539890
e    0.073308
g   -1.182230
k   -0.243550
m   -0.276183
dtype: float64

In [6]: s2.ix['b':'h']
Out[6]:
c   -0.539890
```

(continues on next page)

(continued from previous page)

```
e    0.073308
g   -1.182230
dtype: float64
```

### 1.38.4 Changes to Series [] operator

As as notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the `__getitem__` and `__setitem__` methods). The behavior will be the same as passing similar input to `ix` **except in the case of integer indexing**:

```
In [8]: s = Series(randn(6), index=list('acegkm'))
```

```
In [9]: s
```

```
Out[9]:
```

```
a    -0.800734
c    -0.229737
e    -0.781940
g     0.756053
k     2.613373
m    -0.159310
Length: 6, dtype: float64
```

```
In [10]: s[['m', 'a', 'c', 'e']]
```

```
////////////////////////////////////
↪
m    -0.159310
a    -0.800734
c    -0.229737
e    -0.781940
Length: 4, dtype: float64
```

```
In [11]: s['b':'l']
```

```
////////////////////////////////////
↪
c    -0.229737
e    -0.781940
g     0.756053
k     2.613373
Length: 4, dtype: float64
```

```
In [12]: s['c':'k']
```

```
////////////////////////////////////
↪
c    -0.229737
e    -0.781940
g     0.756053
k     2.613373
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing `ndarray`):

```
In [13]: s = Series(randn(6), index=range(0, 12, 2))
```

```
In [14]: s[[4, 0, 2]]
```

```
Out[14]:
```

(continues on next page)

(continued from previous page)

```

4      0.022862
0     -0.321246
2     -0.707337
Length: 3, dtype: float64

In [15]: s[1:5]
Out[15]:
2     -0.707337
4      0.022862
6      0.306713
8     -0.162222
Length: 4, dtype: float64

```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

### 1.38.5 Other API Changes

- The deprecated `LongPanel` class has been completely removed
- If `Series.sort` is called on a column of a `DataFrame`, an exception will now be raised. Before it was possible to accidentally mutate a `DataFrame`'s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` ([GH316](#))
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`
- `drop` added as an optional parameter to `DataFrame.reset_index` ([GH699](#))

### 1.38.6 Performance improvements

- *Cythonized GroupBy aggregations* no longer presort the data, thus achieving a significant speedup ([GH93](#)). `GroupBy` aggregations with Python functions significantly sped up by clever manipulation of the `ndarray` data type in Cython ([GH496](#)).
- Better error message in `DataFrame` constructor when passed column labels don't match data ([GH497](#))
- Substantially improve performance of multi-`GroupBy` aggregation when a Python function is passed, reuse `ndarray` object in Cython ([GH496](#))
- Can store objects indexed by tuples and floats in `HDFStore` ([GH492](#))
- Don't print length by default in `Series.to_string`, add `length` option ([GH489](#))
- Improve Cython code for multi-groupby to aggregate without having to sort the data ([GH93](#))
- Improve `MultiIndex` reindexing speed by storing tuples in the `MultiIndex`, test for backwards unpickling compatibility
- Improve column reindexing performance by using specialized Cython take function
- Further performance tweaking of `Series.__getitem__` for standard use cases
- Avoid `Index` dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions
- Friendlier error message in `setup.py` if `NumPy` not installed
- Use common set of NA-handling operations (sum, mean, etc.) in `Panel` class also ([GH536](#))
- Default name assignment when calling `reset_index` on `DataFrame` with a regular (non-hierarchical) index ([GH476](#))

- Use Cythonized groupers when possible in Series/DataFrame stat ops with `level` parameter passed (GH545)
- Ported skiplist data structure to C to speed up `rolling_median` by about 5-10x in most typical use cases (GH374)

## 1.39 v.0.6.1 (December 13, 2011)

### 1.39.1 New features

- Can *append single rows* (as Series) to a DataFrame
- Add Spearman and Kendall rank *correlation* options to `Series.corr` and `DataFrame.corr` (GH428)
- *Added* `get_value` and `set_value` methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). `set_value` is capable of producing an enlarged object.
- Add PyQt table widget to sandbox (GH435)
- `DataFrame.align` can *accept Series arguments* and an *axis option* (GH461)
- Implement new *SparseArray* and *SparseList* data structures. `SparseSeries` now derives from `SparseArray` (GH463)
- *Better console printing options* (GH453)
- Implement fast *data ranking* for Series and DataFrame, fast versions of `scipy.stats.rankdata` (GH428)
- Implement *DataFrame.from\_items* alternate constructor (GH444)
- `DataFrame.convert_objects` method for *inferring better dtypes* for object columns (GH302)
- Add *rolling\_corr\_pairwise* function for computing Panel of correlation matrices (GH189)
- Add *margins* option to *pivot\_table* for computing subgroup aggregates (GH114)
- Add `Series.from_csv` function (GH482)
- *Can pass* DataFrame/DataFrame and DataFrame/Series to `rolling_corr/rolling_cov` (GH #462)
- `MultiIndex.get_level_values` can *accept the level name*

### 1.39.2 Performance improvements

- Improve memory usage of *DataFrame.describe* (do not copy data unnecessarily) (PR #425)
- Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
- Fix performance regression in cross-sectional count in DataFrame, affecting `DataFrame.dropna` speed
- Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

## 1.40 v.0.6.0 (November 25, 2011)

### 1.40.1 New Features

- *Added* `melt` function to `pandas.core.reshape`
- *Added* `level` parameter to `group by level` in Series and DataFrame descriptive statistics (GH313)

- *Added* `head` and `tail` methods to `Series`, analogous to `DataFrame` (GH296)
- *Added* `Series.isin` function which checks if each value is contained in a passed sequence (GH289)
- *Added* `float_format` option to `Series.to_string`
- *Added* `skip_footer` (GH291) and `converters` (GH343) options to `read_csv` and `read_table`
- *Added* `drop_duplicates` and `duplicated` functions for removing duplicate `DataFrame` rows and checking for duplicate rows, respectively (GH319)
- *Implemented* operators `&`, `|`, `^`, `-` on `DataFrame` (GH347)
- *Added* `Series.mad`, mean absolute deviation
- *Added* `QuarterEnd` `DateOffset` (GH321)
- *Added* `dot` to `DataFrame` (GH65)
- *Added* `orient` option to `Panel.from_dict` (GH359, GH301)
- *Added* `orient` option to `DataFrame.from_dict`
- *Added* passing list of tuples or list of lists to `DataFrame.from_records` (GH357)
- *Added* multiple levels to `groupby` (GH103)
- *Allow* multiple columns in `by` argument of `DataFrame.sort_index` (GH92, GH362)
- *Added* `fast_get_value` and `put_value` methods to `DataFrame` (GH360)
- *Added* `cov` instance methods to `Series` and `DataFrame` (GH194, GH362)
- *Added* `kind='bar'` option to `DataFrame.plot` (GH348)
- *Added* `idxmin` and `idxmax` to `Series` and `DataFrame` (GH286)
- *Added* `read_clipboard` function to parse `DataFrame` from clipboard (GH300)
- *Added* `nunique` function to `Series` for counting unique elements (GH297)
- *Made* `DataFrame` constructor use `Series` name if no columns passed (GH373)
- *Support* regular expressions in `read_table/read_csv` (GH364)
- *Added* `DataFrame.to_html` for writing `DataFrame` to HTML (GH387)
- *Added* support for `MaskedArray` data in `DataFrame`, masked values converted to `NaN` (GH396)
- *Added* `DataFrame.boxplot` function (GH368)
- *Can* pass extra args, kwds to `DataFrame.apply` (GH376)
- *Implement* `DataFrame.join` with vector on argument (GH312)
- *Added* `legend` boolean flag to `DataFrame.plot` (GH324)
- *Can* pass multiple levels to `stack` and `unstack` (GH370)
- *Can* pass multiple values columns to `pivot_table` (GH381)
- *Use* `Series` name in `GroupBy` for result index (GH363)
- *Added* `raw` option to `DataFrame.apply` for performance if only need `ndarray` (GH309)
- *Added* proper, tested weighted least squares to standard and panel OLS (GH303)

### 1.40.2 Performance Enhancements

- VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the codebase ([GH361](#))
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` ([GH309](#))
- VBENCH Improved performance of `MultiIndex.from_tuples`
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
- VBENCH + DOCUMENT Add `raw` option to `DataFrame.apply` for getting better performance when
- VBENCH Faster cythonized count by level in `Series` and `DataFrame` ([GH341](#))
- VBENCH? Significant `GroupBy` performance enhancement with multiple keys with many “empty” combinations
- VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by ([GH355](#))
- VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a `Series` faster ([GH327](#))
- VBENCH Vastly improved performance of `GroupBy` on axes with a `MultiIndex` ([GH299](#))

## 1.41 v.0.5.0 (October 24, 2011)

### 1.41.1 New Features

- *Added* `DataFrame.align` method with standard join options
- *Added* `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- *Added* `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file ([GH242](#))
- *Added* ability to join on multiple columns in `DataFrame.join` ([GH214](#))
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily ([ENH5c](#))
- *Added* column attribute access to `DataFrame`.
- *Added* Python tab completion hook for `DataFrame` columns. ([GH233](#), [GH230](#))
- *Implemented* `Series.describe` for `Series` containing objects ([GH241](#))
- *Added* inner join option to `DataFrame.join` when joining on key(s) ([GH248](#))
- *Implemented* selecting `DataFrame` columns by passing a list to `__getitem__` ([GH253](#))
- *Implemented* `&` and `|` to intersect / union `Index` objects, respectively ([GH261](#))
- *Added* `pivot_table` convenience function to pandas namespace ([GH234](#))
- *Implemented* `Panel.rename_axis` function ([GH243](#))
- `DataFrame` will show index level names in console output ([GH334](#))
- *Implemented* `Panel.take`
- *Added* `set_eng_float_format` for alternate `DataFrame` floating point string formatting ([ENH61](#))

- *Added* convenience `set_index` function for creating a `DataFrame` index from its existing columns
- *Implemented* `groupby` hierarchical index level name (GH223)
- *Added* support for different delimiters in `DataFrame.to_csv` (GH244)
- TODO: DOCS ABOUT TAKE METHODS

### 1.41.2 Performance Enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to `ndarray` very fast. Speeds up many `MultiIndex`-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type `DataFrame` objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed `DataFrame` objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into `DataFrame` (GH212)
- VBENCH Significantly speed up `DataFrame.__repr__` and `count` on large mixed-type `DataFrame` objects

## 1.42 v.0.4.3 through v0.4.1 (September 25 - October 9, 2011)

### 1.42.1 New Features

- Added Python 3 support using 2to3 (GH200)
- *Added* name attribute to `Series`, now prints as part of `Series.__repr__`
- *Added* instance methods `isnull` and `notnull` to `Series` (GH209, GH203)
- *Added* `Series.align` method for aligning two series with choice of join method (ENH56)
- *Added* method `get_level_values` to `MultiIndex` (GH188)
- Set values in mixed-type `DataFrame` objects via `.ix` indexing attribute (GH135)
- Added new `DataFrame` *methods* `get_dtype_counts` and property `dtypes` (ENHdc)
- Added *ignore\_index* option to `DataFrame.append` to stack `DataFrames` (ENH1b)
- `read_csv` tries to *sniff* delimiters using `csv.Sniffer` (GH146)
- `read_csv` can *read* multiple columns into a `MultiIndex`; `DataFrame`'s `to_csv` method writes out a corresponding `MultiIndex` (GH151)
- `DataFrame.rename` has a new `copy` parameter to *rename* a `DataFrame` in place (ENHed)
- *Enable* unstacking by name (GH142)
- *Enable* `sortlevel` to work by level (GH141)

### 1.42.2 Performance Enhancements

- Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks ([GH205](#))
- Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
- Improved performance of `isnull` and `notnull`, a regression from v0.3.0 ([GH187](#))
- Refactored code related to `DataFrame.join` so that intermediate aligned copies of the data in each `DataFrame` argument do not need to be created. Substantial performance increases result ([GH176](#))
- Substantially improved performance of generic `Index.intersection` and `Index.union`
- Implemented `BlockManager.take` resulting in significantly faster `take` performance on mixed-type `DataFrame` objects ([GH104](#))
- Improved performance of `Series.sort_index`
- Significant groupby performance enhancement: removed unnecessary integrity checks in `DataFrame` internals that were slowing down slicing operations to retrieve groups
- Optimized `_ensure_index` function resulting in performance savings in type-checking `Index` objects
- Wrote fast time series merging / joining methods in Cython. Will be integrated later into `DataFrame.join` and related functions

## INSTALLATION

The easiest way to install pandas is to install it as part of the [Anaconda](#) distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, [PyPI](#), [ActivePython](#), various Linux distributions, or a [development version](#) are also provided.

### 2.1 Plan for dropping Python 2.7

The Python core team plans to stop supporting Python 2.7 on January 1st, 2020. In line with [NumPy's plans](#), all pandas releases through December 31, 2018 will support Python 2.

The final release before **December 31, 2018** will be the last release to support Python 2. The released package will continue to be available on PyPI and through conda.

Starting **January 1, 2019**, all releases will be Python 3 only.

If there are people interested in continued support for Python 2.7 past December 31, 2018 (either backporting bugfixes or funding) please reach out to the maintainers on the issue tracker.

For more information, see the [Python 3 statement](#) and the [Porting to Python 3 guide](#).

### 2.2 Python version support

Officially Python 2.7, 3.5, 3.6, and 3.7.

### 2.3 Installing pandas

#### 2.3.1 Installing with Anaconda

Installing pandas and the rest of the [NumPy](#) and [SciPy](#) stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the [SciPy](#) stack ([IPython](#), [NumPy](#), [Matplotlib](#), ...) is with [Anaconda](#), a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the [SciPy](#) stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for [Anaconda](#) can be found [here](#).

A full list of the packages available as part of the [Anaconda](#) distribution [can be found here](#).

Another advantage to installing Anaconda is that you don't need admin rights to install it. Anaconda can install in the user's home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

## 2.3.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the [Anaconda](#) distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with [Miniconda](#) may be a better solution.

[Conda](#) is the package manager that the [Anaconda](#) distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

[Miniconda](#) allows you to create a minimal self contained Python installation, and then use the [Conda](#) command to install additional packages.

First you will need [Conda](#) to be installed and downloading and running the [Miniconda](#) will do this for you. The installer [can be found here](#)

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full [Anaconda](#) distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```

### 2.3.3 Installing from PyPI

pandas can be installed via pip from PyPI.

```
pip install pandas
```

### 2.3.4 Installing with ActivePython

Installation instructions for [ActivePython](#) can be found [here](#). Versions 2.7 and 3.5 include pandas.

### 2.3.5 Installing using your Linux distribution's package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

Distribution	Status	Download / Repository Link	Install method
Debian	stable	<a href="#">official Debian repository</a>	<code>sudo apt-get install python3-pandas</code>
Debian & Ubuntu	unstable (latest packages)	<a href="#">NeuroDebian</a>	<code>sudo apt-get install python3-pandas</code>
Ubuntu	stable	<a href="#">official Ubuntu repository</a>	<code>sudo apt-get install python3-pandas</code>
OpenSuse	stable	<a href="#">OpenSuse Repository</a>	<code>zypper in python3-pandas</code>
Fedora	stable	<a href="#">official Fedora repository</a>	<code>dnf install python3-pandas</code>
Centos/RHEL	stable	<a href="#">EPEL repository</a>	<code>yum install python3-pandas</code>

**However**, the packages in the linux package managers are often a few versions behind, so to get the newest version of pandas, it's recommended to install using the `pip` or `conda` methods described above.

### 2.3.6 Installing from source

See the [contributing documentation](#) for complete instructions on building from the git source tree. Further, see [creating a development environment](#) if you wish to create a *pandas* development environment.

## 2.4 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the codebase as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` and run:

```
>>> import pandas as pd
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-
packages\pandas
===== test session starts =====
```

(continues on next page)

(continued from previous page)

```
platform win32 -- Python 3.6.2, pytest-3.2.1, py-1.4.34, pluggy-0.4.0
rootdir: C:\Users\TP\Documents\Python\pandasdev\pandas, inifile: setup.cfg
collected 12145 items / 3 skipped

.....S.....
.....S.....
.....

===== 12130 passed, 12 skipped in 368.339 seconds =====
```

## 2.5 Dependencies

- **setuptools**: 24.2.0 or higher
- **NumPy**: 1.9.0 or higher
- **python-dateutil**: 2.5.0 or higher
- **pytz**

### 2.5.1 Recommended Dependencies

- **numexpr**: for accelerating certain numerical operations. **numexpr** uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.4.6 or higher.
- **bottleneck**: for accelerating certain types of nan evaluations. **bottleneck** uses specialized cython routines to achieve large speedups. If installed, must be Version 1.0.0 or higher.

---

**Note:** You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

---

### 2.5.2 Optional Dependencies

- **Cython**: Only necessary to build development version. Version 0.24 or higher.
- **SciPy**: miscellaneous statistical functions, Version 0.14.0 or higher
- **xarray**: pandas like handling for > 2 dims, needed for converting Panels to xarray objects. Version 0.7.0 or higher is recommended.
- **PyTables**: necessary for HDF5-based storage. Version 3.0.0 or higher required, Version 3.2.1 or higher highly recommended.
- **Feather Format**: necessary for feather-based storage, version 0.3.1 or higher.
- **Apache Parquet**, either **pyarrow** (>= 0.4.1) or **fastparquet** (>= 0.0.6) for parquet-based storage. The **snappy** and **brotli** are available for compression support.
- **SQLAlchemy**: for SQL database support. Version 0.8.1 or higher recommended. Besides SQLAlchemy, you also need a database specific driver. You can find an overview of supported drivers for each SQL dialect in the [SQLAlchemy docs](#). Some common drivers are:
  - **psycopg2**: for PostgreSQL

- `pymysql`: for MySQL.
- `SQLite`: for SQLite, this is included in Python’s standard library by default.
- `matplotlib`: for plotting, Version 1.4.3 or higher.
- For Excel I/O:
  - `xlrd/xlwt`: Excel reading (`xlrd`) and writing (`xlwt`)
  - `openpyxl`: `openpyxl` version 2.4.0 for writing `.xlsx` files (`xlrd`  $\geq$  0.9.0)
  - `XlsxWriter`: Alternative Excel writer
- `Jinja2`: Template engine for conditional HTML formatting.
- `s3fs`: necessary for Amazon S3 access (`s3fs`  $\geq$  0.0.7).
- `blosc`: for msgpack compression using `blosc`
- One of `qtpy` (requires `PyQt` or `PySide`), `PyQt5`, `PyQt4`, `pygtk`, `xsel`, or `xclip`: necessary to use `read_clipboard()`. Most package managers on Linux distributions will have `xclip` and/or `xsel` immediately available for installation.
- `pandas-gbq`: for Google BigQuery I/O.
- `Backports.lzma`: Only for Python 2, for writing to and/or reading from an xz compressed DataFrame in CSV; Python 3 support is built into the standard library.
- One of the following combinations of libraries is needed to use the top-level `read_html()` function:  
Changed in version 0.23.0.

---

**Note:** If using BeautifulSoup4 a minimum version of 4.2.1 is required

---

- `BeautifulSoup4` and `html5lib` (Any recent version of `html5lib` is okay.)
- `BeautifulSoup4` and `lxml`
- `BeautifulSoup4` and `html5lib` and `lxml`
- Only `lxml`, although see *HTML Table Parsing* for reasons as to why you should probably **not** take this approach.

**Warning:**

- if you install `BeautifulSoup4` you must install either `lxml` or `html5lib` or both. `read_html()` will **not** work with *only* `BeautifulSoup4` installed.
- You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

---

**Note:**

- if you’re on a system with `apt-get` you can do

```
sudo apt-get build-dep python-lxml
```

to get the necessary dependencies for installation of `lxml`. This will prevent further headaches down the line.

---

---

**Note:** Without the optional dependencies, many useful features will not work. Hence, it is highly recommended that you install these. A packaged distribution like [Anaconda](#), [ActivePython](#) (version 2.7 or 3.5), or [Enthought Canopy](#) may be worth considering.

---

  - *Updating your pull request*
  - *Delete your merged branch (optional)*

## 3.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the [GitHub “issues” tab](#) to find issues that interest you. There are a number of issues listed under [Docs](#) and [good first issue](#) where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

Feel free to ask questions on the [mailing list](#) or on [Gitter](#).

## 3.2 Bug reports and enhancement requests

Bug reports are an important part of making *pandas* more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See [this stackoverflow article](#) and [this blogpost](#) for tips on writing a good bug report.

Trying the bug-producing code out on the *master* branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using [GitHub Flavored Markdown](#):

```
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...)
...
```
```

2. Include the full version string of *pandas* and its dependencies. You can use the built in function:

```
>>> import pandas as pd
>>> pd.show_versions()
```

3. Explain why the current behavior is wrong/not desired and what you expect instead.

The issue will then show up to the *pandas* community and be open to comments/ideas from others.

## 3.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the *pandas* code base.

### 3.3.1 Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to *pandas*. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on [GitHub](#). To contribute you will need to sign up for a [free GitHub account](#). We use [Git](#) for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the [GitHub help pages](#).
- the [NumPy's documentation](#).
- Matthew Brett's [Pydagogue](#).

### 3.3.2 Getting started with Git

[GitHub has instructions](#) for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

### 3.3.3 Forking

You will need your own fork to work on the code. Go to the [pandas project page](#) and hit the `Fork` button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory *pandas-yourname* and connects your repository to the upstream (main project) *pandas* repository.

### 3.3.4 Creating a development environment

To test out code changes, you'll need to build *pandas* from source, which requires a C compiler and Python environment. If you're making documentation changes, you can skip to [Contributing to the documentation](#) but you won't be able to build the documentation locally before pushing your changes.

### 3.3.4.1 Installing a C Compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you're using. Follow the [Cython contributing guidelines](#) for getting a compiler installed. You don't need to do any of the `./configure` or `make` steps; you only need to install the compiler.

For Windows developers, the following links may be helpful.

- <https://blogs.msdn.microsoft.com/pythonengineering/2016/04/11/unable-to-find-vcvarsall-bat/>
- <https://github.com/conda/conda-recipes/wiki/Building-from-Source-on-Windows-32-bit-and-64-bit>
- <https://cowboyprogrammer.org/building-python-wheels-for-windows/>
- <https://blog.ionelmc.ro/2014/12/21/compiling-python-extensions-on-windows/>
- <https://support.enthought.com/hc/en-us/articles/204469260-Building-Python-extensions-with-Canopy>

Let us know if you have any difficulties by opening an issue or reaching out on [Gitter](#).

### 3.3.4.2 Creating a Python Environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either [Anaconda](#) or [miniconda](#)
- Make sure your conda is up to date (`conda update conda`)
- Make sure that you have [cloned the repository](#)
- `cd` to the *pandas* source directory

We'll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f ci/environment-dev.yaml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .

# Install the rest of the optional dependencies
conda install -c defaults -c conda-forge --file=ci/requirements-optional-conda.txt
```

At this point you should be able to import pandas from your locally built version:

```
$ python # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```

This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

### 3.3.4.3 Creating a Python Environment (pip)

If you aren't using conda for your development environment, follow these instructions. You'll need to have at least python3.5 installed on your system.

```
# Create a virtual environment
# Use an ENV_DIR of your choice. We'll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev
# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r ci/requirements_dev.txt
# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .

# Install additional dependencies
python -m pip install -r ci/requirements-optional-pip.txt
```

### 3.3.5 Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to *pandas*. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```

When you want to update the feature branch with changes in master after you created the branch, check the section on *updating a PR*.

## 3.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses *pandas*. We encourage you to help us improve the documentation, and you don't have to be an expert on *pandas* to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn't make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

### Documentation:

- *About the pandas documentation*
- *How to build the pandas documentation*
  - *Requirements*
  - *Building the documentation*
  - *Building master branch documentation*

### 3.4.1 About the *pandas* documentation

The documentation is written in **reStructuredText**, which is almost like writing in plain English, and built using *Sphinx*. The Sphinx Documentation has an excellent [introduction to reST](#). Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The *pandas* documentation consists of two parts: the docstrings in the code itself and the docs in this folder `pandas/doc/`.

The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what's new, installation, etc).

- The docstrings follow a pandas convention, based on the **Numpy Docstring Standard**. Follow the *pandas docstring guide* for detailed instructions on how to write a correct docstring.

#### 3.4.1.1 pandas docstring guide

---

**Note:** [Video tutorial: Pandas docstring guide](#) by Frank Akogun.

---

### About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. *Sphinx* serves this purpose.

Next example gives an idea on how a docstring looks like:

```
def add(num1, num2):
    """
    Add up two integer numbers.

    This function simply wraps the `+` operator, and does not
    do anything interesting, except for illustrating what is
    the docstring of a very simple function.

    Parameters
    -----
    num1 : int
        First number to add
    num2 : int
        Second number to add

    Returns
    -----
    int
        The sum of `num1` and `num2`

    See Also
    -----
    subtract : Subtract one integer from another

    Examples
    -----
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in [PEP-257](#).

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring convention is followed. The conventions is explained in this document:

- [numpydoc docstring guide](#) (which is based in the original [Guide to NumPy/SciPy documentation](#))

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles in plain text files. Documentation about reStructuredText can be found in:

- [Sphinx reStructuredText primer](#)
- [Quick reStructuredText reference](#)
- [Full reStructuredText specification](#)

Pandas has some helpers for sharing docstrings between related classes, see [Sharing Docstrings](#).

The rest of this document will summarize all the above guides, and will provide additional convention specific to the pandas project.

## Writing a docstring

### General rules

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but it is common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. `os`, `list`, `numpy.abs`, `datetime.date`, `True`)
- A pandas class (in the form `:class:`pandas.Series``)
- A pandas method (in the form `:meth:`pandas.Series.sum``)
- A pandas function (in the form `:func:`pandas.to_datetime``)

---

**Note:** To display only the last component of the linked class, method or function, prefix it with `~`. For example, `:class:`~pandas.Series`` will link to `pandas.Series` but only display the last part, `Series` as the link text. See [Sphinx cross-referencing syntax](#) for details.

---

#### Good:

```
def add_values(arr):  
    """  
    Add the values in `arr`.  
  
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.  
  
    Some sections are omitted here for simplicity.  
    """  
    return sum(arr)
```

#### Bad:

```
def func():  
  
    """Some function.  
  
    With several mistakes in the docstring.  
  
    It has a blank line after the signature `def func():`.  
  
    The text 'Some function' should go in the line after the  
    opening quotes of the docstring, not in the same line.  
  
    There is a blank line between the docstring and the first line  
    of code `foo = 1`.  
  
    The closing quotes should be in the next line, not in this one."""  
  
    foo = 1
```

(continues on next page)

(continued from previous page)

```
bar = 2
return foo + bar
```

## Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

### Good:

```
def astype(dtype):
    """
    Cast Series type.

    This section will provide further details.
    """
    pass
```

### Bad:

```
def astype(dtype):
    """
    Casts Series type.

    Verb in third-person of the present simple, should be infinitive.
    """
    pass

def astype(dtype):
    """
    Method to cast Series type.

    Does not start with verb.
    """
    pass

def astype(dtype):
    """
    Cast Series type

    Missing dot at the end.
    """
    pass

def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in
    the parameter dtype.

    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```

## Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```
def unstack():
    """
    Pivot a row index to columns.

    When using a multi-index, a level can be pivoted so each value in
    the index becomes a column. This is especially useful when a subindex
    is repeated for the main index, and data is easier to visualize as a
    pivot table.

    The index level will be automatically removed from the index when added
    as columns.
    """
    pass
```

## Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *\*args* and *\*\*kwargs*, but not *self*.

The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *\*args* and *\*\*kwargs*, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is *None*, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When *None* is a value being used, we will keep the form “str, default None”. For example, in *df.to\_csv(compression=None)*, *None* is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use *str, optional*. Only in cases like *func(value=None)* and *None* is being used in the same way as *0* or *foo* would be used, then we will specify “str, int or None, default None”.

**Good:**

```
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.
```

(continues on next page)

(continued from previous page)

```

Render the data in the Series as a matplotlib plot of the
specified kind.

Parameters
-----
kind : str
    Kind of matplotlib plot.
color : str, default 'blue'
    Color name or rgb code.
**kwargs
    These parameters will be passed to the matplotlib plotting
    function.
"""
pass

```

**Bad:**

```

class Series:
    def plot(self, kind, **kwargs):
        """
        Generate a plot.

        Render the data in the Series as a matplotlib plot of the
        specified kind.

        Note the blank line between the parameters title and the first
        parameter. Also, note that after the name of the parameter `kind`
        and before the colon, a space is missing.

        Also, note that the parameter descriptions do not start with a
        capital letter, and do not finish with a dot.

        Finally, the `**kwargs` parameter is missing.

        Parameters
        -----

        kind: str
            kind of matplotlib plot
        """
        pass

```

**Parameter types**

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For *dict* and *tuple*, as more than one type is present, we use the brackets to help read the type (curly brackets for *dict* and normal brackets for *tuple*):

- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:

- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:

- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:

- numpy.ndarray
- scipy.sparse.coo\_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:

- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:

- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word 'or':

- int or float
- float, decimal.Decimal or None
- str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:

- axis : {0 or 'index', 1 or 'columns', None}, default None

## Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```
def sample():
    """
    Generate and return a random number.

    The value is sampled from a continuous uniform distribution between
    0 and 1.

    Returns
    -----
    float
        Random number generated.
    """
    return random.random()
```

With more than one value:

```
def random_letters():
    """
    Generate and return a sequence of random letters.

    The length of the returned string is also random, and is also
    returned.

    Returns
    -----
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    """
    length = random.randint(1, 10)
    letters = ''.join(random.choice(string.ascii_lowercase)
                      for i in range(length))
    return length, letters
```

If the method yields its value:

```
def sample_values():
    """
    Generate an infinite sequence of random numbers.

    The values are sampled from a continuous uniform distribution between
    0 and 1.
```

(continues on next page)

(continued from previous page)

```

Yields
-----
float
    Random number generated.
"""
while True:
    yield random.random()

```

## Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the *head()* and *tail()* methods. As *tail()* does the equivalent as *head()* but at the end of the *Series* or *DataFrame* instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- `loc` and `iloc`, as they do the same, but in one case providing indices and in the other positions
- `max` and `min`, as they do the opposite
- `iterrows`, `itertuples` and `iteritems`, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- `fillna` and `dropna`, as both methods are used to handle missing values
- `read_csv` and `to_csv`, as they are complementary
- `merge` and `join`, as one is a generalization of the other
- `astype` and `pandas.to_datetime`, as users may be reading the documentation of `astype` to know how to cast as a date, and the way to do it is with `pandas.to_datetime`
- `where` is related to `numpy.where`, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly `numpy`), use the name of the module first (not an alias like `np`). If the function is in a module which is not the main one, like `scipy.sparse`, list the full module (e.g. `scipy.sparse.coo_matrix`).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:

```

class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Returns
        -----
        Series
            Subset of the original series with the 5 first values.

        See Also
        -----
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series,
                      which can also be used to return the first or last n.
        """
        return self.iloc[:5]

```

## Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

## Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. `>>>` is used to present code. `...` is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except `numpy` and `pandas`)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:

```
class Series:
    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Parameters
        -----
        n : int
            Number of values to return.

        Return
        -----
        pandas.Series
            Subset of the original series with the n first values.

        See Also
        -----
        tail : Return the last n elements of the Series.

        Examples
        -----
        >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
        ...               'Lion', 'Monkey', 'Rabbit', 'Zebra'])
        >>> s.head()
        0    Ant
        1    Bear
        2    Cow
        3    Dog
        4    Falcon
        dtype: object

        With the `n` parameter, we can change the number of returned rows:

        >>> s.head(n=3)
        0    Ant
        1    Bear
        2    Cow
        dtype: object
        """
        return self.iloc[:n]
```

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star **\*\*** to make a text bold, like in **\*\*this example\*\***.

### Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in [PEP-8](#))

and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1`, `s2`, `s3...` or `df1`, `df2`, `df3...`. If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```
class Series:
    def mean(self):
        """
        Compute the mean of the input.

        Examples
        -----
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

    def fillna(self, value):
        """
        Replace missing values by `value`.

        Examples
        -----
        >>> s = pd.Series([1, np.nan, 3])
        >>> s.fillna(0)
        [1, 0, 3]
        """
        pass

    def groupby_mean(self):
        """
        Group by index and return mean.

        Examples
        -----
        >>> s = pd.Series([380., 370., 24., 26],
        ...               name='max_speed',
        ...               index=['falcon', 'falcon', 'parrot', 'parrot'])
        >>> s.groupby_mean()
        index
```

(continues on next page)

(continued from previous page)

```

    falcon      375.0
    parrot      25.0
    Name: max_speed, dtype: float64
    """
    pass

def contains(self, pattern, case_sensitive=True, na=numpy.nan):
    """
    Return whether each value contains `pattern`.

    In this case, we are illustrating how to use sections, even
    if the example is simple enough and does not require them.

    Examples
    -----
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', numpy.nan)
    >>> s.contains(pattern='a')
    0    False
    1    False
    2     True
    3     NaN
    dtype: bool

    **Case sensitivity**

    With `case_sensitive` set to `False` we can match `a` with both
    `a` and `A`:

    >>> s.contains(pattern='a', case_sensitive=False)
    0     True
    1    False
    2     True
    3     NaN
    dtype: bool

    **Missing values**

    We can fill missing values in the output using the `na` parameter:

    >>> s.contains(pattern='a', na=False)
    0    False
    1    False
    2     True
    3    False
    dtype: bool
    """
    pass

```

**Bad:**

```

def method(foo=None, bar=None):
    """
    A sample DataFrame method.

    Do not import numpy and pandas.

    Try to use meaningful data, when it makes the example easier

```

(continues on next page)

(continued from previous page)

to understand.

Try to avoid positional arguments like in `df.method(1)`. They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)`, but avoid them otherwise.

When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

Examples

-----

```
>>> import numpy as np
>>> import pandas as pd
>>> df = pd.DataFrame(numpy.random.randn(3, 3),
...                    columns=('a', 'b', 'c'))
>>> df.method(1)
21
>>> df.method(bar=14)
123
"""
pass
```

### Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as `import pandas as pd` and `import numpy as np`) and define all variables you use in the example.
- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

```
>>> np.random.seed(42)
>>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
```

- If you have a code snippet that wraps multiple lines, you need to use `'...'` on the continued lines:

```
>>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
...                    columns=['A', 'B'])
```

- If you want to show a case where an exception is raised, you can do:

```
>>> pd.to_datetime(["712-01-01"])
Traceback (most recent call last):
OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
```

It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object representation), you can use `...` to represent this part.

If you want to show that `s.plot()` returns a matplotlib `AxesSubplot` object, this will fail the doctest

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.. plot::` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.

        Examples
        -----

        .. plot::
            :context: close-figs

            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()

        """
    pass
```

## Sharing Docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%(klass)s`. The variables filled in later on using the `Substitution` decorator. Finally, docstrings can be appended to with the `Appender` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the children’s class names in this docstring.

```
class Parent:
    def my_function(self):
        """Apply my function to %(klass)s."""
        ...

class ChildA(Parent):
    @Substitution(klass="ChildA")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
```

(continues on next page)

(continued from previous page)

```

...

class ChildB(Parent):
    @Substitution(klass="ChildB")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...

```

The resulting docstrings are

```

>>> print(Parent.my_function.__doc__)
Apply my function to %(klass)s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.

```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```

@Appender(template % _shared_doc_kwargs)
def my_function(self):
    ...

```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFrame.fillna` for an example `template`, and `pandas.core.series.Series.fillna` and `pandas.core.generic.frame.fillna` for the filled versions.

- The tutorials make heavy use of the `ipython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```

.. ipython:: python

    x = 2
    x**3

```

will be rendered as:

```

In [1]: x = 2

In [2]: x**3
Out[2]: 8

```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.

- Our API documentation in `doc/source/api.rst` houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. `_templates/autosummary/class.rst`. Use this when you want to automatically generate a page for every public method and attribute on the class. The `Attributes` and `Methods` sections will be automatically added to the class' rendered documentation by `numpydoc`. See `DataFrame` for an example.
2. `_templates/autosummary/class_without_autosummary`. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an `Attributes` and `Methods` section in the class docstring. See `CategoricalIndex` for an example.

Every method should be included in a `toctree` in `api.rst`, else Sphinx will emit a warning.

---

**Note:** The `.rst` files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit `CONTRIBUTING.md` directly, but instead make any changes to `doc/source/contributing.rst`. Then, to generate `CONTRIBUTING.md`, use `pandoc` with the following command:

```
pandoc doc/source/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script `scripts/validate_docstrings.py` can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in `doc/source/api.rst` (which is used to generate the [API Reference](#) page) and the actual public methods. This will identify methods documented in `doc/source/api.rst` that are not actually class methods, and existing methods that are not documented in `doc/source/api.rst`.

## 3.4.2 How to build the *pandas* documentation

### 3.4.2.1 Requirements

First, you need to have a development environment to be able to build pandas (see the docs on [creating a development environment above](#)).

### 3.4.2.2 Building the documentation

So how do you build the docs? Navigate to your local `pandas/doc/` directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder `pandas/doc/build/html/`.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell `make.py` to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.

```
# omit autosummary and API section
python make.py clean
python make.py --no-api

# compile the docs with only a single
# section, that which is in indexing.rst
python make.py clean
python make.py --single indexing

# compile the reference docs for a single function
python make.py clean
python make.py --single DataFrame.join
```

For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
pandas/docs/build/html/index.html
```

And you'll have the satisfaction of seeing your new and improved documentation!

### 3.4.2.3 Building master branch documentation

When pull requests are merged into the *pandas* master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted [here](#), see also the *Continuous Integration* section.

## 3.5 Contributing to the code base

### Code Base:

- *Code standards*
  - *C (cpplint)*
  - *Python (PEP8)*
  - *Backwards Compatibility*
- *Testing With Continuous Integration*
- *Test-driven development/code writing*
  - *Writing tests*
  - *Transitioning to pytest*
  - *Using pytest*
- *Running the test suite*
- *Running the performance test suite*

- *Documenting your code*

### 3.5.1 Code standards

Writing good code is not just about what you write. It is also about *how* you write it. During *Continuous Integration* testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to *pandas*.

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as *backwards compatible* as possible to avoid mass breakages.

Additional standards are outlined on the [code style wiki page](#).

#### 3.5.1.1 C (cpplint)

*pandas* uses the [Google](#) standard. Google provides an open source style checker called `cpplint`, but we use a fork of it that can be found [here](#). Here are *some* of the more common `cpplint` issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

*Continuous Integration* will run the `cpplint` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-  
↳build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=--readability/casting,-runtime/int,-  
↳build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the [ClangFormat](#) tool, which can be downloaded [here](#). To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h  
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct *all* of them. Thus, it is recommended that you run `cpplint` to double check and make any other style fixes manually.

### 3.5.1.2 Python (PEP8)

*pandas* uses the [PEP8](#) standard. There are several tools to ensure you abide by this standard. Here are *some* of the more common PEP8 issues:

- we restrict line-length to 79 characters to promote readability
- passing arguments should have spaces after commas, e.g. `foo(arg1, arg2, kw1='bar')`

*Continuous Integration* will run the [flake8](#) tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself on the diff:

```
git diff master -u -- "*.py" | flake8 --diff
```

This command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
git diff master --name-only -- "*.py" | grep "pandas/" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff master --name-only -- "*.py" | grep "pandas/" | xargs flake8
```

Note that on Windows, these commands are unfortunately not possible because commands like `grep` and `xargs` are not available natively. To imitate the behavior with the commands above, you should run:

```
git diff master --name-only -- "*.py"
```

This will list all of the Python files that have been modified. The only ones that matter during linting are any whose directory filepath begins with “pandas.” For each filepath, copy and paste it after the `flake8` command as shown below:

```
flake8 <python-filepath>
```

Alternatively, you can install the `grep` and `xargs` commands via the [MinGW](#) toolchain, and it will allow you to run the commands above.

### 3.5.1.3 Backwards Compatibility

Please try to maintain backward compatibility. *pandas* has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:

```
def old_func():
    """Summary of the function.

    .. deprecated:: 0.21.0
       Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()
```

### 3.5.2 Testing With Continuous Integration

The *pandas* test suite will run automatically on [Travis-CI](#), [Appveyor](#), and [Circle CI](#) continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for [Travis-CI](#), [Appveyor](#), and [CircleCI](#).

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

Add more commits by pushing to the **period-datetime-overflow** branch on **gfyoun/pandas**.

The screenshot shows a GitHub pull request status bar with a green checkmark icon on the left. The main status is "All checks have passed" with a link to "Hide all checks". Below this, there are five individual check items, each with a green checkmark, an icon, a description, and a "Details" link:

- ci/circleci** — Your tests passed on CircleCI! [Details](#)
- codecov/patch** — 100% of diff hit (target 50%) [Details](#)
- codecov/project** — 91.03% (target 82%) [Details](#)
- continuous-integration/appveyor/pr** — AppVeyor build succeeded [Details](#)
- continuous-integration/travis-ci/pr** — The Travis CI build passed [Details](#)

At the bottom, there is a summary check: "This branch has no conflicts with the base branch" with a note: "Only those with [write access](#) to this repository can merge pull requests."

---

**Note:** Each time you push to *your* fork, a *new* run of the tests will be triggered on the CI. Appveyor will auto-cancel any non-currently-running tests for that same pull-request. You can enable the auto-cancel feature for [Travis-CI](#) here and for [CircleCI](#) here.

---

### 3.5.3 Test-driven development/code writing

*pandas* is serious about testing and strongly encourages contributors to embrace [test-driven development \(TDD\)](#). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount

of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to *pandas*. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, *pandas* uses [pytest](#) and the convenient extensions in [numpy.testing](#).

---

**Note:** The earliest supported pytest version is 3.1.0.

---

### 3.5.3.1 Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the [testing page](#) of the wiki.

The `pandas.util.testing` module has many special `assert` functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

### 3.5.3.2 Transitioning to pytest

*pandas* existing test structure is *mostly* classed based, meaning that you will typically find tests wrapped in a class.

```
class TestReallyCoolFeature(object):
    ....
```

Going forward, we are moving to a more *functional* style using the [pytest](#) framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```
def test_really_cool_feature():
    ....
```

### 3.5.3.3 Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like `test_*` and *only* take arguments that are either fixtures or parameters
- `pytest.mark` can be used to set metadata on test functions, e.g. `skip` or `xfail`.
- using `parametrize`: allow testing of multiple cases
- to set a mark on a parameter, `pytest.param(..., marks=...)` syntax should be used
- `fixture`, code for object construction, on a per-test basis
- using bare `assert` for scalars and truth-testing
- `tm.assert_series_equal` (and its counter part `tm.assert_frame_equal`), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file `test_cool_feature.py` and put in an appropriate place in the `pandas/tests/` structure.

```
import pytest
import numpy as np
import pandas as pd
from pandas.util import testing as tm

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize('dtype', ['float32',
    pytest.param('int16', marks=pytest.mark.skip),
    pytest.param('int32',
        marks=pytest.mark.xfail(reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.2.1, py-1.4.31, pluggy-0.4.0
collected 11 items
```

(continues on next page)

(continued from previous page)

```

tester.py::test_dtypes[int8] PASSED
tester.py::test_dtypes[int16] PASSED
tester.py::test_dtypes[int32] PASSED
tester.py::test_dtypes[int64] PASSED
tester.py::test_mark[float32] PASSED
tester.py::test_mark[int16] SKIPPED
tester.py::test_mark[int32] xfail
tester.py::test_series[int8] PASSED
tester.py::test_series[int16] PASSED
tester.py::test_series[int32] PASSED
tester.py::test_series[int64] PASSED

```

Tests that we have parametrized are now accessible via the test name, for example we could run these with `-k int8` to sub-select *only* those tests which match `int8`.

```

((pandas) bash-3.2$ pytest test_cool_feature.py -v -k int8
===== test session starts =====
platform darwin -- Python 3.6.2, pytest-3.2.1, py-1.4.31, pluggy-0.4.0
collected 11 items

test_cool_feature.py::test_dtypes[int8] PASSED
test_cool_feature.py::test_series[int8] PASSED

```

### 3.5.4 Running the test suite

The tests can then be run directly inside your Git clone (without having to install *pandas*) by typing:

```
pytest pandas
```

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```

pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]

```

Using *pytest-xdist*, one can speed up local testing on multicore machines. To use this feature, you will need to install *pytest-xdist* via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```

This can significantly reduce the time it takes to locally run tests before submitting a pull request.

For more, see the [pytest](#) documentation.

New in version 0.20.0.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

### 3.5.5 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. *pandas* is in the process of migrating to [asv benchmarks](#) to enable easy monitoring of the performance of critical *pandas* operations. These benchmarks are all found in the `pandas/asv_bench` directory. *asv* supports both python2 and python3.

To use all features of *asv*, you will need either `conda` or `virtualenv`. For more details please check the [asv installation webpage](#).

To install *asv*:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to `asv_bench/` and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace `HEAD` with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses `conda` by default for creating the benchmark environments. If you want to use `virtualenv` instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The `-E virtualenv` option should be added to all *asv* commands that run benchmarks. The default value is defined in `asv.conf.json`.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the `-b` flag, which takes a regular expression. For example, this will only run tests from a `pandas/asv_bench/benchmarks/groupby.py` file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using `.` as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the `GroupByMethods` benchmark defined in `groupby.py`.

You can also run the benchmark suite using the version of *pandas* already installed in your current Python environment. This can be useful if you do not have `virtualenv` or `conda`, or are using the `setup.py develop` approach discussed above; for the in-place build you need to set `PYTHONPATH`, e.g. `PYTHONPATH="$PWD/.."` `asv [remaining arguments]`. You can run benchmarks using an existing Python environment by:

```
asv run -e -E existing
```

or, to use a specific Python interpreter,:

```
asv run -e -E existing:python3.5
```

This will display stderr from the benchmarks, and use your local `python` that comes from your `$PATH`.

Information on how to write a benchmark and how to use `asv` can be found in the [asv documentation](#).

### 3.5.6 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.txt`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234`` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation [above](#). Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```
.. versionadded:: 0.21.0
```

This will put the text *New in version 0.21.0* wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method ([example](#)) or a new keyword argument ([example](#)).

## 3.6 Contributing your changes to *pandas*

### 3.6.1 Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you've made changes, you can see them by typing:

```
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```
git add path/to/file-to-be-added.py
```

Doing 'git status' again should give something like:

```
# On branch shiny-new-feature
#
#       modified:   /relative/path/to/file-you-added.py
#
```

Finally, commit your changes to your local repository with an explanatory message. *Pandas* uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix

- DOC: Additions/updates to documentation
- TST: Additions/updates to tests
- BLD: Updates to the build process/scripts
- PERF: Performance improvement
- CLN: Code cleanup

The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```
git commit -m
```

### 3.6.2 Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch's commits:

```
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream      git://github.com/pandas-dev/pandas.git (fetch)
upstream      git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the *pandas* project. For that to happen, a pull request needs to be submitted on GitHub.

### 3.6.3 Review your code

When you're ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – <https://github.com/your-user-name/pandas>
2. Click on `Branches`
3. Click on the `Compare` button for your feature branch
4. Select the `base` and `compare` branches, if necessary. This will be `master` and `shiny-new-feature`, respectively.

### 3.6.4 Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the `Pull Request` button
3. You can then click on `Commits` and `Files Changed` to make sure everything looks okay one last time
4. Write a description of your changes in the `Preview Discussion` tab
5. Click `Send Pull Request`.

This request then goes to the repository maintainers, and they will review the code.

### 3.6.5 Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the *Continuous Integration* tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at <https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/> for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to `stash` them prior to updating (see the [stash docs](#)). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

### 3.6.6 Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:

```
git fetch upstream
git checkout master
git merge upstream/master
```

Then you can do:

```
git branch -d shiny-new-feature
```

Make sure you use a lower-case `-d`, or else git won't warn you if your feature branch has not actually been merged.

The branch will still exist on GitHub, so to delete it there do:

```
git push origin --delete shiny-new-feature
```

## PACKAGE OVERVIEW

*pandas* is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the *Python* programming language.

*pandas* consists of the following elements:

- A set of labeled array data structures, the primary of which are Series and DataFrame.
- Index objects enabling both simple axis indexing and multi-level / hierarchical axis indexing.
- An integrated group by engine for aggregating and transforming data sets.
- Date range generation (`date_range`) and custom date offsets enabling the implementation of customized frequencies.
- Input/Output tools: loading tabular data from flat files (CSV, delimited, Excel 2003), and saving and loading pandas objects from the fast and efficient PyTables/HDF5 format.
- Memory-efficient “sparse” versions of the standard data structures for storing data that is mostly missing or mostly constant (some fixed value).
- Moving window statistics (rolling mean, rolling standard deviation, etc.).

### 4.1 Data Structures

| Dimensions | Name      | Description  |
|------------|-----------|--|
| 1          | Series    | 1D labeled homogeneously-typed array   |
| 2          | DataFrame | General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column |

#### 4.1.1 Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguity matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.

For example, with tabular data (DataFrame) it is more semantically helpful to think of the **index** (the rows) and the **columns** rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```
for col in df.columns:
    series = df[col]
    # do something with series
```

## 4.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to **favor immutability** where sensible.

## 4.3 Getting Support

The first stop for pandas issues and ideas is the [Github Issue Tracker](#). If you have a general question, pandas community experts can answer through [Stack Overflow](#).

## 4.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to [all of our contributors](#).

If you're interested in contributing, please visit [Contributing to pandas webpage](#).

pandas is a [NumFOCUS](#) sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to [donate](#) to the project.

## 4.5 Project Governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in [Project Governance documents](#). The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

## 4.6 Development Team

The list of the Core Team members and more detailed information can be found on the [people's page](#) of the governance repo.

## 4.7 Institutional Partners

The information about current institutional partners can be found on [pandas website page](#).

## 4.8 License

BSD 3-Clause License

## 10 MINUTES TO PANDAS

This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: import matplotlib.pyplot as plt
```

### 5.1 Object Creation

See the *Data Structure Intro section*.

Creating a *Series* by passing a list of values, letting pandas create a default integer index:

```
In [4]: s = pd.Series([1,3,5,np.nan,6,8])
In [5]: s
Out[5]:
0    1.0
1    3.0
2    5.0
3    NaN
4    6.0
5    8.0
dtype: float64
```

Creating a *DataFrame* by passing a NumPy array, with a datetime index and labeled columns:

```
In [6]: dates = pd.date_range('20130101', periods=6)
In [7]: dates
Out[7]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
In [8]: df = pd.DataFrame(np.random.randn(6,4), index=dates, columns=list('ABCD'))
In [9]: df
Out[9]:
```

(continues on next page)

(continued from previous page)

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |
| 2013-01-06 | -0.673690 | 0.113648  | -1.478427 | 0.524988  |

Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```
In [10]: df2 = pd.DataFrame({ 'A' : 1.,
.....:                      'B' : pd.Timestamp('20130102'),
.....:                      'C' : pd.Series(1, index=list(range(4)), dtype='float32'),
.....:                      'D' : np.array([3] * 4, dtype='int32'),
.....:                      'E' : pd.Categorical(["test", "train", "test", "train"]),
.....:                      'F' : 'foo' })
```

```
In [11]: df2
```

```
Out[11]:
```

|   | A   | B          | C   | D | E     | F   |
|---|-----|------------|-----|---|-------|-----|
| 0 | 1.0 | 2013-01-02 | 1.0 | 3 | test  | foo |
| 1 | 1.0 | 2013-01-02 | 1.0 | 3 | train | foo |
| 2 | 1.0 | 2013-01-02 | 1.0 | 3 | test  | foo |
| 3 | 1.0 | 2013-01-02 | 1.0 | 3 | train | foo |

The columns of the resulting DataFrame have different *dtypes*.

```
In [12]: df2.dtypes
```

```
Out[12]:
```

|        |                |
|--------|----------------|
| A      | float64        |
| B      | datetime64[ns] |
| C      | float32        |
| D      | int32          |
| E      | category       |
| F      | object         |
| dtype: | object         |

If you're using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here's a subset of the attributes that will be completed:

```
In [13]: df2.<TAB>
df2.A          df2.bool
df2.abs        df2.boxplot
df2.add        df2.C
df2.add_prefix df2.clip
df2.add_suffix df2.clip_lower
df2.align      df2.clip_upper
df2.all        df2.columns
df2.any        df2.combine
df2.append     df2.combine_first
df2.apply      df2.compound
df2.applymap   df2.consolidate
df2.D
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.

## 5.2 Viewing Data

See the *Basics section*.

Here is how to view the top and bottom rows of the frame:

```
In [14]: df.head()
Out[14]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |

```
In [15]: df.tail(3)
Out[15]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |
| 2013-01-06 | -0.673690 | 0.113648  | -1.478427 | 0.524988  |

Display the index, columns, and the underlying NumPy data:

```
In [16]: df.index
Out[16]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')

In [17]: df.columns
Out[17]:
Index(['A', 'B', 'C', 'D'], dtype='object')

In [18]: df.values
Out[18]:
array([[ 0.4691, -0.2829, -1.5091, -1.1356],
       [ 1.2121, -0.1732,  0.1192, -1.0442],
       [-0.8618, -2.1046, -0.4949,  1.0718],
       [ 0.7216, -0.7068, -1.0396,  0.2719],
       [-0.425 ,  0.567 ,  0.2762, -1.0874],
       [-0.6737,  0.1136, -1.4784,  0.525 ]])
```

`describe()` shows a quick statistic summary of your data:

```
In [19]: df.describe()
Out[19]:
```

|       | A         | B         | C         | D         |
|-------|-----------|-----------|-----------|-----------|
| count | 6.000000  | 6.000000  | 6.000000  | 6.000000  |
| mean  | 0.073711  | -0.431125 | -0.687758 | -0.233103 |
| std   | 0.843157  | 0.922818  | 0.779887  | 0.973118  |
| min   | -0.861849 | -2.104569 | -1.509059 | -1.135632 |
| 25%   | -0.611510 | -0.600794 | -1.368714 | -1.076610 |
| 50%   | 0.022070  | -0.228039 | -0.767252 | -0.386188 |
| 75%   | 0.658444  | 0.041933  | -0.034326 | 0.461706  |
| max   | 1.212112  | 0.567020  | 0.276232  | 1.071804  |

Transposing your data:

```
In [20]: df.T
Out[20]:
```

|   | 2013-01-01 | 2013-01-02 | 2013-01-03 | 2013-01-04 | 2013-01-05 | 2013-01-06 |
|---|------------|------------|------------|------------|------------|------------|
| A | 0.469112   | 1.212112   | -0.861849  | 0.721555   | -0.424972  | -0.673690  |
| B | -0.282863  | -0.173215  | -2.104569  | -0.706771  | 0.567020   | 0.113648   |
| C | -1.509059  | 0.119209   | -0.494929  | -1.039575  | 0.276232   | -1.478427  |
| D | -1.135632  | -1.044236  | 1.071804   | 0.271860   | -1.087401  | 0.524988   |

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
```

|            | D         | C         | B         | A         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | -1.135632 | -1.509059 | -0.282863 | 0.469112  |
| 2013-01-02 | -1.044236 | 0.119209  | -0.173215 | 1.212112  |
| 2013-01-03 | 1.071804  | -0.494929 | -2.104569 | -0.861849 |
| 2013-01-04 | 0.271860  | -1.039575 | -0.706771 | 0.721555  |
| 2013-01-05 | -1.087401 | 0.276232  | 0.567020  | -0.424972 |
| 2013-01-06 | 0.524988  | -1.478427 | 0.113648  | -0.673690 |

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2013-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-06 | -0.673690 | 0.113648  | -1.478427 | 0.524988  |
| 2013-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |

## 5.3 Selection

---

**Note:** While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

---

See the indexing documentation [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#).

### 5.3.1 Getting

Selecting a single column, which yields a `Series`, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
```

|            |           |
|------------|-----------|
| 2013-01-01 | 0.469112  |
| 2013-01-02 | 1.212112  |
| 2013-01-03 | -0.861849 |
| 2013-01-04 | 0.721555  |

(continues on next page)

```
2013-01-05    -0.424972
2013-01-06    -0.673690
Freq: D, Name: A, dtype: float64
```

Out[24]:

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |

Out[26]:

|   |           |
|---|-----------|
| A | 0.469112  |
| B | -0.282863 |
| C | -1.509059 |
| D | -1.135632 |

Out [27]:

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-01 | 0.469112  | -0.282863 |
| 2013-01-02 | 1.212112  | -0.173215 |
| 2013-01-03 | -0.861849 | -2.104569 |
| 2013-01-04 | 0.721555  | -0.706771 |
| 2013-01-05 | -0.424972 | 0.567020  |
| 2013-01-06 | -0.673690 | 0.113648  |

Out [28]:

|            | A         | B         |
|------------|-----------|-----------|
| 2013-01-02 | 1.212112  | -0.173215 |
| 2013-01-03 | -0.861849 | -2.104569 |
| 2013-01-04 | 0.721555  | -0.706771 |

Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
A      1.212112
B     -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]: 0.46911229990718628
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]: 0.46911229990718628
```

### 5.3.3 Selection by Position

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
A      0.721555
B     -0.706771
C     -1.039575
D      0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5, 0:2]
Out[33]:
           A          B
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
```

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1, 2, 4], [0, 2]]
Out[34]:
           A          C
2013-01-02  1.212112  0.119209
2013-01-03 -0.861849 -0.494929
2013-01-05 -0.424972  0.276232
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3, :]
Out[35]:
           A          B          C          D
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

For slicing columns explicitly:

```
In [36]: df.iloc[:,1:3]
Out[36]:
```

|            | B         | C         |
|------------|-----------|-----------|
| 2013-01-01 | -0.282863 | -1.509059 |
| 2013-01-02 | -0.173215 | 0.119209  |
| 2013-01-03 | -2.104569 | -0.494929 |
| 2013-01-04 | -0.706771 | -1.039575 |
| 2013-01-05 | 0.567020  | 0.276232  |
| 2013-01-06 | 0.113648  | -1.478427 |

For getting a value explicitly:

```
In [37]: df.iloc[1,1]
Out[37]: -0.17321464905330858
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [38]: df.iat[1,1]
Out[38]: -0.17321464905330858
```

### 5.3.4 Boolean Indexing

Using a single column's values to select data.

```
In [39]: df[df.A > 0]
Out[39]:
```

|            | A        | B         | C         | D         |
|------------|----------|-----------|-----------|-----------|
| 2013-01-01 | 0.469112 | -0.282863 | -1.509059 | -1.135632 |
| 2013-01-02 | 1.212112 | -0.173215 | 0.119209  | -1.044236 |
| 2013-01-04 | 0.721555 | -0.706771 | -1.039575 | 0.271860  |

Selecting values from a DataFrame where a boolean condition is met.

```
In [40]: df[df > 0]
Out[40]:
```

|            | A        | B        | C        | D        |
|------------|----------|----------|----------|----------|
| 2013-01-01 | 0.469112 | NaN      | NaN      | NaN      |
| 2013-01-02 | 1.212112 | NaN      | 0.119209 | NaN      |
| 2013-01-03 | NaN      | NaN      | NaN      | 1.071804 |
| 2013-01-04 | 0.721555 | NaN      | NaN      | 0.271860 |
| 2013-01-05 | NaN      | 0.567020 | 0.276232 | NaN      |
| 2013-01-06 | NaN      | 0.113648 | NaN      | 0.524988 |

Using the `isin()` method for filtering:

```
In [41]: df2 = df.copy()

In [42]: df2['E'] = ['one', 'one', 'two', 'three', 'four', 'three']

In [43]: df2
Out[43]:
```

|            | A        | B         | C         | D         | E   |
|------------|----------|-----------|-----------|-----------|-----|
| 2013-01-01 | 0.469112 | -0.282863 | -1.509059 | -1.135632 | one |
| 2013-01-02 | 1.212112 | -0.173215 | 0.119209  | -1.044236 | one |

(continues on next page)

(continued from previous page)

```

2013-01-03 -0.861849 -2.104569 -0.494929 1.071804 two
2013-01-04 0.721555 -0.706771 -1.039575 0.271860 three
2013-01-05 -0.424972 0.567020 0.276232 -1.087401 four
2013-01-06 -0.673690 0.113648 -1.478427 0.524988 three

```

```
In [44]: df2[df2['E'].isin(['two', 'four'])]
```

```

////////////////////////////////////
↪
      A      B      C      D      E
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804 two
2013-01-05 -0.424972 0.567020 0.276232 -1.087401 four

```

### 5.3.5 Setting

Setting a new column automatically aligns the data by the indexes.

```
In [45]: s1 = pd.Series([1,2,3,4,5,6], index=pd.date_range('20130102', periods=6))
```

```
In [46]: s1
```

```
Out[46]:
```

```

2013-01-02    1
2013-01-03    2
2013-01-04    3
2013-01-05    4
2013-01-06    5
2013-01-07    6
Freq: D, dtype: int64

```

```
In [47]: df['F'] = s1
```

Setting values by label:

```
In [48]: df.at[dates[0], 'A'] = 0
```

Setting values by position:

```
In [49]: df.iat[0,1] = 0
```

Setting by assigning with a NumPy array:

```
In [50]: df.loc[:, 'D'] = np.array([5] * len(df))
```

The result of the prior setting operations.

```
In [51]: df
```

```
Out[51]:
```

```

      A      B      C      D      F
2013-01-01  0.000000  0.000000 -1.509059  5  NaN
2013-01-02  1.212112 -0.173215  0.119209  5  1.0
2013-01-03 -0.861849 -2.104569 -0.494929  5  2.0
2013-01-04  0.721555 -0.706771 -1.039575  5  3.0
2013-01-05 -0.424972  0.567020  0.276232  5  4.0
2013-01-06 -0.673690  0.113648 -1.478427  5  5.0

```

A where operation with setting.

```
In [52]: df2 = df.copy()

In [53]: df2[df2 > 0] = -df2

In [54]: df2
Out[54]:
```

|            | A         | B         | C         | D  | F    |
|------------|-----------|-----------|-----------|----|------|
| 2013-01-01 | 0.000000  | 0.000000  | -1.509059 | -5 | NaN  |
| 2013-01-02 | -1.212112 | -0.173215 | -0.119209 | -5 | -1.0 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | -5 | -2.0 |
| 2013-01-04 | -0.721555 | -0.706771 | -1.039575 | -5 | -3.0 |
| 2013-01-05 | -0.424972 | -0.567020 | -0.276232 | -5 | -4.0 |
| 2013-01-06 | -0.673690 | -0.113648 | -1.478427 | -5 | -5.0 |

## 5.4 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

```
In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])

In [56]: df1.loc[dates[0]:dates[1], 'E'] = 1

In [57]: df1
Out[57]:
```

|            | A         | B         | C         | D | F   | E   |
|------------|-----------|-----------|-----------|---|-----|-----|
| 2013-01-01 | 0.000000  | 0.000000  | -1.509059 | 5 | NaN | 1.0 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | 5 | 1.0 | 1.0 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 5 | 2.0 | NaN |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 5 | 3.0 | NaN |

To drop any rows that have missing data.

```
In [58]: df1.dropna(how='any')
Out[58]:
```

|            | A        | B         | C        | D | F   | E   |
|------------|----------|-----------|----------|---|-----|-----|
| 2013-01-02 | 1.212112 | -0.173215 | 0.119209 | 5 | 1.0 | 1.0 |

Filling missing data.

```
In [59]: df1.fillna(value=5)
Out[59]:
```

|            | A         | B         | C         | D | F   | E   |
|------------|-----------|-----------|-----------|---|-----|-----|
| 2013-01-01 | 0.000000  | 0.000000  | -1.509059 | 5 | 5.0 | 1.0 |
| 2013-01-02 | 1.212112  | -0.173215 | 0.119209  | 5 | 1.0 | 1.0 |
| 2013-01-03 | -0.861849 | -2.104569 | -0.494929 | 5 | 2.0 | 5.0 |
| 2013-01-04 | 0.721555  | -0.706771 | -1.039575 | 5 | 3.0 | 5.0 |

To get the boolean mask where values are nan.

```
In [60]: pd.isna(df1)
Out[60]:
```

|  | A | B | C | D | F | E |
|--|---|---|---|---|---|---|
|--|---|---|---|---|---|---|

(continues on next page)

(continued from previous page)

|            |       |       |       |       |       |       |
|------------|-------|-------|-------|-------|-------|-------|
| 2013-01-01 | False | False | False | False | True  | False |
| 2013-01-02 | False | False | False | False | False | False |
| 2013-01-03 | False | False | False | False | False | True  |
| 2013-01-04 | False | False | False | False | False | True  |

## 5.5 Operations

See the *Basic section on Binary Ops*.

### 5.5.1 Stats

Operations in general *exclude* missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A    -0.004474
B    -0.383981
C    -0.687758
D     5.000000
F     3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01    0.872735
2013-01-02    1.431621
2013-01-03    0.707731
2013-01-04    1.395042
2013-01-05    1.883656
2013-01-06    1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1,3,5,np.nan,6,8], index=dates).shift(2)
In [64]: s
Out[64]:
2013-01-01    NaN
2013-01-02    NaN
2013-01-03     1.0
2013-01-04     3.0
2013-01-05     5.0
2013-01-06    NaN
Freq: D, dtype: float64
```

```
In [65]: df.sub(s, axis='index')
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////Out [70]
↪
4      5
6      2
2      2
1      1
dtype: int64

```

## 5.5.4 String Methods

Series is equipped with a set of string processing methods in the *str* attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in *str* generally uses [regular expressions](#) by default (and in some cases always uses them). See more at [Vectorized String Methods](#).

```

In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])

In [72]: s.str.lower()
Out [72]:
0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object

```

## 5.6 Merge

### 5.6.1 Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the [Merging section](#).

Concatenating pandas objects together with `concat()`:

```

In [73]: df = pd.DataFrame(np.random.randn(10, 4))

In [74]: df
Out [74]:
   0         1         2         3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867

```

(continues on next page)

(continued from previous page)

```

7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

# break it into pieces
In [75]: pieces = [df[:3], df[3:7], df[7:]]

In [76]: pd.concat(pieces)
Out[76]:
   0         1         2         3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
7 -0.932132  1.956030  0.017587 -0.016692
8 -0.575247  0.254161 -1.143704  0.215897
9  1.193555 -0.077118 -0.408530 -0.862495

```

## 5.6.2 Join

SQL style merges. See the [Database style joining](#) section.

```

In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})

In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})

In [79]: left
Out[79]:
   key  lval
0  foo     1
1  foo     2

In [80]: right
Out[80]:
   key  rval
0  foo     4
1  foo     5

In [81]: pd.merge(left, right, on='key')
Out[81]:
   key  lval  rval
0  foo     1     4
1  foo     1     5
2  foo     2     4
3  foo     2     5

```

Another example that can be given is:

```

In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})

In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})

```

(continues on next page)

(continued from previous page)

```

In [84]: left
Out[84]:
   key  lval
0  foo     1
1  bar     2

In [85]: right
Out[85]:
   key  rval
0  foo     4
1  bar     5

In [86]: pd.merge(left, right, on='key')
Out[86]:
   key  lval  rval
0  foo     1     4
1  bar     2     5

```

### 5.6.3 Append

Append rows to a dataframe. See the *Appending* section.

```

In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A', 'B', 'C', 'D'])

In [88]: df
Out[88]:
   A         B         C         D
0  1.346061  1.511763  1.627081 -0.990582

7 -0.096701  0.803351  1.715071 -0.708758
8  1.453749  1.208843 -0.080952 -0.264610

```

## 5.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the *Grouping section*.

```
In [91]: df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
....:                             'foo', 'bar', 'foo', 'foo'],
....:                      'B' : ['one', 'one', 'two', 'three',
....:                             'two', 'two', 'one', 'three'],
....:                      'C' : np.random.randn(8),
....:                      'D' : np.random.randn(8) })
....:
```

```
In [92]: df
Out[92]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | -1.202872 | -0.055224 |
| 1 | bar | one   | -1.814470 | 2.395985  |
| 2 | foo | two   | 1.018601  | 1.552825  |
| 3 | bar | three | -0.595447 | 0.166599  |
| 4 | foo | two   | 1.395433  | 0.047609  |
| 5 | bar | two   | -0.392670 | -0.136473 |
| 6 | foo | one   | 0.007207  | -0.561757 |
| 7 | foo | three | 1.928123  | -1.623033 |

Grouping and then applying the `sum()` function to the resulting groups.

```
In [93]: df.groupby('A').sum()
Out[93]:
```

|     | C         | D        |
|-----|-----------|----------|
| A   |           |          |
| bar | -2.802588 | 2.42611  |
| foo | 3.146492  | -0.63958 |

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```
In [94]: df.groupby(['A', 'B']).sum()
Out[94]:
```

|     |       | C         | D         |
|-----|-------|-----------|-----------|
| A   | B     |           |           |
| bar | one   | -1.814470 | 2.395985  |
|     | three | -0.595447 | 0.166599  |
|     | two   | -0.392670 | -0.136473 |
| foo | one   | -1.195665 | -0.616981 |
|     | three | 1.928123  | -1.623033 |
|     | two   | 2.414034  | 1.600434  |

## 5.8 Reshaping

See the sections on *Hierarchical Indexing* and *Reshaping*.

### 5.8.1 Stack

```
In [95]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz'],
.....:                        ['foo', 'foo', 'qux', 'qux'],
.....:                        ['one', 'two', 'one', 'two'],
.....:                        ['one', 'two', 'one', 'two']]))
.....:

In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [98]: df2 = df[:4]

In [99]: df2
Out[99]:
```

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | 0.029399  | -0.542108 |
|       | two    | 0.282696  | -0.087302 |
| baz   | one    | -1.575170 | 1.771208  |
|       | two    | 0.816482  | 1.100230  |

The `stack()` method “compresses” a level in the DataFrame’s columns.

```
In [100]: stacked = df2.stack()

In [101]: stacked
Out[101]:
first second
bar      one      A      0.029399
          one      B     -0.542108
          two      A      0.282696
          two      B     -0.087302
baz      one      A     -1.575170
          one      B      1.771208
          two      A      0.816482
          two      B      1.100230
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the **last level**:

```
In [102]: stacked.unstack()
Out[102]:
```

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | 0.029399  | -0.542108 |
|       | two    | 0.282696  | -0.087302 |
| baz   | one    | -1.575170 | 1.771208  |
|       | two    | 0.816482  | 1.100230  |

```
In [103]: stacked.unstack(1)
////////////////////////////////////
```

|        | one | two |
|--------|-----|-----|
| second |     |     |
| first  |     |     |

(continues on next page)

(continued from previous page)

```
bar   A   0.029399   0.282696
      B  -0.542108  -0.087302
baz   A  -1.575170   0.816482
      B   1.771208   1.100230
```

```
In [104]: stacked.unstack(0)
```

```
////////////////////////////////////
```

```
↪
first      bar      baz
second
one   A   0.029399 -1.575170
      B  -0.542108   1.771208
two   A   0.282696   0.816482
      B  -0.087302   1.100230
```

## 5.8.2 Pivot Tables

See the section on *Pivot Tables*.

```
In [105]: df = pd.DataFrame({'A' : ['one', 'one', 'two', 'three'] * 3,
.....:                      'B' : ['A', 'B', 'C'] * 4,
.....:                      'C' : ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2,
.....:                      'D' : np.random.randn(12),
.....:                      'E' : np.random.randn(12)})
```

```
In [106]: df
```

```
Out[106]:
```

|    | A     | B | C   | D         | E         |
|----|-------|---|-----|-----------|-----------|
| 0  | one   | A | foo | 1.418757  | -0.179666 |
| 1  | one   | B | foo | -1.879024 | 1.291836  |
| 2  | two   | C | foo | 0.536826  | -0.009614 |
| 3  | three | A | bar | 1.006160  | 0.392149  |
| 4  | one   | B | bar | -0.029716 | 0.264599  |
| 5  | one   | C | bar | -1.146178 | -0.057409 |
| 6  | two   | A | foo | 0.100900  | -1.425638 |
| 7  | three | B | foo | -1.035018 | 1.024098  |
| 8  | one   | C | foo | 0.314665  | -0.106062 |
| 9  | one   | A | bar | -0.773723 | 1.824375  |
| 10 | two   | B | bar | -1.170653 | 0.595974  |
| 11 | three | C | bar | 0.648740  | 1.167115  |

We can produce pivot tables from this data very easily:

```
In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
```

```
Out[107]:
```

|       |   | bar       | foo       |
|-------|---|-----------|-----------|
| A     |   |           |           |
| B     |   |           |           |
| one   | A | -0.773723 | 1.418757  |
|       | B | -0.029716 | -1.879024 |
|       | C | -1.146178 | 0.314665  |
| three |   |           |           |
|       | A | 1.006160  | NaN       |
|       | B | NaN       | -1.035018 |
|       | C | 0.648740  | NaN       |
| two   |   |           |           |
|       | A | NaN       | 0.100900  |

(continues on next page)

(continued from previous page)

|   |           |          |
|---|-----------|----------|
| B | -1.170653 | NaN      |
| C | NaN       | 0.536826 |

## 5.9 Time Series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the *Time Series section*.

```
In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')

In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)

In [110]: ts.resample('5Min').sum()
Out[110]:
2012-01-01    25083
Freq: 5T, dtype: int64
```

Time zone representation:

```
In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')

In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [113]: ts
Out[113]:
2012-03-06    0.464000
2012-03-07    0.227371
2012-03-08   -0.496922
2012-03-09    0.306389
2012-03-10   -2.290613
Freq: D, dtype: float64

In [114]: ts_utc = ts.tz_localize('UTC')

In [115]: ts_utc
Out[115]:
2012-03-06 00:00:00+00:00    0.464000
2012-03-07 00:00:00+00:00    0.227371
2012-03-08 00:00:00+00:00   -0.496922
2012-03-09 00:00:00+00:00    0.306389
2012-03-10 00:00:00+00:00   -2.290613
Freq: D, dtype: float64
```

Converting to another time zone:

```
In [116]: ts_utc.tz_convert('US/Eastern')
Out[116]:
2012-03-05 19:00:00-05:00    0.464000
2012-03-06 19:00:00-05:00    0.227371
2012-03-07 19:00:00-05:00   -0.496922
2012-03-08 19:00:00-05:00    0.306389
2012-03-09 19:00:00-05:00   -2.290613
Freq: D, dtype: float64
```

```
In [118]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
```

Out [119]:

```
In [120]: ps = ts.to_period()
```

Out [121] :

```
In [122]: ps.to_timestamp()
```

```
2012-01-01    -1.134623
2012-02-01    -1.561819
2012-03-01    -0.260838
2012-04-01     0.281957
2012-05-01     1.523962
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [124]: ts = pd.Series(np.random.randn(len(prng)), prng)
```

```
In [126]: ts.head()
```

Out [126] :

```
1990-03-01 09:00 -0.902937
1990-06-01 09:00 0.068159
1990-09-01 09:00 -0.057873
1990-12-01 09:00 -0.368204
1991-03-01 09:00 -1.144073
Freq: H, dtype: float64
```

## 5.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the [categorical introduction](#) and the [API documentation](#).

```
In [127]: df = pd.DataFrame({"id": [1, 2, 3, 4, 5, 6], "raw_grade": ['a', 'b', 'b', 'a', 'a',
↪ 'e']})
```

Convert the raw grades to a categorical data type.

```
In [128]: df["grade"] = df["raw_grade"].astype("category")
```

```
In [129]: df["grade"]
```

```
Out[129]:
```

```
0      a
1      b
2      b
3      a
4      a
5      e
Name: grade, dtype: category
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories` is inplace!).

```
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under `Series.cat` return a new Series by default).

```
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium",
↪ "good", "very good"])
```

```
In [132]: df["grade"]
```

```
Out[132]:
```

```
0      very good
1           good
2           good
3      very good
4      very good
5      very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```
In [133]: df.sort_values(by="grade")
```

```
Out[133]:
```

```
   id raw_grade  grade
5   6         e  very bad
1   2         b    good
2   3         b    good
0   1         a  very good
3   4         a  very good
4   5         a  very good
```

Grouping by a categorical column also shows empty categories.

```
In [134]: df.groupby("grade").size()
Out[134]:
grade
very bad    1
bad         0
medium      0
good        2
very good   3
dtype: int64
```

## 5.11 Plotting

See the [Plotting](#) docs.

```
In [135]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000',
↳ periods=1000))

In [136]: ts = ts.cumsum()

In [137]: ts.plot()
Out[137]: <matplotlib.axes._subplots.AxesSubplot at 0x1192135f8>
```

On a DataFrame, the `plot()` method is a convenience to plot all of the columns with labels:

```

In [138]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index,
.....:                      columns=['A', 'B', 'C', 'D'])
.....:

In [139]: df = df.cumsum()

In [140]: plt.figure(); df.plot(); plt.legend(loc='best')
Out[140]: <matplotlib.legend.Legend at 0x1234e1dd8>

```

## 5.12 Getting Data In/Out

### 5.12.1 CSV

*Writing to a csv file.*

```
In [141]: df.to_csv('foo.csv')
```

*Reading from a csv file.*

```
In [142]: pd.read_csv('foo.csv')
```

```

Out[142]:
   Unnamed: 0      A      B      C      D

```

(continues on next page)

(continued from previous page)

```

```

### 5.12.2 HDF5

Reading and writing to *HDFStores*.

Writing to a HDF5 Store.

```
In [143]: df.to_hdf('foo.h5', 'df')
```

Reading from a HDF5 Store.

```

In [144]: pd.read_hdf('foo.h5', 'df')
Out[144]:
```

|            | A          | B          | C         | D         |
|------------|------------|------------|-----------|-----------|
| 2000-01-01 | 0.266457   | -0.399641  | -0.219582 | 1.186860  |
| 2000-01-02 | -1.170732  | -0.345873  | 1.653061  | -0.282953 |

### 5.12.3 Excel

Reading and writing to *MS Excel*.

Writing to an excel file.

```
In [145]: df.to_excel('foo.xlsx', sheet_name='Sheet1')
```

Reading from an excel file.

```
In [146]: pd.read_excel('foo.xlsx', 'Sheet1', index_col=None, na_values=['NA'])
```

Out[146]:

|            | A          | B          | C         | D         |
|------------|------------|------------|-----------|-----------|
| 2000-01-01 | 0.266457   | -0.399641  | -0.219582 | 1.186860  |
| 2000-01-02 | -1.170732  | -0.345873  | 1.653061  | -0.282953 |
| 2000-01-03 | -1.734933  | 0.530468   | 2.060811  | -0.515536 |
| 2000-01-04 | -1.555121  | 1.452620   | 0.239859  | -1.156896 |

| 2000-01-07 | 1.235339   | -0.091757  | -1.543861 | -1.084753 |
| ...        | ...        | ...        | ...       | ...       |
| 2002-09-20 | -10.628548 | -9.153563  | -7.883146 | 28.313940 |
| 2002-09-21 | -10.390377 | -8.727491  | -6.399645 | 30.914107 |
| 2002-09-22 | -8.985362  | -8.485624  | -4.669462 | 31.367740 |
| 2002-09-23 | -9.558560  | -8.781216  | -4.499815 | 30.518439 |
| 2002-09-24 | -9.902058  | -9.340490  | -4.386639 | 30.105593 |
| 2002-09-25 | -10.216020 | -9.480682  | -3.933802 | 29.758560 |
| 2002-09-26 | -11.856774 | -10.671012 | -3.216025 | 29.369368 |

[1000 rows x 4 columns]

## 5.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```
>>> if pd.Series([False, True, False]):
    print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See [Comparisons](#) for an explanation and what to do.

See [Gotchas](#) as well.

## TUTORIALS

This is a guide to many pandas tutorials, geared mainly for new users.

### 6.1 Internal Guides

pandas' own *10 Minutes to pandas*.

More complex recipes are in the *Cookbook*.

A handy pandas [cheat sheet](#).

### 6.2 pandas Cookbook

The goal of this 2015 cookbook (by [Julia Evans](#)) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails.

Here are links to the v0.2 release. For an up-to-date table of contents, see the [pandas-cookbook GitHub repository](#). To run the examples in this tutorial, you'll need to clone the GitHub repository and get IPython Notebook running. See [How to use this cookbook](#).

- [A quick tour of the IPython Notebook](#): Shows off IPython's awesome tab completion and magic functions.
- [Chapter 1](#): Reading your data into pandas is pretty much the easiest thing. Even when the encoding is wrong!
- [Chapter 2](#): It's not totally obvious how to select data from a pandas dataframe. Here we explain the basics (how to take slices and get columns)
- [Chapter 3](#): Here we get into serious slicing and dicing and learn how to filter dataframes in complicated ways, really fast.
- [Chapter 4](#): Groupby/aggregate is seriously my favorite thing about pandas and I use it all the time. You should probably read this.
- [Chapter 5](#): Here you get to find out if it's cold in Montreal in the winter (spoiler: yes). Web scraping with pandas is fun! Here we combine dataframes.
- [Chapter 6](#): Strings with pandas are great. It has all these vectorized string operations and they're the best. We will turn a bunch of strings containing "Snow" into vectors of numbers in a trice.
- [Chapter 7](#): Cleaning up messy data is never a joy, but with pandas it's easier.
- [Chapter 8](#): Parsing Unix timestamps is confusing at first but it turns out to be really easy.
- [Chapter 9](#): Reading data from SQL databases.

## 6.3 Lessons for new pandas users

For more resources, please visit the main [repository](#).

- **01 - Lesson:** - Importing libraries - Creating data sets - Creating data frames - Reading from CSV - Exporting to CSV - Finding maximums - Plotting data
- **02 - Lesson:** - Reading from TXT - Exporting to TXT - Selecting top/bottom records - Descriptive statistics - Grouping/sorting data
- **03 - Lesson:** - Creating functions - Reading from EXCEL - Exporting to EXCEL - Outliers - Lambda functions - Slice and dice data
- **04 - Lesson:** - Adding/deleting columns - Index operations
- **05 - Lesson:** - Stack/Unstack/Transpose functions
- **06 - Lesson:** - GroupBy function
- **07 - Lesson:** - Ways to calculate outliers
- **08 - Lesson:** - Read from Microsoft SQL databases
- **09 - Lesson:** - Export to CSV/EXCEL/TXT
- **10 - Lesson:** - Converting between different kinds of formats
- **11 - Lesson:** - Combining data from various sources

## 6.4 Practical data analysis with Python

This [guide](#) is a comprehensive introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as follows:

- [Munging Data](#)
- [Aggregating Data](#)
- [Visualizing Data](#)
- [Time Series](#)

## 6.5 Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main [repository](#).

- [01 - Getting & Knowing Your Data](#)
- [02 - Filtering & Sorting](#)
- [03 - Grouping](#)
- [04 - Apply](#)
- [05 - Merge](#)
- [06 - Stats](#)
- [07 - Visualization](#)
- [08 - Creating Series and DataFrames](#)

- [09 - Time Series](#)
- [10 - Deleting](#)

## 6.6 Modern pandas

Tutorial series written in 2016 by [Tom Augspurger](#). The source may be found in the GitHub repository [TomAugspurger/effective-pandas](#).

- [Modern Pandas](#)
- [Method Chaining](#)
- [Indexes](#)
- [Performance](#)
- [Tidy Data](#)
- [Visualization](#)
- [Timeseries](#)

## 6.7 Excel charts with pandas, vincent and xlsxwriter

- [Using Pandas and XlsxWriter to create Excel charts](#)

## 6.8 Video Tutorials

- [Pandas From The Ground Up \(2015\) \(2:24\) GitHub repo](#)
- [Introduction Into Pandas \(2016\) \(1:28\) GitHub repo](#)
- [Pandas: .head\(\) to .tail\(\) \(2016\) \(1:26\) GitHub repo](#)

## 6.9 Various Tutorials

- [Wes McKinney's \(pandas BDFL\) blog](#)
- [Statistical analysis made easy in Python with SciPy and pandas DataFrames](#), by Randal Olson
- [Statistical Data Analysis in Python](#), tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- [Financial analysis in Python](#), by Thomas Wiecki
- [Intro to pandas data structures](#), by Greg Reda
- [Pandas and Python: Top 10](#), by Manish Amde
- [Pandas Tutorial](#), by Mikhail Semeniuk
- [Pandas DataFrames Tutorial](#), by Karlijn Willems
- [A concise tutorial with real life examples](#)

## COOKBOOK

This is a repository for *short and sweet* examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great *First Pull Request*.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 7.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```
In [1]: df = pd.DataFrame(
...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
...:
Out[1]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 20  | 50  |
| 2 | 6   | 30  | -30 |
| 3 | 7   | 40  | -50 |

#### 7.1.1 if-then...

An if-then on one column

```
In [2]: df.loc[df.AAA >= 5, 'BBB'] = -1; df
Out[2]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | -1  | 50  |
| 2 | 6   | -1  | -30 |
| 3 | 7   | -1  | -50 |

An if-then with assignment to 2 columns:

```
In [3]: df.loc[df.AAA >= 5, ['BBB', 'CCC']] = 555; df
Out[3]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 555 | 555 |
| 2 | 6   | 555 | 555 |
| 3 | 7   | 555 | 555 |

Add another line with different logic, to do the -else

```
In [4]: df.loc[df.AAA < 5, ['BBB', 'CCC']] = 2000; df
Out[4]:
```

|   | AAA | BBB  | CCC  |
|---|-----|------|------|
| 0 | 4   | 2000 | 2000 |
| 1 | 5   | 555  | 555  |
| 2 | 6   | 555  | 555  |
| 3 | 7   | 555  | 555  |

Or use pandas where after you've set up a mask

```
In [5]: df_mask = pd.DataFrame({'AAA' : [True] * 4, 'BBB' : [False] * 4, 'CCC' : [True,
↪False] * 2})

In [6]: df.where(df_mask, -1000)
Out[6]:
```

|   | AAA | BBB   | CCC   |
|---|-----|-------|-------|
| 0 | 4   | -1000 | 2000  |
| 1 | 5   | -1000 | -1000 |
| 2 | 6   | -1000 | 555   |
| 3 | 7   | -1000 | -1000 |

if-then-else using numpy's where()

```
In [7]: df = pd.DataFrame(
...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
...:
Out[7]:
```

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |
| 1 | 5   | 20  | 50  |
| 2 | 6   | 30  | -30 |
| 3 | 7   | 40  | -50 |

```
In [8]: df['logic'] = np.where(df['AAA'] > 5, 'high', 'low'); df
Out[8]:
```

|   | AAA | BBB | CCC | logic |
|---|-----|-----|-----|-------|
| 0 | 4   | 10  | 100 | low   |
| 1 | 5   | 20  | 50  | low   |
| 2 | 6   | 30  | -30 | high  |
| 3 | 7   | 40  | -50 | high  |

## 7.1.2 Splitting

Split a frame with a boolean criterion

```
In [9]: df = pd.DataFrame(
...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]}; df
...:
```

```
Out[9]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

```
In [10]: dflow = df[df.AAA <= 5]; dflow
```

```
Out[10]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
```

```
In [11]: dfhigh = df[df.AAA > 5]; dfhigh
```

```
Out[11]:
   AAA  BBB  CCC
2     6   30  -30
3     7   40  -50
```

### 7.1.3 Building Criteria

Select with multi-column criteria

```
In [12]: df = pd.DataFrame(
...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]}; df
...:
```

```
Out[12]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

... and (without assignment returns a Series)

```
In [13]: newseries = df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']; newseries
Out[13]:
0     4
1     5
Name: AAA, dtype: int64
```

... or (without assignment returns a Series)

```
In [14]: newseries = df.loc[(df['BBB'] > 25) | (df['CCC'] >= -40), 'AAA']; newseries;
```

... or (with assignment modifies the DataFrame.)

```
In [15]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1; df
Out[15]:
   AAA  BBB  CCC
0  0.1   10  100
```

(continues on next page)

(continued from previous page)

```
1  5.0   20   50
2  0.1   30  -30
3  0.1   40  -50
```

Select rows with data closest to certain value using argsort

```
In [16]: df = pd.DataFrame(
.....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
.....:
Out[16]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [17]: aValue = 43.0

In [18]: df.loc[(df.CCC-aValue).abs().argsort()]
Out[18]:
   AAA  BBB  CCC
1     5   20   50
0     4   10  100
2     6   30  -30
3     7   40  -50
```

Dynamically reduce a list of criteria using a binary operators

```
In [19]: df = pd.DataFrame(
.....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
.....:
Out[19]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [20]: Crit1 = df.AAA <= 5.5

In [21]: Crit2 = df.BBB == 10.0

In [22]: Crit3 = df.CCC > -40.0
```

One could hard code:

```
In [23]: AllCrit = Crit1 & Crit2 & Crit3
```

...Or it can be done with a list of dynamically built criteria

```
In [24]: CritList = [Crit1,Crit2,Crit3]

In [25]: AllCrit = functools.reduce(lambda x,y: x & y, CritList)

In [26]: df[AllCrit]
Out[26]:
```

(continues on next page)

(continued from previous page)

|   | AAA | BBB | CCC |
|---|-----|-----|-----|
| 0 | 4   | 10  | 100 |

## 7.2 Selection

### 7.2.1 DataFrames

The *indexing* docs.

Using both row labels and value conditionals

```
In [27]: df = pd.DataFrame(
.....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
.....:
```

```
Out [27]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50
```

```
In [28]: df[(df.AAA <= 6) & (df.index.isin([0,2,4]))]
```

```
Out [28]:
```

```
↪
   AAA  BBB  CCC
0     4   10  100
2     6   30  -30
```

Use `loc` for label-oriented slicing and `iloc` positional slicing

```
In [29]: data = {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]}
```

```
In [30]: df = pd.DataFrame(data=data, index=['foo', 'bar', 'boo', 'kar'])
df
```

```
Out [30]:
   AAA  BBB  CCC
foo     4   10  100
bar     5   20   50
boo     6   30  -30
kar     7   40  -50
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```
In [31]: df.loc['bar':'kar'] #Label
```

```
Out [31]:
   AAA  BBB  CCC
bar     5   20   50
boo     6   30  -30
kar     7   40  -50
```

(continues on next page)

(continued from previous page)

```
# Generic
In [32]: df.iloc[0:3]
Out[32]:
   AAA  BBB  CCC
foo   4   10  100
bar   5   20   50
boo   6   30  -30

In [33]: df.loc['bar':'kar']
Out[33]:
   AAA  BBB  CCC
bar   5   20   50
boo   6   30  -30
kar   7   40  -50
```

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

```
In [34]: df2 = pd.DataFrame(data=data, index=[1,2,3,4]); #Note index starts at 1.

In [35]: df2.iloc[1:3] #Position-oriented
Out[35]:
   AAA  BBB  CCC
2     5   20   50
3     6   30  -30

In [36]: df2.loc[1:3] #Label-oriented
Out[36]:
   AAA  BBB  CCC
1     4   10  100
2     5   20   50
3     6   30  -30
```

Using inverse operator (~) to take the complement of a mask

```
In [37]: df = pd.DataFrame(
.....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]})
Out[37]:
   AAA  BBB  CCC
0     4   10  100
1     5   20   50
2     6   30  -30
3     7   40  -50

In [38]: df[~((df.AAA <= 6) & (df.index.isin([0,2,4])))]
Out[38]:
   AAA  BBB  CCC
1     5   20   50
3     7   40  -50
```

## 7.2.2 Panels

Extend a panel frame by transposing, adding a new dimension, and transposing back to the original dimensions

```
In [39]: rng = pd.date_range('1/1/2013', periods=100, freq='D')

In [40]: data = np.random.randn(100, 4)

In [41]: cols = ['A', 'B', 'C', 'D']

In [42]: df1, df2, df3 = pd.DataFrame(data, rng, cols), pd.DataFrame(data, rng, cols),
↳ pd.DataFrame(data, rng, cols)

In [43]: pf = pd.Panel({'df1':df1, 'df2':df2, 'df3':df3}); pf
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 4 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to D

In [44]: pf.loc[:, :, 'F'] = pd.DataFrame(data, rng, cols); pf
////////////////////////////////////
↳
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 5 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to F
```

Mask a panel by using `np.where` and then reconstructing the panel with the new masked values

## 7.2.3 New Columns

Efficiently and dynamically creating new columns using `applymap`

```
In [45]: df = pd.DataFrame(
.....:     {'AAA' : [1,2,1,3], 'BBB' : [1,1,2,2], 'CCC' : [2,1,3,1]})
.....:
Out[45]:
   AAA  BBB  CCC
0    1    1    2
1    2    1    1
2    1    2    3
3    3    2    1

In [46]: source_cols = df.columns # or some subset would work too.

In [47]: new_cols = [str(x) + "_cat" for x in source_cols]

In [48]: categories = {1 : 'Alpha', 2 : 'Beta', 3 : 'Charlie' }

In [49]: df[new_cols] = df[source_cols].applymap(categories.get); df
Out[49]:
   AAA  BBB  CCC  AAA_cat BBB_cat  CCC_cat
0    1    1    2   Alpha   Alpha   Beta
```

(continues on next page)

(continued from previous page)

|   |   |   |   |         |       |         |
|---|---|---|---|---------|-------|---------|
| 1 | 2 | 1 | 1 | Beta    | Alpha | Alpha   |
| 2 | 1 | 2 | 3 | Alpha   | Beta  | Charlie |
| 3 | 3 | 2 | 1 | Charlie | Beta  | Alpha   |

Keep other columns when using min() with groupby

```
In [50]: df = pd.DataFrame(
.....:     {'AAA' : [1,1,1,2,2,2,3,3], 'BBB' : [2,1,3,4,5,1,2,3]})
.....:
Out[50]:
```

|   | AAA | BBB |
|---|-----|-----|
| 0 | 1   | 2   |
| 1 | 1   | 1   |
| 2 | 1   | 3   |
| 3 | 2   | 4   |
| 4 | 2   | 5   |
| 5 | 2   | 1   |
| 6 | 3   | 2   |
| 7 | 3   | 3   |

Method 1 : idxmin() to get the index of the mins

```
In [51]: df.loc[df.groupby("AAA")["BBB"].idxmin()]
Out[51]:
```

|   | AAA | BBB |
|---|-----|-----|
| 1 | 1   | 1   |
| 5 | 2   | 1   |
| 6 | 3   | 2   |

Method 2 : sort then take first of each

```
In [52]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[52]:
```

|   | AAA | BBB |
|---|-----|-----|
| 0 | 1   | 1   |
| 1 | 2   | 1   |
| 2 | 3   | 2   |

Notice the same results, with the exception of the index.

## 7.3 MultiIndexing

The *multindexing* docs.

Creating a multi-index from a labeled frame

```
In [53]: df = pd.DataFrame({'row' : [0,1,2],
.....:                     'One_X' : [1.1,1.1,1.1],
.....:                     'One_Y' : [1.2,1.2,1.2],
.....:                     'Two_X' : [1.11,1.11,1.11],
.....:                     'Two_Y' : [1.22,1.22,1.22]}); df
.....:
Out[53]:
```

|   | row | One_X | One_Y | Two_X | Two_Y |
|---|-----|-------|-------|-------|-------|
| 0 | 0   | 1.1   | 1.2   | 1.11  | 1.22  |

(continues on next page)

(continued from previous page)

```

1      1      1.1      1.2      1.11      1.22
2      2      1.1      1.2      1.11      1.22

# As Labelled Index
In [54]: df = df.set_index('row');df
////////////////////////////////////
↪
      One_X  One_Y  Two_X  Two_Y
row
0      1.1    1.2    1.11    1.22
1      1.1    1.2    1.11    1.22
2      1.1    1.2    1.11    1.22

# With Hierarchical Columns
In [55]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_')) for c in df.
↪columns]);df
////////////////////////////////////
↪
      One      Two
      X      Y      X      Y
row
0      1.1  1.2  1.11  1.22
1      1.1  1.2  1.11  1.22
2      1.1  1.2  1.11  1.22

# Now stack & Reset
In [56]: df = df.stack(0).reset_index(1);df
////////////////////////////////////
↪
      level_1      X      Y
row
0      One  1.10  1.20
0      Two  1.11  1.22
1      One  1.10  1.20
1      Two  1.11  1.22
2      One  1.10  1.20
2      Two  1.11  1.22

# And fix the labels (Notice the label 'level_1' got added automatically)
In [57]: df.columns = ['Sample', 'All_X', 'All_Y'];df
////////////////////////////////////
↪
      Sample  All_X  All_Y
row
0      One  1.10  1.20
0      Two  1.11  1.22
1      One  1.10  1.20
1      Two  1.11  1.22
2      One  1.10  1.20
2      Two  1.11  1.22

```

### 7.3.1 Arithmetic

Performing arithmetic with a multi-index that needs broadcasting

```
In [58]: cols = pd.MultiIndex.from_tuples([(x,y) for x in ['A','B','C'] for y in ['O',
↳ 'I']])
```

```
In [59]: df = pd.DataFrame(np.random.randn(2,6),index=['n','m'],columns=cols); df
```

```
Out[59]:
```

|   | A         |           | B         |          | C        |           |
|---|-----------|-----------|-----------|----------|----------|-----------|
|   | O         | I         | O         | I        | O        | I         |
| n | 1.920906  | -0.388231 | -2.314394 | 0.665508 | 0.402562 | 0.399555  |
| m | -1.765956 | 0.850423  | 0.388054  | 0.992312 | 0.744086 | -0.739776 |

```
In [60]: df = df.div(df['C'],level=1); df
```

```
////////////////////////////////////
```

```
↳
```

|   | A         |           | B         |           | C   |     |
|---|-----------|-----------|-----------|-----------|-----|-----|
|   | O         | I         | O         | I         | O   | I   |
| n | 4.771702  | -0.971660 | -5.749162 | 1.665625  | 1.0 | 1.0 |
| m | -2.373321 | -1.149568 | 0.521518  | -1.341367 | 1.0 | 1.0 |

## 7.3.2 Slicing

Slicing a multi-index with xs

```
In [61]: coords = [('AA','one'),('AA','six'),('BB','one'),('BB','two'),('BB','six')]
```

```
In [62]: index = pd.MultiIndex.from_tuples(coords)
```

```
In [63]: df = pd.DataFrame([11,22,33,44,55],index,['MyData']); df
```

```
Out[63]:
```

|        | MyData |
|--------|--------|
| AA one | 11     |
| AA six | 22     |
| BB one | 33     |
| BB two | 44     |
| BB six | 55     |

To take the cross section of the 1st level and 1st axis the index:

```
In [64]: df.xs('BB',level=0,axis=0) #Note : level and axis are optional, and default_
↳ to zero
```

```
Out[64]:
```

|     | MyData |
|-----|--------|
| one | 33     |
| two | 44     |
| six | 55     |

... and now the 2nd level of the 1st axis.

```
In [65]: df.xs('six',level=1,axis=0)
```

```
Out[65]:
```

|    | MyData |
|----|--------|
| AA | 22     |
| BB | 55     |

Slicing a multi-index with xs, method #2

(continued from previous page)

        Comp      70  71      72  73

```

Partial Selection, the need for sortedness;

### 7.3.4 Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

## 7.4 Missing Data

The *missing data* docs.

Fill forward a reversed timeseries

```
In [79]: df = pd.DataFrame(np.random.randn(6,1), index=pd.date_range('2013-08-01',
↳ periods=6, freq='B'), columns=list('A'))
```

```
In [80]: df.loc[df.index[3], 'A'] = np.nan
```

```
In [81]: df
```

```
Out [81]:
```

```
          A
2013-08-01 -1.054874
2013-08-02 -0.179642
2013-08-05  0.639589
2013-08-06      NaN
2013-08-07  1.906684
2013-08-08  0.104050
```

```
In [82]: df.reindex(df.index[::-1]).ffill()
```

```
////////////////////////////////////
↳
          A
2013-08-08  0.104050
2013-08-07  1.906684
2013-08-06  1.906684
2013-08-05  0.639589
2013-08-02 -0.179642
2013-08-01 -1.054874
```

cumsum reset at NaN values

## 7.4.1 Replace

Using replace with backrefs

## 7.5 Grouping

The *grouping* docs.

Basic grouping with apply

Unlike agg, apply's callable is passed a sub-DataFrame which gives you access to all the columns

```
In [83]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
.....:                      'size': list('SSMMLL'),
.....:                      'weight': [8, 10, 11, 1, 20, 12, 12],
.....:                      'adult' : [False] * 5 + [True] * 2}); df
```

```
Out [83]:
```

```
  animal size  weight  adult
0   cat    S      8   False
1   dog    S     10   False
2   cat    M     11   False
3  fish    M      1   False
4   dog    M     20   False
5   cat    L     12    True
6   cat    L     12    True
```

(continues on next page)

(continued from previous page)

```
#List the size of the animals with the highest weight.
In [84]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].
↳idxmax()])
↳
animal
cat      L
dog      M
fish     M
dtype: object
```

### Using get\_group

```
In [85]: gb = df.groupby(['animal'])

In [86]: gb.get_group('cat')
Out[86]:
  animal size  weight  adult
0    cat   S        8   False
2    cat   M       11   False
5    cat   L       12    True
6    cat   L       12    True
```

### Apply to different items in a group

```
In [87]: def GrowUp(x):
.....:     avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
.....:     avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
.....:     avg_weight += sum(x[x['size'] == 'L'].weight)
.....:     avg_weight /= len(x)
.....:     return pd.Series(['L', avg_weight, True], index=['size', 'weight', 'adult'])
.....:

In [88]: expected_df = gb.apply(GrowUp)

In [89]: expected_df
Out[89]:
      size  weight  adult
animal
cat      L  12.4375   True
dog      L  20.0000   True
fish     L   1.2500   True
```

### Expanding Apply

```
In [90]: S = pd.Series([i / 100.0 for i in range(1,11)])

In [91]: def CumRet(x,y):
.....:     return x * (1 + y)
.....:

In [92]: def Red(x):
.....:     return functools.reduce(CumRet, x, 1.0)
.....:

In [93]: S.expanding().apply(Red, raw=True)
Out[93]:
```

(continues on next page)

(continued from previous page)

```

0    1.010000
1    1.030200
2    1.061106
3    1.103550
4    1.158728
5    1.228251
6    1.314229
7    1.419367
8    1.547110
9    1.701821
dtype: float64

```

### Replacing some values with mean of the rest of a group

```

In [94]: df = pd.DataFrame({'A' : [1, 1, 2, 2], 'B' : [1, -1, 1, 2]})

In [95]: gb = df.groupby('A')

In [96]: def replace(g):
....:     mask = g < 0
....:     g.loc[mask] = g[~mask].mean()
....:     return g
....:

In [97]: gb.transform(replace)
Out[97]:
   B
0  1.0
1  1.0
2  1.0
3  2.0

```

### Sort groups by aggregated data

```

In [98]: df = pd.DataFrame({'code': ['foo', 'bar', 'baz'] * 2,
....:                      'data': [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
....:                      'flag': [False, True] * 3})
....:

In [99]: code_groups = df.groupby('code')

In [100]: agg_n_sort_order = code_groups[['data']].transform(sum).sort_values(by='data
↪')

In [101]: sorted_df = df.loc[agg_n_sort_order.index]

In [102]: sorted_df
Out[102]:
   code  data  flag
1  bar -0.21  True
4  bar -0.59 False
0  foo  0.16 False
3  foo  0.45  True
2  baz  0.33 False
5  baz  0.62  True

```

### Create multiple aggregated columns

```
In [103]: rng = pd.date_range(start="2014-10-07", periods=10, freq='2min')
```

```
In [104]: ts = pd.Series(data = list(range(10)), index = rng)
```

```
In [105]: def MyCust(x):
.....:     if len(x) > 2:
.....:         return x[1] * 1.234
.....:     return pd.NaT
.....:
```

```
In [106]: mhc = {'Mean' : np.mean, 'Max' : np.max, 'Custom' : MyCust}
```

```
In [107]: ts.resample("5min").apply(mhc)
```

Out [107] :

|        |                     |       |
|--------|---------------------|-------|
| Custom | 2014-10-07 00:00:00 | 1.234 |

```

### Create a value counts column and reassign back to the DataFrame

```
In [109]: df = pd.DataFrame({'Color': 'Red Red Red Blue'.split(),
.....:                       'Value': [100, 150, 50, 50]}); df
```

Out [109]:

|   | Color | Value |
|---|-------|-------|
| 0 | Red   | 100   |
| 1 | Red   | 150   |
| 2 | Red   | 50    |
| 3 | Blue  | 50    |

```
In [110]: df['Counts'] = df.groupby(['Color']).transform(len)
```

(continues on next page)

(continued from previous page)

```
In [111]: df
Out[111]:
```

|   | Color | Value | Counts |
|---|-------|-------|--------|
| 0 | Red   | 100   | 3      |
| 1 | Red   | 150   | 3      |
| 2 | Red   | 50    | 3      |
| 3 | Blue  | 50    | 1      |

Shift groups of the values in a column based on the index

```
In [112]: df = pd.DataFrame(
.....:     {'line_race': [10, 10, 8, 10, 10, 8],
.....:      'beyer': [99, 102, 103, 103, 88, 100]},
.....:     index=[u'Last Gunfighter', u'Last Gunfighter', u'Last Gunfighter',
.....:            u'Paynter', u'Paynter', u'Paynter']); df
Out[112]:
```

|                 | line_race | beyer |
|-----------------|-----------|-------|
| Last Gunfighter | 10        | 99    |
| Last Gunfighter | 10        | 102   |
| Last Gunfighter | 8         | 103   |
| Paynter         | 10        | 103   |
| Paynter         | 10        | 88    |
| Paynter         | 8         | 100   |

```
In [113]: df['beyer_shifted'] = df.groupby(level=0)['beyer'].shift(1)

In [114]: df
Out[114]:
```

|                 | line_race | beyer | beyer_shifted |
|-----------------|-----------|-------|---------------|
| Last Gunfighter | 10        | 99    | NaN           |
| Last Gunfighter | 10        | 102   | 99.0          |
| Last Gunfighter | 8         | 103   | 102.0         |
| Paynter         | 10        | 103   | NaN           |
| Paynter         | 10        | 88    | 103.0         |
| Paynter         | 8         | 100   | 88.0          |

Select row with maximum value from each group

```
In [115]: df = pd.DataFrame({'host': ['other', 'other', 'that', 'this', 'this'],
.....:                       'service': ['mail', 'web', 'mail', 'mail', 'web'],
.....:                       'no': [1, 2, 1, 2, 1]}).set_index(['host', 'service'])
.....:

In [116]: mask = df.groupby(level=0).agg('idxmax')

In [117]: df_count = df.loc[mask['no']].reset_index()

In [118]: df_count
Out[118]:
```

|   | host  | service | no |
|---|-------|---------|----|
| 0 | other | web     | 2  |
| 1 | that  | mail    | 1  |
| 2 | this  | mail    | 2  |

Grouping like Python's `itertools.groupby`

```
In [119]: df = pd.DataFrame([0, 1, 0, 1, 1, 1, 0, 1, 1], columns=['A'])
```

```
In [120]: df.A.groupby((df.A != df.A.shift()).cumsum()).groups
```

```
Out[120]:
```

```
{1: Int64Index([0], dtype='int64'),
 2: Int64Index([1], dtype='int64'),
 3: Int64Index([2], dtype='int64'),
 4: Int64Index([3, 4, 5], dtype='int64'),
 5: Int64Index([6], dtype='int64'),
 6: Int64Index([7, 8], dtype='int64')}
```

```
In [121]: df.A.groupby((df.A != df.A.shift()).cumsum()).cumsum()
```

```

0      0
1      1
2      0
3      1
4      2
5      3
6      0
7      1
8      2
Name: A, dtype: int64
```

## 7.5.1 Expanding Data

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval

## 7.5.2 Splitting

Splitting a frame

Create a list of dataframes, split using a delineation based on logic included in rows.

```
In [122]: df = pd.DataFrame(data={'Case' : ['A', 'A', 'A', 'B', 'A', 'A', 'B', 'A', 'A'],
.....:                           'Data' : np.random.randn(9)})
.....:
```

```
In [123]: dfs = list(zip(*df.groupby((1*(df['Case']=='B')).cumsum().rolling(window=3,
↳min_periods=1).median())))[-1])
```

```
In [124]: dfs[0]
```

```
Out[124]:
```

```
Case      Data
0      A  0.174068
1      A -0.439461
2      A -0.741343
3      B -0.079673
```

```
In [125]: dfs[1]
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////Out [125]:
↪
Case      Data
4      A -0.922875
5      A  0.303638
6      B -0.917368

In [126]: dfs[2]
////////////////////////////////////
↪
Case      Data
7      A -1.624062
8      A -0.758514

```

### 7.5.3 Pivot

The *Pivot* docs.

Partial sums and subtotals

```

In [127]: df = pd.DataFrame(data={'Province' : ['ON','QC','BC','AL','AL','MN','ON'],
.....:                               'City' : ['Toronto','Montreal','Vancouver','Calgary',
↪      'Edmonton','Winnipeg','Windsor'],
.....:                               'Sales' : [13,6,16,8,4,3,1]})
.....:

In [128]: table = pd.pivot_table(df, values='Sales', index=['Province'], columns=['City',
↪      ''], aggfunc=np.sum, margins=True)

In [129]: table.stack('City')
Out[129]:

```

| Province | City      | Sales |
|----------|-----------|-------|
| AL       | All       | 12.0  |
|          | Calgary   | 8.0   |
|          | Edmonton  | 4.0   |
| BC       | All       | 16.0  |
|          | Vancouver | 16.0  |
| MN       | All       | 3.0   |
|          | Winnipeg  | 3.0   |
| ...      |           | ...   |
| All      | Calgary   | 8.0   |
|          | Edmonton  | 4.0   |
|          | Montreal  | 6.0   |
|          | Toronto   | 13.0  |
|          | Vancouver | 16.0  |
|          | Windsor   | 1.0   |
|          | Winnipeg  | 3.0   |

[20 rows x 1 columns]

Frequency table like *plyr* in R

```

In [130]: grades = [48,99,75,80,42,80,72,68,36,78]

```

(continues on next page)

(continued from previous page)

```

In [131]: df = pd.DataFrame( {'ID': ["x%d" % r for r in range(10)],
.....:                      'Gender' : ['F', 'M', 'F', 'M', 'F', 'M', 'F', 'M', 'M',
↪ 'M'],
.....:                      'ExamYear': ['2007','2007','2007','2008','2008','2008',
↪ '2008','2009','2009','2009'],
.....:                      'Class': ['algebra', 'stats', 'bio', 'algebra', 'algebra
↪ ', 'stats', 'stats', 'algebra', 'bio', 'bio'],
.....:                      'Participated': ['yes','yes','yes','yes','no','yes','yes
↪ ','yes','yes','yes'],
.....:                      'Passed': ['yes' if x > 50 else 'no' for x in grades],
.....:                      'Employed': [True,True,True,False,False,False,False,
↪ True,True,False],
.....:                      'Grade': grades})

In [132]: df.groupby('ExamYear').agg({'Participated': lambda x: x.value_counts()['yes
↪ '],
.....:                      'Passed': lambda x: sum(x == 'yes'),
.....:                      'Employed' : lambda x : sum(x),
.....:                      'Grade' : lambda x : sum(x) / len(x)})

Out[132]:

```

|          | Participated | Passed | Employed | Grade     |
|----------|--------------|--------|----------|-----------|
| ExamYear |              |        |          |           |
| 2007     | 3            | 2      | 3        | 74.000000 |
| 2008     | 3            | 3      | 0        | 68.500000 |
| 2009     | 3            | 2      | 2        | 60.666667 |

### Plot pandas DataFrame with year over year data

To create year and month crosstabulation:

```

In [133]: df = pd.DataFrame({'value': np.random.randn(36)},
.....:                      index=pd.date_range('2011-01-01', freq='M', periods=36))
.....:

In [134]: pd.pivot_table(df, index=df.index.month, columns=df.index.year,
.....:                      values='value', aggfunc='sum')
.....:

Out[134]:

```

|    | 2011      | 2012      | 2013      |
|----|-----------|-----------|-----------|
| 1  | -0.560859 | 0.120930  | 0.516870  |
| 2  | -0.589005 | -0.210518 | 0.343125  |
| 3  | -1.070678 | -0.931184 | 2.137827  |
| 4  | -1.681101 | 0.240647  | 0.452429  |
| 5  | 0.403776  | -0.027462 | 0.483103  |
| 6  | 0.609862  | 0.033113  | 0.061495  |
| 7  | 0.387936  | -0.658418 | 0.240767  |
| 8  | 1.815066  | 0.324102  | 0.782413  |
| 9  | 0.705200  | -1.403048 | 0.628462  |
| 10 | -0.668049 | -0.581967 | -0.880627 |
| 11 | 0.242501  | -1.233862 | 0.777575  |
| 12 | 0.313421  | -3.520876 | -0.779367 |

## 7.5.4 Apply

Rolling Apply to Organize - Turning embedded lists into a multi-index frame

```
In [135]: df = pd.DataFrame(data={'A' : [[2,4,8,16],[100,200],[10,20,30]], 'B' : [['a'
→ 'b','c'],['jj','kk'],['ccc']]},index=['I','II','III'])

In [136]: def SeriesFromSubList(aList):
.....:     return pd.Series(aList)
.....:

In [137]: df_orgz = pd.concat(dict([ (ind,row.apply(SeriesFromSubList)) for ind,row_
→ in df.iterrows() ]))
```

Rolling Apply with a DataFrame returning a Series

Rolling Apply to multiple columns where function calculates a Series before a Scalar from the Series is returned

```
In [138]: df = pd.DataFrame(data=np.random.randn(2000,2)/10000,
.....:                      index=pd.date_range('2001-01-01',periods=2000),
.....:                      columns=['A','B']); df
.....:

Out[138]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2001-01-01 | 0.000032  | -0.000004 |

## 7.6 Timeseries

Between times

Using indexer between time

Constructing a datetime range that excludes weekends and includes only certain times

Vectorized Lookup

Aggregation and plotting time series

Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series.

How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency

Calculate the first day of the month for each entry in a DatetimeIndex

```

In [147]: dates = pd.date_range('2000-01-01', periods=5)

In [148]: dates.to_period(freq='M').to_timestamp()
Out[148]:
DatetimeIndex(['2000-01-01', '2000-01-01', '2000-01-01', '2000-01-01',
                '2000-01-01'],
              dtype='datetime64[ns]', freq=None)

```

### 7.6.1 Resampling

The *Resample* docs.

Using Grouper instead of TimeGrouper for time grouping of values

Time grouping with some missing values

Valid frequency arguments to Grouper

Grouping using a MultiIndex

Using TimeGrouper and another grouping to create subgroups, then apply a custom function

Resampling with custom periods

Resample intraday frame without adding new days

Resample minute data

Resample with groupby

## 7.7 Merge

The *Concat* docs. The *Join* docs.

Append two dataframes with overlapping index (emulate R rbind)

```
In [149]: rng = pd.date_range('2000-01-01', periods=6)

In [150]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C']
↳ )

In [151]: df2 = df1.copy()
```

Depending on df construction, ignore\_index may be needed

```
In [152]: df = df1.append(df2, ignore_index=True); df
Out[152]:
```

|    | A         | B         | C         |
|----|-----------|-----------|-----------|
| 0  | -0.480676 | -1.305282 | -0.212846 |
| 1  | 1.979901  | 0.363112  | -0.275732 |
| 2  | -1.433852 | 0.580237  | -0.013672 |
| 3  | 1.776623  | -0.803467 | 0.521517  |
| 4  | -0.302508 | -0.442948 | -0.395768 |
| 5  | -0.249024 | -0.031510 | 2.413751  |
| 6  | -0.480676 | -1.305282 | -0.212846 |
| 7  | 1.979901  | 0.363112  | -0.275732 |
| 8  | -1.433852 | 0.580237  | -0.013672 |
| 9  | 1.776623  | -0.803467 | 0.521517  |
| 10 | -0.302508 | -0.442948 | -0.395768 |
| 11 | -0.249024 | -0.031510 | 2.413751  |

Self Join of a DataFrame

```
In [153]: df = pd.DataFrame(data={'Area' : ['A'] * 5 + ['C'] * 2,
.....:                          'Bins' : [110] * 2 + [160] * 3 + [40] * 2,
.....:                          'Test_0' : [0, 1, 0, 1, 2, 0, 1],
.....:                          'Data' : np.random.randn(7)});df
Out[153]:
```

|   | Area | Bins | Test_0 | Data      |
|---|------|------|--------|-----------|
| 0 | A    | 110  | 0      | -0.378914 |
| 1 | A    | 110  | 1      | -1.032527 |
| 2 | A    | 160  | 0      | -1.402816 |
| 3 | A    | 160  | 1      | 0.715333  |
| 4 | A    | 160  | 2      | -0.091438 |
| 5 | C    | 40   | 0      | 1.608418  |
| 6 | C    | 40   | 1      | 0.753207  |

```
In [154]: df['Test_1'] = df['Test_0'] - 1

In [155]: pd.merge(df, df, left_on=['Bins', 'Area', 'Test_0'], right_on=['Bins', 'Area']
↳ , 'Test_1', suffixes=('_L', '_R'))
Out[155]:
```

|   | Area | Bins | Test_0_L | Data_L    | Test_1_L | Test_0_R | Data_R    | Test_1_R |
|---|------|------|----------|-----------|----------|----------|-----------|----------|
| 0 | A    | 110  | 0        | -0.378914 | -1       | 1        | -1.032527 | 0        |
| 1 | A    | 160  | 0        | -1.402816 | -1       | 1        | 0.715333  | 0        |
| 2 | A    | 160  | 1        | 0.715333  | 0        | 2        | -0.091438 | 1        |
| 3 | C    | 40   | 0        | 1.608418  | -1       | 1        | 0.753207  | 0        |

How to set the index and join

KDB like asof join

Join with a criteria based on the values

Using searchsorted to merge based on values inside a range

## 7.8 Plotting

The *Plotting* docs.

Make Matplotlib look like R

Setting x-axis major and minor labels

Plotting multiple charts in an ipython notebook

Creating a multi-line plot

Plotting a heatmap

Annotate a time-series plot

Annotate a time-series plot #2

Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter

Boxplot for each quartile of a stratifying variable

```
In [156]: df = pd.DataFrame(
.....:     {u'stratifying_var': np.random.uniform(0, 100, 20),
.....:      u'price': np.random.normal(100, 5, 20)})
.....:

In [157]: df[u'quartiles'] = pd.qcut(
.....:     df[u'stratifying_var'],
.....:     4,
.....:     labels=[u'0-25%', u'25-50%', u'50-75%', u'75-100%'])
.....:

In [158]: df.boxplot(column=u'price', by=u'quartiles')
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x11f845470>
```

## 7.9 Data In/Out

Performance comparison of SQL vs HDF5

### 7.9.1 CSV

The *CSV* docs

`read_csv` in action

appending to a csv

Reading a csv chunk-by-chunk

Reading only certain rows of a csv chunk-by-chunk

Reading the first few lines of a frame

Reading a file that is compressed but not by `gzip/bz2` (the native compressed formats which `read_csv` understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. [See here](#)

Inferring dtypes from a file

Dealing with bad lines

Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

### 7.9.1.1 Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```
In [159]: for i in range(3):
.....:     data = pd.DataFrame(np.random.randn(10, 4))
.....:     data.to_csv('file_{}.csv'.format(i))
.....:

In [160]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [161]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```
In [162]: import glob

In [163]: files = glob.glob('file_*.csv')

In [164]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*` (...) functions described in the *io docs*.

### 7.9.1.2 Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```
In [30]: i = pd.date_range('20000101', periods=10000)

In [31]: df = pd.DataFrame(dict(year = i.year, month = i.month, day = i.day))

In [32]: df.head()
Out[32]:
   day  month  year
0    1     1  2000
1    2     1  2000
2    3     1  2000
3    4     1  2000
4    5     1  2000

In [33]: %timeit pd.to_datetime(df.year*10000+df.month*100+df.day, format='%Y%m%d')
100 loops, best of 3: 7.08 ms per loop

# simulate combining into a string, then parsing
In [34]: ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'], x['month'], x['day']),
    ↪ axis=1)

In [35]: ds.head()
Out[35]:
```

(continues on next page)

(continued from previous page)

```
0    20000101
1    20000102
2    20000103
3    20000104
4    20000105
dtype: object

In [36]: %timeit pd.to_datetime(ds)
1 loops, best of 3: 488 ms per loop
```

### 7.9.1.3 Skip row between header and data

```
In [165]: data = """;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   ;;;;
.....:   date;Param1;Param2;Param4;Param5
.....:       ;m2; °C;m2;m
.....:   ;;;;
.....:   01.01.1990  00:00;1;1;2;3
.....:   01.01.1990  01:00;5;3;4;5
.....:   01.01.1990  02:00;9;5;6;7
.....:   01.01.1990  03:00;13;7;8;9
.....:   01.01.1990  04:00;17;9;10;11
.....:   01.01.1990  05:00;21;11;12;13
.....:   """
.....:
.....:
```

### Option 1: pass rows explicitly to skiprows

```
In [166]: pd.read_csv(StringIO(data), sep=';', skiprows=[11,12],
.....:                  index_col=0, parse_dates=True, header=10)
.....:
Out[166]:
```

|                     | Param1 | Param2 | Param4 | Param5 |
|---------------------|--------|--------|--------|--------|
| date                |        |        |        |        |
| 1990-01-01 00:00:00 | 1      | 1      | 2      | 3      |
| 1990-01-01 01:00:00 | 5      | 3      | 4      | 5      |
| 1990-01-01 02:00:00 | 9      | 5      | 6      | 7      |
| 1990-01-01 03:00:00 | 13     | 7      | 8      | 9      |
| 1990-01-01 04:00:00 | 17     | 9      | 10     | 11     |
| 1990-01-01 05:00:00 | 21     | 11     | 12     | 13     |

## Option 2: read column names and then data

```
In [167]: pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
Out[167]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')
```

```
In [168]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
```

```
In [169]: pd.read_csv(StringIO(data), sep=';', index_col=0,
.....:                header=12, parse_dates=True, names=columns)
.....:
Out[169]:
```

|                     | Param1 | Param2 | Param4 | Param5 |
|---------------------|--------|--------|--------|--------|
| date                |        |        |        |        |
| 1990-01-01 00:00:00 | 1      | 1      | 2      | 3      |
| 1990-01-01 01:00:00 | 5      | 3      | 4      | 5      |
| 1990-01-01 02:00:00 | 9      | 5      | 6      | 7      |
| 1990-01-01 03:00:00 | 13     | 7      | 8      | 9      |
| 1990-01-01 04:00:00 | 17     | 9      | 10     | 11     |
| 1990-01-01 05:00:00 | 21     | 11     | 12     | 13     |

## 7.9.2 SQL

The *SQL* docs

Reading from databases with SQL

## 7.9.3 Excel

The *Excel* docs

Reading from a filelike handle

Modifying formatting in XlsxWriter output

## 7.9.4 HTML

Reading HTML tables from a server that cannot handle the default request header

## 7.9.5 HDFStore

The *HDFStores* docs

Simple Queries with a Timestamp Index

Managing heterogeneous data using a linked multiple table hierarchy

Merging on-disk tables with millions of rows

Avoiding inconsistencies when writing to a store from multiple processes/threads

De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. [See here](#)

Creating a store chunk-by-chunk from a csv file

Appending to a store, while creating a unique index

Large Data work flows

Reading in a sequence of files, then providing a global unique index to a store while appending

Groupby on a HDFStore with low group density

Groupby on a HDFStore with high group density

Hierarchical queries on a HDFStore

Counting with a HDFStore

Troubleshoot HDFStore exceptions

Setting min\_itemsize with strings

Using ptpack to create a completely-sorted-index on a store

Storing Attributes to a group node

```
In [170]: df = pd.DataFrame(np.random.randn(8,3))

In [171]: store = pd.HDFStore('test.h5')

In [172]: store.put('df',df)

# you can store an arbitrary Python object via pickle
In [173]: store.get_storer('df').attrs.my_attribute = dict(A = 10)

In [174]: store.get_storer('df').attrs.my_attribute
Out[174]: {'A': 10}
```

## 7.9.6 Binary Files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of an array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }
}
```

(continues on next page)

(continued from previous page)

```

FILE *file = fopen("binary.dat", "wb");
fwrite(&d, sizeof(Data), n, file);
fclose(file);

return 0;
}

```

the following Python code will read the binary file 'binary.dat' into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```

names = 'count', 'avg', 'scale'

# note that the offsets are larger than the size of the type because of
# struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'
dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
              align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))

```

**Note:** The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas' IO facilities.

## 7.10 Computation

Numerical integration (sample-based) of a time series

### 7.11 Timedeltas

The *Timedeltas* docs.

Using *timedeltas*

```

In [175]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [176]: s - s.max()
Out[176]:
0    -2 days
1    -1 days
2     0 days
dtype: timedelta64[ns]

In [177]: s.max() - s
Out[177]:
0     2 days
1     1 days
2     0 days
dtype: timedelta64[ns]

```

(continues on next page)

(continued from previous page)

```
In [178]: s - datetime.datetime(2011,1,1,3,5)
```

```

////////////////////////////////////
↪
0    364 days 20:55:00
1    365 days 20:55:00
2    366 days 20:55:00
dtype: timedelta64[ns]
```

```
In [179]: s + datetime.timedelta(minutes=5)
```

```

////////////////////////////////////
↪
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

```
In [180]: datetime.datetime(2011,1,1,3,5) - s
```

```

////////////////////////////////////
↪
0    -365 days +03:05:00
1    -366 days +03:05:00
2    -367 days +03:05:00
dtype: timedelta64[ns]
```

```
In [181]: datetime.timedelta(minutes=5) + s
```

```

////////////////////////////////////
↪
0    2012-01-01 00:05:00
1    2012-01-02 00:05:00
2    2012-01-03 00:05:00
dtype: datetime64[ns]
```

### Adding and subtracting deltas and dates

```
In [182]: deltas = pd.Series([ datetime.timedelta(days=i) for i in range(3) ])
```

```
In [183]: df = pd.DataFrame(dict(A = s, B = deltas)); df
```

```
Out[183]:
```

|   | A                 | B |
|---|-------------------|---|
| 0 | 2012-01-01 0 days |   |
| 1 | 2012-01-02 1 days |   |
| 2 | 2012-01-03 2 days |   |

```
In [184]: df['New Dates'] = df['A'] + df['B'];
```

```
In [185]: df['Delta'] = df['A'] - df['New Dates']; df
```

```
Out[185]:
```

|   | A                 | B | New Dates          | Delta |
|---|-------------------|---|--------------------|-------|
| 0 | 2012-01-01 0 days |   | 2012-01-01 0 days  |       |
| 1 | 2012-01-02 1 days |   | 2012-01-03 -1 days |       |
| 2 | 2012-01-03 2 days |   | 2012-01-05 -2 days |       |

```
In [186]: df.dtypes
```

```

////////////////////////////////////
↪
A    datetime64[ns]
```

(continues on next page)

(continued from previous page)

```

B          timedelta64[ns]
New Dates   datetime64[ns]
Delta       timedelta64[ns]
dtype: object

```

### Another example

Values can be set to NaT using np.nan, similar to datetime

```

In [187]: y = s - s.shift(); y
Out[187]:
0      NaT
1    1 days
2    1 days
dtype: timedelta64[ns]

In [188]: y[1] = np.nan; y
Out[188]:
0      NaT
1      NaT
2    1 days
dtype: timedelta64[ns]

```

## 7.12 Aliasing Axis Names

To globally provide aliases for axis names, one can define these 2 functions:

```

In [189]: def set_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES[alias] = axis
.....:

```

```

In [190]: def clear_axis_alias(cls, axis, alias):
.....:     if axis not in cls._AXIS_NUMBERS:
.....:         raise Exception("invalid axis [%s] for alias [%s]" % (axis, alias))
.....:     cls._AXIS_ALIASES.pop(alias, None)
.....:

```

```

In [191]: set_axis_alias(pd.DataFrame, 'columns', 'myaxis2')

In [192]: df2 = pd.DataFrame(np.random.randn(3,2), columns=['c1', 'c2'], index=['i1', 'i2', 'i3'])

In [193]: df2.sum(axis='myaxis2')
Out[193]:
i1    0.745167
i2   -0.176251
i3    0.014354
dtype: float64

In [194]: clear_axis_alias(pd.DataFrame, 'columns', 'myaxis2')

```

## 7.13 Creating Example Data

To create a dataframe from every combination of some given values, like R's `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```
In [195]: def expand_grid(data_dict):
.....:     rows = itertools.product(*data_dict.values())
.....:     return pd.DataFrame.from_records(rows, columns=data_dict.keys())
.....:

In [196]: df = expand_grid(
.....:     {'height': [60, 70],
.....:      'weight': [100, 140, 180],
.....:      'sex': ['Male', 'Female']})
.....:

In [197]: df
Out[197]:
```

|    | height | weight | sex    |
|----|--------|--------|--------|
| 0  | 60     | 100    | Male   |
| 1  | 60     | 100    | Female |
| 2  | 60     | 140    | Male   |
| 3  | 60     | 140    | Female |
| 4  | 60     | 180    | Male   |
| 5  | 60     | 180    | Female |
| 6  | 70     | 100    | Male   |
| 7  | 70     | 100    | Female |
| 8  | 70     | 140    | Male   |
| 9  | 70     | 140    | Female |
| 10 | 70     | 180    | Male   |
| 11 | 70     | 180    | Female |

## INTRO TO DATA STRUCTURES

We'll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic**. The link between labels and data will not be broken unless done so explicitly by you.

We'll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 8.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, *data* can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what **data** is:

#### From ndarray

If *data* is an ndarray, **index** must be the same length as **data**. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [4]: s
Out[4]:
a      0.4691
b     -0.2829
```

(continues on next page)

(continued from previous page)

```
c    -1.5091
d    -1.1356
e     1.2121
dtype: float64

In [5]: s.index
Out[5]:
Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [6]: pd.Series(np.random.randn(5))
Out[6]:
0    -0.1732
1     0.1192
2    -1.0442
3    -0.8618
4    -2.1046
dtype: float64
```

---

**Note:** pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

---

### From dict

Series can be instantiated from dicts:

```
In [7]: d = {'b' : 1, 'a' : 0, 'c' : 2}

In [8]: pd.Series(d)
Out[8]:
b    1
a    0
c    2
dtype: int64
```

---

**Note:** When the data is a dict, and an index is not passed, the `Series` index will be ordered by the dict's insertion order, if you're using Python version `>= 3.6` and Pandas version `>= 0.23`.

If you're using Python `< 3.6` or Pandas `< 0.23`, and an index is not passed, the `Series` index will be the lexically ordered list of dict keys.

---

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the `Series` would be ordered by the lexical order of the dict keys (i.e. `['a', 'b', 'c']` rather than `['b', 'a', 'c']`).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a' : 0., 'b' : 1., 'c' : 2.}

In [10]: pd.Series(d)
Out[10]:
a    0.0
b    1.0
c    2.0
```

(continues on next page)

(continued from previous page)

```
dtype: float64

In [11]: pd.Series(d, index=['b', 'c', 'd', 'a'])
Out[11]:
b    1.0
c    2.0
d    NaN
a    0.0
dtype: float64
```

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

### From scalar value

If data is a scalar value, an index must be provided. The value will be repeated to match the length of **index**.

```
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
a    5.0
b    5.0
c    5.0
d    5.0
e    5.0
dtype: float64
```

## 8.1.1 Series is ndarray-like

Series acts very similarly to a ndarray, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```
In [13]: s[0]
Out[13]: 0.46911229990718628

In [14]: s[:3]
Out[14]:
a    0.4691
b   -0.2829
c   -1.5091
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
a    0.4691
e    1.2121
dtype: float64

In [16]: s[[4, 3, 1]]
Out[16]:
e    1.2121
d   -1.1356
b   -0.2829
```

(continues on next page)

(continued from previous page)

```
dtype: float64
```

```
In [17]: np.exp(s)
```

```

a      1.5986
b      0.7536
c      0.2211
d      0.3212
e      3.3606
dtype: float64

```

We will address array-based indexing in a separate *section*.

### 8.1.2 Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```
In [18]: s['a']
```

```
Out[18]: 0.46911229990718628
```

```
In [19]: s['e'] = 12.
```

```
In [20]: s
```

Out [20] :

|   |        |
|---|--------|
| a | 0.4691 |
|---|--------|

|   |         |
|---|---------|
| b | -0.2829 |
|---|---------|

|   |         |
|---|---------|
| c | -1.5091 |
|---|---------|

|   |         |
|---|---------|
| d | -1.1356 |
|---|---------|

|   |         |
|---|---------|
| e | 12.0000 |
|---|---------|

```
dtype: float64
```

```
In [21]: 'e' in s
```

↪ True

```
In [22]: 'f' in s
```

```

// ...
return false;
}
}

```

If a label is not contained, an exception is raised:

```
>>> s['f']
```

```
KeyError: 'f'
```

Using the `get` method, a missing label will return `None` or specified default:

```
In [23]: s.get('f')
```

```
In [24]: s.get('f', np.nan)
```

```
Out[24]: nan
```

See also the *section on attribute access*.

### 8.1.3 Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [25]: s + s
Out[25]:
a      0.9382
b     -0.5657
c     -3.0181
d     -2.2713
e      24.0000
dtype: float64

In [26]: s * 2
Out[26]:
a      0.9382
b     -0.5657
c     -3.0181
d     -2.2713
e      24.0000
dtype: float64

In [27]: np.exp(s)
Out[27]:
a      1.5986
b      0.7536
c      0.2211
d      0.3212
e    162754.7914
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [28]: s[1:] + s[:-1]
Out[28]:
a      NaN
b     -0.5657
c     -3.0181
d     -2.2713
e      NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with

missing data via the **dropna** function.

### 8.1.4 Name attribute

Series can also have a name attribute:

```
In [29]: s = pd.Series(np.random.randn(5), name='something')
```

```
In [30]: s
```

Out[30]:

|   |         |
|---|---------|
| 0 | -0.4949 |
|---|---------|

|   |        |
|---|--------|
| 1 | 1.0718 |
|---|--------|

|   |        |
|---|--------|
| 2 | 0.7216 |
|---|--------|

|   |         |
|---|---------|
| 3 | -0.7068 |
|---|---------|

|   |         |
|---|---------|
| 4 | -1.0396 |
|---|---------|

```
Name: something, dtype: float64
```

```
In [31]: s.name
```

```
↳ 'something'
```

The Series `name` will be assigned automatically in many cases, in particular when taking 1D slices of `DataFrame` as you will see below.

New in version 0.18.0.

You can rename a Series with the `pandas.Series.rename()` method.

```
In [32]: s2 = s.rename("different")
```

```
In [33]: s2.name
```

```
Out[33]: 'different'
```

Note that `s` and `s2` refer to different objects.

## 8.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D numpy.ndarray
- **Structured or record** ndarray
- A Series
- **Another** DataFrame

Along with the data, you can optionally pass **index** (row labels) and **columns** (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.

**Note:** When the data is a dict, and `columns` is not specified, the `DataFrame` columns will be ordered by the dict's insertion order, if you are using Python version  $\geq 3.6$  and Pandas  $\geq 0.23$ .

If you are using Python  $< 3.6$  or Pandas  $< 0.23$ , and `columns` is not specified, the `DataFrame` columns will be the lexically ordered list of dict keys.

## 8.2.1 From dict of Series or dicts

The resulting **index** will be the **union** of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [34]: d = {'one' : pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
....:        'two' : pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
....:

In [35]: df = pd.DataFrame(d)

In [36]: df
Out[36]:
   one  two
a  1.0  1.0
b  2.0  2.0
c  3.0  3.0
d  NaN  4.0

In [37]: pd.DataFrame(d, index=['d', 'b', 'a'])
Out[37]:
   one  two
d  NaN  4.0
b  2.0  2.0
a  1.0  1.0

In [38]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
Out[38]:
   two three
d  4.0   NaN
b  2.0   NaN
a  1.0   NaN
```

The row and column labels can be accessed respectively by accessing the **index** and **columns** attributes:

**Note:** When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [39]: df.index
Out[39]: Index(['a', 'b', 'c', 'd'], dtype='object')

In [40]: df.columns
Out[40]: Index(['one', 'two'], dtype='object')
```

## 8.2.2 From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be `range(n)`, where `n` is the array length.

```
In [41]: d = {'one' : [1., 2., 3., 4.],
....:       'two' : [4., 3., 2., 1.]}
....:

In [42]: pd.DataFrame(d)
Out[42]:
   one two
0  1.0  4.0
1  2.0  3.0
2  3.0  2.0
3  4.0  1.0

In [43]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
Out[43]:
   one two
a  1.0  4.0
b  2.0  3.0
c  3.0  2.0
d  4.0  1.0
```

## 8.2.3 From structured or record array

This case is handled identically to a dict of arrays.

```
In [44]: data = np.zeros((2,), dtype=[('A', 'i4'), ('B', 'f4'), ('C', 'a10')])

In [45]: data[:] = [(1, 2., 'Hello'), (2, 3., "World")]

In [46]: pd.DataFrame(data)
Out[46]:
   A    B    C
0  1  2.0 b'Hello'
1  2  3.0 b'World'

In [47]: pd.DataFrame(data, index=['first', 'second'])
Out[47]:
      A    B    C
first  1  2.0 b'Hello'
second 2  3.0 b'World'

In [48]: pd.DataFrame(data, columns=['C', 'A', 'B'])
Out[48]:
   C    A    B
0 b'Hello'  1  2.0
1 b'World'  2  3.0
```

**Note:** DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.

## 8.2.4 From a list of dicts

```
In [49]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]

In [50]: pd.DataFrame(data2)
Out[50]:
   a  b    c
0  1  2  NaN
1  5 10 20.0

In [51]: pd.DataFrame(data2, index=['first', 'second'])
Out[51]:
      a  b    c
first  1  2  NaN
second 5 10 20.0

In [52]: pd.DataFrame(data2, columns=['a', 'b'])
Out[52]:
   a  b
0  1  2
1  5 10
```

## 8.2.5 From a dict of tuples

You can automatically create a multi-indexed frame by passing a tuples dictionary.

```
In [53]: pd.DataFrame({'a', 'b': {('A', 'B'): 1, ('A', 'C'): 2,
....:                             ('a', 'a'): 3, ('a', 'b'): 4,
....:                             ('a', 'c'): 5, ('a', 'd'): 6,
....:                             ('b', 'a'): 7, ('b', 'b'): 8,
....:                             ('b', 'c'): 9, ('b', 'd'): 10}})
Out[53]:
      a  b
A B  1.0  4.0  5.0  8.0 10.0
C  2.0  3.0  6.0  7.0  NaN
D  NaN  NaN  NaN  NaN  9.0
```

## 8.2.6 From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

### Missing Data

Much more will be said on this topic in the [Missing data](#) section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

## 8.2.7 Alternate Constructors

### DataFrame.from\_dict

`DataFrame.from_dict` takes a dict of dicts or a dict of array-like sequences and returns a `DataFrame`. It operates like the `DataFrame` constructor except for the `orient` parameter which is `'columns'` by default, but which can be set to `'index'` in order to use the dict keys as row labels.

```
In [54]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[54]:
```

|   | A | B |
|---|---|---|
| 0 | 1 | 4 |
| 1 | 2 | 5 |
| 2 | 3 | 6 |

If you pass `orient='index'`, the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [55]: pd.DataFrame.from_dict(dict([( 'A', [1, 2, 3]), ( 'B', [4, 5, 6])]),
....:                             orient='index', columns=['one', 'two', 'three'])
....:
Out[55]:
```

|   | one | two | three |
|---|-----|-----|-------|
| A | 1   | 2   | 3     |
| B | 4   | 5   | 6     |

## DataFrame.from\_records

`DataFrame.from_records` takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal `DataFrame` constructor, except that the resulting `DataFrame` index may be a specific field of the structured dtype. For example:

```
In [56]: data
Out[56]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])

In [57]: pd.DataFrame.from_records(data, index='C')
//////////
↪
      A      B
C
b'Hello'  1  2.0
b'World'  2  3.0
```

### 8.2.8 Column selection, addition, deletion

You can treat a `DataFrame` semantically like a dict of like-indexed `Series` objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [58]: df['one']
Out[58]:
a      1.0
b      2.0
c      3.0
d      NaN
Name: one, dtype: float64

In [59]: df['three'] = df['one'] * df['two']
```

(continues on next page)

(continued from previous page)

```
In [60]: df['flag'] = df['one'] > 2
```

```
In [61]: df
```

```
Out[61]:
```

|   | one | two | three | flag  |
|---|-----|-----|-------|-------|
| a | 1.0 | 1.0 | 1.0   | False |
| b | 2.0 | 2.0 | 4.0   | False |
| c | 3.0 | 3.0 | 9.0   | True  |
| d | NaN | 4.0 | NaN   | False |

Columns can be deleted or popped like with a dict:

```
In [62]: del df['two']
```

```
In [63]: three = df.pop('three')
```

```
In [64]: df
```

```
Out[64]:
```

|   | one | flag  |
|---|-----|-------|
| a | 1.0 | False |
| b | 2.0 | False |
| c | 3.0 | True  |
| d | NaN | False |

When inserting a scalar value, it will naturally be propagated to fill the column:

```
In [65]: df['foo'] = 'bar'
```

```
In [66]: df
```

```
Out[66]:
```

|   | one | flag  | foo |
|---|-----|-------|-----|
| a | 1.0 | False | bar |
| b | 2.0 | False | bar |
| c | 3.0 | True  | bar |
| d | NaN | False | bar |

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

```
In [67]: df['one_trunc'] = df['one'][:2]
```

```
In [68]: df
```

```
Out[68]:
```

|   | one | flag  | foo | one_trunc |
|---|-----|-------|-----|-----------|
| a | 1.0 | False | bar | 1.0       |
| b | 2.0 | False | bar | 2.0       |
| c | 3.0 | True  | bar | NaN       |
| d | NaN | False | bar | NaN       |

You can insert raw ndarrays but their length must match the length of the DataFrame's index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

```
In [69]: df.insert(1, 'bar', df['one'])
```

```
In [70]: df
```

(continues on next page)

(continued from previous page)

```
Out [70]:
```

|   | one | bar | flag  | foo | one_trunc |
|---|-----|-----|-------|-----|-----------|
| a | 1.0 | 1.0 | False | bar | 1.0       |
| b | 2.0 | 2.0 | False | bar | 2.0       |
| c | 3.0 | 3.0 | True  | bar | NaN       |
| d | NaN | NaN | False | bar | NaN       |

## 8.2.9 Assigning New Columns in Method Chains

Inspired by `dplyr`'s `mutate` verb, `DataFrame` has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```
In [71]: iris = pd.read_csv('data/iris.data')
```

```
In [72]: iris.head()
```

```
Out [72]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        |
|---|-------------|------------|-------------|------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa |

```
In [73]: (iris.assign(sepal_ratio = iris['SepalWidth'] / iris['SepalLength']))
```

```
.....: .head())
```

```
.....:
```

```
=====
```

```
↪
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.6863      |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.6122      |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.6809      |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.6739      |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.7200      |

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the `DataFrame` being assigned to.

```
In [74]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] /
```

```
.....: x['SepalLength'])).head()
```

```
.....:
```

```
Out [74]:
```

|   | SepalLength | SepalWidth | PetalLength | PetalWidth | Name        | sepal_ratio |
|---|-------------|------------|-------------|------------|-------------|-------------|
| 0 | 5.1         | 3.5        | 1.4         | 0.2        | Iris-setosa | 0.6863      |
| 1 | 4.9         | 3.0        | 1.4         | 0.2        | Iris-setosa | 0.6122      |
| 2 | 4.7         | 3.2        | 1.3         | 0.2        | Iris-setosa | 0.6809      |
| 3 | 4.6         | 3.1        | 1.5         | 0.2        | Iris-setosa | 0.6739      |
| 4 | 5.0         | 3.6        | 1.4         | 0.2        | Iris-setosa | 0.7200      |

`assign` **always** returns a copy of the data, leaving the original `DataFrame` untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don't have a reference to the `DataFrame` at hand. This is common when using `assign` in a chain of operations. For example, we can limit the `DataFrame` to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:

```

In [75]: (iris.query('SepalLength > 5')
.....:      .assign(SepalRatio = lambda x: x.SepalWidth / x.SepalLength,
.....:              PetalRatio = lambda x: x.PetalWidth / x.PetalLength)
.....:      .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
.....:
Out [75]: <matplotlib.axes._subplots.AxesSubplot at 0x1c259fd7b8>

```

Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that's been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn't have a reference to the *filtered* DataFrame available.

The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. A *copy* of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of `**kwargs` is preserved. This allows for *dependent* assignment, where an expression later in `**kwargs` can refer to a column created earlier in the same `assign()`.

```

In [76]: dfa = pd.DataFrame({"A": [1, 2, 3],
.....:                      "B": [4, 5, 6]})
.....:

In [77]: dfa.assign(C=lambda x: x['A'] + x['B'],
.....:              D=lambda x: x['A'] + x['C'])

```

(continues on next page)

(continued from previous page)

```
.....:
Out [77]:
   A  B  C  D
0  1  4  5  6
1  2  5  7  9
2  3  6  9 12
```

In the second expression, `x[ 'C' ]` will refer to the newly created column, that's equal to `dfa[ 'A' ] + dfa[ 'B' ]`. To write code compatible with all versions of Python, split the assignment in two.

```
In [78]: dependent = pd.DataFrame({"A": [1, 1, 1]})

In [79]: (dependent.assign(A=lambda x: x[ 'A' ] + 1)
.....:               .assign(B=lambda x: x[ 'A' ] + 2))
.....:
Out [79]:
   A  B
0  2  4
1  2  4
2  2  4
```

**Warning:** Dependent assignment maybe subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish write code that supports versions of python before and after 3.6, you'll need to take care when passing assign expressions that

- Updating an existing column
- Referring to the newly updated column in the same assign

For example, we'll update column "A" and then refer to it when creating "B".

```
>>> dependent = pd.DataFrame({"A": [1, 1, 1]})
>>> dependent.assign(A=lambda x: x["A"] + 1,
.....:               B=lambda x: x["A"] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the "old" value of A, `[1, 1, 1]`. The output is then

```
   A  B
0  2  3
1  2  3
2  2  3
```

For Python 3.6 and later, the expression creating A refers to the "new" value of A, `[2, 2, 2]`, which results in

```
   A  B
0  2  4
1  2  4
2  2  4
```

## 8.2.10 Indexing / Selection

The basics of indexing are as follows:

```
In [80]: df.loc['b']
Out[80]:
one          2
bar          2
flag        False
foo          bar
one_trunc    2
Name: b, dtype: object
```

```
In [81]: df.iloc[2]
\\/////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
one          3
bar          3
flag         True
foo          bar
one_trunc    NaN
Name: c, dtype: object
```

```
In [82]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
```

```
In [83]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
```

```
In [84]: df + df2
```

Out [84]:

|   | A       | B       | C       | D   |
|---|---------|---------|---------|-----|
| 0 | 0.0457  | -0.0141 | 1.3809  | NaN |
| 1 | -0.9554 | -1.5010 | 0.0372  | NaN |
| 2 | -0.6627 | 1.5348  | -0.8597 | NaN |
| 3 | -2.4529 | 1.2373  | -0.1337 | NaN |
| 4 | 1.4145  | 1.9517  | -2.3204 | NaN |
| 5 | -0.4949 | -1.6497 | -1.0846 | NaN |
| 6 | -1.0476 | -0.7486 | -0.8055 | NaN |
| 7 | NaN     | NaN     | NaN     | NaN |
| 8 | NaN     | NaN     | NaN     | NaN |
| 9 | NaN     | NaN     | NaN     | NaN |

When doing an operation between DataFrame and Series, the default behavior is to align the Series **index** on the DataFrame **columns**, thus **broadcasting** row-wise. For example:

```
In [85]: df - df.iloc[0]
Out[85]:
```

|   | A       | B       | C       | D       |
|---|---------|---------|---------|---------|
| 0 | 0.0000  | 0.0000  | 0.0000  | 0.0000  |
| 1 | -1.3593 | -0.2487 | -0.4534 | -1.7547 |
| 2 | 0.2531  | 0.8297  | 0.0100  | -1.9912 |
| 3 | -1.3111 | 0.0543  | -1.7249 | -1.6205 |
| 4 | 0.5730  | 1.5007  | -0.6761 | 1.3673  |
| 5 | -1.7412 | 0.7820  | -1.2416 | -2.0531 |
| 6 | -1.2408 | -0.8696 | -0.1533 | 0.0004  |
| 7 | -0.7439 | 0.4110  | -0.9296 | -0.2824 |
| 8 | -1.1949 | 1.3207  | 0.2382  | -1.4826 |
| 9 | 2.2938  | 1.8562  | 0.7733  | -1.4465 |

In the special case of working with time series data, and the DataFrame index also contains dates, the broadcasting will be column-wise:

```
In [86]: index = pd.date_range('1/1/2000', periods=8)
In [87]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
```

```
In [88]: df
Out[88]:
```

|            | A       | B       | C       |
|------------|---------|---------|---------|
| 2000-01-01 | -1.2268 | 0.7698  | -1.2812 |
| 2000-01-02 | -0.7277 | -0.1213 | -0.0979 |
| 2000-01-03 | 0.6958  | 0.3417  | 0.9597  |
| 2000-01-04 | -1.1103 | -0.6200 | 0.1497  |
| 2000-01-05 | -0.7323 | 0.6877  | 0.1764  |
| 2000-01-06 | 0.4033  | -0.1550 | 0.3016  |
| 2000-01-07 | -2.1799 | -1.3698 | -0.9542 |
| 2000-01-08 | 1.4627  | -1.7432 | -0.8266 |

[illegible]

```
In [90]: df - df['A']
\
↪
2000-01-01 00:00:00 2000-01-02 00:00:00 2000-01-03 00:00:00 \

2000-01-06      NaN ...      NaN NaN NaN NaN
2000-01-07      NaN ...      NaN NaN NaN NaN
2000-01-08      NaN ...      NaN NaN NaN NaN

[8 rows x 11 columns]
```

```
df = df['A']
```

```
df.sub(df['A'], axis=0)
```

Operations with scalars are just as you would expect:

Out [91] :

```
In [92]: 1 / df
```

```
In [93]: df ** 4
```

|            | A       | B      | C          |
|------------|---------|--------|------------|
| 2000-01-01 | 2.2653  | 0.3512 | 2.6948e+00 |
| 2000-01-02 | 0.2804  | 0.0002 | 9.1796e-05 |
| 2000-01-03 | 0.2344  | 0.0136 | 8.4838e-01 |
| 2000-01-04 | 1.5199  | 0.1477 | 5.0286e-04 |
| 2000-01-05 | 0.2876  | 0.2237 | 9.6924e-04 |
| 2000-01-06 | 0.0265  | 0.0006 | 8.2769e-03 |
| 2000-01-07 | 22.5795 | 3.5212 | 8.2903e-01 |
| 2000-01-08 | 4.5774  | 9.2332 | 4.6683e-01 |

Boolean operators work as well:

```
In [94]: df1 = pd.DataFrame({'a' : [1, 0, 1], 'b' : [0, 1, 1] }, dtype=bool)
In [95]: df2 = pd.DataFrame({'a' : [0, 1, 1], 'b' : [1, 1, 0] }, dtype=bool)
In [96]: df1 & df2
Out[96]:
   a      b
0  False False
1  False  True
2   True False

In [97]: df1 | df2
Out[97]:
   a      b
0   True  True
1   True  True
2   True  True

In [98]: df1 ^ df2
Out[98]:
   a      b
0   True  True
1   True False
2  False  True

In [99]: ~df1
Out[99]:
   a      b
0 False  True
1  True False
2 False False
```

## 8.2.12 Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an `ndarray`:

```
# only show the first 5 rows
In [100]: df[:5].T
Out[100]:
2000-01-01  2000-01-02  2000-01-03  2000-01-04  2000-01-05
A      -1.2268    -0.7277     0.6958    -1.1103    -0.7323
B       0.7698    -0.1213     0.3417    -0.6200     0.6877
C      -1.2812    -0.0979     0.9597     0.1497     0.1764
```

## 8.2.13 DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (`log`, `exp`, `sqrt`, ...) and various other NumPy functions can be used with no issues on `DataFrame`, assuming the data within are numeric:

```
In [101]: np.exp(df)
Out[101]:
```

(continues on next page)

(continued from previous page)

```

      A      B      C
2000-01-01  0.2932  2.1593  0.2777
2000-01-02  0.4830  0.8858  0.9068
2000-01-03  2.0053  1.4074  2.6110
2000-01-04  0.3294  0.5380  1.1615
2000-01-05  0.4808  1.9892  1.1930
2000-01-06  1.4968  0.8565  1.3521
2000-01-07  0.1131  0.2541  0.3851
2000-01-08  4.3176  0.1750  0.4375

```

```
In [102]: np.asarray(df)
```

```

////////////////////////////////////
↪
array([[ -1.2268,   0.7698,  -1.2812],
       [ -0.7277,  -0.1213,  -0.0979],
       [  0.6958,   0.3417,   0.9597],
       [ -1.1103,  -0.62   ,   0.1497],
       [ -0.7323,   0.6877,   0.1764],
       [  0.4033,  -0.155  ,   0.3016],
       [ -2.1799,  -1.3698,  -0.9542],
       [  1.4627,  -1.7432,  -0.8266]])

```

The dot method on DataFrame implements matrix multiplication:

```
In [103]: df.T.dot(df)
```

```
Out[103]:
```

```

      A      B      C
A  11.3419 -0.0598  3.0080
B  -0.0598  6.5206  2.0833
C   3.0080  2.0833  4.3105

```

Similarly, the dot method on Series implements dot product:

```
In [104]: s1 = pd.Series(np.arange(5,10))
```

```
In [105]: s1.dot(s1)
```

```
Out[105]: 255
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics are quite different in places from a matrix.

## 8.2.14 Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the **baseball** dataset from the **plyr** R package):

```
In [106]: baseball = pd.read_csv('data/baseball.csv')
```

```
In [107]: print(baseball)
```

```

   id  player  year  stint  ...  hbp  sh  sf  gidp
0  88641  womacto01  2006     2  ...  0.0  3.0  0.0   0.0
1  88643  schilcu01  2006     1  ...  0.0  0.0  0.0   0.0
..  ...      ...      ...  ...  ...  ...  ...  ...
98  89533  aloumo01  2007     1  ...  2.0  0.0  3.0  13.0
99  89534  alomasa02  2007     1  ...  0.0  0.0  0.0   0.0

```

(continues on next page)

(continued from previous page)

```
[100 rows x 23 columns]

In [108]: baseball.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
id            100 non-null int64
player       100 non-null object
year         100 non-null int64
stint        100 non-null int64
team         100 non-null object
lg           100 non-null object
g            100 non-null int64
ab           100 non-null int64
r            100 non-null int64
h            100 non-null int64
X2b          100 non-null int64

gidp         100 non-null float64
dtypes: float64(9), int64(11), object(3)
memory usage: 18.0+ KB
```

However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won't always fit the console width:

| In [109]: print(baseball.iloc[-20:, :12].to_string()) |       |           |      |       |      |    |     |     |    |     |     |     |
|---|-------|-----------|------|-------|------|----|-----|-----|----|-----|-----|-----|
|   | id    | player    | year | stint | team | lg | g   | ab  | r  | h   | X2b | X3b |

(continues on next page)

(continued from previous page)

|    |       |           |      |   |     |    |     |     |    |     |    |   |
|----|-------|-----------|------|---|-----|----|-----|-----|----|-----|----|---|
| 97 | 89530 | ausmubr01 | 2007 | 1 | HOU | NL | 117 | 349 | 38 | 82  | 16 | 3 |
| 98 | 89533 | aloumo01  | 2007 | 1 | NYN | NL | 87  | 328 | 51 | 112 | 19 | 1 |
| 99 | 89534 | alomasa02 | 2007 | 1 | NYN | NL | 8   | 22  | 1  | 3   | 1  | 0 |

Wide DataFrames will be printed across multiple rows by default:

```
In [110]: pd.DataFrame(np.random.randn(3, 12))
Out[110]:
```

|   | 0         | 1         | 2         | 3        | 4        | ... | 7         | 8         | ... | 11  |
|---|-----------|-----------|-----------|----------|----------|-----|-----------|-----------|-----|-----|
| 0 | -0.345352 | 1.314232  | 0.690579  | 0.995761 | 2.396780 | ... | -0.317441 | -1.236269 | 0.  | ... |
| 1 | -2.182937 | 0.380396  | 0.084844  | 0.432390 | 1.519970 | ... | 0.274230  | 0.132885  | -0. | ... |
| 2 | 0.206053  | -0.251905 | -2.213588 | 1.063327 | 1.266143 | ... | 0.408204  | -1.048089 | -0. | ... |

[3 rows x 12 columns]

You can change how much to print on a single row by setting the `display.width` option:

```
In [111]: pd.set_option('display.width', 40) # default is 80
In [112]: pd.DataFrame(np.random.randn(3, 12))
Out[112]:
```

|   | 0        | 1         | 2         | 3         | 4         | ... | 7         | 8         | ... | 11  |
|---|----------|-----------|-----------|-----------|-----------|-----|-----------|-----------|-----|-----|
| 0 | 1.262731 | 1.289997  | 0.082423  | -0.055758 | 0.536580  | ... | -0.034571 | -2.484478 | -0. | ... |
| 1 | 1.126203 | -0.977349 | 1.474071  | -0.064034 | -1.282782 | ... | 0.441153  | 2.353925  | 0.  | ... |
| 2 | 0.758527 | 1.729689  | -0.964980 | -0.845696 | -1.340896 | ... | 1.682706  | -1.717693 | 0.  | ... |

[3 rows x 12 columns]

You can adjust the max width of the individual columns by setting `display.max_colwidth`

```
In [113]: datafile={'filename': ['filename_01', 'filename_02'],
.....:               'path': ["media/user_name/storage/folder_01/filename_01",
.....:                        "media/user_name/storage/folder_02/filename_02"]}
In [114]: pd.set_option('display.max_colwidth', 30)
In [115]: pd.DataFrame(datafile)
Out[115]:
```

|   | filename    | path                          |
|---|-------------|-------------------------------|
| 0 | filename_01 | media/user_name/storage/fo... |
| 1 | filename_02 | media/user_name/storage/fo... |

```
In [116]: pd.set_option('display.max_colwidth', 100)
In [117]: pd.DataFrame(datafile)
Out[117]:
```

|   | filename    | path  |
|---|-------------|---|
| 0 | filename_01 | media/user_name/storage/folder_01/filename_01 |
| 1 | filename_02 | media/user_name/storage/folder_02/filename_02 |

(continues on next page)

(continued from previous page)

```
0 filename_01 media/user_name/storage/folder_01/filename_01
1 filename_02 media/user_name/storage/folder_02/filename_02
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.

### 8.2.15 DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```
In [118]: df = pd.DataFrame({'foo1' : np.random.randn(5),
.....:                       'foo2' : np.random.randn(5)})
.....:
```

```
In [119]: df
```

Out [119] :

|   | foo1      | foo2      |
|---|-----------|-----------|
| 0 | 1.171216  | -0.858447 |
| 1 | 0.520260  | 0.306996  |
| 2 | -1.197071 | -0.028665 |
| 3 | -1.066969 | 0.384316  |
| 4 | -0.303421 | 1.574159  |

```
In [120]: df.foo1
```

```
0    1.171216
1    0.520260
2   -1.197071
3   -1.066969
4   -0.303421
Name: fool, dtype: float64
```

The columns are also connected to the `IPython` completion mechanism so they can be tab-completed:

```
In [5]: df.fo<TAB>
df.foo1  df.foo2
```

## 8.3 Panel

**Warning:** In 0.20.0, `Panel` is deprecated and will be removed in a future version. See the section [Deprecate Panel](#).

Panel is a somewhat less-used, but still important container for 3-dimensional data. The term **panel data** is derived from econometrics and is partially responsible for the name pandas: pan(el)-da(ta)-s. The names for the 3 axes are intended to give some semantic meaning to describing operations involving panel data and, in particular, econometric analysis of panel data. However, for the strict purposes of slicing and dicing a collection of DataFrame objects, you may find the axis names slightly arbitrary:

- **items:** axis 0, each item corresponds to a DataFrame contained inside
- **major axis:** axis 1, it is the **index** (rows) of each of the DataFrames

- **minor\_axis**: axis 2, it is the **columns** of each of the DataFrames

Construction of Panels works about like you would expect:

### 8.3.1 From 3D ndarray with optional axis labels

```
In [121]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
.....:                  major_axis=pd.date_range('1/1/2000', periods=5),
.....:                  minor_axis=['A', 'B', 'C', 'D'])
.....:

In [122]: wp
Out[122]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

### 8.3.2 From dict of DataFrame objects

```
In [123]: data = {'Item1' : pd.DataFrame(np.random.randn(4, 3)),
.....:            'Item2' : pd.DataFrame(np.random.randn(4, 2))}
.....:

In [124]: pd.Panel(data)
Out[124]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 3
Minor_axis axis: 0 to 2
```

Note that the values in the dict need only be **convertible to DataFrame**. Thus, they can be any of the other valid inputs to DataFrame as per above.

One helpful factory method is `Panel.from_dict`, which takes a dictionary of DataFrames as above, and the following named parameters:

| Parameter              | Default            | Description  |
|------------------------|--------------------|--|
| <code>intersect</code> | <code>False</code> | drops elements whose indices do not align                        |
| <code>orient</code>    | <code>items</code> | use <code>minor</code> to use DataFrames' columns as panel items |

For example, compare to the construction above:

```
In [125]: pd.Panel.from_dict(data, orient='minor')
Out[125]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: 0 to 2
Major_axis axis: 0 to 3
Minor_axis axis: Item1 to Item2
```

`Orient` is especially useful for mixed-type DataFrames. If you pass a dict of DataFrame objects with mixed-type columns, all of the data will get upcasted to `dtype=object` unless you pass `orient='minor'`:

```

In [126]: df = pd.DataFrame({'a': ['foo', 'bar', 'baz'],
.....:                      'b': np.random.randn(3)})
.....:

In [127]: df
Out[127]:
   a      b
0  foo -0.308853
1  bar -0.681087
2  baz  0.377953

In [128]: data = {'item1': df, 'item2': df}

In [129]: panel = pd.Panel.from_dict(data, orient='minor')

In [130]: panel['a']
Out[130]:
   item1 item2
0   foo   foo
1   bar   bar
2   baz   baz

In [131]: panel['b']
Out[131]:
   item1 item2
0 -0.308853 -0.308853
1 -0.681087 -0.681087
2  0.377953  0.377953

In [132]: panel['b'].dtypes
Out[132]:
item1    float64
item2    float64
dtype: object

```

**Note:** Panel, being less commonly used than Series and DataFrame, has been slightly neglected feature-wise. A number of methods and options available in DataFrame are not available in Panel.

### 8.3.3 From DataFrame using `to_panel` method

`to_panel` converts a DataFrame with a two-level index to a Panel.

```

In [133]: midx = pd.MultiIndex(levels=[['one', 'two'], ['x', 'y']], labels=[[1, 1, 0, 0],
.....:                               [1, 0, 1, 0]])
.....:

In [134]: df = pd.DataFrame({'A': [1, 2, 3, 4], 'B': [5, 6, 7, 8]}, index=midx)

In [135]: df.to_panel()
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: A to B

```

(continues on next page)

(continued from previous page)

```
Major_axis axis: one to two
Minor_axis axis: x to y
```

### 8.3.4 Item selection / addition / deletion

Similar to DataFrame functioning as a dict of Series, Panel is like a dict of DataFrames:

```
In [136]: wp['Item1']
Out[136]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 1.588931  | 0.476720  | 0.473424  | -0.242861 |
| 2000-01-02 | -0.014805 | -0.284319 | 0.650776  | -1.461665 |
| 2000-01-03 | -1.137707 | -0.891060 | -0.693921 | 1.613616  |
| 2000-01-04 | 0.464000  | 0.227371  | -0.496922 | 0.306389  |
| 2000-01-05 | -2.290613 | -1.134623 | -1.561819 | -0.260838 |

```
In [137]: wp['Item3'] = wp['Item1'] / wp['Item2']
```

The API for insertion and deletion is the same as for DataFrame. And as with DataFrame, if the item is a valid Python identifier, you can access it as an attribute and tab-complete it in IPython.

### 8.3.5 Transposing

A Panel can be rearranged using its `transpose` method (which does not make a copy by default unless the data are heterogeneous):

```
In [138]: wp.transpose(2, 0, 1)
Out[138]:
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 5 (minor_axis)
Items axis: A to D
Major_axis axis: Item1 to Item3
Minor_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
```

### 8.3.6 Indexing / Selection

| Operation                     | Syntax                        | Result    |
|-------------------------------|-------------------------------|-----------|
| Select item                   | <code>wp[item]</code>         | DataFrame |
| Get slice at major_axis label | <code>wp.major_xs(val)</code> | DataFrame |
| Get slice at minor_axis label | <code>wp.minor_xs(val)</code> | DataFrame |

For example, using the earlier example data, we could do:

```
In [139]: wp['Item1']
Out[139]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 1.588931  | 0.476720  | 0.473424  | -0.242861 |
| 2000-01-02 | -0.014805 | -0.284319 | 0.650776  | -1.461665 |
| 2000-01-03 | -1.137707 | -0.891060 | -0.693921 | 1.613616  |
| 2000-01-04 | 0.464000  | 0.227371  | -0.496922 | 0.306389  |

(continues on next page)

(continued from previous page)

```
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838
```

```
In [140]: wp.major_xs(wp.major_axis[2])
```

```

////////////////////////////////////
↪
      Item1      Item2      Item3
A -1.137707  0.800193 -1.421791
B -0.891060  0.782098 -1.139320
C -0.693921 -1.069094  0.649074
D  1.613616 -1.099248 -1.467927

```

```
In [141]: wp.minor_axis
```

```

////////////////////////////////////
↪Index(['A', 'B', 'C', 'D'], dtype='object')
```

```
In [142]: wp.minor_xs('C')
```

```

////////////////////////////////////
↪
      Item1      Item2      Item3
2000-01-01  0.473424 -0.902937 -0.524316
2000-01-02  0.650776 -1.144073 -0.568824
2000-01-03 -0.693921 -1.069094  0.649074
2000-01-04 -0.496922  0.661084 -0.751678
2000-01-05 -1.561819 -1.056652  1.478083

```

### 8.3.7 Squeezing

Another way to change the dimensionality of an object is to squeeze a 1-len object, similar to `wp['Item1']`.

```
In [143]: wp.reindex(items=['Item1']).squeeze()
```

```
Out[143]:
      A      B      C      D
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02 -0.014805 -0.284319  0.650776 -1.461665
2000-01-03 -1.137707 -0.891060 -0.693921  1.613616
2000-01-04  0.464000  0.227371 -0.496922  0.306389
2000-01-05 -2.290613 -1.134623 -1.561819 -0.260838
```

```
In [144]: wp.reindex(items=['Item1'], minor=['B']).squeeze()
```

```

////////////////////////////////////
↪
2000-01-01    0.476720
2000-01-02   -0.284319
2000-01-03   -0.891060
2000-01-04    0.227371
2000-01-05   -1.134623
Freq: D, Name: B, dtype: float64

```

### 8.3.8 Conversion to DataFrame

A Panel can be represented in 2D form as a hierarchically indexed DataFrame. See the section [hierarchical indexing](#) for more on this. To convert a Panel to a DataFrame, use the `to_frame` method:

```
In [145]: panel = pd.Panel(np.random.randn(3, 5, 4), items=['one', 'two', 'three'],
.....:                    major_axis=pd.date_range('1/1/2000', periods=5),
.....:                    minor_axis=['a', 'b', 'c', 'd'])
.....:
```

```
In [146]: panel.to_frame()
```

```
Out[146]:
```

|            |            | one       | two       | three     |           |
|------------|------------|-----------|-----------|-----------|-----------|
| major      | minor      |           |           |           |           |
|            | 2000-01-01 | a         | 0.493672  | 1.219492  | -1.290493 |
|            |            | b         | -2.461467 | 0.062297  | 0.787872  |
|            |            | c         | -1.553902 | -0.110388 | 1.515707  |
| 2000-01-02 | d          | 2.015523  | -1.184357 | -0.276487 |           |
|            | a          | -1.833722 | -0.558081 | -0.223762 |           |
|            | b          | 1.771740  | 0.077849  | 1.397431  |           |
|            | c          | -0.670027 | 0.629498  | 1.503874  |           |
| 2000-01-03 | d          | 0.049307  | -1.035260 | -0.478905 |           |

## 8.4 Deprecate Panel

Over the last few years, pandas has increased in both breadth and depth, with new features, datatype support, and manipulation routines. As a result, supporting efficient indexing and functional routines for Series, DataFrame and Panel has contributed to an increasingly fragmented and difficult-to-understand codebase.

The 3-D structure of a Panel is much less common for many types of data analysis, than the 1-D of the Series or the 2-D of the DataFrame. Going forward it makes sense for pandas to focus on these areas exclusively.

Oftentimes, one can simply use a MultiIndex DataFrame for easily working with higher dimensional data.

In addition, the xarray package was built from the ground up, specifically in order to support the multi-dimensional analysis that is one of Panel's main usecases. [Here is a link to the xarray panel-transition documentation.](#)

```
In [147]: p = tm.makePanel()
```

```
In [148]: p
```

```
Out[148]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 30 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-02-11 00:00:00
Minor_axis axis: A to D
```

Convert to a MultiIndex DataFrame.

```
In [149]: p.to_frame()
```

```
Out [149]:
```

|            |       | ItemA     | ItemB     | ItemC     |
|------------|-------|-----------|-----------|-----------|
| major      | minor |           |           |           |

           B      -0.026671 -0.899454  0.124808
           C      -0.244548 -2.019610  0.931536
           D      -0.917368  0.479630  0.870690

```

```
[120 rows x 3 columns]
```

Alternatively, one can convert to an xarray DataArray.

```

In [150]: p.to_xarray()
Out [150]:
<xarray.DataArray (items: 3, major_axis: 30, minor_axis: 4)>
array([[[ -0.390201,  1.562443, -1.085663,  0.136235],
        [ 1.207122,  0.763264, -1.114738,  0.886313],
        ...,
        [ 1.592673, -0.571329,  1.998044,  0.303638],
        [ 1.559318, -0.026671, -0.244548, -0.917368]],

       [[ -1.624062,  0.483103,  0.768159, -0.021763],
        [-0.758514,  0.061495,  0.225441, -0.047152],
        ...,
        [ 2.137827, -1.761442,  0.292058,  0.388254],
        [ 0.452429, -0.899454, -2.01961 ,  0.47963 ]],

       [[ -0.605044,  0.583129, -0.273458, -0.700648],
        [ 0.878404, -0.87669 , -0.335117, -1.166607],
        ...,
        [-1.82874 , -0.826439, -0.280343, -0.500569],
        [-1.716981,  0.124808,  0.931536,  0.87069 ]]])
Coordinates:
  * items          (items) object 'ItemA' 'ItemB' 'ItemC'
  * major_axis     (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05 ...
  * minor_axis     (minor_axis) object 'A' 'B' 'C' 'D'

```

You can see the full-documentation for the [xarray](#) package.

## ESSENTIAL BASIC FUNCTIONALITY

Here we discuss a lot of the essential functionality common to the pandas data structures. Here's how to create some of the objects used in the examples from the previous section:

```
In [1]: index = pd.date_range('1/1/2000', periods=8)

In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index,
...:                      columns=['A', 'B', 'C'])
...:
...:

In [4]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
...:                 major_axis=pd.date_range('1/1/2000', periods=5),
...:                 minor_axis=['A', 'B', 'C', 'D'])
...:
...:
```

### 9.1 Head and Tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```
In [5]: long_series = pd.Series(np.random.randn(1000))

In [6]: long_series.head()
Out[6]:
0    0.229453
1    0.304418
2    0.736135
3   -0.859631
4   -0.424100
dtype: float64

In [7]: long_series.tail(3)
Out[7]:
997   -0.351587
998    1.136249
999   -0.448789
dtype: float64
```

## 9.2 Attributes and the raw ndarray(s)

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray
- Axis labels
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*
  - **Panel**: *items*, *major\_axis*, and *minor\_axis*

Note, these attributes can be safely assigned to!

```
In [8]: df[:2]
Out[8]:
```

|            | A         | B         | C        |
|------------|-----------|-----------|----------|
| 2000-01-01 | 0.048869  | -1.360687 | -0.47901 |
| 2000-01-02 | -0.859661 | -0.231595 | -0.52775 |

```
In [9]: df.columns = [x.lower() for x in df.columns]

In [10]: df
Out[10]:
```

|            | a         | b         | c         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | 0.048869  | -1.360687 | -0.479010 |
| 2000-01-02 | -0.859661 | -0.231595 | -0.527750 |
| 2000-01-03 | -1.296337 | 0.150680  | 0.123836  |
| 2000-01-04 | 0.571764  | 1.555563  | -0.823761 |
| 2000-01-05 | 0.535420  | -1.032853 | 1.469725  |
| 2000-01-06 | 1.304124  | 1.449735  | 0.203109  |
| 2000-01-07 | -1.032011 | 0.969818  | -0.962723 |
| 2000-01-08 | 1.382083  | -0.938794 | 0.669142  |

To get the actual data inside a data structure, one need only access the **values** property:

```
In [11]: s.values
Out[11]: array([-1.9339,  0.3773,  0.7341,  2.1416, -0.0112])

In [12]: df.values
Out[12]:
```

```
array([[ 0.0489, -1.3607, -0.479 ],
       [-0.8597, -0.2316, -0.5278],
       [-1.2963,  0.1507,  0.1238],
       [ 0.5718,  1.5556, -0.8238],
       [ 0.5354, -1.0329,  1.4697],
       [ 1.3041,  1.4497,  0.2031],
       [-1.032 ,  0.9698, -0.9627],
       [ 1.3821, -0.9388,  0.6691]])

In [13]: wp.values
Out[13]:
```

```
array([[[-0.4336, -0.2736,  0.6804, -0.3084],
        [-0.2761, -1.8212, -1.9936, -1.9274],
        [-2.0279,  1.625 ,  0.5511,  3.0593],
        [ 0.4553, -0.0307,  0.9357,  1.0612],
```

(continues on next page)

(continued from previous page)

```

[-2.1079,  0.1999,  0.3236, -0.6416]],
[[-0.5875,  0.0539,  0.1949, -0.382 ],
 [ 0.3186,  2.0891, -0.7283, -0.0903],
 [-0.7482,  1.3189, -2.0298,  0.7927],
 [ 0.461 , -0.5427, -0.3054, -0.4792],
 [ 0.095 , -0.2701, -0.7071, -0.7739]]])

```

If a `DataFrame` or `Panel` contains homogeneously-typed data, the `ndarray` can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the `DataFrame`'s columns are not all the same dtype), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the dtype of the resulting `ndarray` will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

## 9.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the `numexpr` library and the `bottleneck` libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. `numexpr` uses smart chunking, caching, and multiple cores. `bottleneck` is a set of specialized cython routines that are especially fast when dealing with arrays that have nans.

Here is a sample (using 100 column x 100,000 row `DataFrames`):

| Operation                 | 0.11.0 (ms) | Prior Version (ms) | Ratio to Prior |
|---------------------------|-------------|--------------------|----------------|
| <code>df1 &gt; df2</code> | 13.32       | 125.35             | 0.1063         |
| <code>df1 * df2</code>    | 21.71       | 36.63              | 0.5928         |
| <code>df1 + df2</code>    | 22.04       | 36.50              | 0.6039         |

You are highly encouraged to install both libraries. See the section [Recommended Dependencies](#) for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```

pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)

```

## 9.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. `DataFrame`) and lower-dimensional (e.g. `Series`) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.

### 9.4.1 Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the *index* or *columns* via the *axis* keyword:

```
In [14]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c']
↳ ),
.....:                    'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c'
↳ ', 'd']),
.....:                    'three' : pd.Series(np.random.randn(3), index=['b', 'c',
↳ 'd'])})
.....:

In [15]: df
Out[15]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | -1.101558 | 1.124472  | NaN       |
| b | -0.177289 | 2.487104  | -0.634293 |
| c | 0.462215  | -0.486066 | 1.931194  |
| d | NaN       | -0.456288 | -1.222918 |

```
In [16]: row = df.iloc[1]

In [17]: column = df['two']

In [18]: df.sub(row, axis='columns')
Out[18]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | -0.924269 | -1.362632 | NaN       |
| b | 0.000000  | 0.000000  | 0.000000  |
| c | 0.639504  | -2.973170 | 2.565487  |
| d | NaN       | -2.943392 | -0.588625 |

```
In [19]: df.sub(row, axis=1)
////////////////////////////////////
↳
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | -0.924269 | -1.362632 | NaN       |
| b | 0.000000  | 0.000000  | 0.000000  |
| c | 0.639504  | -2.973170 | 2.565487  |

1    1
2    2
3    0
4    0
5    1
6    1
7    2
8    2
9    3
dtype: int64
```

## 9.4.2 Missing data / operations with fill values

In Series and DataFrame, the arithmetic functions have the option of inputting a *fill\_value*, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using `fillna` if you wish).

```
In [41]: df
```

```
Out[41]:
```

```
   one    two    three
a -1.101558  1.124472    NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d      NaN -0.456288 -1.222918
```

```
In [42]: df2
```

```
   one    two    three
a -1.101558  1.124472  1.000000
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d      NaN -0.456288 -1.222918
```

(continues on next page)

(continued from previous page)

**In [43]:** df + df2

```

////////////////////////////////////
↪
      one      two      three
a -2.203116  2.248945      NaN
b -0.354579  4.974208 -1.268586
c  0.924429 -0.972131  3.862388
d         NaN -0.912575 -2.445837

```

**In [44]:** df.add(df2, fill\_value=0)

```

////////////////////////////////////
↪
      one      two      three
a -2.203116  2.248945  1.000000
b -0.354579  4.974208 -1.268586
c  0.924429 -0.972131  3.862388
d         NaN -0.912575 -2.445837

```

### 9.4.3 Flexible Comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

**In [45]:** df.gt(df2)**Out[45]:**

```

      one      two      three
a False False False
b False False False
c False False False
d False False False

```

**In [46]:** df2.ne(df)

```

////////////////////////////////////
↪
      one      two      three
a False False  True
b False False False
c False False False
d  True False False

```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on [Boolean indexing](#).

### 9.4.4 Boolean Reductions

You can apply the reductions: `empty()`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

**In [47]:** (df > 0).all()**Out[47]:**

```

one      False
two      False
three    False

```

(continues on next page)

(continued from previous page)

```
dtype: bool

In [48]: (df > 0).any()
\\Out[48]:
one      True
two      True
three    True
dtype: bool
```

You can reduce to a final boolean value.

```
In [49]: (df > 0).any().any()
Out[49]: True
```

You can test if a pandas object is empty, via the *empty* property.

```
In [50]: df.empty
Out[50]: False

In [51]: pd.DataFrame(columns=list('ABC')).empty
\\Out[51]: True
```

To evaluate single-element pandas objects in a boolean context, use the method *bool()*:

```
In [52]: pd.Series([True]).bool()
Out[52]: True

In [53]: pd.Series([False]).bool()
\\Out[53]: False

In [54]: pd.DataFrame([[True]]).bool()
\\Out[54]: True

In [55]: pd.DataFrame([[False]]).bool()
\\Out[55]: False
```

**Warning:** You might be tempted to do the following:

```
>>> if df:
    ...
```

Or

```
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.
->all().
```

See *gotchas* for a more detailed discussion.

### 9.4.5 Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df+df` and `df*2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df+df == df*2).all()`. But in fact, this expression is `False`:

```
In [56]: df+df == df*2
```

```
Out[56]:
```

```
      one  two  three
a   True  True  False
b   True  True   True
c   True  True   True
d  False  True   True
```

```
In [57]: (df+df == df*2).all()
```

```

////////////////////////////////////
↪
one      False
two       True
three    False
dtype: bool
```

Notice that the boolean DataFrame `df+df == df*2` contains some `False` values! This is because NaNs do not compare as equals:

```
In [58]: np.nan == np.nan
```

```
Out[58]: False
```

So, NDFrames (such as Series, DataFrames, and Panels) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [59]: (df+df).equals(df*2)
```

```
Out[59]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be `True`:

```
In [60]: df1 = pd.DataFrame({'col': ['foo', 0, np.nan]})
```

```
In [61]: df2 = pd.DataFrame({'col': [np.nan, 0, 'foo']}, index=[2,1,0])
```

```
In [62]: df1.equals(df2)
```

```
Out[62]: False
```

```
In [63]: df1.equals(df2.sort_index())
```

```
Out[63]: True
```

### 9.4.6 Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [64]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
```

```
Out[64]:
```

```
0      True
1     False
2     False
dtype: bool
```

(continues on next page)

(continued from previous page)

```
In [65]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[65]: array([ True, False,  False], dtype=bool)
```

Pandas also handles element-wise comparisons between different array-like objects of the same length:

```
In [66]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[66]:
0    True
1    True
2   False
dtype: bool

In [67]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[67]:
0    True
1    True
2   False
dtype: bool
```

Trying to compare Index or Series objects of different lengths will raise a `ValueError`:

```
In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare
```

Note that this is different from the NumPy behavior where a comparison can be broadcast:

```
In [68]: np.array([1, 2, 3]) == np.array([2])
Out[68]: array([False,  True, False], dtype=bool)
```

or it can return `False` if broadcasting can not be done:

```
In [69]: np.array([1, 2, 3]) == np.array([1, 2])
Out[69]: False
```

## 9.4.7 Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two `DataFrame` objects where missing values in one `DataFrame` are conditionally filled with like-labeled values from the other `DataFrame`. The function implementing this operation is `combine_first()`, which we illustrate:

```
In [70]: df1 = pd.DataFrame({'A' : [1., np.nan, 3., 5., np.nan],
.....:                      'B' : [np.nan, 2., 3., np.nan, 6.]})

In [71]: df2 = pd.DataFrame({'A' : [5., 2., 4., np.nan, 3., 7.],
.....:                      'B' : [np.nan, np.nan, 3., 4., 6., 8.]})
```

(continues on next page)

(continued from previous page)

```

.....:

In [72]: df1
Out[72]:
   A    B
0  1.0 NaN
1  NaN  2.0
2  3.0  3.0
3  5.0 NaN
4  NaN  6.0

In [73]: df2
Out[73]:
   A    B
0  5.0 NaN
1  2.0 NaN
2  4.0  3.0
3  NaN  4.0
4  3.0  6.0
5  7.0  8.0

In [74]: df1.combine_first(df2)
Out[74]:
   A    B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0

```

### 9.4.8 General DataFrame Combine

The `combine_first()` method above calls the more general `DataFrame.combine()`. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```

In [75]: combiner = lambda x, y: np.where(pd.isna(x), y, x)

In [76]: df1.combine(df2, combiner)
Out[76]:
   A    B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0

```

## 9.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on *Series*, *DataFrame*, and *Panel*. Most of these are aggregations (hence producing a lower-dimensional result) like `sum()`, `mean()`, and `quantile()`, but some of them, like `cumsum()` and `cumprod()`, produce an object of the same size. Generally speaking, these methods take an **axis** argument, just like `ndarray.{sum, std, ...}`, but the axis can be specified by name or integer:

- **Series:** no axis argument needed
- **DataFrame:** “index” (axis=0, default), “columns” (axis=1)
- **Panel:** “items” (axis=0), “major” (axis=1, default), “minor” (axis=2)

For example:

```
In [77]: df
Out[77]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | -1.101558 | 1.124472  | NaN       |
| b | -0.177289 | 2.487104  | -0.634293 |
| c | 0.462215  | -0.486066 | 1.931194  |
| d | NaN       | -0.456288 | -1.222918 |

```
In [78]: df.mean(0)
```

```

////////////////////////////////////
↪
one      -0.272211
two       0.667306
three     0.024661
dtype: float64
```

```
In [79]: df.mean(1)
```

```

////////////////////////////////////
↪
a      0.011457
b      0.558507
c      0.635781
d     -0.839603
dtype: float64
```

All such methods have a `skipna` option signaling whether to exclude missing data (True by default):

```
In [80]: df.sum(0, skipna=False)
```

```

Out[80]:
one      NaN
two      2.669223
three     NaN
dtype: float64
```

```
In [81]: df.sum(axis=1, skipna=True)
```

```

////////////////////////////////////Out[81]:
↪
a      0.022914
b      1.675522
c      1.907343
d     -1.679206
dtype: float64
```

Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```
In [82]: ts_stand = (df - df.mean()) / df.std()

In [83]: ts_stand.std()
Out[83]:
one      1.0
two      1.0
three    1.0
dtype: float64

In [84]: xs_stand = df.sub(df.mean(1), axis=0).div(df.std(1), axis=0)

In [85]: xs_stand.std(1)
Out[85]:
a      1.0
b      1.0
c      1.0
d      1.0
dtype: float64
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see [this note](#).

```
In [86]: df.cumsum()
Out[86]:
```

|   | one       | two      | three     |
|---|-----------|----------|-----------|
| a | -1.101558 | 1.124472 | NaN       |
| b | -1.278848 | 3.611576 | -0.634293 |
| c | -0.816633 | 3.125511 | 1.296901  |
| d | NaN       | 2.669223 | 0.073983  |

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a [hierarchical index](#).

| Function | Description                                |
|----------|--|
| count    | Number of non-NA observations              |
| sum      | Sum of values                              |
| mean     | Mean of values                             |
| mad      | Mean absolute deviation                    |
| median   | Arithmetic median of values                |
| min      | Minimum                                    |
| max      | Maximum                                    |
| mode     | Mode                                       |
| abs      | Absolute Value                             |
| prod     | Product of values                          |
| std      | Bessel-corrected sample standard deviation |
| var      | Unbiased variance                          |
| sem      | Standard error of the mean                 |
| skew     | Sample skewness (3rd moment)               |
| kurt     | Sample kurtosis (4th moment)               |
| quantile | Sample quantile (value at %)               |
| cumsum   | Cumulative sum                             |
| cumprod  | Cumulative product                         |
| cummax   | Cumulative maximum                         |
| cummin   | Cumulative minimum                         |

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```
In [87]: np.mean(df['one'])
Out[87]: -0.27221094480450114

In [88]: np.mean(df['one'].values)
Out[88]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```
In [89]: series = pd.Series(np.random.randn(500))

In [90]: series[20:500] = np.nan

In [91]: series[10:20] = 5

In [92]: series.nunique()
Out[92]: 11
```

### 9.5.1 Summarizing data: describe

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```
In [93]: series = pd.Series(np.random.randn(1000))

In [94]: series[::2] = np.nan

In [95]: series.describe()
Out[95]:
```

(continues on next page)

(continued from previous page)

```

count      500.000000
mean       -0.032127
std        1.067484
min        -3.463789
25%        -0.725523
50%        -0.053230
75%         0.679790
max         3.120271
dtype: float64

In [96]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd',
↳ 'e'])

In [97]: frame.iloc[::2] = np.nan

In [98]: frame.describe()
Out[98]:
```

|       | a          | b          | c          | d          | e          |
|-------|------------|------------|------------|------------|------------|
| count | 500.000000 | 500.000000 | 500.000000 | 500.000000 | 500.000000 |
| mean  | -0.045109  | -0.052045  | 0.024520   | 0.006117   | 0.001141   |
| std   | 1.029268   | 1.002320   | 1.042793   | 1.040134   | 1.005207   |
| min   | -2.915767  | -3.294023  | -3.610499  | -2.907036  | -3.010899  |
| 25%   | -0.763783  | -0.720389  | -0.609600  | -0.665896  | -0.682900  |
| 50%   | -0.086033  | -0.048843  | 0.006093   | 0.043191   | -0.001651  |
| 75%   | 0.663399   | 0.620980   | 0.728382   | 0.735973   | 0.656439   |
| max   | 3.400646   | 2.925597   | 3.416896   | 3.331522   | 3.007143   |

You can select specific percentiles to include in the output:

```

In [99]: series.describe(percentiles=[.05, .25, .75, .95])
Out[99]:
```

|       |            |
|-------|------------|
| count | 500.000000 |
| mean  | -0.032127  |
| std   | 1.067484   |
| min   | -3.463789  |
| 5%    | -1.733545  |
| 25%   | -0.725523  |
| 50%   | -0.053230  |
| 75%   | 0.679790   |
| 95%   | 1.854383   |
| max   | 3.120271   |

```

dtype: float64

```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```

In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])

In [101]: s.describe()
Out[101]:
```

|        |   |
|--------|---|
| count  | 9 |
| unique | 4 |
| top    | a |
| freq   | 5 |

```

dtype: object

```

Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```
In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})

In [103]: frame.describe()
Out[103]:
```

|       | b        |
|-------|----------|
| count | 4.000000 |
| mean  | 1.500000 |
| std   | 1.290994 |
| min   | 0.000000 |
| 25%   | 0.750000 |
| 50%   | 1.500000 |
| 75%   | 2.250000 |
| max   | 3.000000 |

This behaviour can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```
In [104]: frame.describe(include=['object'])
Out[104]:
```

|        | a   |
|--------|-----|
| count  | 4   |
| unique | 2   |
| top    | Yes |
| freq   | 2   |

```
In [105]: frame.describe(include=['number'])
Out[105]:
```

|       | b        |
|-------|----------|
| count | 4.000000 |
| mean  | 1.500000 |
| std   | 1.290994 |
| min   | 0.000000 |
| 25%   | 0.750000 |
| 50%   | 1.500000 |
| 75%   | 2.250000 |
| max   | 3.000000 |

```
In [106]: frame.describe(include='all')
Out[106]:
```

|        | a   | b        |
|--------|-----|----------|
| count  | 4   | 4.000000 |
| unique | 2   | NaN      |
| top    | Yes | NaN      |
| freq   | 2   | NaN      |
| mean   | NaN | 1.500000 |
| std    | NaN | 1.290994 |
| min    | NaN | 0.000000 |
| 25%    | NaN | 0.750000 |
| 50%    | NaN | 1.500000 |
| 75%    | NaN | 2.250000 |
| max    | NaN | 3.000000 |

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.

## 9.5.2 Index of Min/Max Values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```
In [107]: s1 = pd.Series(np.random.randn(5))

In [108]: s1
Out[108]:
0    -1.649461
1     0.169660
2     1.246181
3     0.131682
4    -2.001988
dtype: float64

In [109]: s1.idxmin(), s1.idxmax()
Out[109]:
(4, 2)

In [110]: df1 = pd.DataFrame(np.random.randn(5, 3), columns=['A', 'B', 'C'])

In [111]: df1
Out[111]:
   A         B         C
0 -1.273023  0.870502  0.214583
1  0.088452 -0.173364  1.207466
2  0.546121  0.409515 -0.310515
3  0.585014 -0.490528 -0.054639
4 -0.239226  0.701089  0.228656

In [112]: df1.idxmin(axis=0)
Out[112]:
A    0
B    3
C    2
dtype: int64

In [113]: df1.idxmax(axis=1)
Out[113]:
0    B
1    C
2    A
3    A
4    B
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))

In [115]: df3
Out[115]:
   A
e  2.0
```

(continues on next page)

```
In [116]: df3['A'].idxmin()
Out[116]: 'd'
```

```
In [118]: data
Out[118]:
array([[3, 3, 0, 2, 1, 0, 5, 5, 3, 6, 1, 5, 6, 2, 0, 0, 6, 3, 3, 5, 0, 4, 3,
        3, 3, 0, 6, 1, 3, 5, 5, 0, 4, 0, 6, 3, 6, 5, 4, 3, 2, 1, 5, 0, 1, 1,
        6, 4, 1, 4]])
```

```
In [120]: s.value_counts()
```

```
3      11
0       9
5       8
6       7
1       7
4       5
2       3
dtype: int64
```

```
Out[121]:
3      11
0       9
5       8
6       7
1       7
4       5
2       3
dtype: int64
```

```
In [123]: s5.mode()
```

(continued from previous page)

```

Out[123]:
0      3
1      7
dtype: int64

In [124]: df5 = pd.DataFrame({"A": np.random.randint(0, 7, size=50),
.....:                      "B": np.random.randint(-10, 15, size=50)})
.....:

In [125]: df5.mode()
Out[125]:
   A  B
0  2 -5

```

## 9.5.4 Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```

In [126]: arr = np.random.randn(20)

In [127]: factor = pd.cut(arr, 4)

In [128]: factor
Out[128]:
[(-2.611, -1.58], (0.473, 1.499], (-2.611, -1.58], (-1.58, -0.554], (-0.554, 0.473], .
↪.., (0.473, 1.499], (0.473, 1.499], (-0.554, 0.473], (-0.554, 0.473], (-0.554, 0.
↪473]]
Length: 20
Categories (4, interval[float64]): [(-2.611, -1.58] < (-1.58, -0.554] < (-0.554, 0.
↪473] <
                                     (0.473, 1.499]]

In [129]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

In [130]: factor
Out[130]:
[(-5, -1], (0, 1], (-5, -1], (-1, 0], (-1, 0], ..., (1, 5], (1, 5], (-1, 0], (-1, 0], ↪
↪(-1, 0]]
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5]]

```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quantiles like so:

```

In [131]: arr = np.random.randn(30)

In [132]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])

In [133]: factor
Out[133]:
[(0.544, 1.976], (0.544, 1.976], (-1.255, -0.375], (0.544, 1.976], (-0.103, 0.544], ..
↪.., (-0.103, 0.544], (0.544, 1.976], (-0.103, 0.544], (-1.255, -0.375], (-0.375, -0.
↪103]]
Length: 30

```

(continues on next page)

(continued from previous page)

```
Categories (4, interval[float64]): [(-1.255, -0.375] < (-0.375, -0.103] < (-0.103, 0.
↪ 544] <
                                     (0.544, 1.976]]
```

```
In [134]: pd.value_counts(factor)
```

```
//////////////////////////////////////
↪
(0.544, 1.976]      8
(-1.255, -0.375]   8
(-0.103, 0.544]    7
(-0.375, -0.103]   7
dtype: int64
```

We can also pass infinite values to define the bins:

```
In [135]: arr = np.random.randn(20)
```

```
In [136]: factor = pd.cut(arr, [-np.inf, 0, np.inf])
```

```
In [137]: factor
```

```
Out[137]:
[(0.0, inf], (0.0, inf], (0.0, inf], (0.0, inf], (-inf, 0.0], ..., (-inf, 0.0], (-inf,
↪ 0.0], (0.0, inf], (-inf, 0.0], (0.0, inf]]
Length: 20
Categories (2, interval[float64]): [(-inf, 0.0] < (0.0, inf]]
```

## 9.6 Function application

To apply your own or another library's functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire `DataFrame` or `Series`, row- or column-wise, or elementwise.

1. *Tablewise Function Application: `pipe()`*
2. *Row or Column-wise Function Application: `apply()`*
3. *Aggregation API: `agg()` and `transform()`*
4. *Applying Elementwise Functions: `applymap()`*

### 9.6.1 Tablewise Function Application

`DataFrames` and `Series` can of course just be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method. Compare the following

```
# f, g, and h are functions taking and returning ``DataFrames``
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```
>>> (df.pipe(h)
     .pipe(g, arg1=1)
     .pipe(f, arg2=2, arg3=3)
     )
```

Pandas encourages the second style, which is known as method chaining. `pipe` makes it easy to use your own or another library's functions in method chains, alongside pandas' methods.

In the example above, the functions `f`, `g`, and `h` each expected the `DataFrame` as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide `pipe` with a tuple of (callable, `data_keyword`). `pipe` will route the `DataFrame` to the argument specified in the tuple.

For example, we can fit a regression using `statsmodels`. Their API expects a formula first and a `DataFrame` as the second argument, `data`. We pass in the function, keyword pair (`sm.ols`, `'data'`) to `pipe`:

```
In [138]: import statsmodels.formula.api as sm

In [139]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [140]: (bb.query('h > 0')
.....:      .assign(ln_h = lambda df: np.log(df.h))
.....:      .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
.....:      .fit()
.....:      .summary()
.....: )
Out[140]:
<class 'statsmodels.iolib.summary.Summary'>
"""

    ↪specified.
[2] The condition number is large, 1.49e+07. This might indicate that there are
    strong multicollinearity or other numerical problems.
"""
```

The `pipe` method is inspired by unix pipes and more recently `dplyr` and `magrittr`, which have introduced the popular (`%>%`) (read pipe) operator for `R`. The implementation of `pipe` here is quite clean and feels right at home in python.

We encourage you to view the source code of `pipe()`.

## 9.6.2 Row or Column-wise Function Application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```
In [141]: df.apply(np.mean)
Out[141]:
one      -0.272211
two       0.667306
three     0.024661
dtype: float64

In [142]: df.apply(np.mean, axis=1)
Out[142]:
a      0.011457
b      0.558507
c      0.635781
d     -0.839603
dtype: float64

In [143]: df.apply(lambda x: x.max() - x.min())
Out[143]:
one      1.563773
two      2.973170
three    3.154112
dtype: float64

In [144]: df.apply(np.cumsum)
Out[144]:
      one      two      three
a -1.101558  1.124472      NaN
b -1.278848  3.611576 -0.634293
c -0.816633  3.125511  1.296901
d      NaN  2.669223  0.073983

In [145]: df.apply(np.exp)
Out[145]:
      one      two      three
a  0.332353  3.078592      NaN
b  0.837537 12.026397  0.53031
c  1.587586  0.615041  6.89774
d      NaN  0.633631  0.29437
```

The `apply()` method will also dispatch on a string method name.

```
In [146]: df.apply('mean')
Out[146]:
one      -0.272211
two       0.667306
three     0.024661
dtype: float64
```

(continues on next page)

(continued from previous page)

```

In [147]: df.apply('mean', axis=1)
Out[147]:
a    0.011457
b    0.558507
c    0.635781
d   -0.839603
dtype: float64

```

The return type of the function passed to `apply()` affects the type of the final output from `DataFrame.apply` for the default behaviour:

- If the applied function returns a `Series`, the final output is a `DataFrame`. The columns match the index of the `Series` returned by the applied function.
- If the applied function returns any other type, the final output is a `Series`.

This default behaviour can be overridden using the `result_type`, which accepts three options: `reduce`, `broadcast`, and `expand`. These will determine how list-like return values expand (or not) to a `DataFrame`.

`apply()` combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

```

In [148]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=1000))
.....:

In [149]: tsdf.apply(lambda x: x.idxmax())
Out[149]:
A    2001-04-25
B    2002-05-31
C    2002-09-25
dtype: datetime64[ns]

```

You may also pass additional arguments and keyword arguments to the `apply()` method. For instance, consider the following function you would like to apply:

```

def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide

```

You may then apply this function as follows:

```
df.apply(subtract_and_divide, args=(5,), divide=3)
```

Another useful feature is the ability to pass `Series` methods to carry out some `Series` operation on each column or row:

```

In [150]: tsdf
Out[150]:
          A          B          C
2000-01-01 -0.720299  0.546303 -0.082042
2000-01-02  0.200295 -0.577554 -0.908402
2000-01-03  0.102533  1.653614  0.303319
2000-01-04         NaN         NaN         NaN
2000-01-05         NaN         NaN         NaN
2000-01-06         NaN         NaN         NaN
2000-01-07         NaN         NaN         NaN

```

(continues on next page)

(continued from previous page)

2000-01-09  0.330418  1.761200  0.567133
2000-01-10 -0.251020  1.020099  1.893177

```

```
In [151]: tsdf.apply(pd.Series.interpolate)
```

```

////////////////////////////////////
↪
      A      B      C
2000-01-01 -0.720299  0.546303 -0.082042
2000-01-02  0.200295 -0.577554 -0.908402
2000-01-03  0.102533  1.653614  0.303319
2000-01-04  0.188539  1.391201  0.272754
2000-01-05  0.274546  1.128788  0.242189
2000-01-06  0.360553  0.866374  0.211624
2000-01-07  0.446559  0.603961  0.181059
2000-01-08  0.532566  0.341548  0.150493
2000-01-09  0.330418  1.761200  0.567133
2000-01-10 -0.251020  1.020099  1.893177

```

Finally, `apply()` takes an argument `raw` which is `False` by default, which converts each row or column into a `Series` before applying the function. When set to `True`, the passed function will instead receive an `ndarray` object, which has positive performance implications if you do not need the indexing functionality.

### 9.6.3 Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see [groupby API](#), the [window functions API](#), and the [resample API](#). The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```
In [152]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
.....:
```

```
In [153]: tsdf.iloc[3:7] = np.nan
```

```
In [154]: tsdf
```

```

Out[154]:
      A      B      C
2000-01-01  0.170247 -0.916844  0.835024
2000-01-02  1.259919  0.801111  0.445614
2000-01-03  1.453046  2.430373  0.653093
2000-01-04      NaN      NaN      NaN
2000-01-05      NaN      NaN      NaN
2000-01-06      NaN      NaN      NaN
2000-01-07      NaN      NaN      NaN
2000-01-08 -1.874526  0.569822 -0.609644
2000-01-09  0.812462  0.565894 -1.461363
2000-01-10 -0.985475  1.388154 -0.078747

```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a `Series` of the aggregated output:

```

In [155]: tsdf.agg(np.sum)
Out[155]:
A    0.835673
B    4.838510
C   -0.216025
dtype: float64

In [156]: tsdf.agg('sum')
Out[156]:
A    0.835673
B    4.838510
C   -0.216025
dtype: float64

# these are equivalent to a ``.sum()`` because we are aggregating on a single function
In [157]: tsdf.sum()
Out[157]:
A    0.835673
B    4.838510
C   -0.216025
dtype: float64

```

Single aggregations on a Series this will return a scalar value:

```

In [158]: tsdf.A.agg('sum')
Out[158]: 0.83567297915820504

```

### 9.6.3.1 Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

```

In [159]: tsdf.agg(['sum'])
Out[159]:
      A      B      C
sum  0.835673  4.83851 -0.216025

```

Multiple functions yield multiple rows:

```

In [160]: tsdf.agg(['sum', 'mean'])
Out[160]:
      A      B      C
sum  0.835673  4.838510 -0.216025
mean 0.139279  0.806418 -0.036004

```

On a Series, multiple functions return a Series, indexed by the function names:

```

In [161]: tsdf.A.agg(['sum', 'mean'])
Out[161]:
sum    0.835673
mean   0.139279
Name: A, dtype: float64

```

Passing a lambda function will yield a <lambda> named row:

```
In [162]: tsdf.A.agg(['sum', lambda x: x.mean()])
Out[162]:
sum          0.835673
<lambda>     0.139279
Name: A, dtype: float64
```

Passing a named function will yield that name for the row:

```
In [163]: def mymean(x):
.....:     return x.mean()
.....:

In [164]: tsdf.A.agg(['sum', mymean])
Out[164]:
sum          0.835673
mymean       0.139279
Name: A, dtype: float64
```

### 9.6.3.2 Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an `OrderedDict` instead to guarantee ordering.

```
In [165]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[165]:
A      0.139279
B      4.838510
dtype: float64
```

Passing a list-like will generate a `DataFrame` output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be `NaN`:

```
In [166]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[166]:
      A      B
mean  0.139279  NaN
min   -1.874526  NaN
sum      NaN  4.83851
```

### 9.6.3.3 Mixed Dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how `groupby.agg` works.

```
In [167]: mdf = pd.DataFrame({'A': [1, 2, 3],
.....:                        'B': [1., 2., 3.],
.....:                        'C': ['foo', 'bar', 'baz'],
.....:                        'D': pd.date_range('20130101', periods=3)})
.....:

In [168]: mdf.dtypes
Out[168]:
A      int64
```

(continues on next page)

(continued from previous page)

```

B          float64
C          object
D    datetime64[ns]
dtype: object

```

```

In [169]: mdf.agg(['min', 'sum'])
Out[169]:
      A      B      C      D
min  1  1.0      bar 2013-01-01
sum  6  6.0 foobarbaz      NaT

```

### 9.6.3.4 Custom describe

With `.agg()` it is possible to easily create a custom describe function, similar to the built in *describe* function.

```

In [170]: from functools import partial

In [171]: q_25 = partial(pd.Series.quantile, q=0.25)

In [172]: q_25.__name__ = '25%'

In [173]: q_75 = partial(pd.Series.quantile, q=0.75)

In [174]: q_75.__name__ = '75%'

In [175]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])
Out[175]:
      A      B      C
count  6.000000  6.000000  6.000000
mean   0.139279  0.806418 -0.036004
std    1.323362  1.100830  0.874990
min   -1.874526 -0.916844 -1.461363
25%   -0.696544  0.566876 -0.476920
median  0.491354  0.685467  0.183433
75%    1.148055  1.241393  0.601223
max    1.453046  2.430373  0.835024

```

### 9.6.4 Transform API

New in version 0.20.0.

The *transform()* method returns an object that is indexed the same (same size) as the original. This API allows you to provide *multiple* operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```

In [176]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
.....:                        index=pd.date_range('1/1/2000', periods=10))
.....:

In [177]: tsdf.iloc[3:7] = np.nan

In [178]: tsdf
Out[178]:

```

(continues on next page)

|            | A         | B         | C         |

| 2000-01-10 | 0.354653 | 0.563622 | 0.365106 |

[illegible]

(continued from previous page)

|            |          |          |          |
|------------|----------|----------|----------|
| 2000-01-09 | 1.010924 | 0.672504 | 1.139222 |
| 2000-01-10 | 0.354653 | 0.563622 | 0.365106 |

Here `transform()` received a single function; this is equivalent to a `ufunc` application.

```
In [182]: np.abs(tsdf)
Out[182]:
```

|            | A        | B        | C        |
|------------|----------|----------|----------|
| 2000-01-01 | 0.578465 | 0.503335 | 0.987140 |
| 2000-01-02 | 0.767147 | 0.266046 | 1.083797 |
| 2000-01-03 | 0.195348 | 0.722247 | 0.894537 |
| 2000-01-04 | NaN      | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      | NaN      |
| 2000-01-08 | 0.556397 | 0.542165 | 0.308675 |
| 2000-01-09 | 1.010924 | 0.672504 | 1.139222 |
| 2000-01-10 | 0.354653 | 0.563622 | 0.365106 |

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.

```
In [183]: tsdf.A.transform(np.abs)
Out[183]:
```

|            |          |
|------------|----------|
| 2000-01-01 | 0.578465 |
| 2000-01-02 | 0.767147 |
| 2000-01-03 | 0.195348 |
| 2000-01-04 | NaN      |
| 2000-01-05 | NaN      |
| 2000-01-06 | NaN      |

| 2000-01-10 | 0.354653 |

Freq: D, Name: A, dtype: float64

### 9.6.4.1 Transform with multiple functions

Passing multiple functions will yield a column multi-indexed `DataFrame`. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```
In [184]: tsdf.transform([np.abs, lambda x: x+1])
Out[184]:
```

|            | A        |           | B        |          | C        |           |
|------------|----------|-----------|----------|----------|----------|-----------|
|            | absolute | <lambda>  | absolute | <lambda> | absolute | <lambda>  |
| 2000-01-01 | 0.578465 | 0.421535  | 0.503335 | 0.496665 | 0.987140 | 0.012860  |
| 2000-01-02 | 0.767147 | 0.232853  | 0.266046 | 0.733954 | 1.083797 | 2.083797  |
| 2000-01-03 | 0.195348 | 1.195348  | 0.722247 | 1.722247 | 0.894537 | 0.105463  |
| 2000-01-04 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-05 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-06 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-07 | NaN      | NaN       | NaN      | NaN      | NaN      | NaN       |
| 2000-01-08 | 0.556397 | 0.443603  | 0.542165 | 1.542165 | 0.308675 | 0.691325  |
| 2000-01-09 | 1.010924 | -0.010924 | 0.672504 | 0.327496 | 1.139222 | -0.139222 |
| 2000-01-10 | 0.354653 | 1.354653  | 0.563622 | 1.563622 | 0.365106 | 0.634894  |

Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```
In [185]: tsdf.A.transform([np.abs, lambda x: x+1])
```

```
Out [185]:
```

|            | absolute | <lambda>  |
|------------|----------|-----------|
| 2000-01-01 | 0.578465 | 0.421535  |
| 2000-01-02 | 0.767147 | 0.232853  |
| 2000-01-03 | 0.195348 | 1.195348  |
| 2000-01-04 | NaN      | NaN       |
| 2000-01-05 | NaN      | NaN       |
| 2000-01-06 | NaN      | NaN       |
| 2000-01-07 | NaN      | NaN       |
| 2000-01-08 | 0.556397 | 0.443603  |
| 2000-01-09 | 1.010924 | -0.010924 |
| 2000-01-10 | 0.354653 | 1.354653  |

### 9.6.4.2 Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```
In [186]: tsdf.transform({'A': np.abs, 'B': lambda x: x+1})
```

```
Out [186]:
```

|            | A        | B        |
|------------|----------|----------|
| 2000-01-01 | 0.578465 | 0.496665 |
| 2000-01-02 | 0.767147 | 0.733954 |
| 2000-01-03 | 0.195348 | 1.722247 |
| 2000-01-04 | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      |
| 2000-01-08 | 0.556397 | 1.542165 |
| 2000-01-09 | 1.010924 | 0.327496 |
| 2000-01-10 | 0.354653 | 1.563622 |

Passing a dict of lists will generate a multi-indexed DataFrame with these selective transforms.

```
In [187]: tsdf.transform({'A': np.abs, 'B': [lambda x: x+1, 'sqrt']})
```

```
Out [187]:
```

|            | A        | B        |          |
|------------|----------|----------|----------|
|            | absolute | <lambda> | sqrt     |
| 2000-01-01 | 0.578465 | 0.496665 | NaN      |
| 2000-01-02 | 0.767147 | 0.733954 | NaN      |
| 2000-01-03 | 0.195348 | 1.722247 | 0.849851 |
| 2000-01-04 | NaN      | NaN      | NaN      |
| 2000-01-05 | NaN      | NaN      | NaN      |
| 2000-01-06 | NaN      | NaN      | NaN      |
| 2000-01-07 | NaN      | NaN      | NaN      |
| 2000-01-08 | 0.556397 | 1.542165 | 0.736318 |
| 2000-01-09 | 1.010924 | 0.327496 | NaN      |
| 2000-01-10 | 0.354653 | 1.563622 | 0.750748 |

### 9.6.5 Applying Elementwise Functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and

returning a single value. For example:

```
In [188]: df4
Out[188]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | -1.101558 | 1.124472  | NaN       |
| b | -0.177289 | 2.487104  | -0.634293 |
| c | 0.462215  | -0.486066 | 1.931194  |
| d | NaN       | -0.456288 | -1.222918 |

```
In [189]: f = lambda x: len(str(x))

In [190]: df4['one'].map(f)
Out[190]:
```

|   |    |
|---|----|
| a | 19 |
| b | 20 |
| c | 18 |
| d | 3  |

```
Name: one, dtype: int64

In [191]: df4.applymap(f)
Out[191]:
```

|   | one | two | three |
|---|-----|-----|-------|
| a | 19  | 18  | 3     |
| b | 20  | 18  | 19    |
| c | 18  | 20  | 18    |
| d | 3   | 19  | 19    |

`Series.map()` has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to *merging/joining functionality*:

```
In [192]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
.....:                  index=['a', 'b', 'c', 'd', 'e'])
.....:

In [193]: t = pd.Series({'six' : 6., 'seven' : 7.})

In [194]: s
Out[194]:
```

|   |       |
|---|-------|
| a | six   |
| b | seven |
| c | six   |
| d | seven |
| e | six   |

```
dtype: object

In [195]: s.map(t)
Out[195]:
```

|   |     |
|---|-----|
| a | 6.0 |
| b | 7.0 |
| c | 6.0 |
| d | 7.0 |
| e | 6.0 |

```
dtype: float64
```

```
In [196]: import pandas.util.testing as tm

In [197]: panel = tm.makePanel(5)

In [198]: panel
Out[198]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [199]: panel['ItemA']
////////////////////////////////////
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 1.092702  | 0.604244  | -2.927808 | 0.339642  |
| 2000-01-04 | -1.481449 | -0.487265 | 0.082065  | 1.499953  |
| 2000-01-05 | 1.781190  | 1.990533  | 0.456554  | -0.317818 |
| 2000-01-06 | -0.031543 | 0.327007  | -1.757911 | 0.447371  |
| 2000-01-07 | 0.480993  | 1.053639  | 0.982407  | -1.315799 |

```
In [200]: result = panel.apply(lambda x: x*2, axis='items')

In [201]: result
Out[201]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [202]: result['ItemA']
////////////////////////////////////
↪
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 2.185405  | 1.208489  | -5.855616 | 0.679285  |
| 2000-01-04 | -2.962899 | -0.974530 | 0.164130  | 2.999905  |
| 2000-01-05 | 3.562379  | 3.981066  | 0.913107  | -0.635635 |
| 2000-01-06 | -0.063086 | 0.654013  | -3.515821 | 0.894742  |
| 2000-01-07 | 0.961986  | 2.107278  | 1.964815  | -2.631598 |

```
In [203]: panel.apply(lambda x: x.dtype, axis='items')
Out[203]:
```

|            | A       | B       | C       | D       |
|------------|---------|---------|---------|---------|
| 2000-01-03 | float64 | float64 | float64 | float64 |
| 2000-01-04 | float64 | float64 | float64 | float64 |
| 2000-01-05 | float64 | float64 | float64 | float64 |

## 9.6. Function application

(continued from previous page)

|            |         |         |         |         |
|------------|---------|---------|---------|---------|
| 2000-01-06 | float64 | float64 | float64 | float64 |
| 2000-01-07 | float64 | float64 | float64 | float64 |

A similar reduction type operation.

```
In [204]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[204]:
```

|   | ItemA     | ItemB     | ItemC     |
|---|-----------|-----------|-----------|
| A | 1.841893  | 0.918017  | -1.160547 |
| B | 3.488158  | -2.629773 | 0.603397  |
| C | -3.164692 | 0.805970  | 0.806501  |
| D | 0.653349  | -0.152299 | 0.252577  |

This last reduction is equivalent to:

```
In [205]: panel.sum('major_axis')
Out[205]:
```

|   | ItemA     | ItemB     | ItemC     |
|---|-----------|-----------|-----------|
| A | 1.841893  | 0.918017  | -1.160547 |
| B | 3.488158  | -2.629773 | 0.603397  |
| C | -3.164692 | 0.805970  | 0.806501  |
| D | 0.653349  | -0.152299 | 0.252577  |

A transformation operation that returns a `Panel`, but is computing the z-score across the `major_axis`.

```
In [206]: result = panel.apply(
.....:         lambda x: (x-x.mean())/x.std(),
.....:         axis='major_axis')
.....:

In [207]: result
Out[207]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [208]: result['ItemA']
////////////////////////////////////
↪
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-03 | 0.585813  | -0.102070 | -1.394063 | 0.201263  |
| 2000-01-04 | -1.496089 | -1.295066 | 0.434343  | 1.318766  |
| 2000-01-05 | 1.142642  | 1.413112  | 0.661833  | -0.431942 |
| 2000-01-06 | -0.323445 | -0.405085 | -0.683386 | 0.305017  |
| 2000-01-07 | 0.091079  | 0.389108  | 0.981273  | -1.393105 |

Apply can also accept multiple axes in the `axis` argument. This will pass a `DataFrame` of the cross-section to the applied function.

```
In [209]: f = lambda x: ((x.T-x.mean(1))/x.std(1)).T
In [210]: result = panel.apply(f, axis = ['items','major_axis'])
In [211]: result
```

(continues on next page)

(continued from previous page)

```
Out [211]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
```

```
In [212]: result.loc[:, :, 'ItemA']
```

```

////////////////////////////////////
↪
      A      B      C      D
2000-01-03  0.859304  0.448509 -1.109374  0.397237
2000-01-04 -1.053319 -1.063370  0.986639  1.152266
2000-01-05  1.106511  1.143185 -0.093917 -0.583083
2000-01-06  0.561619 -0.835608 -1.075936  0.194525
2000-01-07 -0.339514  1.097901  0.747522 -1.147605
```

This is equivalent to the following:

```
In [213]: result = pd.Panel(dict([ (ax, f(panel.loc[:, :, ax]))
.....:                             for ax in panel.minor_axis ]))
.....:
```

```
In [214]: result
```

```
Out [214]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
```

```
In [215]: result.loc[:, :, 'ItemA']
```

```

////////////////////////////////////
↪
      A      B      C      D
2000-01-03  0.859304  0.448509 -1.109374  0.397237
2000-01-04 -1.053319 -1.063370  0.986639  1.152266
2000-01-05  1.106511  1.143185 -0.093917 -0.583083
2000-01-06  0.561619 -0.835608 -1.075936  0.194525
2000-01-07 -0.339514  1.097901  0.747522 -1.147605
```

## 9.7 Reindexing and altering labels

`reindex()` is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To *reindex* means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, **fill** data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:

```
In [216]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
```

```
In [217]: s
```

```
Out[217]:
a    -0.454087
b    -0.360309
c    -0.951631
d    -0.535459
e     0.835231
dtype: float64
```

```
In [218]: s.reindex(['e', 'b', 'f', 'd'])
```

```
Out[218]:
e     0.835231
b    -0.360309
f         NaN
d    -0.535459
dtype: float64
```

Here, the `f` label was not contained in the Series and hence appears as `NaN` in the result.

With a `DataFrame`, you can simultaneously reindex the index and columns:

```
In [219]: df
```

```
Out[219]:
   one    two    three
a -1.101558  1.124472    NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d         NaN -0.456288 -1.222918
```

```
In [220]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
```

```
Out[220]:
   three    two    one
c  1.931194 -0.486066  0.462215
f         NaN         NaN         NaN
b -0.634293  2.487104 -0.177289
```

You may also use `reindex` with an `axis` keyword:

```
In [221]: df.reindex(['c', 'f', 'b'], axis='index')
```

```
Out[221]:
   one    two    three
c  0.462215 -0.486066  1.931194
f         NaN         NaN         NaN
b -0.177289  2.487104 -0.634293
```

Note that the `Index` objects containing the actual axis labels can be **shared** between objects. So if we have a `Series` and a `DataFrame`, the following can be done:

```
In [222]: rs = s.reindex(df.index)
```

```
In [223]: rs
```

```
Out[223]:
a    -0.454087
b    -0.360309
```

(continues on next page)

(continued from previous page)

```
c    -0.951631
d    -0.535459
dtype: float64
```

```
In [224]: rs.index is df.index
```

```
Out[224]: True
```

This means that the reindexed Series's index is the same Python object as the DataFrame's index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single labels argument and the axis it applies to.

```
In [225]: df.reindex(['c', 'f', 'b'], axis='index')
```

```
Out[225]:
```

```
      one    two    three
c  0.462215 -0.486066  1.931194
f      NaN      NaN      NaN
b -0.177289  2.487104 -0.634293
```

```
In [226]: df.reindex(['three', 'two', 'one'], axis='columns')
```

```
Out[226]:
```

```
      three    two    one
a      NaN  1.124472 -1.101558
b -0.634293  2.487104 -0.177289
c  1.931194 -0.486066  0.462215
d -1.222918 -0.456288      NaN
```

### See also:

*MultiIndex / Advanced Indexing* is an even more concise way of doing reindexing.

**Note:** When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: **many operations are faster on pre-aligned data**. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

## 9.7.1 Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```
In [227]: df2
```

```
Out[227]:
```

```
      one    two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066
```

```
In [228]: df3
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
      one      two
a -0.829347  0.082635
b  0.094922  1.445267
c  0.734426 -1.527903

In [229]: df.reindex_like(df2)
////////////////////////////////////
↪
      one      two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066

```

## 9.7.2 Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to *joining and merging*):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object's index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```

In [230]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [231]: s1 = s[:4]

In [232]: s2 = s[1:]

In [233]: s1.align(s2)
Out[233]:
(a    0.505453
 b    1.788110
 c   -0.405908
 d   -0.801912
 e         NaN
dtype: float64, a         NaN
 b    1.788110
 c   -0.405908
 d   -0.801912
 e    0.768460
dtype: float64)

In [234]: s1.align(s2, join='inner')
////////////////////////////////////
↪
(b    1.788110
 c   -0.405908
 d   -0.801912
dtype: float64, b    1.788110

```

(continues on next page)

(continued from previous page)

```
c    -0.405908
d    -0.801912
dtype: float64)
```

```
In [235]: s1.align(s2, join='left')
```

```
////////////////////////////////////
↪
(a    0.505453
 b    1.788110
 c    -0.405908
 d    -0.801912
 dtype: float64, a          NaN
 b    1.788110
 c    -0.405908
 d    -0.801912
 dtype: float64)
```

For DataFrames, the join method will be applied to both the index and the columns by default:

```
In [236]: df.align(df2, join='inner')
```

```
Out [236]:
```

```
(      one      two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066,      one      two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066)
```

You can also pass an axis option to only align on the specified axis:

```
In [237]: df.align(df2, join='inner', axis=0)
```

```
Out [237]:
```

```
(      one      two      three
a -1.101558  1.124472          NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194,      one      two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066)
```

If you pass a Series to `DataFrame.align()`, you can choose to align both objects either on the DataFrame's index or columns using the axis argument:

```
In [238]: df.align(df2.iloc[0], axis=1)
```

```
Out [238]:
```

```
(      one      three      two
a -1.101558          NaN  1.124472
b -0.177289 -0.634293  2.487104
c  0.462215  1.931194 -0.486066
d          NaN -1.222918 -0.456288, one      -1.101558
three          NaN
two          1.124472
Name: a, dtype: float64)
```

### 9.7.3 Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

| Method           | Action                            |
|------------------|-----------------------------------|
| pad / ffill      | Fill values forward               |
| bfill / backfill | Fill values backward              |
| nearest          | Fill from the nearest index value |

We illustrate these fill methods on a simple Series:

```
In [239]: rng = pd.date_range('1/3/2000', periods=8)
```

```
In [240]: ts = pd.Series(np.random.randn(8), index=rng)
```

```
In [241]: ts2 = ts[[0, 3, 6]]
```

```
In [242]: ts
```

```
Out [242]:

2000-01-04    0.785367
2000-01-05    0.785367
2000-01-06    0.785367
2000-01-07   -0.493153
2000-01-08   -0.493153
2000-01-09   -0.493153
2000-01-10         NaN
Freq: D, dtype: float64

```

```
In [247]: ts2.reindex(ts.index, method='nearest')
```

```

////////////////////////////////////
↪
2000-01-03    0.466284
2000-01-04    0.466284
2000-01-05    0.785367
2000-01-06    0.785367
2000-01-07    0.785367
2000-01-08   -0.493153
2000-01-09   -0.493153
2000-01-10   -0.493153
Freq: D, dtype: float64

```

These methods require that the indexes are **ordered** increasing or decreasing.

Note that the same result could have been achieved using *fillna* (except for `method='nearest'`) or *interpolate*:

```
In [248]: ts2.reindex(ts.index).fillna(method='ffill')
```

```
Out [248]:
```

```

2000-01-03    0.466284
2000-01-04    0.466284
2000-01-05    0.466284
2000-01-06    0.785367
2000-01-07    0.785367
2000-01-08    0.785367
2000-01-09   -0.493153
2000-01-10   -0.493153
Freq: D, dtype: float64

```

*reindex()* will raise a `ValueError` if the index is not monotonically increasing or decreasing. *fillna()* and *interpolate()* will not perform any checks on the order of the index.

## 9.7.4 Limits on filling while reindexing

The `limit` and `tolerance` arguments provide additional control over filling while reindexing. `Limit` specifies the maximum count of consecutive matches:

```
In [249]: ts2.reindex(ts.index, method='ffill', limit=1)
Out[249]:
2000-01-03    0.466284
2000-01-04    0.466284
2000-01-05         NaN
2000-01-06    0.785367
2000-01-07    0.785367
2000-01-08         NaN
2000-01-09   -0.493153
2000-01-10   -0.493153
Freq: D, dtype: float64
```

In contrast, `tolerance` specifies the maximum distance between the index and indexer values:

```
In [250]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out[250]:
2000-01-03    0.466284
2000-01-04    0.466284
2000-01-05         NaN
2000-01-06    0.785367
2000-01-07    0.785367
2000-01-08         NaN
2000-01-09   -0.493153
2000-01-10   -0.493153
Freq: D, dtype: float64
```

Notice that when used on a `DatetimeIndex`, `TimedeltaIndex` or `PeriodIndex`, `tolerance` will be coerced into a `Timedelta` if possible. This allows you to specify tolerance with appropriate strings.

## 9.7.5 Dropping labels from an axis

A method closely related to `reindex` is the `drop()` function. It removes a set of labels from an axis:

```
In [251]: df
Out[251]:
      one      two      three
a -1.101558  1.124472      NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d         NaN -0.456288 -1.222918

In [252]: df.drop(['a', 'd'], axis=0)
↪
      one      two      three
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194

In [253]: df.drop(['one'], axis=1)
↪
      two      three
a  1.124472      NaN
b  2.487104 -0.634293
c -0.486066  1.931194
d -0.456288 -1.222918
```

Note that the following also works, but is a bit less obvious / clean:

```
In [254]: df.reindex(df.index.difference(['a', 'd']))
Out[254]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| b | -0.177289 | 2.487104  | -0.634293 |
| c | 0.462215  | -0.486066 | 1.931194  |

## 9.7.6 Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```
In [255]: s
Out[255]:
```

| a | 0.505453  |
|---|-----------|
| b | 1.788110  |
| c | -0.405908 |
| d | -0.801912 |
| e | 0.768460  |

dtype: float64

```
In [256]: s.rename(str.upper)
Out[256]:
```

| A | 0.505453  |
|---|-----------|
| B | 1.788110  |
| C | -0.405908 |
| D | -0.801912 |
| E | 0.768460  |

dtype: float64

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [257]: df.rename(columns={'one': 'foo', 'two': 'bar'},
.....:               index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
Out[257]:
```

|        | foo       | bar       | three     |
|--------|-----------|-----------|-----------|
| apple  | -1.101558 | 1.124472  | NaN       |
| banana | -0.177289 | 2.487104  | -0.634293 |
| c      | 0.462215  | -0.486066 | 1.931194  |
| durian | NaN       | -0.456288 | -1.222918 |

If the mapping doesn't include a column/index label, it isn't renamed. Note that extra labels in the mapping don't throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [258]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[258]:
```

|   | foo       | bar      | three     |
|---|-----------|----------|-----------|
| a | -1.101558 | 1.124472 | NaN       |
| b | -0.177289 | 2.487104 | -0.634293 |

(continues on next page)

(continued from previous page)

```
c  0.462215 -0.486066  1.931194
d      NaN -0.456288 -1.222918
```

```
In [259]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')
```

```

////////////////////////////////////
↪
           one      two      three
apple -1.101558  1.124472      NaN
banana -0.177289  2.487104 -0.634293
c      0.462215 -0.486066  1.931194
durian      NaN -0.456288 -1.222918
```

The `rename()` method also provides an `inplace` named parameter that is by default `False` and copies the underlying data. Pass `inplace=True` to rename the data in place.

New in version 0.18.0.

Finally, `rename()` also accepts a scalar or list-like for altering the `Series.name` attribute.

```
In [260]: s.rename("scalar-name")
```

```
Out[260]:
```

```
a      0.505453
b      1.788110
c     -0.405908
d     -0.801912
e      0.768460
Name: scalar-name, dtype: float64
```

The `Panel` class has a related `rename_axis()` class which can rename any of its three axes.

## 9.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a `Series`, it is regarded as array-like, and basic iteration produces the values. Other data structures, like `DataFrame` and `Panel`, follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (`for i in object`) produces:

- **Series:** values
- **DataFrame:** column labels
- **Panel:** item labels

Thus, for example, iterating over a `DataFrame` gives you the column names:

```
In [261]: df = pd.DataFrame({'col1' : np.random.randn(3), 'col2' : np.random.randn(3)})
↪,
.....:                index=['a', 'b', 'c'])
.....:
```

```
In [262]: for col in df:
.....:     print(col)
.....:
```

```
col1
col2
```

Pandas objects also have the dict-like `iteritems()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally **slow**. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a *vectorized* solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing, ...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on *function application*.
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the *enhancing performance* section for some examples of this approach.

**Warning:** You should **never modify** something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```
In [263]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})

In [264]: for index, row in df.iterrows():
.....:     row['a'] = 10
.....:

In [265]: df
Out[265]:
   a  b
0  1  a
1  2  b
2  3  c
```

### 9.8.1 iteritems

Consistent with the dict-like interface, `iteritems()` iterates through key-value pairs:

- **Series:** (index, scalar value) pairs
- **DataFrame:** (column, Series) pairs
- **Panel:** (item, DataFrame) pairs

For example:

```
In [266]: for item, frame in wp.iteritems():
.....:     print(item)
.....:     print(frame)
.....:
```

(continues on next page)

(continued from previous page)

```

Item1

2000-01-05  0.095031 -0.270099 -0.707140 -0.773882

```

## 9.8.2 iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```

In [267]: for row_index, row in df.iterrows():
.....:     print('%s\n%s' % (row_index, row))
.....:
0
a    1
b    a
Name: 0, dtype: object
1
a    2
b    b
Name: 1, dtype: object
2
a    3
b    c
Name: 2, dtype: object

```

**Note:** Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```

In [268]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [269]: df_orig.dtypes
Out[269]:
int      int64
float    float64
dtype: object

In [270]: row = next(df_orig.iterrows())[1]

In [271]: row
Out[271]:
int      1.0
float    1.5
Name: 0, dtype: float64

```

All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column `x`:

```
In [272]: row['int'].dtype
Out[272]: dtype('float64')

In [273]: df_orig['int'].dtype
Out[273]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [274]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})  
  
In [275]: print(df2)  
      x  y  
0     1  4  
1     2  5  
2     3  6  
  
In [276]: print(df2.T)  
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\    0   1   2  
x     1   2   3  
y     4   5   6  
  
In [277]: df2_t = pd.DataFrame(dict((idx, values) for idx, values in df2.iterrows()))  
  
In [278]: print(df2_t)  
      0   1   2  
x     1   2   3  
y     4   5   6
```

### 9.8.3 itertuples

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row's corresponding index value, while the remaining values are the row values.

For instance:

```
In [279]: for row in df.itertuples():
.....:     print(row)
.....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.

## 9.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the *values* of the Series, if it is a date-time/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
In [280]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [281]: s
Out[281]:
0    2013-01-01 09:10:12
1    2013-01-02 09:10:12
2    2013-01-03 09:10:12
3    2013-01-04 09:10:12
dtype: datetime64[ns]

In [282]: s.dt.hour
Out[282]:
0    9
1    9
2    9
3    9
dtype: int64

In [283]: s.dt.second
Out[283]:
0    12
1    12
2    12
3    12
dtype: int64

In [284]: s.dt.day
Out[284]:
0    1
1    2
2    3
3    4
dtype: int64
```

This enables nice expressions like this:

```
In [285]: s[s.dt.day==2]
Out[285]:
1    2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produces tz aware transformations:

```
In [286]: stz = s.dt.tz_localize('US/Eastern')

In [287]: stz
Out[287]:
0    2013-01-01 09:10:12-05:00
```

(continues on next page)

(continued from previous page)

```

1    2013-01-02 09:10:12-05:00
2    2013-01-03 09:10:12-05:00
3    2013-01-04 09:10:12-05:00
dtype: datetime64[ns, US/Eastern]

```

```
In [288]: stz.dt.tz
```

```

////////////////////////////////////
↪ <DstTzInfo 'US/Eastern' LMT-1 day, 19:04:00 STD>

```

You can also chain these types of operations:

```
In [289]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
```

```
Out[289]:
```

```

0    2013-01-01 04:10:12-05:00
1    2013-01-02 04:10:12-05:00
2    2013-01-03 04:10:12-05:00
3    2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]

```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
```

```
In [290]: s = pd.Series(pd.date_range('20130101', periods=4))
```

```
In [291]: s
```

```
Out[291]:
```

```

0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: datetime64[ns]

```

```
In [292]: s.dt.strftime('%Y/%m/%d')
```

```

////////////////////////////////////Out [292]:
↪
0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object

```

```
# PeriodIndex
```

```
In [293]: s = pd.Series(pd.period_range('20130101', periods=4))
```

```
In [294]: s
```

```
Out[294]:
```

```

0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: object

```

```
In [295]: s.dt.strftime('%Y/%m/%d')
```

```

////////////////////////////////////Out [295]:
↪

```

(continues on next page)

(continued from previous page)

```

0    2013/01/01
1    2013/01/02
2    2013/01/03
3    2013/01/04
dtype: object

```

The `.dt` accessor works for period and timedelta dtypes.

```

# period
In [296]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [297]: s
Out[297]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
3    2013-01-04
dtype: object

In [298]: s.dt.year
Out[298]:
0    2013
1    2013
2    2013
3    2013
dtype: int64

In [299]: s.dt.day
Out[299]:
0    1
1    2
2    3
3    4
dtype: int64

```

```

# timedelta
In [300]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [301]: s
Out[301]:
0    1 days 00:00:05
1    1 days 00:00:06
2    1 days 00:00:07
3    1 days 00:00:08
dtype: timedelta64[ns]

In [302]: s.dt.days
Out[302]:
0    1
1    1
2    1
3    1
dtype: int64

```

(continues on next page)

(continued from previous page)

**In [303]:** s.dt.seconds

```

////////////////////////////////////
↪
0      5
1      6
2      7
3      8
dtype: int64

```

**In [304]:** s.dt.components

```

////////////////////////////////////
↪
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0     1     0         0         5             0             0             0
1     1     0         0         6             0             0             0
2     1     0         0         7             0             0             0
3     1     0         0         8             0             0             0

```

---

**Note:** `Series.dt` will raise a `TypeError` if you access with a non-datetime-like values.

---

## 9.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series's `str` attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

```

In [305]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog
↪', 'cat'])

```

**In [306]:** s.str.lower()**Out [306]:**

```

0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7    dog
8    cat
dtype: object

```

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses [regular expressions](#) by default (and in some cases always uses them).

Please see [Vectorized String Methods](#) for a complete description.

## 9.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

### 9.11.1 By Index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```
In [307]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c',
↳ '']),
↳ .....:                                'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c',
↳ 'd']),
↳ .....:                                'three' : pd.Series(np.random.randn(3), index=['b', 'c',
↳ 'd'])})
↳ .....:
```

[illegible]

```
In [309]: unsorted_df
Out[309]:
```

|   | three     | two       | one       |
|---|-----------|-----------|-----------|
| a | NaN       | 0.708543  | 0.036274  |
| d | -0.540166 | 0.586626  | NaN       |
| c | 0.410238  | 1.121731  | 1.044630  |
| b | -0.282532 | -2.038777 | -0.490032 |

```
# DataFrame
```

```
In [310]: unsorted_df.sort_index()
```

```
In [311]: unsorted_df.sort_index(ascending=False)
```

```
In [312]: unsorted_df.sort_index(axis=1)
```

(continues on next page)

(continued from previous page)

```
b -0.490032 -0.282532 -2.038777
```

```
# Series
```

```
In [313]: unsorted_df['three'].sort_index()
```

```
////////////////////////////////////
```

```
↪
```

```
a      NaN
```

```
b    -0.282532
```

```
c     0.410238
```

```
d    -0.540166
```

```
Name: three, dtype: float64
```

### 9.11.2 By Values

The `Series.sort_values()` method is used to sort a *Series* by its values. The `DataFrame.sort_values()` method is used to sort a *DataFrame* by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may be used to specify one or more columns to use to determine the sorted order.

```
In [314]: df1 = pd.DataFrame({'one': [2, 1, 1, 1], 'two': [1, 3, 2, 4], 'three': [5, 4, 3, 2]})
```

```
In [315]: df1.sort_values(by='two')
```

```
Out[315]:
```

|   | one | two | three |
|---|-----|-----|-------|
| 0 | 2   | 1   | 5     |
| 2 | 1   | 2   | 3     |
| 1 | 1   | 3   | 4     |
| 3 | 1   | 4   | 2     |

The `by` parameter can take a list of column names, e.g.:

```
In [316]: df1[['one', 'two', 'three']].sort_values(by=['one', 'two'])
```

```
Out[316]:
```

|   | one | two | three |
|---|-----|-----|-------|
| 2 | 1   | 2   | 3     |
| 1 | 1   | 3   | 4     |
| 3 | 1   | 4   | 2     |
| 0 | 2   | 1   | 5     |

These methods have special treatment of NA values via the `na_position` argument:

```
In [317]: s[2] = np.nan
```

```
In [318]: s.sort_values()
```

```
Out[318]:
```

|   |      |
|---|------|
| 0 | A    |
| 3 | Aaba |
| 1 | B    |
| 4 | Baca |
| 6 | CABA |
| 8 | cat  |
| 7 | dog  |
| 2 | NaN  |
| 5 | NaN  |

dtype: object

(continues on next page)

(continued from previous page)

```
In [319]: s.sort_values(na_position='first')
```

```

////////////////////////////////////
↪
2      NaN
5      NaN
0       A
3     Aaba
1       B
4     Baca
6     CABA
8     cat
7     dog
dtype: object

```

### 9.11.3 By Indexes and Values

New in version 0.23.0.

Strings passed as the `by` parameter to `DataFrame.sort_values()` may refer to either columns or index level names.

```

# Build MultiIndex
In [320]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
.....:                                   ('b', 2), ('b', 1), ('b', 1)])
.....:

In [321]: idx.names = ['first', 'second']

# Build DataFrame
In [322]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
.....:                             index=idx)
.....:

In [323]: df_multi
Out[323]:

```

|   | first | second | A |
|---|-------|--------|---|
| a | 1     | 2      | 6 |
|   | 2     | 2      | 5 |
|   | 2     | 4      | 4 |
| b | 2     | 3      | 3 |
|   | 1     | 2      | 2 |
|   | 1     | 1      | 1 |

Sort by 'second' (index) and 'A' (column)

```
In [324]: df_multi.sort_values(by=['second', 'A'])
Out[324]:
```

|   | first | second | A |
|---|-------|--------|---|
| b | 1     | 1      | 1 |
|   | 1     | 2      | 2 |
| a | 1     | 2      | 6 |
| b | 2     | 3      | 3 |
| a | 2     | 4      | 4 |
|   | 2     | 5      | 5 |

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

### 9.11.5 smallest / largest values

```
In [332]: s = pd.Series(np.random.permutation(10))

In [333]: s
Out[333]:
0      8
1      2
2      9
3      5
4      6
5      0
6      1
7      7
8      4
9      3
dtype: int64

In [334]: s.sort_values()
Out[334]:
5      0
6      1
```

(continues on next page)

(continued from previous page)

```

1      2
9      3
8      4
3      5
4      6
7      7
0      8
2      9
dtype: int64

```

```
In [335]: s.nsmallest(3)
```

```

////////////////////////////////////
↪
5      0
6      1
1      2
dtype: int64

```

```
In [336]: s.nlargest(3)
```

```

////////////////////////////////////
↪
2      9
0      8
7      7
dtype: int64

```

DataFrame also has the `nlargest` and `nsmallest` methods.

```
In [337]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
.....:                      'b': list('abdceff'),
.....:                      'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})
.....:
```

```
In [338]: df.nlargest(3, 'a')
```

```
Out[338]:
   a  b    c
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN

```

```
In [339]: df.nlargest(5, ['a', 'c'])
```

```

////////////////////////////////////Out[339]:
   a  b    c
6  -1 f  4.0
5  11 f  3.0
3  10 c  3.2
4   8 e  NaN
2   1 d  4.0

```

```
In [340]: df.nsmallest(3, 'a')
```

```

////////////////////////////////////
↪
   a  b    c
0  -2 a  1.0
1  -1 b  2.0
6  -1 f  4.0

```

(continues on next page)

(continued from previous page)

```
In [341]: df.nsmallest(5, ['a', 'c'])
```

```

////////////////////////////////////
↪
   a  b    c
0 -2  a  1.0
2  1  d  4.0
4  8  e  NaN
1 -1  b  2.0
6 -1  f  4.0

```

### 9.11.6 Sorting by a multi-index column

You must be explicit about sorting when the column is a multi-index, and fully specify all levels to `by`.

```
In [342]: df1.columns = pd.MultiIndex.from_tuples([('a', 'one'), ('a', 'two'), ('b', 'three')])
```

```
In [343]: df1.sort_values(by=('a', 'two'))
```

```
Out[343]:
      a      b
  one two three
0    2    1     5
2    1    2     3
1    1    3     4
3    1    4     2

```

## 9.12 Copying

The `copy()` method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that **it is seldom necessary to copy objects**. For example, there are only a handful of ways to alter a DataFrame *in-place*:

- Inserting, deleting, or modifying a column.
- Assigning to the `index` or `columns` attributes.
- For homogeneous data, directly modifying the values via the `values` attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

## 9.13 dtypes

The main types stored in pandas objects are `float`, `int`, `bool`, `datetime64[ns]` and `datetime64[ns, tz]`, `timedelta[ns]`, `category` and `object`. In addition these dtypes have item sizes, e.g. `int64` and `int32`. See [Series with TZ](#) for more detail on `datetime64[ns, tz]` dtypes.

A convenient `dtypes` attribute for DataFrame returns a Series with the data type of each column.

```
In [344]: dft = pd.DataFrame(dict(A = np.random.rand(3),
.....:                             B = 1,
```

(continues on next page)

(continued from previous page)

```

.....:
.....:
.....:
.....:
.....:
.....:
.....:
C = 'foo',
D = pd.Timestamp('20010102'),
E = pd.Series([1.0]*3).astype('float32'),
F = False,
G = pd.Series([1]*3, dtype='int8'))

In [345]: dft
Out[345]:

```

|   | A        | B | C   | D          | E   | F     | G |
|---|----------|---|-----|------------|-----|-------|---|
| 0 | 0.809585 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |
| 1 | 0.128238 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |
| 2 | 0.775752 | 1 | foo | 2001-01-02 | 1.0 | False | 1 |

```

In [346]: dft.dtypes
dtype: object
A          float64
B           int64
C           object
D    datetime64[ns]
E          float32
F             bool
G           int8
dtype: object

```

On a Series object, use the `dtype` attribute.

```

In [347]: dft['A'].dtype
Out[347]: dtype('float64')

```

If a pandas object contains data with multiple dtypes *in a single column*, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

```

# these ints are coerced to floats
In [348]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[348]:
0    1.0
1    2.0
2    3.0
3    4.0
4    5.0
5    6.0
dtype: float64

# string data forces an ``object`` dtype
In [349]: pd.Series([1, 2, 3, 6., 'foo'])
Out[349]:
0    1
1    2
2    3
3    6
4   foo
dtype: object

```

The number of columns of each type in a DataFrame can be found by calling `get_dtype_counts()`.

```
In [350]: dft.get_dtype_counts()
Out[350]:
float64      1
float32      1
int64        1
int8         1
datetime64[ns] 1
bool         1
object       1
dtype: int64
```

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the `dtype` keyword, a passed `ndarray`, or a passed `Series`, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will **NOT** be combined. The following example will give you a taste.

```
In [351]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')

In [352]: df1
Out[352]:
      A
0  0.890400
1  0.283331
2 -0.303613
3 -1.192210
4  0.065420
5  0.455918
6  2.008328
7  0.188942

In [353]: df1.dtypes
=====
A      float32
dtype: object

In [354]: df2 = pd.DataFrame(dict( A = pd.Series(np.random.randn(8), dtype='float16'),
.....:                               B = pd.Series(np.random.randn(8)),
.....:                               C = pd.Series(np.array(np.random.randn(8), dtype=
→ 'uint8')) ))
.....:

In [355]: df2
Out[355]:
      A      B      C
0 -0.454346  0.200071  255
1 -0.916504 -0.557756  255
2  0.640625 -0.141988    0
3  2.675781 -0.174060    0
4 -0.007866  0.258626    0
5 -0.204224  0.941688    0
6 -0.100098 -1.849045    0
7 -0.402100 -0.949458    0

In [356]: df2.dtypes
=====
A      float16
```

(continues on next page)

(continued from previous page)

```
B    float64
C      uint8
dtype: object
```

### 9.13.1 defaults

By default integer types are `int64` and float types are `float64`, *regardless* of platform (32-bit or 64-bit). The following will all result in `int64` dtypes.

```
In [357]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[357]:
a    int64
dtype: object

In [358]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[358]:
a    int64
dtype: object

In [359]: pd.DataFrame({'a': 1 }, index=list(range(2))).dtypes
Out[359]:
a    int64
dtype: object
```

Note that Numpy will choose *platform-dependent* types when creating arrays. The following **WILL** result in `int32` on 32-bit platform.

```
In [360]: frame = pd.DataFrame(np.array([1, 2]))
```

### 9.13.2 upcasting

Types can potentially be *upcasted* when combined with other types, meaning they are promoted from the current type (e.g. `int` to `float`).

```
In [361]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [362]: df3
Out[362]:
```

|   | A         | B         | C     |
|---|-----------|-----------|-------|
| 0 | 0.436054  | 0.200071  | 255.0 |
| 1 | -0.633173 | -0.557756 | 255.0 |
| 2 | 0.337012  | -0.141988 | 0.0   |
| 3 | 1.483571  | -0.174060 | 0.0   |
| 4 | 0.057555  | 0.258626  | 0.0   |
| 5 | 0.251695  | 0.941688  | 0.0   |
| 6 | 1.908231  | -1.849045 | 0.0   |
| 7 | -0.213158 | -0.949458 | 0.0   |

```
In [363]: df3.dtypes
Out[363]:
A    float32
B    float64
```

(continues on next page)

```
C      float64
dtype: object
```

```
In [364]: df3.values.dtype
Out[364]: dtype('float64')
```

```
In [365]: df3
Out[365]:
```

|   | A         | B         | C     |
|---|-----------|-----------|-------|
| 0 | 0.436054  | 0.200071  | 255.0 |
| 1 | -0.633173 | -0.557756 | 255.0 |
| 2 | 0.337012  | -0.141988 | 0.0   |
| 3 | 1.483571  | -0.174060 | 0.0   |
| 4 | 0.057555  | 0.258626  | 0.0   |
| 5 | 0.251695  | 0.941688  | 0.0   |
| 6 | 1.908231  | -1.849045 | 0.0   |
| 7 | -0.213158 | -0.949458 | 0.0   |

```

A      float32
B      float64
C      float64
dtype: object

```

```
In [367]: df3.astype('float32').dtypes
\\/////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↪
A      float32
B      float32
C      float32
dtype: object
```

(continued from previous page)

```

Out [370]:
   a  b  c
0  1  4  7
1  2  5  8
2  3  6  9

In [371]: dft.dtypes
Out [371]:
a      uint8
b      uint8
c      int64
dtype: object

```

New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```

In [372]: dft1 = pd.DataFrame({'a': [1,0,1], 'b': [4,5,6], 'c': [7, 8, 9]})

In [373]: dft1 = dft1.astype({'a': np.bool, 'c': np.float64})

In [374]: dft1
Out [374]:
   a  b  c
0  True  4  7.0
1 False  5  8.0
2  True  6  9.0

In [375]: dft1.dtypes
Out [375]:
a      bool
b      int64
c     float64
dtype: object

```

**Note:** When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while `[]` will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```

In [376]: dft = pd.DataFrame({'a': [1,2,3], 'b': [4,5,6], 'c': [7, 8, 9]})

In [377]: dft.loc[:, ['a', 'b']].astype(np.uint8).dtypes
Out [377]:
a      uint8
b      uint8
dtype: object

In [378]: dft.loc[:, ['a', 'b']] = dft.loc[:, ['a', 'b']].astype(np.uint8)

In [379]: dft.dtypes
Out [379]:
a      int64
b      int64
c      int64

```

(continues on next page)

(continued from previous page)

```
dtype: object
```

### 9.13.4 object conversion

pandas offers various functions to try to force conversion of types from the `object` dtype to other types. In cases where the data is already of the correct type, but stored in an `object` array, the `DataFrame.infer_objects()` and `Series.infer_objects()` methods can be used to soft convert to the correct type.

[illegible]

Because the data was transposed the original inference stored all columns as object, which `infer_objects` will correct.

```
In [385]: df.infer_objects().dtypes
Out[385]:
0          int64
1         object
2    datetime64[ns]
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- `to_numeric()` (conversion to numeric dtypes)

```
In [386]: m = ['1.1', 2, 3]

In [387]: pd.to_numeric(m)
Out[387]: array([ 1.1,  2. ,  3. ])
```

- `to_datetime()` (conversion to datetime objects)

```
In [388]: import datetime

In [389]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]

In [390]: pd.to_datetime(m)
Out[390]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]',
↳ freq=None)
```

- `to_timedelta()` (conversion to timedelta objects)

```
In [391]: m = ['5us', pd.Timedelta('1day')]

In [392]: pd.to_timedelta(m)
Out[392]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype=
↳ 'timedelta64[ns]', freq=None)
```

To force a conversion, we can pass in an `errors` argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, `errors='raise'`, meaning that any errors encountered will be raised during the conversion process. However, if `errors='coerce'`, these errors will be ignored and pandas will convert problematic elements to `pd.NaT` (for datetime and timedelta) or `np.nan` (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

```
In [393]: import datetime

In [394]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [395]: pd.to_datetime(m, errors='coerce')
Out[395]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [396]: m = ['apple', 2, 3]

In [397]: pd.to_numeric(m, errors='coerce')
Out[397]: array([ nan,   2.,   3.])

In [398]: m = ['apple', pd.Timedelta('1day')]

In [399]: pd.to_timedelta(m, errors='coerce')
Out[399]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)
```

The `errors` parameter has a third option of `errors='ignore'`, which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

```
In [400]: import datetime

In [401]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [402]: pd.to_datetime(m, errors='ignore')
Out[402]: array(['apple', datetime.datetime(2016, 3, 2, 0, 0)], dtype=object)

In [403]: m = ['apple', 2, 3]

In [404]: pd.to_numeric(m, errors='ignore')
Out[404]: array(['apple', 2, 3], dtype=object)

In [405]: m = ['apple', pd.Timedelta('1day')]
```

(continues on next page)

(continued from previous page)

```
In [406]: pd.to_timedelta(m, errors='ignore')
Out [406]: array(['apple', Timedelta('1 days 00:00:00')], dtype=object)
```

In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

```
In [407]: m = ['1', 2, 3]

In [408]: pd.to_numeric(m, downcast='integer')    # smallest signed int dtype
Out [408]: array([1, 2, 3], dtype=int8)

In [409]: pd.to_numeric(m, downcast='signed')     # same as 'integer'
Out [409]: array([1, 2, 3], dtype=int8)

In [410]: pd.to_numeric(m, downcast='unsigned')   # smallest unsigned int dtype
Out [410]: array([1, 2, 3], dtype=uint8)

In [411]: pd.to_numeric(m, downcast='float')      # smallest float dtype
Out [411]: array([ 1.,  2.,  3.], dtype=float32)
```

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

```
In [412]: import datetime

In [413]: df = pd.DataFrame(['2016-07-09', datetime.datetime(2016, 3, 2)] * 2,
                             dtype='O')

In [414]: df
Out [414]:
           0           1
0  2016-07-09  2016-03-02 00:00:00
1  2016-07-09  2016-03-02 00:00:00

In [415]: df.apply(pd.to_datetime)
Out [415]:
           0           1
0  2016-07-09  2016-03-02
1  2016-07-09  2016-03-02

In [416]: df = pd.DataFrame(['1.1', 2, 3] * 2, dtype='O')

In [417]: df
Out [417]:
           0  1  2
0  1.1  2  3
1  1.1  2  3

In [418]: df.apply(pd.to_numeric)
Out [418]:
           0  1  2
0  1.1  2  3
```

(continues on next page)

(continued from previous page)

```

1  1.1  2  3

In [419]: df = pd.DataFrame([[ '5us', pd.Timedelta('1day')]] * 2, dtype='O')

In [420]: df
Out[420]:
      0      1
0  5us  1 days 00:00:00
1  5us  1 days 00:00:00

In [421]: df.apply(pd.to_timedelta)
Out[421]:
      0      1
0 00:00:00.000005 1 days
1 00:00:00.000005 1 days

```

### 9.13.5 gotchas

Performing selection operations on integer type data can easily upcast the data to `floating`. The dtype of the input data will be preserved in cases where nans are not introduced. See also *Support for integer NA*.

```

In [422]: dfi = df3.astype('int32')

In [423]: dfi['E'] = 1

In [424]: dfi
Out[424]:
   A  B  C  E
0  0  0 255  1
1  0  0 255  1
2  0  0   0  1
3  1  0   0  1
4  0  0   0  1
5  0  0   0  1
6  1 -1   0  1
7  0  0   0  1

In [425]: dfi.dtypes
Out[425]:

B      float64
C      float64
dtype: object

```

## 9.14 Selecting columns based on dtype

The `select_dtypes()` method implements subsetting of columns based on their dtype.

First, let's create a *DataFrame* with a slew of different dtypes:

```

In [435]: df = pd.DataFrame({'string': list('abc'),
.....:                     'int64': list(range(1, 4)),
.....:                     'uint8': np.arange(3, 6).astype('u1'),
.....:                     'float64': np.arange(4.0, 7.0),
.....:                     'bool1': [True, False, True],
.....:                     'bool2': [False, True, False],
.....:                     'dates': pd.date_range('now', periods=3).values,
.....:                     'category': pd.Series(list("ABC")).astype('category')})
.....:

In [436]: df['tdeltas'] = df.dates.diff()

In [437]: df['uint64'] = np.arange(3, 6).astype('u8')

In [438]: df['other_dates'] = pd.date_range('20130101', periods=3).values

In [439]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [440]: df
Out[440]:
   string  int64  uint8  float64  ...  tdeltas  uint64  other_
↪dates              tz_aware_dates
0      a      1      3      4.0  ...      NaT      3  2013-01-
↪01 2013-01-01 00:00:00-05:00
1      b      2      4      5.0  ...      1 days      4  2013-01-
↪02 2013-01-02 00:00:00-05:00
2      c      3      5      6.0  ...      1 days      5  2013-01-
↪03 2013-01-03 00:00:00-05:00

[3 rows x 12 columns]

```

And the dtypes:

```

In [441]: df.dtypes
Out[441]:
string              object
int64               int64
uint8               uint8
float64             float64
bool1               bool
bool2               bool
dates               datetime64[ns]
category            category
tdeltas             timedelta64[ns]
uint64              uint64
other_dates         datetime64[ns]
tz_aware_dates      datetime64[ns, US/Eastern]
dtype: object

```

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns *with* these dtypes” (include) and/or “give the columns *without* these dtypes” (exclude).

For example, to select `bool` columns:

```

In [442]: df.select_dtypes(include=[bool])
Out[442]:
   bool1  bool2
0    True  False

```

(continues on next page)

(continued from previous page)

```
1 False   True
2   True  False
```

You can also pass the name of a dtype in the [NumPy dtype hierarchy](#):

```
In [443]: df.select_dtypes(include=['bool'])
Out[443]:
   bool1  bool2
0   True  False
1  False   True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```
In [444]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[444]:
   int64  float64  bool1  bool2  dteltas
0      1      4.0   True  False     NaT
1      2      5.0  False   True  1 days
2      3      6.0   True  False  1 days
```

To select string columns you must use the object dtype:

```
In [445]: df.select_dtypes(include=['object'])
Out[445]:
   string
0      a
1      b
2      c
```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```
In [446]: def subdtypes(dtype):
.....:     subs = dtype.__subclasses__()
.....:     if not subs:
.....:         return dtype
.....:     return [dtype, [subdtypes(dt) for dt in subs]]
.....:
```

All NumPy dtypes are subclasses of `numpy.generic`:

```
In [447]: subdtypes(np.generic)
Out[447]:
[numpy.generic,
 [ [numpy.number,
    [ [numpy.integer,
      [ [numpy.signedinteger,
        [numpy.int8,
         numpy.int16,
         numpy.int32,
         numpy.int64,
         numpy.int64,
         numpy.timedelta64]],
        [numpy.unsignedinteger,
```

(continues on next page)

(continued from previous page)

```
[numpy.uint8,
 numpy.uint16,
 numpy.uint32,
 numpy.uint64,
 numpy.uint64]]],
[numpy.inexact,
 [[numpy.floating,
  [numpy.float16, numpy.float32, numpy.float64, numpy.float128]],
 [numpy.complexfloating,
  [numpy.complex64, numpy.complex128, numpy.complex256]]]]],
[numpy.flexible,
 [[numpy.character, [numpy.bytes_, numpy.str_]],
 [numpy.void, [numpy.record]]]],
numpy.bool_,
numpy.datetime64,
numpy.object_]]
```

---

**Note:** Pandas also defines the types `category`, and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won't show up with the above function.

---

## WORKING WITH TEXT DATA

Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```
In [2]: s.str.lower()
```

```
Out[2]:
```

```
0      a
1      b
2      c
3    aaba
4    baca
5     NaN
6    caba
7     dog
8     cat
dtype: object
```

```
In [3]: s.str.upper()
```

```
////////////////////////////////////
↪
0      A
1      B
2      C
3    AABA
4    BACA
5     NaN
6    CABA
7     DOG
8     CAT
dtype: object
```

```
In [4]: s.str.len()
```

```
////////////////////////////////////
↪
0      1.0
1      1.0
2      1.0
3      4.0
4      4.0
5     NaN
6      4.0
7      3.0
```

(continues on next page)

(continued from previous page)

```
8      3.0
dtype: float64
```

```
In [5]: idx = pd.Index([' jack', 'jill ', ' jesse ', 'frank'])

In [6]: idx.str.strip()
Out[6]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [7]: idx.str.lstrip()
Out[7]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')

In [8]: idx.str.rstrip()
Out[8]: Index([' jack', 'jill ', ' jesse ', 'frank'], dtype='object')
```

The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(randn(3, 2), columns=[' Column A ', ' Column B '],
...:                      index=range(3))
...:

In [10]: df
Out[10]:
   Column A  Column B
0 -1.425575 -1.336299
1  0.740933  1.032121
2 -1.585660  0.913812
```

Since `df.columns` is an Index object, we can use the `.str` accessor

```
In [11]: df.columns.str.strip()
Out[11]: Index(['Column A', 'Column B'], dtype='object')

In [12]: df.columns.str.lower()
Out[12]: Index(['column a', 'column b'], dtype='object')
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lowercasing all names, and replacing any remaining whitespaces with underscores:

```
In [13]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')

In [14]: df
Out[14]:
   column_a  column_b
0 -1.425575 -1.336299
1  0.740933  1.032121
2 -1.585660  0.913812
```

**Note:** If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type category and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for Series of type category, the string operations are done on the `.categories` and not on

each element of the Series.

Please note that a Series of type `category` with string `.categories` has some limitations in comparison of Series of type `string` (e.g. you can't add strings to each other: `s + " " + s` won't work if `s` is a Series of type `category`). Also, `.str` methods which operate on elements of type `list` are not available on such a Series.

## 10.1 Splitting and Replacing Strings

Methods like `split` return a Series of lists:

```
In [15]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'])

In [16]: s2.str.split('_')
Out[16]:
0      [a, b, c]
1      [c, d, e]
2           NaN
3      [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using `get` or `[]` notation:

```
In [17]: s2.str.split('_').str.get(1)
Out[17]:
0      b
1      d
2     NaN
3      g
dtype: object

In [18]: s2.str.split('_').str[1]
Out[18]:
0      b
1      d
2     NaN
3      g
dtype: object
```

It is easy to expand this to return a DataFrame using `expand`.

```
In [19]: s2.str.split('_', expand=True)
Out[19]:
   0  1  2
0  a  b  c
1  c  d  e
2 NaN NaN NaN
3  f  g  h
```

It is also possible to limit the number of splits:

```
In [20]: s2.str.split('_', expand=True, n=1)
Out[20]:
   0  1
0  a b_c
1  c d_e
```

(continues on next page)

(continued from previous page)

```
2 NaN NaN
3 f g_h
```

`rsplit` is similar to `split` except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```
In [21]: s2.str.rsplit('_', expand=True, n=1)
Out[21]:
   0  1
0 a_b  c
1 c_d  e
2 NaN NaN
3 f_g  h
```

`replace` by default replaces regular expressions:

```
In [22]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
.....:                  '', np.nan, 'CABA', 'dog', 'cat'])
.....:
```

```
In [23]: s3
```

```
Out[23]:
0      A
1      B
2      C
3  Aaba
4  Baca
5
6   NaN
7  CABA
8   dog
9   cat
dtype: object
```

```
In [24]: s3.str.replace('^.a|dog', 'XX-XX ', case=False)
```

```

////////////////////////////////////
↪
0      A
1      B
2      C
3  XX-XX ba
4  XX-XX ca
5
6      NaN
7  XX-XX BA
8  XX-XX
9  XX-XX t
dtype: object
```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of `$`:

```
# Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])

# This does what you'd naively expect:
```

(continues on next page)

(continued from previous page)

```

In [26]: dollars.str.replace('$', '')
Out[26]:
0      12
1     -10
2    10,000
dtype: object

# But this doesn't:
In [27]: dollars.str.replace('-$', '-')
Out[27]:
0      12
1     -10
2    $10,000
dtype: object

# We need to escape the special character (for >1 len patterns)
In [28]: dollars.str.replace(r'\-$', '-')
Out[28]:
0      12
1     -10
2    $10,000
dtype: object

```

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to `str.replace()`), you can set the optional `regex` parameter to `False`, rather than escaping each character. In this case both `pat` and `repl` must be strings:

```

# These lines are equivalent
In [29]: dollars.str.replace(r'\-$', '-')
Out[29]:
0      12
1     -10
2    $10,000
dtype: object

In [30]: dollars.str.replace('-', '-', regex=False)
Out[30]:
0      12
1     -10
2    $10,000
dtype: object

```

New in version 0.20.0.

The `replace` method can also take a callable as replacement. It is called on every `pat` using `re.sub()`. The callable should expect one positional argument (a regex object) and return a string.

```

# Reverse every lowercase alphabetic word
In [31]: pat = r'[a-z]+'

In [32]: repl = lambda m: m.group(0)[::-1]

In [33]: pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(pat, repl)
Out[33]:
0    oof 123

```

(continues on next page)

(continued from previous page)

```

1    rab zab
2      NaN
dtype: object

# Using regex groups
In [34]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [35]: repl = lambda m: m.group('two').swapcase()

In [36]: pd.Series(['Foo Bar Baz', np.nan]).str.replace(pat, repl)
Out[36]:
0    bAR
1     NaN
dtype: object

```

New in version 0.20.0.

The `replace` method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

```

In [37]: import re

In [38]: regex_pat = re.compile(r'^.a|dog', flags=re.IGNORECASE)

In [39]: s3.str.replace(regex_pat, 'XX-XX ')
Out[39]:
0          A
1          B
2          C
3    XX-XX ba
4    XX-XX ca
5
6          NaN
7    XX-XX BA
8    XX-XX
9    XX-XX t
dtype: object

```

Including a `flags` argument when calling `replace` with a compiled regular expression object will raise a `ValueError`.

```

In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
-----
ValueError: case and flags cannot be set when pat is a compiled regex

```

## 10.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

### 10.2.1 Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:

```
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])
```

```
In [42]: s.str.cat(sep=',')
```

```
Out[42]: 'a,b,c,d'
```

If not specified, the keyword `sep` for the separator defaults to the empty string, `sep=''`:

```
In [43]: s.str.cat()
```

```
Out[43]: 'abcd'
```

By default, missing values are ignored. Using `na_rep`, they can be given a representation:

```
In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])
```

```
In [45]: t.str.cat(sep=',')
```

```
Out[45]: 'a,b,d'
```

```
In [46]: t.str.cat(sep=',', na_rep='-')
```

```
Out[46]: 'a,b,-,d'
```

## 10.2.2 Concatenating a Series and something list-like into a Series

The first argument to `cat()` can be a list-like object, provided that it matches the length of the calling `Series` (or `Index`).

```
In [47]: s.str.cat(['A', 'B', 'C', 'D'])
```

```
Out[47]:
```

```
0    aA
```

```
1    bB
```

```
2    cC
```

```
3    dD
```

```
dtype: object
```

Missing values on either side will result in missing values in the result as well, *unless* `na_rep` is specified:

```
In [48]: s.str.cat(t)
```

```
Out[48]:
```

```
0    aa
```

```
1    bb
```

```
2    NaN
```

```
3    dd
```

```
dtype: object
```

```
In [49]: s.str.cat(t, na_rep='-')
```

```
Out[49]:
```

```
0    aa
```

```
1    bb
```

```
2    c-
```

```
3    dd
```

```
dtype: object
```

## 10.2.3 Concatenating a Series and something array-like into a Series

New in version 0.23.0.

The parameter `others` can also be two-dimensional. In this case, the number of rows must match the lengths of the calling Series (or Index).

```
In [50]: d = pd.concat([t, s], axis=1)

In [51]: s
Out[51]:
0    a
1    b
2    c
3    d
dtype: object

In [52]: d
Out[52]:
0 1
0 a a
1 b b
2 NaN c
3 d d

In [53]: s.str.cat(d, na_rep='-')
Out[53]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: object
```

## 10.2.4 Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a Series or DataFrame, it is possible to align the indexes before concatenation by setting the `join-keyword`.

```
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])

In [55]: s
Out[55]:
0    a
1    b
2    c
3    d
dtype: object

In [56]: u
Out[56]:
1    b
3    d
0    a
2    c
dtype: object

In [57]: s.str.cat(u)
```

(continues on next page)

(continued from previous page)

```

0    ab
1    bd
2    ca
3    dc
dtype: object

```

```
In [58]: s.str.cat(u, join='left')
```

```

////////////////////////////////////
↪
0    aa
1    bb
2    cc
3    dd
dtype: object

```

**Warning:** If the `join` keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of `'left'`, `'outer'`, `'inner'`, `'right'`). In particular, alignment also means that the different lengths do not need to coincide anymore.

```
In [59]: v = pd.Series(['z', 'a', 'b', 'd', 'e'], index=[-1, 0, 1, 3, 4])
```

```
In [60]: s
```

```

Out[60]:
0    a
1    b
2    c
3    d
dtype: object

```

```
In [61]: v
```

```

////////////////////////////////////Out[61]:
-1    z
0     a
1     b
3     d
4     e
dtype: object

```

```
In [62]: s.str.cat(v, join='left', na_rep='-')
```

```

////////////////////////////////////
↪
0    aa
1    bb
2    c-
3    dd
dtype: object

```

```
In [63]: s.str.cat(v, join='outer', na_rep='-')
```

```

////////////////////////////////////
↪
-1    -z

```

(continues on next page)

(continued from previous page)

```

0    aa
1    bb
2    c-
3    dd
4    -e
dtype: object

```

The same alignment can be used when `others` is a `DataFrame`:

```

In [64]: f = d.loc[[3, 2, 1, 0], :]

In [65]: s
Out[65]:
0    a
1    b
2    c
3    d
dtype: object

In [66]: f
Out[66]:
0 1
3 d d
2 NaN c
1 b b
0 a a

In [67]: s.str.cat(f, join='left', na_rep='-')
Out[67]:
0    aaa
1    bbb
2    c-c
3    ddd
dtype: object

```

## 10.2.5 Concatenating a Series and many objects into a Series

All one-dimensional list-likes can be arbitrarily combined in a list-like container (including iterators, `dict`-views, etc.):

```

In [68]: s
Out[68]:
0    a
1    b
2    c
3    d
dtype: object

In [69]: u
Out[69]:
1    b
3    d
0    a
2    c

```

(continues on next page)

## 10.3 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan,
.....:                  'CABA', 'dog', 'cat'])
.....:
```

```
In [77]: s.str[0]
```

```
Out[77]:
```

```
0      A
1      B
2      C
3      A
4      B
5    NaN
6      C
7      d
8      c
dtype: object
```

```
In [78]: s.str[1]
```

```

////////////////////////////////////
↪
0    NaN
1    NaN
2    NaN
3     a
4     a
5    NaN
6     A
7     o
8     a
dtype: object
```

## 10.4 Extracting Substrings

### 10.4.1 Extract first match in each subject (extract)

**Warning:** In version 0.18.0, `extract` gained the `expand` argument. When `expand=False` it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When `expand=True` it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user. `expand=True` is the default since version 0.23.0.

The `extract` method accepts a [regular expression](#) with at least one capture group.

Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [79]: pd.Series(['a1', 'b2', 'c3']).str.extract('([ab])(\d)', expand=False)
Out[79]:
   0  1
```

(continues on next page)

(continued from previous page)

```
0    a    1
1    b    2
2  NaN  NaN
```

Elements that do not match return a row filled with NaN. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The dtype of the result is always object, even if no match is found and the result only contains NaN.

Named groups like

```
In [80]: pd.Series(['a1', 'b2', 'c3']).str.extract('(P<letter>[ab])(P<digit>\d)',
↳ expand=False)
Out [80]:
   letter digit
0      a      1
1      b      2
2    NaN    NaN
```

and optional groups like

```
In [81]: pd.Series(['a1', 'b2', '3']).str.extract('([ab])?(\d)', expand=False)
Out [81]:
   0  1
0   a  1
1   b  2
2  NaN 3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a DataFrame with one column if `expand=True`.

```
In [82]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=True)
Out [82]:
   0
0   1
1   2
2  NaN
```

It returns a Series if `expand=False`.

```
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=False)
Out [83]:
0      1
1      2
2    NaN
dtype: object
```

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if `expand=True`.

```
In [84]: s = pd.Series(['a1', 'b2', 'c3'], ['A11', 'B22', 'C33'])

In [85]: s
Out [85]:
A11    a1
```

(continues on next page)

(continued from previous page)

```

B22    b2
C33    c3
dtype: object

In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
\\Out [86]:
  letter
0      A
1      B
2      C

```

It returns an Index if `expand=False`.

```

In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out [87]: Index(['A', 'B', 'C'], dtype='object', name='letter')

```

Calling on an Index with a regex with more than one capture group returns a DataFrame if `expand=True`.

```

In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out [88]:
  letter  1
0      A  11
1      B  22
2      C  33

```

It raises `ValueError` if `expand=False`.

```

>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

```

The table below summarizes the behavior of `extract` (`expand=False`) (input subject in first column, number of groups in regex in first row)

|        | 1 group | >1 group   |
|--------|---------|------------|
| Index  | Index   | ValueError |
| Series | Series  | DataFrame  |

## 10.4.2 Extract all matches in each subject (extractall)

New in version 0.18.0.

Unlike `extract` (which returns only the first match),

```

In [89]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])

In [90]: s
Out [90]:
A    a1a2
B     b1
C     c1
dtype: object

In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'

```

(continues on next page)

(continued from previous page)

```
In [92]: s.str.extract(two_groups, expand=True)
```

Out [92] :

|   | letter | digit |
|---|--------|-------|
| A | a      | 1     |
| B | b      | 1     |
| C | c      | 1     |

the `extractall` method returns every match. The result of `extractall` is always a `DataFrame` with a `MultiIndex` on its rows. The last level of the `MultiIndex` is named `match` and indicates the order in the subject.

```
In [93]: s.str.extractall(two_groups)
```

Out [93] :

|   |       | letter | digit |
|---|-------|--------|-------|
|   | match |        |       |
| A | 0     | a      | 1     |
|   | 1     | a      | 2     |
| B | 0     | b      | 1     |
| C | 0     | c      | 1     |

When each subject string in the Series has exactly one match,

```
In [94]: s = pd.Series(['a3', 'b3', 'c2'])
```

In [95]: s

Out [95] :

```
0      a3
1      b3
2      c2
dtype: object
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```
In [96]: extract_result = s.str.extract(two_groups, expand=True)
```

```
In [97]: extract_result
```

Out [97] :

```

letter digit
0      a      3
1      b      3
2      c      2

```

```
In [98]: extractall_result = s.str.extractall(two_groups)
```

```
In [99]: extractall_result
```

Out [99] :

|       |   | letter | digit |
|-------|---|--------|-------|
| match |   |        |       |
| 0     | 0 | a      | 3     |
| 1     | 0 | b      | 3     |
| 2     | 0 | c      | 2     |

```
In [100]: extractall_result.xs(0, level="match")
```

(continues on next page)

(continued from previous page)

|   |   |   |
|---|---|---|
| 0 | a | 3 |
| 1 | b | 3 |
| 2 | c | 2 |

Index also supports `.str.extractall`. It returns a `DataFrame` which has the same result as a `Series.str.extractall` with a default index (starts from 0).

New in version 0.19.0.

```
In [101]: pd.Index(["a1a2", "b1", "c1"]).str.extractall(two_groups)
```

```
Out[101]:
```

|   |       | letter | digit |
|---|-------|--------|-------|
|   | match |        |       |
| 0 | 0     | a      | 1     |
|   | 1     | a      | 2     |
| 1 | 0     | b      | 1     |
| 2 | 0     | c      | 1     |

```
In [102]: pd.Series(["a1a2", "b1", "c1"]).str.extractall(two_groups)
```

```

////////////////////////////////////
↪
```

|   |       | letter | digit |
|---|-------|--------|-------|
|   | match |        |       |
| 0 | 0     | a      | 1     |
|   | 1     | a      | 2     |
| 1 | 0     | b      | 1     |
| 2 | 0     | c      | 1     |

## 10.5 Testing for Strings that Match or Contain a Pattern

You can check whether elements contain a pattern:

```
In [103]: pattern = r'[0-9][a-z]'
```

```
In [104]: pd.Series(['1', '2', '3a', '3b', '03c']).str.contains(pattern)
```

```
Out[104]:
```

```

0    False
1    False
2     True
3     True
4     True
dtype: bool
```

Or whether elements match a pattern:

```
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
```

```
Out[105]:
```

```

0    False
1    False
2     True
3     True
4    False
dtype: bool
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered `True` or `False`:

```
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat',
→])

In [107]: s4.str.contains('A', na=False)
Out[107]:
0      True
1     False
2     False
3      True
4     False
5     False
6      True
7     False
8     False
dtype: bool
```

## 10.6 Creating Indicator Variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])

In [109]: s.str.get_dummies(sep='|')
Out[109]:
   a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1
```

String Index also supports `get_dummies` which returns a `MultiIndex`.

New in version 0.18.1.

```
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [111]: idx.str.get_dummies(sep='|')
Out[111]:
MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
            labels=[[1, 1, 0, 1], [0, 1, 0, 0], [0, 0, 0, 1]],
            names=['a', 'b', 'c'])
```

See also `get_dummies()`.

## 10.7 Method Summary

| Method                       | Description  |
|------------------------------|--|
| <code>cat()</code>           | Concatenate strings  |
| <code>split()</code>         | Split strings on delimiter   |
| <code>rsplit()</code>        | Split strings on delimiter working from the end of the string  |
| <code>get()</code>           | Index into each element (retrieve i-th element)  |
| <code>join()</code>          | Join strings in each element of the Series with passed separator   |
| <code>get_dummies()</code>   | Split strings on the delimiter returning DataFrame of dummy variables  |
| <code>contains()</code>      | Return boolean array if each string contains pattern/regex   |
| <code>replace()</code>       | Replace occurrences of pattern/regex/string with some other string or the return value of a callable given the occurrence                  |
| <code>repeat()</code>        | Duplicate values ( <code>s.str.repeat(3)</code> equivalent to <code>x * 3</code> )   |
| <code>pad()</code>           | Add whitespace to left, right, or both sides of strings  |
| <code>center()</code>        | Equivalent to <code>str.center</code>  |
| <code>ljust()</code>         | Equivalent to <code>str.ljust</code>   |
| <code>rjust()</code>         | Equivalent to <code>str.rjust</code>   |
| <code>zfill()</code>         | Equivalent to <code>str.zfill</code>   |
| <code>wrap()</code>          | Split long strings into lines with length less than a given width  |
| <code>slice()</code>         | Slice each string in the Series  |
| <code>slice_replace()</code> | Replace slice in each string with passed value   |
| <code>count()</code>         | Count occurrences of pattern   |
| <code>startswith()</code>    | Equivalent to <code>str.startswith(pat)</code> for each element  |
| <code>endswith()</code>      | Equivalent to <code>str.endswith(pat)</code> for each element  |
| <code>findall()</code>       | Compute list of all occurrences of pattern/regex for each string   |
| <code>match()</code>         | Call <code>re.match</code> on each element, returning matched groups as list   |
| <code>extract()</code>       | Call <code>re.search</code> on each element, returning DataFrame with one row for each element and one column for each regex capture group |
| <code>extractall()</code>    | Call <code>re.findall</code> on each element, returning DataFrame with one row for each match and one column for each regex capture group  |
| <code>len()</code>           | Compute string lengths   |
| <code>strip()</code>         | Equivalent to <code>str.strip</code>   |
| <code>rstrip()</code>        | Equivalent to <code>str.rstrip</code>  |
| <code>lstrip()</code>        | Equivalent to <code>str.lstrip</code>  |
| <code>partition()</code>     | Equivalent to <code>str.partition</code>   |
| <code>rpartition()</code>    | Equivalent to <code>str.rpartition</code>  |
| <code>lower()</code>         | Equivalent to <code>str.lower</code>   |
| <code>upper()</code>         | Equivalent to <code>str.upper</code>   |
| <code>find()</code>          | Equivalent to <code>str.find</code>  |
| <code>rfind()</code>         | Equivalent to <code>str.rfind</code>   |
| <code>index()</code>         | Equivalent to <code>str.index</code>   |
| <code>rindex()</code>        | Equivalent to <code>str.rindex</code>  |
| <code>capitalize()</code>    | Equivalent to <code>str.capitalize</code>  |
| <code>swapcase()</code>      | Equivalent to <code>str.swapcase</code>  |
| <code>normalize()</code>     | Return Unicode normal form. Equivalent to <code>unicodedata.normalize</code>   |
| <code>translate()</code>     | Equivalent to <code>str.translate</code>   |
| <code>isalnum()</code>       | Equivalent to <code>str.isalnum</code>   |
| <code>isalpha()</code>       | Equivalent to <code>str.isalpha</code>   |
| <code>isdigit()</code>       | Equivalent to <code>str.isdigit</code>   |
| <code>isspace()</code>       | Equivalent to <code>str.isspace</code>   |
| <code>islower()</code>       | Equivalent to <code>str.islower</code>   |
| <code>isupper()</code>       | Equivalent to <code>str.isupper</code>   |
| <code>istitle()</code>       | Equivalent to <code>str.istitle</code>   |

| Method                   | Description                              |
|--------------------------|--|
| <code>isnumeric()</code> | Equivalent to <code>str.isnumeric</code> |
| <code>isdecimal()</code> | Equivalent to <code>str.isdecimal</code> |

## OPTIONS AND SETTINGS

### 11.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. `display.max_rows`). You can get/set options directly as attributes of the top-level `options` attribute:

```
In [1]: import pandas as pd

In [2]: pd.options.display.max_rows
Out[2]: 15

In [3]: pd.options.display.max_rows = 999

In [4]: pd.options.display.max_rows
Out[4]: 999
```

The API is composed of 5 relevant functions, available directly from the `pandas` namespace:

- `get_option()` / `set_option()` - get/set the value of a single option.
- `reset_option()` - reset one or more options to their default value.
- `describe_option()` - print the descriptions of one or more options.
- `option_context()` - execute a codeblock with a set of options that revert to prior settings after execution.

**Note:** Developers can check out [pandas/core/config.py](#) for more information.

All of the functions above accept a regexp pattern (`re.search` style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

```
In [5]: pd.get_option("display.max_rows")
Out[5]: 999

In [6]: pd.set_option("display.max_rows", 101)

In [7]: pd.get_option("display.max_rows")
Out[7]: 101

In [8]: pd.set_option("max_r", 102)

In [9]: pd.get_option("display.max_rows")
Out[9]: 102
```

The following will **not work** because it matches multiple option names, e.g. `display.max_colwidth`, `display.max_rows`, `display.max_columns`:

```
In [10]: try:
.....:     pd.get_option("column")
.....: except KeyError as e:
.....:     print(e)
.....:
'Pattern matched multiple keys'
```

**Note:** Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with `describe_option`. When called with no argument `describe_option` will print out the descriptions for all available options.

## 11.2 Getting and Setting Options

As described above, `get_option()` and `set_option()` are available from the pandas namespace. To change an option, call `set_option('option regex', new_value)`.

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

**Note:** The option ‘mode.sim\_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use `reset_option` to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It’s also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

`option_context` context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the *with* block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
.....:     print(pd.get_option("display.max_rows"))
.....:     print(pd.get_option("display.max_columns"))
```

(continues on next page)

(continued from previous page)

```

.....:
10
5

In [21]: print(pd.get_option("display.max_rows"))
\\\\"60

In [22]: print(pd.get_option("display.max_columns"))
\\\\"0

```

## 11.3 Setting Startup Options in python/ipython Environment

Using startup scripts for the python/ipython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the [ipython documentation](#). An example startup script for pandas is displayed below:

```

import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)

```

## 11.4 Frequently Used Options

The following is a walkthrough of the more frequently used display options.

`display.max_rows` and `display.max_columns` sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```

In [23]: df = pd.DataFrame(np.random.randn(7,2))

In [24]: pd.set_option('max_rows', 7)

In [25]: df
Out[25]:
      0         1
0  0.469112 -0.282863
1 -1.509059 -1.135632
2  1.212112 -0.173215
3  0.119209 -1.044236
4 -0.861849 -2.104569
5 -0.494929  1.071804
6  0.721555 -0.706771

In [26]: pd.set_option('max_rows', 5)

In [27]: df
Out[27]:

```

(continues on next page)

(continued from previous page)

```

      0      1
0  0.469112 -0.282863
1 -1.509059 -1.135632
..      ...      ...
5 -0.494929  1.071804
6  0.721555 -0.706771

```

```
[7 rows x 2 columns]
```

```
In [28]: pd.reset_option('max_rows')
```

`display.expand_frame_repr` allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

```
In [29]: df = pd.DataFrame(np.random.randn(5,10))
```

```
In [30]: pd.set_option('expand_frame_repr', True)
```

```
In [31]: df
```

```
Out[31]:
```

```

      0      1      2      3      4      5      6      7      8      9
0 -1.039575  0.271860 -0.424972  0.567020  0.276232 -1.087401 -0.673690  0.113648 -1.478427  0.524988

```

```
In [32]: pd.set_option('expand_frame_repr', False)
```

```
In [33]: df
```

```
Out[33]:
```

```

      0      1      2      3      4      5      6      7      8      9
0 -1.039575  0.271860 -0.424972  0.567020  0.276232 -1.087401 -0.673690  0.113648 -1.478427  0.524988
1  0.404705  0.577046 -1.715002 -1.039268 -0.370647 -1.157892 -1.344312  0.844885  1.075770 -0.109050
2  1.643563 -1.469388  0.357021 -0.674600 -1.776904 -0.968914 -1.294524  0.413738  0.276662 -0.472035
3 -0.013960 -0.362543 -0.006154 -0.923061  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309
4 -1.170299 -0.226169  0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737

```

```
In [34]: pd.reset_option('expand_frame_repr')
```

`display.large_repr` lets you select whether to display dataframes that exceed `max_columns` or `max_rows` as a truncated frame, or as a summary.

```
In [35]: df = pd.DataFrame(np.random.randn(10,10))
```

(continues on next page)

(continued from previous page)

```

In [36]: pd.set_option('max_rows', 5)

In [37]: pd.set_option('large_repr', 'truncate')

In [38]: df
Out[38]:

In [54]: pd.reset_option('max_info_columns')

```

`display.max_info_rows: df.info()` will usually show null-counts for each column. For large frames this can be quite slow. `max_info_rows` and `max_info_cols` limit this null check only to frames with smaller dimensions than specified. Note that you can specify the option `df.info(null_counts=True)` to override on showing a particular frame.

```

In [55]: df = pd.DataFrame(np.random.choice([0,1,np.nan], size=(10,10)))

## 11.5 Available Options

| Option                           | Default  | Function  |
|----------------------------------|----------|---|
| display.chop_threshold           | None     | If set to a float value, all float values smaller then the given threshold will be displayed.   |
| display.colheader_justify        | right    | Controls the justification of column headers. used by DataFrameFormatter.                       |
| display.column_space             | 12       | No description available.   |
| display.date_dayfirst            | False    | When True, prints and parses dates with the day first, eg 20/01/2005                            |
| display.date_yearfirst           | False    | When True, prints and parses dates with the year first, eg 2005/01/20                           |
| display.encoding                 | UTF-8    | Defaults to the detected encoding of the console. Specifies the encoding to be used.            |
| display.expand_frame_repr        | True     | Whether to print out the full DataFrame repr for wide DataFrames across multiple lines.         |
| display.float_format             | None     | The callable should accept a floating point number and return a string with the desired format. |
| display.large_repr               | truncate | For DataFrames exceeding max_rows/max_cols, the repr (and HTML repr) can be truncated.          |
| display.latex.repr               | False    | Whether to produce a latex DataFrame representation for jupyter frontends that support it.      |
| display.latex.escape             | True     | Escapes special characters in DataFrames, when using the to_latex method.                       |
| display.latex.longtable          | False    | Specifies if the to_latex method of a DataFrame uses the longtable format.                      |
| display.latex.multicolumn        | True     | Combines columns when using a MultiIndex  |
| display.latex.multicolumn_format | 'l'      | Alignment of multicolumn labels   |
| display.latex.multirow           | False    | Combines rows when using a MultiIndex. Centered instead of top-aligned, separated by &#x2013;   |
| display.max_columns              | 0 or 20  | max_rows and max_columns are used in __repr__() methods to decide if to truncate.               |
| display.max_colwidth             | 50       | The maximum width in characters of a column in the repr of a pandas data structure.             |

| Option                                  | Default  | Function  |
|---|----------|---|
| display.max_info_columns                | 100      | max_info_columns is used in DataFrame.info method to decide if per column info        |
| display.max_info_rows                   | 1690785  | df.info() will usually show null-counts for each column. For large frames this ca     |
| display.max_rows                        | 60       | This sets the maximum number of rows pandas should output when printing out           |
| display.max_seq_items                   | 100      | when pretty-printing a long sequence, no more then <i>max_seq_items</i> will be print |
| display.memory_usage                    | True     | This specifies if the memory usage of a DataFrame should be displayed when th         |
| display.multi_sparse                    | True     | “Sparsify” MultiIndex display (don’t display repeated elements in outer levels w      |
| display.notebook_repr_html              | True     | When True, IPython notebook will use html representation for pandas objects (if       |
| display.pprint_nest_depth               | 3        | Controls the number of nested levels to process when pretty-printing                  |
| display.precision                       | 6        | Floating point output precision in terms of number of places after the decimal, fo    |
| display.show_dimensions                 | truncate | Whether to print out dimensions at the end of DataFrame repr. If ‘truncate’ is sp     |
| display.width                           | 80       | Width of the display in characters. In case python/IPython is running in a termin     |
| display.html.table_schema               | False    | Whether to publish a Table Schema representation for frontends that support it.       |
| display.html.border                     | 1        | A border=value attribute is inserted in the <table> tag for the DataFrame             |
| display.html.use_mathjax                | True     | When True, Jupyter notebook will process table contents using MathJax, renderi        |
| io.excel.xls.writer                     | xlwt     | The default Excel writer engine for ‘xls’ files.                                      |
| io.excel.xlsm.writer                    | openpyxl | The default Excel writer engine for ‘xlsm’ files. Available options: ‘openpyxl’ (t    |
| io.excel.xlsx.writer                    | openpyxl | The default Excel writer engine for ‘xlsx’ files.                                     |
| io.hdf.default_format                   | None     | default format writing format, if None, then put will default to ‘fixed’ and appen    |
| io.hdf.dropna_table                     | True     | drop ALL nan rows when appending to a table   |
| io.parquet.engine                       | None     | The engine to use as a default for parquet reading and writing. If None then try ‘    |
| mode.chained_assignment                 | warn     | Controls SettingWithCopyWarning: ‘raise’, ‘warn’, or None. Raise an ex                |
| mode.sim_interactive                    | False    | Whether to simulate interactive mode for purposes of testing.                         |
| mode.use_inf_as_na                      | False    | True means treat None, NaN, -INF, INF as NA (old way), False means None and           |
| compute.use_bottleneck                  | True     | Use the bottleneck library to accelerate computation if it is installed.              |
| compute.use_numexpr                     | True     | Use the numexpr library to accelerate computation if it is installed.                 |
| plotting.matplotlib.register_converters | True     | Register custom converters with matplotlib. Set to False to de-register.              |

## 11.6 Number Formatting

pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```
In [79]: import numpy as np

In [80]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)

In [81]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])

In [82]: s/1.e3
Out[82]:
a    -236.866u
b     846.974u
c    -685.597u
d     609.099u
e    -303.961u
dtype: float64
```

(continues on next page)

(continued from previous page)

```
In [83]: s/1.e6
```

```

////////////////////////////////////Out [83]:
↪
a    -236.866n
b     846.974n
c    -685.597n
d     609.099n
e    -303.961n
dtype: float64

```

To round floats on a case-by-case basis, you can also use `round()` and `round()`.

## 11.7 Unicode Formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```
In [84]: df = pd.DataFrame({'u': ['UK', u''], u': ['Alice', u'']})
```

```
In [85]: df;
```

```

>>> df = pd.DataFrame({'u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})
>>> df
   名前  国籍
0  Alice  UK
1  のぶ  日本

```

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```
In [86]: pd.set_option('display.unicode.east_asian_width', True)
```

```
In [87]: df;
```

```

>>> pd.set_option('display.unicode.east_asian_width', True)
>>> df
   名前  国籍
0  Alice  UK
1  のぶ  日本

```

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.

By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```
In [88]: df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
In [89]: df;

>>> df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
>>> df
   a    b
0 xxx  yyy
1  ¡¡  ¡¡
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.)

However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
In [91]: df;

>>> pd.set_option('display.unicode.ambiguous_as_wide', True)
>>> df
   a    b
0 xxx  yyy
1  ¡¡  ¡¡
```

## 11.8 Table Schema Display

New in version 0.20.0.

`DataFrame` and `Series` will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```
In [92]: pd.set_option('display.html.table_schema', True)
```

Only `'display.max_rows'` are serialized and published.

## INDEXING AND SELECTING DATA

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e. provides *metadata*) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

---

**Note:** The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there's little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn't known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

---

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see [here](#).

See the [MultiIndex / Advanced Indexing](#) for `MultiIndex` and more advanced indexing documentation.

See the [cookbook](#) for some advanced strategies.

### 12.1 Different Choices for Indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See [Slicing with labels](#).).
- A boolean array
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at [Selection by Label](#).

- `.iloc` is primarily integer position based (from 0 to `length-1` of the axis), but may also be used with a boolean array. `.iloc` will raise `IndexError` if a requested indexer is out-of-bounds, except *slice* indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy *slice* semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array.
  - A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at [Selection by Position](#), [Advanced Indexing](#) and [Advanced Hierarchical](#).

- `.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. See more at [Selection By Callable](#).

Getting values from an object with multi-axes selection uses the following notation (using `.loc` as an example, but the following applies to `.iloc` as well). Any of the axes accessors may be the null slice `:`. Axes left out of the specification are assumed to be `:`, e.g. `p.loc['a']` is equivalent to `p.loc['a', :, :]`.

| Object Type | Indexers   |
|-------------|--|
| Series      | <code>s.loc[indexer]</code>                                    |
| DataFrame   | <code>df.loc[row_indexer, column_indexer]</code>               |
| Panel       | <code>p.loc[item_indexer, major_indexer, minor_indexer]</code> |

## 12.2 Basics

As mentioned when introducing the data structures in the [last section](#), the primary function of indexing with `[]` (a.k.a. `__getitem__` for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with `[]`:

| Object Type | Selection                    | Return Value Type                       |
|-------------|------------------------------|---|
| Series      | <code>series[label]</code>   | scalar value                            |
| DataFrame   | <code>frame[colname]</code>  | Series corresponding to colname         |
| Panel       | <code>panel[itemname]</code> | DataFrame corresponding to the itemname |

Here we construct a simple time series data set to use for illustrating the indexing functionality:

```
In [1]: dates = pd.date_range('1/1/2000', periods=8)

In [2]: df = pd.DataFrame(np.random.randn(8, 4), index=dates, columns=['A', 'B', 'C',
↪ 'D'])

In [3]: df
Out[3]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 0.469112  | -0.282863 | -1.509059 | -1.135632 |
| 2000-01-02 | 1.212112  | -0.173215 | 0.119209  | -1.044236 |
| 2000-01-03 | -0.861849 | -2.104569 | -0.494929 | 1.071804  |
| 2000-01-04 | 0.721555  | -0.706771 | -1.039575 | 0.271860  |
| 2000-01-05 | -0.424972 | 0.567020  | 0.276232  | -1.087401 |
| 2000-01-06 | -0.673690 | 0.113648  | -1.478427 | 0.524988  |
| 2000-01-07 | 0.404705  | 0.577046  | -1.715002 | -1.039268 |
| 2000-01-08 | -0.370647 | -1.157892 | -1.344312 | 0.844885  |

```
In [4]: panel = pd.Panel({'one' : df, 'two' : df - df.mean()})

In [5]: panel
Out[5]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 8 (major_axis) x 4 (minor_axis)
Items axis: one to two
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-08 00:00:00
Minor_axis axis: A to D
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```
In [6]: s = df['A']

In [7]: s[dates[5]]
Out[7]: -0.67368970808837059

In [8]: panel['two']
Out[8]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | 0.409571  | 0.113086  | -0.610826 | -0.936507 |
| 2000-01-02 | 1.152571  | 0.222735  | 1.017442  | -0.845111 |
| 2000-01-03 | -0.921390 | -1.708620 | 0.403304  | 1.270929  |
| 2000-01-04 | 0.662014  | -0.310822 | -0.141342 | 0.470985  |
| 2000-01-05 | -0.484513 | 0.962970  | 1.174465  | -0.888276 |
| 2000-01-06 | -0.733231 | 0.509598  | -0.580194 | 0.724113  |
| 2000-01-07 | 0.345164  | 0.972995  | -0.816769 | -0.840143 |
| 2000-01-08 | -0.430188 | -0.761943 | -0.446079 | 1.044010  |

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```
In [9]: df
Out[9]:
```

|  | A | B | C | D |
|--|---|---|---|---|
|--|---|---|---|---|

(continues on next page)

(continued from previous page)

```

2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885

```

```
In [10]: df[['B', 'A']] = df[['A', 'B']]
```

```
In [11]: df
```

```
Out[11]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -0.282863 | 0.469112  | -1.509059 | -1.135632 |
| 2000-01-02 | -0.173215 | 1.212112  | 0.119209  | -1.044236 |
| 2000-01-03 | -2.104569 | -0.861849 | -0.494929 | 1.071804  |
| 2000-01-04 | -0.706771 | 0.721555  | -1.039575 | 0.271860  |
| 2000-01-05 | 0.567020  | -0.424972 | 0.276232  | -1.087401 |
| 2000-01-06 | 0.113648  | -0.673690 | -1.478427 | 0.524988  |
| 2000-01-07 | 0.577046  | 0.404705  | -1.715002 | -1.039268 |
| 2000-01-08 | -1.157892 | -0.370647 | -1.344312 | 0.844885  |

You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting Series and DataFrame from `.loc`, and `.iloc`.

This will **not** modify `df` because the column alignment is before value assignment.

```
In [12]: df[['A', 'B']]
```

```
Out[12]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2000-01-01 | -0.282863 | 0.469112  |
| 2000-01-02 | -0.173215 | 1.212112  |
| 2000-01-03 | -2.104569 | -0.861849 |
| 2000-01-04 | -0.706771 | 0.721555  |
| 2000-01-05 | 0.567020  | -0.424972 |
| 2000-01-06 | 0.113648  | -0.673690 |
| 2000-01-07 | 0.577046  | 0.404705  |
| 2000-01-08 | -1.157892 | -0.370647 |

```
In [13]: df.loc[:, ['B', 'A']] = df[['A', 'B']]
```

```
In [14]: df[['A', 'B']]
```

```
Out[14]:
```

|            | A         | B         |
|------------|-----------|-----------|
| 2000-01-01 | -0.282863 | 0.469112  |
| 2000-01-02 | -0.173215 | 1.212112  |
| 2000-01-03 | -2.104569 | -0.861849 |
| 2000-01-04 | -0.706771 | 0.721555  |
| 2000-01-05 | 0.567020  | -0.424972 |
| 2000-01-06 | 0.113648  | -0.673690 |
| 2000-01-07 | 0.577046  | 0.404705  |
| 2000-01-08 | -1.157892 | -0.370647 |

The correct way to swap column values is by using raw values:

You may access an index on a `Series`, column on a `DataFrame`, and an item on a `Panel` directly as an attribute:

```
In [18]: dfa = df.copy()
```

Out [19]: 2

```
\\\\\\\\\\\\\\\\\\\\Out[20]:
```

```
In [21]: panel.one
```

```
In [22]: sa.a = 5
```

```
In [23]: sa
```

---

(continues on next page)

(continued from previous page)

```

Out [23]:
a      5
b      2
c      3
dtype: int64

In [24]: dfa.A = list(range(len(dfa.index))) # ok if A already exists

In [25]: dfa
Out [25]:
           A          B          C          D
2000-01-01  0 -0.282863 -1.509059 -1.135632
2000-01-02  1 -0.173215  0.119209 -1.044236
2000-01-03  2 -2.104569 -0.494929  1.071804
2000-01-04  3 -0.706771 -1.039575  0.271860
2000-01-05  4  0.567020  0.276232 -1.087401
2000-01-06  5  0.113648 -1.478427  0.524988
2000-01-07  6  0.577046 -1.715002 -1.039268
2000-01-08  7 -1.157892 -1.344312  0.844885

In [26]: dfa['A'] = list(range(len(dfa.index))) # use this form to create a new_
↪column

In [27]: dfa
Out [27]:
           A          B          C          D
2000-01-01  0 -0.282863 -1.509059 -1.135632
2000-01-02  1 -0.173215  0.119209 -1.044236
2000-01-03  2 -2.104569 -0.494929  1.071804
2000-01-04  3 -0.706771 -1.039575  0.271860
2000-01-05  4  0.567020  0.276232 -1.087401
2000-01-06  5  0.113648 -1.478427  0.524988
2000-01-07  6  0.577046 -1.715002 -1.039268
2000-01-08  7 -1.157892 -1.344312  0.844885

```

**Warning:**

- You can use this access only if the index element is a valid Python identifier, e.g. `s.1` is not allowed. See [here for an explanation of valid identifiers](#).
- The attribute will not be available if it conflicts with an existing method name, e.g. `s.min` is not allowed.
- Similarly, the attribute will not be available if it conflicts with any of the following list: `index`, `major_axis`, `minor_axis`, `items`.
- In any of these cases, standard indexing will still work, e.g. `s['1']`, `s['min']`, and `s['index']` will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a `dict` to a row of a `DataFrame`:

```

In [28]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [29]: x.iloc[1] = dict(x=9, y=99)

```

(continues on next page)

(continued from previous page)

```
In [30]: x
```

Out [30] :

|   | x | y  |
|---|---|----|
| 0 | 1 | 3  |
| 1 | 9 | 99 |
| 2 | 3 | 5  |

You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
```

```
In[2]: df.two = [4, 5, 6]
```

```
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns -
↳ see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute\_access
```

```
In[3]: df
```

Out [3]:

|   | one |
|---|-----|
| 0 | 1.0 |
| 1 | 2.0 |
| 2 | 3.0 |

## 12.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the *Selection by Position* section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With `Series`, the syntax works exactly as with an `ndarray`, returning a slice of the values and the corresponding labels:

```
In [31]: s[:5]
```

Out [31]:

```
2000-01-01    0.469112
2000-01-02    1.212112
2000-01-03   -0.861849
2000-01-04    0.721555
2000-01-05   -0.424972
Freq: D, Name: A, dtype: float64
```

```
In [32]: s[::2]
```

```

2000-01-01    0.469112
2000-01-03   -0.861849
2000-01-05   -0.424972
2000-01-07    0.404705
Freq: 2D, Name: A, dtype: float64

```

```
In [33]: s[::-1]
```

↪

|            |           |
|------------|-----------|
| 2000-01-08 | -0.370647 |
| 2000-01-07 | 0.404705  |
| 2000-01-06 | -0.673690 |
| 2000-01-05 | -0.424972 |

(continues on next page)

(continued from previous page)

```

2000-01-04    0.721555
2000-01-03   -0.861849
2000-01-02    1.212112
2000-01-01    0.469112
Freq: -1D, Name: A, dtype: float64

```

Note that setting works as well:

```

In [34]: s2 = s.copy()

In [35]: s2[:5] = 0

In [36]: s2
Out[36]:
2000-01-01    0.000000
2000-01-02    0.000000
2000-01-03    0.000000
2000-01-04    0.000000
2000-01-05    0.000000
2000-01-06   -0.673690
2000-01-07    0.404705
2000-01-08   -0.370647
Freq: D, Name: A, dtype: float64

```

With DataFrame, slicing inside of `[]` **slices the rows**. This is provided largely as a convenience since it is such a common operation.

```

In [37]: df[:3]
Out[37]:
           A          B          C          D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804

In [38]: df[::-1]
Out[38]:
           A          B          C          D
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632

```

## 12.5 Selection By Label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See *Returning a View versus Copy*.

**Warning:**

.loc is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a DatetimeIndex. These will raise a TypeError.

```
In [39]: df1 = pd.DataFrame(np.random.randn(5,4), columns=list('ABCD'), index=pd.
↳date_range('20130101',periods=5))
```

```
In [40]: df1
```

```
Out [40]:
```

|            | A         | B         | C         | D         |

**Warning:** Starting in 0.21.0, pandas will show a FutureWarning if indexing with a list with missing labels. In the future this will raise a KeyError. See *list-like Using loc with missing keys in a list is Deprecated*.

pandas provides a suite of methods in order to have **purely label based indexing**. This is a strict inclusion based protocol. Every label asked for must be in the index, or a `KeyError` will be raised. When slicing, both the start bound **AND** the stop bound are *included*, if present in the index. Integers are valid labels, but they refer to the label **and not the position**.

The `.loc` attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a *label* of the index. This use is **not** an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a': 'f' (Note that contrary to usual python slices, **both** the start and the stop are included, when present in the index! See *Slicing with labels*.).
- A boolean array.
- A callable, see *Selection By Callable*.

```
In [42]: s1 = pd.Series(np.random.randn(6), index=list('abcdef'))
```

```
In [43]: s1
```

```
Out [43]:
```

|   |          |
|---|----------|
| a | 1.431256 |
|---|----------|

f -1.281247 -0.727707 -0.121306 -0.097883
```

```
In [50]: df1.loc[['a', 'b', 'd'], :]
```

```

////////////////////////////////////
↪
      A         B         C         D
a  0.132003 -0.827317 -0.076467 -1.187678
b  1.130127 -1.436737 -1.413681  1.607920
```

(continues on next page)

(continued from previous page)

```
d  0.974466 -2.006747 -0.410001 -0.078638
```

Accessing via label slices:

```
In [51]: df1.loc['d':, 'A':'C']
Out[51]:
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| d | 0.974466  | -2.006747 | -0.410001 |
| e | 0.545952  | -1.219217 | -1.226825 |
| f | -1.281247 | -0.727707 | -0.121306 |

For getting a cross section using a label (equivalent to `df.xs('a')`):

```
In [52]: df1.loc['a']
Out[52]:
```

|   | A         |
|---|-----------|
| A | 0.132003  |
| B | -0.827317 |
| C | -0.076467 |
| D | -1.187678 |

Name: a, dtype: float64

For getting values with a boolean array:

```
In [53]: df1.loc['a'] > 0
Out[53]:
```

|   | A     |
|---|-------|
| A | True  |
| B | False |
| C | False |
| D | False |

Name: a, dtype: bool

```
In [54]: df1.loc[:, df1.loc['a'] > 0]
Out[54]:
```

|   | A         |
|---|-----------|
| a | 0.132003  |
| b | 1.130127  |
| c | 1.024180  |
| d | 0.974466  |
| e | 0.545952  |
| f | -1.281247 |

For getting a value explicitly (equivalent to deprecated `df.get_value('a', 'A')`):

```
# this is also equivalent to ``df1.at['a', 'A']``
In [55]: df1.loc['a', 'A']
Out[55]: 0.13200317033032932
```

### 12.5.1 Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements *located* between the two (including them) are returned:

```
In [56]: s = pd.Series(list('abcde'), index=[0,3,2,5,4])
In [57]: s.loc[3:5]
```

(continues on next page)

(continued from previous page)

```
Out [57]:
3      b
2      c
5      d
dtype: object
```

If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which *rank* between the two:

```
In [58]: s.sort_index()
Out [58]:
0      a
2      c
3      b
4      e
5      d
dtype: object

In [59]: s.sort_index().loc[1:6]
Out [59]:
2      c
3      b
4      e
5      d
dtype: object
```

However, if at least one of the two is absent *and* the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

## 12.6 Selection By Position

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

Pandas provides a suite of methods in order to get **purely integer based indexing**. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bounds is *included*, while the upper bound is *excluded*. Trying to use a non-integer, even a **valid** label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers `[4, 3, 0]`.
- A slice object with ints `1:7`.
- A boolean array.
- A callable, see [Selection By Callable](#).

```
In [60]: s1 = pd.Series(np.random.randn(5), index=list(range(0,10,2)))
In [61]: s1
```

(continues on next page)

(continued from previous page)

**Out [61]:**

```
0    0.695775
2    0.341734
4    0.959726
6   -1.110336
8   -0.619976
dtype: float64
```

**In [62]:** s1.iloc[:3]

```
Out [62]:
0    0.695775
2    0.341734
4    0.959726
dtype: float64
```

**In [63]:** s1.iloc[3]

```
Out [63]:
-1.1103361028911669
```

Note that setting works as well:

**In [64]:** s1.iloc[:3] = 0**In [65]:** s1**Out [65]:**

```
0    0.000000
2    0.000000
4    0.000000
6   -1.110336
8   -0.619976
dtype: float64
```

With a DataFrame:

```
In [66]: df1 = pd.DataFrame(np.random.randn(6,4),
.....:                      index=list(range(0,12,2)),
.....:                      columns=list(range(0,8,2)))
.....:
```

**In [67]:** df1**Out [67]:**

```
      0         2         4         6
0  0.149748 -0.732339  0.687738  0.176444

8  0.995761  2.396780  0.014871  3.357427
10 -0.317441 -1.236269  0.896171 -0.487602
```

Select via integer slicing:

**In [68]:** df1.iloc[:3]**Out [68]:**

```
      0         2         4         6
0  0.149748 -0.732339  0.687738  0.176444
2  0.403310 -0.154951  0.301624 -2.179861
```

(continues on next page)

(continued from previous page)

```
4 -1.369849 -0.954208 1.462696 -1.743161
```

```
In [69]: df1.iloc[1:5, 2:4]
```

```
////////////////////////////////////
```

```
↪
      4      6
2  0.301624 -2.179861
4  1.462696 -1.743161
6  1.314232  0.690579
8  0.014871  3.357427
```

Select via integer list:

```
In [70]: df1.iloc[[1, 3, 5], [1, 3]]
```

```
Out [70]:
```

```
      2      6
2 -0.154951 -2.179861
6 -0.345352  0.690579
10 -1.236269 -0.487602
```

```
In [71]: df1.iloc[1:3, :]
```

```
Out [71]:
```

```
      0      2      4      6
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
```

```
In [72]: df1.iloc[:, 1:3]
```

```
Out [72]:
```

```
      2      4
0 -0.732339  0.687738
2 -0.154951  0.301624
4 -0.954208  1.462696
6 -0.345352  1.314232
8  2.396780  0.014871
10 -1.236269  0.896171
```

```
# this is also equivalent to ``df1.iat[1,1]``
```

```
In [73]: df1.iloc[1, 1]
```

```
Out [73]: -0.15495077442490321
```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```
In [74]: df1.iloc[1]
```

```
Out [74]:
```

```
0    0.403310
2   -0.154951
4    0.301624
6   -2.179861
Name: 2, dtype: float64
```

Out of range slice indexes are handled gracefully just as in Python/Numpy.

```
# these are allowed in python/numpy.
```

```
In [75]: x = list('abcdef')
```

(continues on next page)

(continued from previous page)

```

In [76]: x
Out[76]: ['a', 'b', 'c', 'd', 'e', 'f']

In [77]: x[4:10]
\\Out[77]: ['e', 'f']

In [78]: x[8:10]
\\Out[78]: []

In [79]: s = pd.Series(x)

In [80]: s
Out[80]:
0    a

A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

```
df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds

df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

## 12.7 Selection By Callable

New in version 0.18.1.

`.loc`, `.iloc`, and also `[]` indexing can accept a callable as indexer. The callable must be a function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing.

```
In [88]: df1 = pd.DataFrame(np.random.randn(6, 4),
.....:                      index=list('abcdef'),
.....:                      columns=list('ABCD'))
.....:
```

```
In [89]: df1
```

```
Out[89]:
      A      B      C      D

## 12.8 IX Indexer is Deprecated

**Warning:** Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to *label* index.
- `.iloc` if you want to *positionally* index.

```
In [97]: dfd = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6]},
.....:                      index=list('abc'))
.....:
```

```
In [98]: dfd
```

```
Out[98]:
```

```
   A  B
a  1  4
b  2  5
c  3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the 'A' column.

```
In [3]: dfd.ix[[0, 2], 'A']
```

```
Out[3]:
```

```
a    1
c    3
Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use *label* indexing.

```
In [99]: dfd.loc[dfd.index[[0, 2]], 'A']
```

```
Out[99]:
```

```
a    1
c    3
Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using *positional* indexing to select things.

```
In [100]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
```

```
Out[100]:
```

(continues on next page)

(continued from previous page)

```
a    1
c    3
Name: A, dtype: int64
```

For getting *multiple* indexers, using `.get_indexer`:

```
In [101]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[101]:
   A  B
a  1  4
c  3  6
```

## 12.9 Indexing with list with missing labels is Deprecated

**Warning:** Starting in 0.21.0, using `.loc` or `[]` with a list with one or more missing labels, is deprecated, in favor of `.reindex`.

In prior versions, using `.loc[list-of-labels]` would work as long as *at least 1* of the keys was found (otherwise it would raise a `KeyError`). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use `.reindex()`.

For example.

```
In [102]: s = pd.Series([1, 2, 3])

In [103]: s
Out[103]:
0    1
1    2
2    3
dtype: int64
```

Selection with all keys found is unchanged.

```
In [104]: s.loc[[1, 2]]
Out[104]:
1    2
2    3
dtype: int64
```

Previous Behavior

```
In [4]: s.loc[[1, 2, 3]]
Out[4]:
1    2.0
2    3.0
3    NaN
dtype: float64
```

Current Behavior

```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
→listlike

Out[4]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

## 12.9.1 Reindexing

The idiomatic way to achieve selecting potentially not-found elements is via `.reindex()`. See also the section on *reindexing*.

```
In [105]: s.reindex([1, 2, 3])
Out[105]:
1      2.0
2      3.0
3      NaN
dtype: float64
```

Alternatively, if you want to select only *valid* keys, the following is idiomatic and efficient; it is guaranteed to preserve the dtype of the selection.

```
In [106]: labels = [1, 2, 3]

In [107]: s.loc[s.index.intersection(labels)]
Out[107]:
1      2
2      3
dtype: int64
```

Having a duplicated index will raise for a `.reindex()`:

```
In [108]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])

In [109]: labels = ['c', 'd']
```

```
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

Generally, you can intersect the desired labels with the current axis, and then reindex.

```
In [110]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[110]:
c      3.0
d      NaN
dtype: float64
```

However, this would *still* raise if your resulting index is duplicated.

```
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)
ValueError: cannot reindex from a duplicate axis
```

## 12.10 Selecting Random Samples

A random selection of rows or columns from a Series, DataFrame, or Panel with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [111]: s = pd.Series([0,1,2,3,4,5])

# When no arguments are passed, returns 1 row.
In [112]: s.sample()
Out[112]:
4      4
dtype: int64

# One may specify either a number of rows:
In [113]: s.sample(n=3)
Out[113]:
0      0
4      4
1      1
dtype: int64

# Or a fraction of the rows:
In [114]: s.sample(frac=0.5)
Out[114]:
5      5
3      3
1      1
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [115]: s = pd.Series([0,1,2,3,4,5])

# Without replacement (default):
In [116]: s.sample(n=6, replace=False)
Out[116]:
0      0
1      1
5      5
3      3
2      2
4      4
dtype: int64

# With replacement:
In [117]: s.sample(n=6, replace=True)
Out[117]:
0      0
4      4
```

(continues on next page)

(continued from previous page)

```
3      3
2      2
4      4
4      4
dtype: int64
```

By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and `inf` values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```
In [118]: s = pd.Series([0,1,2,3,4,5])

In [119]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [120]: s.sample(n=3, weights=example_weights)
Out[120]:
5      5
4      4
3      3
dtype: int64

# Weights will be re-normalized automatically
In [121]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [122]: s.sample(n=1, weights=example_weights2)
Out[122]:
0      0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```
In [123]: df2 = pd.DataFrame({'col1':[9,8,7,6], 'weight_column':[0.5, 0.4, 0.1, 0]})

In [124]: df2.sample(n = 3, weights = 'weight_column')
Out[124]:
   col1  weight_column
1      8             0.4
0      9             0.5
2      7             0.1
```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```
In [125]: df3 = pd.DataFrame({'col1':[1,2,3], 'col2':[2,3,4]})

In [126]: df3.sample(n=1, axis=1)
Out[126]:
   col1
0      1
1      2
2      3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.

## 12.11 Setting With Enlargement

The `.loc/[]` operations can perform enlargement when setting a non-existent key for that axis.

In the `Series` case this is effectively an appending operation.

```
In [130]: se = pd.Series([1,2,3])
```

```
In [131]: se
```

Out [131] :

```
0      1
1      2
2      3
dtype: int64
```

```
In [132]: se[5] = 5.
```

In [133]: se

```
Out[133]:
0      1.0
1      2.0
2      3.0
5      5.0
dtype: float64
```

A DataFrame can be enlarged on either axis via `.loc`.

```
In [134]: dfi = pd.DataFrame(np.arange(6).reshape(3,2),
.....:                        columns=['A', 'B'])
.....:
```

```
In [135]: dfi
```

Out [135] :

|   | A | B |
|---|---|---|
| 0 | 0 | 1 |
| 1 | 2 | 3 |
| 2 | 4 | 5 |

```
In [136]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']
```

(continues on next page)

(continued from previous page)

```
In [137]: dfi
Out[137]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
```

This is like an append operation on the DataFrame.

```
In [138]: dfi.loc[3] = 5

In [139]: dfi
Out[139]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

## 12.12 Fast scalar value getting and setting

Since indexing with `[]` must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you're asking for. If you only want to access a scalar value, the fastest way is to use the `at` and `iat` methods, which are implemented on all of the data structures.

Similarly to `loc`, `at` provides **label** based scalar lookups, while, `iat` provides **integer** based lookups analogously to `iloc`

```
In [140]: s.iat[5]
Out[140]: 5

In [141]: df.at[dates[5], 'A']
Out[141]: -0.67368970808837059

In [142]: df.iat[3, 0]
Out[142]: 0.72155516224436689
```

You can also set using these same indexers.

```
In [143]: df.at[dates[5], 'E'] = 7

In [144]: df.iat[3, 0] = 7
```

`at` may enlarge the object in-place as above if the indexer is missing.

```
In [145]: df.at[dates[-1]+1, 0] = 7

In [146]: df
Out[146]:
              A              B              C              D              E              0
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632      NaN      NaN
2000-01-02  1.212112 -0.173215  0.119209 -1.044236      NaN      NaN
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804      NaN      NaN
2000-01-04  7.000000 -0.706771 -1.039575  0.271860      NaN      NaN
```

(continues on next page)

(continued from previous page)

|            |           |           |           |           |     |     |

## 12.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: `|` for `or`, `&` for `and`, and `~` for `not`. These **must** be grouped by using parentheses, since by default Python will evaluate an expression such as `df.A > 2 & df.B < 3` as `df.A > (2 & df.B) < 3`, while the desired evaluation order is `(df.A > 2) & (df.B < 3)`.

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```
In [147]: s = pd.Series(range(-3, 4))

In [148]: s
Out[148]:
0    -3
1    -2
2    -1
3     0
4     1
5     2
6     3
dtype: int64

In [149]: s[s > 0]
Out[149]:
4     1
5     2
6     3
dtype: int64

In [150]: s[(s < -1) | (s > 0.5)]
Out[150]:
0    -3
1    -2
4     1
5     2
6     3
dtype: int64

In [151]: s[~(s < 0)]
Out[151]:
3     0
4     1
5     2
6     3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame's index (for example,

something derived from one of the columns of the DataFrame):

```
In [152]: df[df['A'] > 0]
Out[152]:
```

|            | A        | B         | C         | D         | E   | 0   |
|------------|----------|-----------|-----------|-----------|-----|-----|
| 2000-01-01 | 0.469112 | -0.282863 | -1.509059 | -1.135632 | NaN | NaN |
| 2000-01-02 | 1.212112 | -0.173215 | 0.119209  | -1.044236 | NaN | NaN |
| 2000-01-04 | 7.000000 | -0.706771 | -1.039575 | 0.271860  | NaN | NaN |
| 2000-01-07 | 0.404705 | 0.577046  | -1.715002 | -1.039268 | NaN | NaN |

List comprehensions and `map` method of `Series` can also be used to produce more complex criteria:

```
In [153]: df2 = pd.DataFrame({'a' : ['one', 'one', 'two', 'three', 'two', 'one', 'six',
↳ ],
.....:                        'b' : ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
.....:                        'c' : np.random.randn(7)})
.....:
```

```
# only want 'two' or 'three'
```

```
In [154]: criterion = df2['a'].map(lambda x: x.startswith('t'))
```

```
In [155]: df2[criterion]
```

```
Out [155] :
```

|   | a     | b | c         |
|---|-------|---|-----------|
| 2 | two   | y | 0.041290  |
| 3 | three | x | 0.361719  |
| 4 | two   | y | -0.238075 |

```
# equivalent but slower
```

```
In [156]: df2[[x.startswith('t') for x in df2['a']]]
```

|   | a     | b | c         |
|---|-------|---|-----------|
| 2 | two   | y | 0.041290  |
| 3 | three | x | 0.361719  |
| 4 | two   | y | -0.238075 |

```
# Multiple criteria
```

```
In [157]: df2[criterion & (df2['b'] == 'x')]
```

|   | a     | b | c        |
|---|-------|---|----------|
| 3 | three | x | 0.361719 |

With the choice methods *Selection by Label*, *Selection by Position*, and *Advanced Indexing* you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [158]: df2.loc[criterion & (df2['b'] == 'x'), 'b':'c']
```

```
Out[158]:
```

|     | b        | c |
|-----|----------|---|
| 3 x | 0.361719 |   |

## 12.14 Indexing with isin

Consider the `isin()` method of `Series`, which returns a boolean vector that is true wherever the `Series` elements exist in the passed list. This allows you to select rows where one or more columns have values you want:

```
In [159]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')
```

```
In [160]: s
```

```
Out[160]:
4    0
3    1
2    2
1    3
0    4
dtype: int64
```

```
In [161]: s.isin([2, 4, 6])
```

```
Out[161]:
4    False
3    False
2     True
1    False
0     True
dtype: bool
```

```
In [162]: s[s.isin([2, 4, 6])]
```

```
Out[162]:
2    2
0    4
dtype: int64
```

The same method is available for Index objects and is useful for the cases when you don't know which of the sought labels are in fact present:

```
In [163]: s[s.index.isin([2, 4, 6])]
```

```
Out[163]:
4    0
2    2
dtype: int64
```

```
# compare it to the following
```

```
In [164]: s.reindex([2, 4, 6])
```

```
Out[164]:
2    2.0
4    0.0
6    NaN
dtype: float64
```

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

```
In [165]: s_mi = pd.Series(np.arange(6),
.....:                    index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']],
.....:                    names=['level0', 'level1']))
```

```
In [166]: s_mi
```

```
Out[166]:
level0 level1  value
0     a      0      0
      b      1      1
      c      2      2
1     a      3      3
```

(continues on next page)

(continued from previous page)

```

    b    4
    c    5
dtype: int64

In [167]: s_mi.iloc[s_mi.index.isin([(1, 'a'), (2, 'b'), (0, 'c')])]
Out[167]:
↪
0  c    2
1  a    3
dtype: int64

In [168]: s_mi.iloc[s_mi.index.isin(['a', 'c', 'e'], level=1)]
Out[168]:
↪
0  a    0
   c    2
1  a    3
   c    5
dtype: int64

```

DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```

In [169]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
.....:                      'ids2': ['a', 'n', 'c', 'n']})
.....:

In [170]: values = ['a', 'b', 1, 3]

In [171]: df.isin(values)
Out[171]:
   vals  ids  ids2
0  True  True  True
1 False  True False
2  True False False
3 False False False

```

Oftentimes you'll want to match certain values with certain columns. Just make values a dict where the key is the column, and the value is a list of items you want to check for.

```

In [172]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [173]: df.isin(values)
Out[173]:
   vals  ids  ids2
0  True  True False
1 False  True False
2  True False False
3 False False False

```

Combine DataFrame's `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```

In [174]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}

```

(continues on next page)

(continued from previous page)

```
In [175]: row_mask = df.isin(values).all(1)
```

```
In [176]: df[row_mask]
```

```
Out[176]:
   vals ids ids2
0     1  a     a
```

## 12.15 The where () Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the `where` method in `Series` and `DataFrame`.

To return only the selected rows:

```
In [177]: s[s > 0]
```

```
Out[177]:
3     1
2     2
1     3
0     4
dtype: int64
```

To return a Series of the same shape as the original:

```
In [178]: s.where(s > 0)
```

```
Out[178]:
4     NaN
3     1.0
2     2.0
1     3.0
0     4.0
dtype: float64
```

Selecting values from a `DataFrame` with a boolean criterion now also preserves input data shape. `where` is used under the hood as the implementation. The code below is equivalent to `df[df < 0]`.

```
In [179]: df[df < 0]
```

```
Out[179]:
           A           B           C           D
2000-01-01 -2.104139 -1.309525        NaN        NaN
2000-01-02 -0.352480         NaN -1.192319        NaN
2000-01-03 -0.864883         NaN -0.227870        NaN
2000-01-04         NaN -1.222082         NaN -1.233203
2000-01-05         NaN -0.605656 -1.169184         NaN
2000-01-06         NaN -0.948458         NaN -0.684718
2000-01-07 -2.670153 -0.114722         NaN -0.048048
2000-01-08         NaN         NaN -0.048788 -0.808838
```

In addition, `where` takes an optional `other` argument for replacement of values where the condition is `False`, in the returned copy.

```
In [180]: df.where(df < 0, -df)
```

```
Out[180]:
           A           B           C           D
```

(continues on next page)

(continued from previous page)

```

2000-01-01 -2.104139 -1.309525 -0.485855 -0.245166
2000-01-02 -0.352480 -0.390389 -1.192319 -1.655824
2000-01-03 -0.864883 -0.299674 -0.227870 -0.281059
2000-01-04 -0.846958 -1.222082 -0.600705 -1.233203
2000-01-05 -0.669692 -0.605656 -1.169184 -0.342416
2000-01-06 -0.868584 -0.948458 -2.297780 -0.684718
2000-01-07 -2.670153 -0.114722 -0.168904 -0.048048
2000-01-08 -0.801196 -1.392071 -0.048788 -0.808838

```

You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```

In [181]: s2 = s.copy()

In [182]: s2[s2 < 0] = 0

In [183]: s2
Out[183]:
4      0
3      1
2      2
1      3
0      4
dtype: int64

In [184]: df2 = df.copy()

In [185]: df2[df2 < 0] = 0

In [186]: df2
Out[186]:
              A              B              C              D
2000-01-01  0.000000  0.000000  0.485855  0.245166
2000-01-02  0.000000  0.390389  0.000000  1.655824
2000-01-03  0.000000  0.299674  0.000000  0.281059
2000-01-04  0.846958  0.000000  0.600705  0.000000
2000-01-05  0.669692  0.000000  0.000000  0.342416
2000-01-06  0.868584  0.000000  2.297780  0.000000
2000-01-07  0.000000  0.000000  0.168904  0.000000
2000-01-08  0.801196  1.392071  0.000000  0.000000

```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```

In [187]: df_orig = df.copy()

In [188]: df_orig.where(df > 0, -df, inplace=True);

In [189]: df_orig
Out[189]:
              A              B              C              D
2000-01-01  2.104139  1.309525  0.485855  0.245166
2000-01-02  0.352480  0.390389  1.192319  1.655824
2000-01-03  0.864883  0.299674  0.227870  0.281059
2000-01-04  0.846958  1.222082  0.600705  1.233203
2000-01-05  0.669692  0.605656  1.169184  0.342416
2000-01-06  0.868584  0.948458  2.297780  0.684718

```

(continues on next page)

(continued from previous page)

|            |          |          |          |          |
|------------|----------|----------|----------|----------|
| 2000-01-07 | 2.670153 | 0.114722 | 0.168904 | 0.048048 |
| 2000-01-08 | 0.801196 | 1.392071 | 0.048788 | 0.808838 |

**Note:** The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)`.

```
In [190]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
```

```
Out [190]:
```

|            | A    | B    | C    | D    |
|------------|------|------|------|------|
| 2000-01-01 | True | True | True | True |
| 2000-01-02 | True | True | True | True |
| 2000-01-03 | True | True | True | True |
| 2000-01-04 | True | True | True | True |
| 2000-01-05 | True | True | True | True |
| 2000-01-06 | True | True | True | True |
| 2000-01-07 | True | True | True | True |
| 2000-01-08 | True | True | True | True |

### alignment

Furthermore, `where` aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.loc` (but on the contents rather than the axis labels).

```
In [191]: df2 = df.copy()
```

```
In [192]: df2[df2[1:4] > 0] = 3
```

```
In [193]: df2
```

```
Out [193]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -2.104139 | -1.309525 | 0.485855  | 0.245166  |
| 2000-01-02 | -0.352480 | 3.000000  | -1.192319 | 3.000000  |
| 2000-01-03 | -0.864883 | 3.000000  | -0.227870 | 3.000000  |
| 2000-01-04 | 3.000000  | -1.222082 | 3.000000  | -1.233203 |
| 2000-01-05 | 0.669692  | -0.605656 | -1.169184 | 0.342416  |
| 2000-01-06 | 0.868584  | -0.948458 | 2.297780  | -0.684718 |
| 2000-01-07 | -2.670153 | -0.114722 | 0.168904  | -0.048048 |
| 2000-01-08 | 0.801196  | 1.392071  | -0.048788 | -0.808838 |

Where can also accept `axis` and `level` parameters to align the input when performing the `where`.

```
In [194]: df2 = df.copy()
```

```
In [195]: df2.where(df2>0,df2['A'],axis='index')
```

```
Out [195]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -2.104139 | -2.104139 | 0.485855  | 0.245166  |
| 2000-01-02 | -0.352480 | 0.390389  | -0.352480 | 1.655824  |
| 2000-01-03 | -0.864883 | 0.299674  | -0.864883 | 0.281059  |
| 2000-01-04 | 0.846958  | 0.846958  | 0.600705  | 0.846958  |
| 2000-01-05 | 0.669692  | 0.669692  | 0.669692  | 0.342416  |
| 2000-01-06 | 0.868584  | 0.868584  | 2.297780  | 0.868584  |
| 2000-01-07 | -2.670153 | -2.670153 | 0.168904  | -2.670153 |
| 2000-01-08 | 0.801196  | 1.392071  | 0.801196  | 0.801196  |

This is equivalent to (but faster than) the following.

```
In [196]: df2 = df.copy()

In [197]: df.apply(lambda x, y: x.where(x>0,y), y=df['A'])
Out[197]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -2.104139 | -2.104139 | 0.485855  | 0.245166  |
| 2000-01-02 | -0.352480 | 0.390389  | -0.352480 | 1.655824  |
| 2000-01-03 | -0.864883 | 0.299674  | -0.864883 | 0.281059  |
| 2000-01-04 | 0.846958  | 0.846958  | 0.600705  | 0.846958  |
| 2000-01-05 | 0.669692  | 0.669692  | 0.669692  | 0.342416  |
| 2000-01-06 | 0.868584  | 0.868584  | 2.297780  | 0.868584  |
| 2000-01-07 | -2.670153 | -2.670153 | 0.168904  | -2.670153 |
| 2000-01-08 | 0.801196  | 1.392071  | 0.801196  | 0.801196  |

New in version 0.18.1.

Where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

```
In [198]: df3 = pd.DataFrame({'A': [1, 2, 3],
.....:                      'B': [4, 5, 6],
.....:                      'C': [7, 8, 9]})
.....:

In [199]: df3.where(lambda x: x > 4, lambda x: x + 10)
Out[199]:
```

|   | A  | B  | C |
|---|----|----|---|
| 0 | 11 | 14 | 7 |
| 1 | 12 | 5  | 8 |
| 2 | 13 | 6  | 9 |

## 12.15.1 Mask

`mask()` is the inverse boolean operation of `where`.

```
In [200]: s.mask(s >= 0)
Out[200]:
```

|   |     |
|---|-----|
| 4 | NaN |
| 3 | NaN |
| 2 | NaN |
| 1 | NaN |
| 0 | NaN |

dtype: float64

```
In [201]: df.mask(df >= 0)
Out[201]:
```

|            | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| 2000-01-01 | -2.104139 | -1.309525 | NaN       | NaN       |
| 2000-01-02 | -0.352480 | NaN       | -1.192319 | NaN       |
| 2000-01-03 | -0.864883 | NaN       | -0.227870 | NaN       |
| 2000-01-04 | NaN       | -1.222082 | NaN       | -1.233203 |
| 2000-01-05 | NaN       | -0.605656 | -1.169184 | NaN       |
| 2000-01-06 | NaN       | -0.948458 | NaN       | -0.684718 |
| 2000-01-07 | -2.670153 | -0.114722 | NaN       | -0.048048 |
| 2000-01-08 | NaN       | NaN       | -0.048788 | -0.808838 |

## 12.16 The `query()` Method

`DataFrame` objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```
In [202]: n = 10

In [203]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [204]: df
Out[204]:
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 0 | 0.438921 | 0.118680 | 0.863670 |
| 1 | 0.138138 | 0.577363 | 0.686602 |
| 2 | 0.595307 | 0.564592 | 0.520630 |
| 3 | 0.913052 | 0.926075 | 0.616184 |
| 4 | 0.078718 | 0.854477 | 0.898725 |
| 5 | 0.076404 | 0.523211 | 0.591538 |
| 6 | 0.792342 | 0.216974 | 0.564056 |
| 7 | 0.397890 | 0.454131 | 0.915716 |
| 8 | 0.074315 | 0.437913 | 0.019794 |
| 9 | 0.559209 | 0.502065 | 0.026437 |

```
# pure python
In [205]: df[(df.a < df.b) & (df.b < df.c)]
///////////////////////////////////////////////////
↪
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 1 | 0.138138 | 0.577363 | 0.686602 |
| 4 | 0.078718 | 0.854477 | 0.898725 |
| 5 | 0.076404 | 0.523211 | 0.591538 |
| 7 | 0.397890 | 0.454131 | 0.915716 |

```
# query
In [206]: df.query('(a < b) & (b < c)')
///////////////////////////////////////////////////
↪
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| 1 | 0.138138 | 0.577363 | 0.686602 |
| 4 | 0.078718 | 0.854477 | 0.898725 |
| 5 | 0.076404 | 0.523211 | 0.591538 |
| 7 | 0.397890 | 0.454131 | 0.915716 |

Do the same thing but fall back on a named index if there is no column with the name `a`.

```
In [207]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))

In [208]: df.index.name = 'a'

In [209]: df
Out[209]:
```

| a | b | c |
|---|---|---|
| 0 | 0 | 4 |
| 1 | 0 | 1 |
| 2 | 3 | 4 |

(continues on next page)

(continued from previous page)

```

3  4  3
4  1  4
5  0  3
6  0  1
7  3  4
8  2  3
9  1  1

```

```
In [210]: df.query('a < b and b < c')
```

```

////////////////////////////////////
↪
   b  c
a
2  3  4

```

If instead you don't want to or cannot name your index, you can use the name `index` in your query expression:

```
In [211]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))
```

```
In [212]: df
```

```
Out[212]:
```

```

   b  c
0  3  1
1  3  0
2  5  6
3  5  2
4  7  4
5  0  1
6  2  5
7  0  1
8  6  0
9  7  9

```

```
In [213]: df.query('index < b < c')
```

```

////////////////////////////////////
↪
   b  c
2  5  6

```

**Note:** If the name of your index overlaps with a column name, the column name is given precedence. For example,

```
In [214]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})
```

```
In [215]: df.index.name = 'a'
```

```
In [216]: df.query('a > 2') # uses the column 'a', not the index
```

```
Out[216]:
```

```

   a
a
1  3
3  3

```

You can still use the index in a query expression by using the special identifier `'index'`:

```
In [217]: df.query('index > 2')
```

(continues on next page)

(continued from previous page)

**Out [217]:**

```

a
a
3  3
4  2

```

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

### 12.16.1 MultiIndex query() Syntax

You can also use the levels of a DataFrame with a *MultiIndex* as if they were columns in the frame:

**In [218]:** `n = 10`**In [219]:** `colors = np.random.choice(['red', 'green'], size=n)`**In [220]:** `foods = np.random.choice(['eggs', 'ham'], size=n)`**In [221]:** `colors`**Out [221]:**

```

array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green',
       'green', 'green'],
      dtype='<U5')

```

**In [222]:** `foods`

```

////////////////////////////////////
↪
array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs',
       'eggs'],
      dtype='<U4')

```

**In [223]:** `index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])`**In [224]:** `df = pd.DataFrame(np.random.randn(n, 2), index=index)`**In [225]:** `df`**Out [225]:**

```

           0           1
color food
red  ham    0.194889 -0.381994
     ham    0.318587  2.089075
     eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
     eggs -2.029766  0.792652
     ham    0.461007 -0.542749
     ham   -0.305384 -0.479195
     eggs  0.095031 -0.270099
     eggs -0.707140 -0.773882
     eggs  0.229453  0.304418

```

**In [226]:** `df.query('color == "red"')`

```

////////////////////////////////////
↪

```

(continues on next page)

(continued from previous page)

```

           0          1
color food
red  ham    0.194889 -0.381994
     ham    0.318587  2.089075
     eggs -0.728293 -0.090255

```

If the levels of the `MultiIndex` are unnamed, you can refer to them using special names:

```
In [227]: df.index.names = [None, None]
```

```
In [228]: df
```

```
Out [228]:
           0          1
red  ham    0.194889 -0.381994
     ham    0.318587  2.089075
     eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
     eggs -2.029766  0.792652
     ham    0.461007 -0.542749
     ham   -0.305384 -0.479195
     eggs  0.095031 -0.270099
     eggs -0.707140 -0.773882
     eggs  0.229453  0.304418

```

```
In [229]: df.query('ilevel_0 == "red"')
```

```

////////////////////////////////////
↪
           0          1
red ham    0.194889 -0.381994
     ham    0.318587  2.089075
     eggs -0.728293 -0.090255

```

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

## 12.16.2 `query()` Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames *without* having to specify which frame you’re interested in querying

```
In [230]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [231]: df
```

```
Out [231]:
           a          b          c
0  0.224283  0.736107  0.139168
1  0.302827  0.657803  0.713897
2  0.611185  0.136624  0.984960
3  0.195246  0.123436  0.627712
4  0.618673  0.371660  0.047902
5  0.480088  0.062993  0.185760
6  0.568018  0.483467  0.445289
7  0.309040  0.274580  0.587101
8  0.258993  0.477769  0.370255
9  0.550459  0.840870  0.304611

```

(continues on next page)

(continued from previous page)

```
In [232]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)
```

```
In [233]: df2
```

```
Out[233]:
```

|    | a        | b        | c        |
|----|----------|----------|----------|
| 0  | 0.357579 | 0.229800 | 0.596001 |
| 1  | 0.309059 | 0.957923 | 0.965663 |
| 2  | 0.123102 | 0.336914 | 0.318616 |
| 3  | 0.526506 | 0.323321 | 0.860813 |
| 4  | 0.518736 | 0.486514 | 0.384724 |
| 5  | 0.190804 | 0.505723 | 0.614533 |
| 6  | 0.891939 | 0.623977 | 0.676639 |
| 7  | 0.480559 | 0.378528 | 0.460858 |
| 8  | 0.420223 | 0.136404 | 0.141295 |
| 9  | 0.732206 | 0.419540 | 0.604675 |
| 10 | 0.604466 | 0.848974 | 0.896165 |
| 11 | 0.589168 | 0.920046 | 0.732716 |

```
In [234]: expr = '0.0 <= a <= c <= 0.5'
```

```
In [235]: map(lambda frame: frame.query(expr), [df, df2])
```

```
Out[235]: <map at 0x1c2b11f5f8>
```

### 12.16.3 query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

```
In [236]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))
```

```
In [237]: df
```

```
Out[237]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 7 | 8 | 9 |
| 1 | 1 | 0 | 7 |
| 2 | 2 | 7 | 2 |
| 3 | 6 | 2 | 2 |
| 4 | 2 | 6 | 3 |
| 5 | 3 | 8 | 2 |
| 6 | 1 | 7 | 2 |
| 7 | 5 | 1 | 5 |
| 8 | 9 | 8 | 0 |
| 9 | 1 | 5 | 0 |

```
In [238]: df.query('(a < b) & (b < c)')
```

```

////////////////////////////////////
↪
   a  b  c
0  7  8  9

```

```
In [239]: df[(df.a < df.b) & (df.b < df.c)]
```

```

////////////////////////////////////
↪
   a  b  c
0  7  8  9

```

Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than `&` and `|`).

```
In [240]: df.query('a < b & b < c')
Out[240]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 7 | 8 | 9 |

Use English instead of symbols:

```
In [241]: df.query('a < b and b < c')
Out[241]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 7 | 8 | 9 |

Pretty close to how you might write it on paper:

```
In [242]: df.query('a < b < c')
Out[242]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 7 | 8 | 9 |

#### 12.16.4 The `in` and `not in` operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a `Series` or `DataFrame`.

```
# get all rows where columns "a" and "b" have overlapping values
In [243]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbbcccc'),
.....:                       'c': np.random.randint(5, size=12),
.....:                       'd': np.random.randint(9, size=12)})
```

```
In [244]: df
Out[244]:
```

|    | a | b | c | d |
|----|---|---|---|---|
| 0  | a | a | 2 | 6 |
| 1  | a | a | 4 | 7 |
| 2  | b | a | 1 | 6 |
| 3  | b | a | 2 | 1 |
| 4  | c | b | 3 | 6 |
| 5  | c | b | 0 | 2 |
| 6  | d | b | 3 | 3 |
| 7  | d | b | 2 | 1 |
| 8  | e | c | 4 | 3 |
| 9  | e | c | 2 | 0 |
| 10 | f | c | 0 | 6 |
| 11 | f | c | 1 | 2 |

```
In [245]: df.query('a in b')
```

|   | a | b | c | d |
|---|---|---|---|---|
| 0 | a | a | 2 | 6 |
| 1 | a | a | 4 | 7 |
| 2 | b | a | 1 | 6 |
| 3 | b | a | 2 | 1 |

(continues on next page)

(continued from previous page)

```
4 c b 3 6
5 c b 0 2
```

```
# How you'd do it in pure Python
```

```
In [246]: df[df.a.isin(df.b)]
```

```

a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
3 b a 2 1
4 c b 3 6
5 c b 0 2
```

```
In [247]: df.query('a not in b')
```

```

a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2
```

```
# pure Python
```

```
In [248]: df[~df.a.isin(df.b)]
```

```

a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2
```

You can combine this with other expressions for very succinct queries:

```
# rows where cols a and b have overlapping values and col c's values are less than_
↳ col d's
```

```
In [249]: df.query('a in b and c < d')
```

```
Out[249]:
```

```

a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
4 c b 3 6
5 c b 0 2
```

```
# pure Python
```

```
In [250]: df[df.b.isin(df.a) & (df.c < df.d)]
```

```

a b c d
0 a a 2 6
```

Out [250]:

(continues on next page)

(continued from previous page)

|    |   |   |   |   |
|----|---|---|---|---|
| 1  | a | a | 4 | 7 |
| 2  | b | a | 1 | 6 |
| 4  | c | b | 3 | 6 |
| 5  | c | b | 0 | 2 |
| 10 | f | c | 0 | 6 |
| 11 | f | c | 1 | 2 |

**Note:** Note that `in` and `not in` are evaluated in Python, since `numexpr` has no equivalent of this operation. However, **only the `in/not in` expression itself** is evaluated in vanilla Python. For example, in the expression

```
df.query('a in b + c + d')
```

`(b + c + d)` is evaluated by `numexpr` and *then* the `in` operation is evaluated in plain Python. In general, any operations that can be evaluated using `numexpr` will be.

## 12.16.5 Special use of the `==` operator with `list` objects

Comparing a `list` of values to a column using `==/!=` works similarly to `in/not in`.

```
In [251]: df.query('b == ["a", "b", "c"]')
```

```
Out[251]:
```

|    | a | b | c | d |
|----|---|---|---|---|
| 0  | a | a | 2 | 6 |
| 1  | a | a | 4 | 7 |
| 2  | b | a | 1 | 6 |
| 3  | b | a | 2 | 1 |
| 4  | c | b | 3 | 6 |
| 5  | c | b | 0 | 2 |
| 6  | d | b | 3 | 3 |
| 7  | d | b | 2 | 1 |
| 8  | e | c | 4 | 3 |
| 9  | e | c | 2 | 0 |
| 10 | f | c | 0 | 6 |
| 11 | f | c | 1 | 2 |

```
# pure Python
```

```
In [252]: df[df.b.isin(["a", "b", "c"])]
```

```

////////////////////////////////////
↪

```

|    | a | b | c | d |
|----|---|---|---|---|
| 0  | a | a | 2 | 6 |
| 1  | a | a | 4 | 7 |
| 2  | b | a | 1 | 6 |
| 3  | b | a | 2 | 1 |
| 4  | c | b | 3 | 6 |
| 5  | c | b | 0 | 2 |
| 6  | d | b | 3 | 3 |
| 7  | d | b | 2 | 1 |
| 8  | e | c | 4 | 3 |
| 9  | e | c | 2 | 0 |
| 10 | f | c | 0 | 6 |
| 11 | f | c | 1 | 2 |

(continues on next page)

(continued from previous page)

```
In [253]: df.query('c == [1, 2]')
```

```

=====
↪
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

```

```
In [254]: df.query('c != [1, 2]')
```

```

=====
↪
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

```

```
# using in/not in
```

```
In [255]: df.query('[1, 2] in c')
```

```

=====
↪
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

```

```
In [256]: df.query('[1, 2] not in c')
```

```

=====
↪
   a  b  c  d
1  a  a  4  7
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
8  e  c  4  3
10 f  c  0  6

```

```
# pure Python
```

```
In [257]: df[df.c.isin([1, 2])]
```

```

=====
↪
   a  b  c  d
0  a  a  2  6
2  b  a  1  6
3  b  a  2  1
7  d  b  2  1
9  e  c  2  0
11 f  c  1  2

```

## 12.16.6 Boolean Operators

You can negate boolean expressions with the word `not` or the `~` operator.

```
In [258]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
```

```
In [259]: df['bools'] = np.random.rand(len(df)) > 0.5
```

```
In [260]: df.query('~bools')
```

```
Out[260]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 2 | 0.697753 | 0.212799 | 0.329209 | False |
| 7 | 0.275396 | 0.691034 | 0.826619 | False |
| 8 | 0.190649 | 0.558748 | 0.262467 | False |

```
In [261]: df.query('not bools')
```

```
Out[261]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 2 | 0.697753 | 0.212799 | 0.329209 | False |
| 7 | 0.275396 | 0.691034 | 0.826619 | False |
| 8 | 0.190649 | 0.558748 | 0.262467 | False |

```
In [262]: df.query('not bools') == df[~df.bools]
```

```
Out[262]:
```

|   | a    | b    | c    | bools |
|---|------|------|------|-------|
| 2 | True | True | True | True  |
| 7 | True | True | True | True  |
| 8 | True | True | True | True  |

Of course, expressions can be arbitrarily complex too:

```
# short query syntax
```

```
In [263]: shorter = df.query('a < b < c and (not bools) or bools > 2')
```

```
# equivalent in pure Python
```

```
In [264]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]
```

```
In [265]: shorter
```

```
Out[265]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 7 | 0.275396 | 0.691034 | 0.826619 | False |

```
In [266]: longer
```

```
Out[266]:
```

|   | a        | b        | c        | bools |
|---|----------|----------|----------|-------|
| 7 | 0.275396 | 0.691034 | 0.826619 | False |

```
In [267]: shorter == longer
```

```
Out[267]:
```

|   | a    | b    | c    | bools |
|---|------|------|------|-------|
| 7 | True | True | True | True  |

### 12.16.7 Performance of `query()`

`DataFrame.query()` using `numexpr` is slightly faster than Python for large frames.

**Note:** You will only see the performance benefits of using the `numexpr` engine with `DataFrame.query()` if your frame has more than approximately 200,000 rows.

This plot was created using a `DataFrame` with 3 columns each containing floating point values generated using `numpy.random.randn()`.

## 12.17 Duplicate Data

If you want to identify and remove duplicate rows in a `DataFrame`, there are two methods that will help: `duplicated` and `drop_duplicates`. Each takes as an argument the columns to use to identify duplicated rows.

- `df.duplicated()` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
- `df.drop_duplicates()` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

- `keep='first'` (default): mark / drop duplicates except for the first occurrence.
- `keep='last'`: mark / drop duplicates except for the last occurrence.
- `keep=False`: mark / drop all duplicates.

```
In [268]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four']
→      ,
      .....:                      'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
      .....:                      'c': np.random.randn(7)})
      .....:
```

```
In [269]: df2
```

```
Out[269]:
```

|   | a     | b | c         |
|---|-------|---|-----------|
| 0 | one   | x | -1.067137 |
| 1 | one   | y | 0.309500  |
| 2 | two   | x | -0.211056 |
| 3 | two   | y | -1.842023 |
| 4 | two   | x | -0.390820 |
| 5 | three | x | -1.964475 |
| 6 | four  | x | 1.298329  |

```
In [270]: df2.duplicated('a')
```

```

→
0    False
1     True
2    False
3     True
4     True
5    False
6    False
dtype: bool
```

```
In [271]: df2.duplicated('a', keep='last')
```

```

→
0     True
1    False
2     True
3     True
4    False
5    False
6    False
dtype: bool
```

```
In [272]: df2.duplicated('a', keep=False)
```

```

→
0     True
1     True
```

(continues on next page)

(continued from previous page)

```

2     True
3     True
4     True
5    False
6    False
dtype: bool

```

```
In [273]: df2.drop_duplicates('a')
```

```

↪
      a  b      c
0  one  x -1.067137
2  two  x -0.211056
5 three  x -1.964475
6  four  x  1.298329

```

```
In [274]: df2.drop_duplicates('a', keep='last')
```

```

↪
      a  b      c
1  one  y  0.309500
4  two  x -0.390820
5 three  x -1.964475
6  four  x  1.298329

```

```
In [275]: df2.drop_duplicates('a', keep=False)
```

```

↪
      a  b      c
5 three  x -1.964475
6  four  x  1.298329

```

Also, you can pass a list of columns to identify duplications.

```
In [276]: df2.duplicated(['a', 'b'])
```

```

Out[276]:
0    False
1    False
2    False
3    False
4     True
5    False
6    False
dtype: bool

```

```
In [277]: df2.drop_duplicates(['a', 'b'])
```

```

↪
      a  b      c
0  one  x -1.067137
1  one  y  0.309500
2  two  x -0.211056
3  two  y -1.842023
5 three  x -1.964475
6  four  x  1.298329

```

To drop duplicates by index value, use `Index.duplicated` then perform slicing. The same set of options are

available for the `keep` parameter.

```
In [278]: df3 = pd.DataFrame({'a': np.arange(6),  
.....:                      'b': np.random.randn(6)},  
.....:                      index=['a', 'a', 'b', 'c', 'b', 'a'])  
.....:
```

```
In [279]: df3
```

Out [279] :

|   | a | b         |
|---|---|-----------|
| a | 0 | 1.440455  |
| a | 1 | 2.456086  |
| b | 2 | 1.038402  |
| c | 3 | -0.894409 |
| b | 4 | 0.683536  |
| a | 5 | 3.082764  |

```
In [280]: df3.index.duplicated()
```

```

\\array([False,  True, False, False,  True,  True], dtype=bool)

```

```
In [281]: df3[~df3.index.duplicated()]
```

$\backslash \backslash \backslash \backslash \backslash \backslash \backslash \backslash \backslash \backslash \backslash \backslash$

$\leftrightarrow$

|   | a | b         |
|---|---|-----------|
| a | 0 | 1.440455  |
| b | 2 | 1.038402  |
| c | 3 | -0.894409 |

```
In [282]: df3[~df3.index.duplicated(keep='last')]
```

|   | a | b         |
|---|---|-----------|
| c | 3 | -0.894409 |
| b | 4 | 0.683536  |
| a | 5 | 3.082764  |

```
In [283]: df3[~df3.index.duplicated(keep=False)]
```

  
 a                      b
   
 c    3   -0.894409

## 12.18 Dictionary-like `get()` method

Each of Series, DataFrame, and Panel have a `get` method which can return a default value.

```
In [284]: s = pd.Series([1,2,3], index=['a','b','c'])
```

```
In [285]: s.get('a') # equivalent to s['a']
```

Out [285]: 1

```
In [286]: s.get('x', default=-1)
```

```
Out[286]: -1
```

## 12.19 The `lookup()` Method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```
In [287]: dflookup = pd.DataFrame(np.random.rand(20,4), columns = ['A','B','C','D'])

In [288]: dflookup.lookup(list(range(0,10,2)), ['B','C','A','B','D'])
Out[288]: array([ 0.3506,  0.4779,  0.4825,  0.9197,  0.5019])
```

## 12.20 Index objects

The pandas *Index* class and its subclasses can be viewed as implementing an *ordered multiset*. Duplicates are allowed. However, if you try to convert an *Index* object with duplicate entries into a set, an exception will be raised.

*Index* also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an *Index* directly is to pass a list or other sequence to *Index*:

```
In [289]: index = pd.Index(['e', 'd', 'a', 'b'])

In [290]: index
Out[290]: Index(['e', 'd', 'a', 'b'], dtype='object')

In [291]: 'd' in index
Out[291]: True
```

You can also pass a name to be stored in the index:

```
In [292]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')

In [293]: index.name
Out[293]: 'something'
```

The name, if set, will be shown in the console display:

```
In [294]: index = pd.Index(list(range(5)), name='rows')

In [295]: columns = pd.Index(['A', 'B', 'C'], name='cols')

In [296]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)

In [297]: df
Out[297]:
cols      A      B      C
rows
0      1.295989  0.185778  0.436259
1      0.678101  0.311369 -0.528378
2     -0.674808 -1.103529 -0.656157
3      1.889957  2.076651 -1.102192
4     -1.211795 -0.791746  0.634724

In [298]: df['A']
```

(continues on next page)

(continued from previous page)

```

rows
0      1.295989
1      0.678101
2     -0.674808
3      1.889957
4     -1.211795
Name: A, dtype: float64

```

### 12.20.1 Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index name (or, for MultiIndex, levels and labels).

You can use the `rename`, `set_names`, `set_levels`, and `set_labels` to set these attributes directly. They default to returning a copy; however, you can specify `inplace=True` to have the data change in place.

See *Advanced Indexing* for usage of MultiIndexes.

```

In [299]: ind = pd.Index([1, 2, 3])

In [300]: ind.rename("apple")
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [301]: ind
Out[301]: Int64Index([1, 2, 3], dtype='int64')

In [302]: ind.set_names(["apple"], inplace=True)

In [303]: ind.name = "bob"

In [304]: ind
Out[304]: Int64Index([1, 2, 3], dtype='int64', name='bob')

```

`set_names`, `set_levels`, and `set_labels` also take an optional *level* argument

```

In [305]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first',
Out[305]: MultiIndex
Out[306]: MultiIndex(levels=[[0, 1, 2], ['one', 'two']],
labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

In [307]: index.levels[1]
Out[307]: Index(['one', 'two'], dtype='object', name='second')

In [308]: index.set_levels(["a", "b"], level=1)
Out[308]: MultiIndex(levels=[[0, 1, 2], ['a', 'b']],
labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

```

## 12.20.2 Set operations on Index objects

The two main operations are `union (|)` and `intersection (&)`. These can be directly called as instance methods or used via overloaded operators. Difference is provided via the `.difference()` method.

```
In [309]: a = pd.Index(['c', 'b', 'a'])

In [310]: b = pd.Index(['c', 'e', 'd'])

In [311]: a | b
Out[311]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')

In [312]: a & b
Out[312]: Index(['c'], dtype='object')

In [313]: a.difference(b)
Out[313]: Index(['a', 'b'], dtype='object')
```

Also available is the `symmetric_difference (^)` operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [314]: idx1 = pd.Index([1, 2, 3, 4])

In [315]: idx2 = pd.Index([2, 3, 4, 5])

In [316]: idx1.symmetric_difference(idx2)
Out[316]: Int64Index([1, 5], dtype='int64')

In [317]: idx1 ^ idx2
Out[317]: Int64Index([1, 5], dtype='int64')
```

**Note:** The resulting index from a set operation will be sorted in ascending order.

## 12.20.3 Missing values

**Important:** Even though `Index` can hold missing values (`NaN`), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

`Index.fillna` fills missing values with specified scalar value.

```
In [318]: idx1 = pd.Index([1, np.nan, 3, 4])

In [319]: idx1
Out[319]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')

In [320]: idx1.fillna(2)
Out[320]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')
```

(continues on next page)

(continued from previous page)

```

In [321]: idx2 = pd.DatetimeIndex([pd.Timestamp('2011-01-01'), pd.NaT, pd.Timestamp(
↳ '2011-01-03')])

In [322]: idx2
Out[322]: DatetimeIndex(['2011-01-01', 'NaT', '2011-01-03'], dtype='datetime64[ns]',
↳ freq=None)

In [323]: idx2.fillna(pd.Timestamp('2011-01-02'))
Out[323]: DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], dtype='datetime64[ns]',
↳ freq=None)

```

## 12.21 Set / Reset Index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you've already done so. There are a couple of different ways.

### 12.21.1 Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```

In [324]: data
Out[324]:
   a  b  c  d
0 bar one z  1.0
1 bar two y  2.0
2 foo one x  3.0
3 foo two w  4.0

In [325]: indexed1 = data.set_index('c')

In [326]: indexed1
Out[326]:
   a  b  d
c
z bar one  1.0
y bar two  2.0
x foo one  3.0
w foo two  4.0

In [327]: indexed2 = data.set_index(['a', 'b'])

In [328]: indexed2
Out[328]:
   c  d
a  b
bar one z  1.0
      two y  2.0
foo one x  3.0
      two w  4.0

```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

### 12.21.2 Reset the index

As a convenience, there is a new function on `DataFrame` called `reset_index()` which transfers the index values into the `DataFrame`'s columns and sets a simple integer index. This is the inverse operation of `set_index()`.

---

(continues on next page)

(continued from previous page)

```

0  bar  one  z  1.0
1  bar  two  y  2.0
2  foo  one  x  3.0
3  foo  two  w  4.0

```

The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the `names` attribute.

You can use the `level` keyword to remove only a portion of the index:

```
In [337]: frame
```

```
Out [337]:
```

```

           c    d
c a    b
z bar one  z  1.0
y bar two  y  2.0
x foo one  x  3.0
w foo two  w  4.0

```

```
In [338]: frame.reset_index(level=1)
```

```

////////////////////////////////////
↪
           a    c    d
c b
z one  bar  z  1.0
y two  bar  y  2.0
x one  foo  x  3.0
w two  foo  w  4.0

```

`reset_index` takes an optional parameter `drop` which if true simply discards the index, instead of putting index values in the DataFrame's columns.

### 12.21.3 Adding an ad hoc index

If you create an index yourself, you can just assign it to the `index` field:

```
data.index = index
```

## 12.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called `chained indexing`. Here is an example.

```

In [339]: dfmi = pd.DataFrame([list('abcd'),
.....:                        list('efgh'),
.....:                        list('ijkl'),
.....:                        list('mnop')],
.....:                        columns=pd.MultiIndex.from_product([['one', 'two'],
.....:                                                              ['first', 'second']]),
↪ ']]))
.....:

In [340]: dfmi

```

(continues on next page)

(continued from previous page)

```
Out [340]:
      one      two
first second first second
0      a      b      c      d
1      e      f      g      h
2      i      j      k      l
3      m      n      o      p
```

Compare these two access methods:

```
In [341]: dfmi['one']['second']
Out [341]:
0      b
1      f
2      j
3      n
Name: second, dtype: object
```

```
In [342]: dfmi.loc[:, ('one', 'second')]
Out [342]:
0      b
1      f
2      j
3      n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (`.loc`) is much preferred over method 1 (chained `[]`).

`dfmi['one']` selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation `dfmi_with_one['second']` selects the series indexed by 'second'. This is indicated by the variable `dfmi_with_one` because pandas sees these operations as separate events. e.g. separate calls to `__getitem__`, so it has to treat them as linear operations, they happen one after another.

Contrast this to `df.loc[:, ('one', 'second')]` which passes a nested tuple of `(slice(None), ('one', 'second'))` to a single call to `__getitem__`. This allows pandas to deal with this as a single entity. Furthermore this order of operations *can* be significantly faster, and allows one to index *both* axes if so desired.

### 12.22.1 Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What's up with the `SettingWithCopy` warning? We don't **usually** throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:, ('one', 'second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```

See that `__getitem__` in there? Outside of simple cases, it's very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the `__setitem__` will modify `dfmi` or a temporary object that gets thrown out immediately afterward. **That's** what `SettingWithCopy` is warning you about!

---

**Note:** You may be wondering whether we should be concerned about the `loc` property in the first example. But `dfmi.loc` is guaranteed to be `dfmi` itself with modified indexing behavior, so `dfmi.loc.__getitem__` / `dfmi.loc.__setitem__` operate on `dfmi` directly. Of course, `dfmi.loc.__getitem__(idx)` may be a view or a copy of `dfmi`.

---

Sometimes a `SettingWithCopy` warning will arise at times when there's no obvious chained indexing going on. **These** are the bugs that `SettingWithCopy` is designed to catch! Pandas is probably trying to warn you that you've done this:

```
def do_something(df):
    foo = df[['bar', 'baz']] # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    foo['quux'] = value      # We don't know whether this will modify df or not!
    return foo
```

Yikes!

## 12.22.2 Evaluation order matters

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the `SettingWithCopyWarning` because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the `option.mode.chained_assignment` to one of these values:

- 'warn', the default, means a `SettingWithCopyWarning` is printed.
- 'raise' means pandas will raise a `SettingWithCopyException` you have to deal with.
- None will suppress the warnings entirely.

```
In [343]: dfb = pd.DataFrame({'a' : ['one', 'one', 'two',
.....:                             'three', 'two', 'one', 'six'],
.....:                       'c' : np.arange(7)})
.....:

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [344]: dfb['c'][dfb.a.str.startswith('o')] = 42
```

This however is operating on a copy and will not work.

```
>>> pd.set_option('mode.chained_assignment', 'warn')
>>> dfb[dfb.a.str.startswith('o')]['c'] = 42
Traceback (most recent call last):
...
SettingWithCopyWarning:
```

(continues on next page)

(continued from previous page)

A value is trying to be set on a copy of a slice from a DataFrame.  
Try using `.loc[row_index,col_indexer] = value` instead

A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc/.iloc`.

This is the correct access method:

```
In [345]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})

In [346]: dfc.loc[0, 'A'] = 11

In [347]: dfc
Out[347]:
   A  B
0  11  1
1  bbb  2
2  ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [348]: dfc = dfc.copy()

In [349]: dfc['A'][0] = 111

In [350]: dfc
Out[350]:
   A  B
0  111  1
1  bbb  2
2  ccc  3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last):
...
SettingWithCopyException:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.

## MULTIINDEX / ADVANCED INDEXING

This section covers indexing with a `MultiIndex` and more advanced indexing features.

See the [Indexing and Selecting Data](#) for general indexing documentation.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called `chained assignment` and should be avoided. See [Returning a View versus Copy](#).

See the [cookbook](#) for some advanced strategies.

### 13.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like `Series` (1d) and `DataFrame` (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing [group by](#) and [pivoting and reshaping data](#), we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the [cookbook](#) for some advanced strategies.

#### 13.1.1 Creating a MultiIndex (hierarchical index) object

The `MultiIndex` object is the hierarchical analogue of the standard `Index` object which typically stores the axis labels in pandas objects. You can think of `MultiIndex` as an array of tuples where each tuple is unique. A `MultiIndex` can be created from a list of arrays (using `MultiIndex.from_arrays`), an array of tuples (using `MultiIndex.from_tuples`), or a crossed set of iterables (using `MultiIndex.from_product`). The `Index` constructor will attempt to return a `MultiIndex` when it is passed a list of tuples. The following examples demonstrate different ways to initialize `MultiIndexes`.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
...:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
...:

In [2]: tuples = list(zip(*arrays))

In [3]: tuples
Out[3]:
[('bar', 'one'),
```

(continues on next page)

(continued from previous page)

```

('bar', 'two'),
('baz', 'one'),
('baz', 'two'),
('foo', 'one'),
('foo', 'two'),
('qux', 'one'),
('qux', 'two')]

In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
            labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
            names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first second
bar   one    0.469112
      two   -0.282863
baz   one   -1.509059
      two   -1.135632
foo   one    1.212112
      two   -0.173215
qux   one    0.119209
      two   -1.044236
dtype: float64

```

When you want every pairing of the elements in two iterables, it can be easier to use the `MultiIndex.from_product` function:

```

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
            labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
            names=['first', 'second'])

```

As a convenience, you can pass a list of arrays directly into `Series` or `DataFrame` to construct a `MultiIndex` automatically:

```

In [10]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
.....:              np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]
.....:

In [11]: s = pd.Series(np.random.randn(8), index=arrays)

In [12]: s
Out[12]:
bar one    -0.861849
      two   -2.104569
baz one    -0.494929

```

(continues on next page)

(continued from previous page)

```

      two    1.071804
foo    one    0.721555
      two   -0.706771
qux    one   -1.039575
      two    0.271860
dtype: float64

```

```
In [13]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)
```

```
In [14]: df
```

Out [14] :

|     |     | 0         | 1         | 2         | 3         |
|-----|-----|-----------|-----------|-----------|-----------|
| bar | one | -0.424972 | 0.567020  | 0.276232  | -1.087401 |
|     | two | -0.673690 | 0.113648  | -1.478427 | 0.524988  |
| baz | one | 0.404705  | 0.577046  | -1.715002 | -1.039268 |
|     | two | -0.370647 | -1.157892 | -1.344312 | 0.844885  |
| foo | one | 1.075770  | -0.109050 | 1.643563  | -1.469388 |
|     | two | 0.357021  | -0.674600 | -1.776904 | -0.968914 |
| qux | one | -1.294524 | 0.413738  | 0.276662  | -0.472035 |
|     | two | -0.013960 | -0.362543 | -0.006154 | -0.923061 |

All of the `MultiIndex` constructors accept a `names` argument which stores string names for the levels themselves. If no names are provided, `None` will be assigned:

```
In [15]: df.index.names
```

```
Out[15]: FrozenList([None, None])
```

This index can back any axis of a pandas object, and the number of **levels** of the index is up to you:

```
In [16]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'], columns=index)
```

```
In [17]: df
```

Out [17]:

| first  | bar       |          | baz       |           | foo       |           | qux       |           |
|--------|-----------|----------|-----------|-----------|-----------|-----------|-----------|-----------|
| second | one       | two      | one       | two       | one       | two       | one       | two       |
| A      | 0.895717  | 0.805244 | -1.206412 | 2.565646  | 1.431256  | 1.340309  | -1.170299 | -0.226169 |
| B      | 0.410835  | 0.813850 | 0.132003  | -0.827317 | -0.076467 | -1.187678 | 1.130127  | -1.436737 |
| C      | -1.413681 | 1.607920 | 1.024180  | 0.569605  | 0.875906  | -2.211372 | 0.974466  | -2.006747 |

```
In [18]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])
```

|       |        | first second |           |           |           |           |           |
|-------|--------|--------------|-----------|-----------|-----------|-----------|-----------|
| first | second | bar one      | two       | baz one   | two       | foo one   | two       |
| bar   | one    | -0.410001    | -0.078638 | 0.545952  | -1.219217 | -1.226825 | 0.769804  |
|       | two    | -1.281247    | -0.727707 | -0.121306 | -0.097883 | 0.695775  | 0.341734  |
| baz   | one    | 0.959726     | -1.110336 | -0.619976 | 0.149748  | -0.732339 | 0.687738  |
|       | two    | 0.176444     | 0.403310  | -0.154951 | 0.301624  | -2.179861 | -1.369849 |
| foo   | one    | -0.954208    | 1.462696  | -1.743161 | -0.826591 | -0.345352 | 1.314232  |
|       | two    | 0.690579     | 0.995761  | 2.396780  | 0.014871  | 3.357427  | -0.317441 |

We've “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the `multi_sparse` option in `pandas.set_options()`:

```
In [19]: with pd.option_context('display.multi_sparse', False):
        ....:     df
        ....:
```

It's worth keeping in mind that there's nothing preventing you from using tuples as atomic labels on an axis:

```
In [20]: pd.Series(np.random.randn(8), index=tuples)
Out[20]:
(bar, one)    -1.236269
(bar, two)     0.896171
(baz, one)    -0.487602
(baz, two)    -0.082240
(foo, one)    -2.182937
(foo, two)     0.380396
(qux, one)     0.084844
(qux, two)     0.432390
dtype: float64
```

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

### 13.1.2 Reconstructing the level labels

The method `get_level_values` will return a vector of the labels for each location at a particular level:

```
In [21]: index.get_level_values(0)
Out[21]: Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], dtype='object',
↳ name='first')

In [22]: index.get_level_values('second')
////////////////////////////////////
↳ Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'], dtype='object',
↳ name='second')
```

### 13.1.3 Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. **Partial** selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular `DataFrame`:

```
In [23]: df['bar']
Out[23]:
second      one      two
A      0.895717  0.805244
B      0.410835  0.813850
C     -1.413681  1.607920

In [24]: df['bar', 'one']
////////////////////////////////////
↳
A      0.895717
B      0.410835
```

(continues on next page)

```
In [31]: df[['foo', 'qux']].columns.remove_unused_levels()
Out[31]:
MultiIndex(levels=[['foo', 'qux'], ['one', 'two']],
            labels=[[0, 0, 1, 1], [0, 1, 0, 1]],
            names=['first', 'second'])
```

### 13.1.5 Data alignment and using `reindex`

Operations between differently-indexed objects having `MultiIndex` on the axes will work as you expect; data alignment will work the same as an `Index` of tuples:

```
In [32]: s + s[:-2]
Out[32]:
bar  one    -1.723698
      two    -4.209138
baz   one    -0.989859
      two     2.143608
foo   one     1.443110
      two    -1.413542
qux   one         NaN
      two         NaN
dtype: float64
```

```
In [33]: s + s[:,2]
```

```

////////////////////////////////////
↪
bar  one    -1.723698
      two         NaN
baz   one    -0.989859
      two         NaN
foo   one     1.443110
      two         NaN
qux   one    -2.079150
      two         NaN
dtype: float64
```

`reindex` can be called with another `MultiIndex`, or even a list or array of tuples:

```
In [34]: s.reindex(index[:3])
```

```
Out[34]:
first second
bar   one    -0.861849
      two    -2.104569
baz   one    -0.494929
dtype: float64
```

```
In [35]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
```

```

////////////////////////////////////
↪
foo  two    -0.706771
bar  one    -0.861849
qux  one    -1.039575
baz  one    -0.494929
dtype: float64
```

## 13.2 Advanced indexing with hierarchical index

Syntactically integrating `MultiIndex` in advanced indexing with `.loc` is a bit challenging, but we’ve made every effort to do so. In general, `MultiIndex` keys take the form of tuples. For example, the following works as you would expect:

```
In [36]: df = df.T
```

```
In [37]: df
```

```
Out[37]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | 0.895717  | 0.410835  | -1.413681 |
|       | two    | 0.805244  | 0.813850  | 1.607920  |
| baz   | one    | -1.206412 | 0.132003  | 1.024180  |
|       | two    | 2.565646  | -0.827317 | 0.569605  |
| foo   | one    | 1.431256  | -0.076467 | 0.875906  |
|       | two    | 1.340309  | -1.187678 | -2.211372 |
| qux   | one    | -1.170299 | 1.130127  | 0.974466  |
|       | two    | -0.226169 | -1.436737 | -2.006747 |

```
In [38]: df.loc[('bar', 'two'),]
```

```

////////////////////////////////////
↪
A    0.805244
B    0.813850
C    1.607920
Name: (bar, two), dtype: float64
```

Note that `df.loc['bar', 'two']` would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with `.loc`, you must use a tuple like this:

```
In [39]: df.loc[('bar', 'two'), 'A']
```

```
Out[39]: 0.80524402538637851
```

You don’t have to specify all levels of the `MultiIndex` by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with `bar` in the first level as follows:

```
df.loc['bar']
```

This is a shortcut for the slightly more verbose notation `df.loc[('bar',),]` (equivalent to `df.loc['bar',]` in this example).

“Partial” slicing also works quite nicely.

```
In [40]: df.loc['baz':'foo']
```

```
Out[40]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| baz   | one    | -1.206412 | 0.132003  | 1.024180  |
|       | two    | 2.565646  | -0.827317 | 0.569605  |
| foo   | one    | 1.431256  | -0.076467 | 0.875906  |
|       | two    | 1.340309  | -1.187678 | -2.211372 |

You can slice with a ‘range’ of values, by providing a slice of tuples.

```
In [41]: df.loc[('baz', 'two'):( 'qux', 'one')]
Out[41]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| baz   | two    | 2.565646  | -0.827317 | 0.569605  |
| foo   | one    | 1.431256  | -0.076467 | 0.875906  |
|       | two    | 1.340309  | -1.187678 | -2.211372 |
| qux   | one    | -1.170299 | 1.130127  | 0.974466  |

```
In [42]: df.loc[('baz', 'two'):'foo']
```

Passing a list of labels or tuples works similar to reindexing:

```
In [43]: df.loc[(['bar', 'two'), ('qux', 'one')]]
Out[43]:
```

|       |        | A         | B        | C        |
|-------|--------|-----------|----------|----------|
| first | second |           |          |          |
| bar   | two    | 0.805244  | 0.813850 | 1.607920 |
| qux   | one    | -1.170299 | 1.130127 | 0.974466 |

**Note:** It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete `MultiIndex` keys, whereas a tuple of lists refer to several values within a level:

```
In [44]: s = pd.Series([1, 2, 3, 4, 5, 6],
.....:                  index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e",
↵"]]))
.....:
```

```
In [45]: s.loc[ [("A", "c"), ("B", "d")]] # list of tuples
```

```
Out [45]:
```

|   |   |   |
|---|---|---|
| A | c | 1 |
| B | d | 5 |

```
dtype: int64
```

```
In [46]: s.loc[(["A", "B"], ["c", "d"])] # tuple of lists
```

```
Out[46]:
A  c    1
   d    2
B  c    4
   d    5
dtype: int64
```

### 13.2.1 Using slicers

You can slice a `MultiIndex` by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see [Selection by Label](#), including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of *that* level. You do not need to specify all the *deeper* levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the **index** and for the **columns**. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing *both* axes, rather than into say the `MultiIndex` for the rows.

You should do this:

```
df.loc[(slice('A1', 'A3'), .....), :]
```

You should **not** do this:

```
df.loc[(slice('A1', 'A3'), .....)]
```

```
In [47]: def mklbl(prefix,n):
.....:     return ["%s%s" % (prefix,i) for i in range(n)]
.....:

In [48]: miindex = pd.MultiIndex.from_product([mklbl('A',4),
.....:                                         mklbl('B',2),
.....:                                         mklbl('C',4),
.....:                                         mklbl('D',2)])
.....:

In [49]: micolumns = pd.MultiIndex.from_tuples([('a','foo'),('a','bar'),
.....:                                         ('b','foo'),('b','bah')],
.....:                                         names=['lv10','lv11'])
.....:

In [50]: dfmi = pd.DataFrame(np.arange(len(miindex)*len(micolumns)).
↳ reshape((len(miindex),len(micolumns))),
.....:                               index=miindex,
.....:                               columns=micolumns).sort_index().sort_index(axis=1)
.....:

In [51]: dfmi
Out[51]:
lv10      a      b
lv11      bar  foo  bah  foo
A0 B0 C0 D0    1    0    3    2
      D1    5    4    7    6
      C1 D0    9    8   11   10
      D1   13   12   15   14
      C2 D0   17   16   19   18
      D1   21   20   23   22
      C3 D0   25   24   27   26
...
A3 B1 C0 D1  229  228  231  230
```

(continues on next page)

(continued from previous page)

```

      C1 D0 233 232 235 234
        D1 237 236 239 238
      C2 D0 241 240 243 242
        D1 245 244 247 246
      C3 D0 249 248 251 250
        D1 253 252 255 254

[64 rows x 4 columns]

```

Basic multi-index slicing using slices, lists, and labels.

```

In [52]: dfmi.loc[(slice('A1','A3'), slice(None), ['C1', 'C3']), :]
Out[52]:
lvl0      a      b
lvl1    bar  foo  bah  foo
A1 B0 C1 D0   73   72   75   74
        D1   77   76   79   78
        C3 D0   89   88   91   90
        D1   93   92   95   94
      B1 C1 D0  105  104  107  106
        D1  109  108  111  110
        C3 D0  121  120  123  122
...
A3 B0 C1 D1  205  204  207  206
        C3 D0  217  216  219  218
        D1  221  220  223  222
      B1 C1 D0  233  232  235  234
        D1  237  236  239  238
        C3 D0  249  248  251  250
        D1  253  252  255  254

[24 rows x 4 columns]

```

You can use `pandas.IndexSlice` to facilitate a more natural syntax using `:`, rather than using `slice(None)`.

```

In [53]: idx = pd.IndexSlice

In [54]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[54]:
lvl0      a      b
lvl1    foo  foo

      B1 C1 D0  232  234
        D1  236  238
        C3 D0  248  250
        D1  252  254

```

(continues on next page)

(continued from previous page)

[32 rows x 2 columns]

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [55]: dfmi.loc['A1', (slice(None), 'foo')]
```

```
Out[55]:
```

```
lvl0      a      b
lvl1      foo    foo
B0 C0 D0    64    66
      D1    68    70
      C1 D0    72    74
      D1    76    78
      C2 D0    80    82
      D1    84    86
      C3 D0    88    90
...
B1 C0 D1   100   102
      C1 D0   104   106
      D1   108   110
      C2 D0   112   114
      D1   116   118
      C3 D0   120   122
      D1   124   126
```

[16 rows x 2 columns]

```
In [56]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
////////////////////////////////////
```

```
↪
lvl0      a      b
lvl1      foo    foo
A0 B0 C1 D0     8    10
      D1    12    14
      C3 D0    24    26
      D1    28    30
      B1 C1 D0    40    42
      D1    44    46
      C3 D0    56    58
...
A3 B0 C1 D1   204   206
      C3 D0   216   218
      D1   220   222
      B1 C1 D0   232   234
      D1   236   238
      C3 D0   248   250
      D1   252   254
```

[32 rows x 2 columns]

Using a boolean indexer you can provide selection related to the *values*.

```
In [57]: mask = dfmi[('a', 'foo')] > 200
```

```
In [58]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
```

```
Out[58]:
```

```
lvl0      a      b
lvl1      foo    foo
```

(continues on next page)

(continued from previous page)

```

A3 B0 C1 D1 204 206
      C3 D0 216 218
          D1 220 222
      B1 C1 D0 232 234
          D1 236 238
      C3 D0 248 250
          D1 252 254

```

You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```
In [59]: dfmi.loc(axis=0)[: , :, ['C1', 'C3']]
```

```
Out[59]:
```

```

lvl0          a          b
lvl1      bar  foo  bah  foo
A0 B0 C1 D0    9    8   11   10
          D1   13   12   15   14
          C3 D0   25   24   27   26
          D1   29   28   31   30
      B1 C1 D0   41   40   43   42
          D1   45   44   47   46
          C3 D0   57   56   59   58
...
A3 B0 C1 D1  205  204  207  206
      C3 D0  217  216  219  218
          D1  221  220  223  222
      B1 C1 D0  233  232  235  234
          D1  237  236  239  238
          C3 D0  249  248  251  250
          D1  253  252  255  254

```

```
[32 rows x 4 columns]
```

Furthermore you can *set* the values using the following methods.

```
In [60]: df2 = dfmi.copy()
```

```
In [61]: df2.loc(axis=0)[: , :, ['C1', 'C3']] = -10
```

```
In [62]: df2
```

```
Out[62]:
```

```

lvl0          a          b
lvl1      bar  foo  bah  foo
A0 B0 C0 D0    1    0    3    2
          D1    5    4    7    6
          C1 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10
          C2 D0   17   16   19   18
          D1   21   20   23   22
          C3 D0  -10  -10  -10  -10
...
A3 B1 C0 D1  229  228  231  230
      C1 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10
          C2 D0  241  240  243  242
          D1  245  244  247  246
          C3 D0  -10  -10  -10  -10
          D1  -10  -10  -10  -10

```

(continues on next page)

(continued from previous page)

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```
In [63]: df2 = dfmi.copy()
```

```
In [64]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000
```

```
In [65]: df2
```

```
Out[65]:
```

| lvl0 |    |    |    | a      | b      |        |        |
|------|----|----|----|--------|--------|--------|--------|
| lvl1 |    |    |    | bar    | foo    | bah    | foo    |
| A0   | B0 | C0 | D0 | 1      | 0      | 3      | 2      |
|      |    |    | D1 | 5      | 4      | 7      | 6      |
|      |    | C1 | D0 | 9000   | 8000   | 11000  | 10000  |
|      |    |    | D1 | 13000  | 12000  | 15000  | 14000  |
|      |    | C2 | D0 | 17     | 16     | 19     | 18     |
|      |    |    | D1 | 21     | 20     | 23     | 22     |
|      |    | C3 | D0 | 25000  | 24000  | 27000  | 26000  |
| ...  |    |    |    | ...    | ...    | ...    | ...    |
| A3   | B1 | C0 | D1 | 229    | 228    | 231    | 230    |
|      |    | C1 | D0 | 233000 | 232000 | 235000 | 234000 |
|      |    |    | D1 | 237000 | 236000 | 239000 | 238000 |
|      |    | C2 | D0 | 241    | 240    | 243    | 242    |
|      |    |    | D1 | 245    | 244    | 247    | 246    |
|      |    | C3 | D0 | 249000 | 248000 | 251000 | 250000 |
|      |    |    | D1 | 253000 | 252000 | 255000 | 254000 |

[64 rows x 4 columns]

## 13.2.2 Cross-section

The `xs` method of `DataFrame` additionally takes a `level` argument to make selecting data at a particular level of a `MultiIndex` easier.

```
In [66]: df
```

```
Out[66]:
```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | 0.895717  | 0.410835  | -1.413681 |
|       | two    | 0.805244  | 0.813850  | 1.607920  |
| baz   | one    | -1.206412 | 0.132003  | 1.024180  |
|       | two    | 2.565646  | -0.827317 | 0.569605  |
| foo   | one    | 1.431256  | -0.076467 | 0.875906  |
|       | two    | 1.340309  | -1.187678 | -2.211372 |
| qux   | one    | -1.170299 | 1.130127  | 0.974466  |
|       | two    | -0.226169 | -1.436737 | -2.006747 |

```
In [67]: df.xs('one', level='second')
```

```

////////////////////////////////////
↪
      A      B      C
first
bar  0.895717  0.410835 -1.413681
```

(continues on next page)

(continued from previous page)

```

baz    -1.206412    0.132003    1.024180
foo     1.431256   -0.076467    0.875906
qux    -1.170299    1.130127    0.974466

```

```

# using the slicers
In [68]: df.loc[(slice(None), 'one'), :]
Out [68]:

```

|       |        | A         | B         | C         |
|-------|--------|-----------|-----------|-----------|
| first | second |           |           |           |
| bar   | one    | 0.895717  | 0.410835  | -1.413681 |
| baz   | one    | -1.206412 | 0.132003  | 1.024180  |
| foo   | one    | 1.431256  | -0.076467 | 0.875906  |
| qux   | one    | -1.170299 | 1.130127  | 0.974466  |

You can also select on the columns with `xs()`, by providing the axis argument.

```

In [69]: df = df.T

In [70]: df.xs('one', level='second', axis=1)
Out [70]:

```

|   | first     | bar       | baz       | foo       | qux |
|---|-----------|-----------|-----------|-----------|-----|
| A | 0.895717  | -1.206412 | 1.431256  | -1.170299 |     |
| B | 0.410835  | 0.132003  | -0.076467 | 1.130127  |     |
| C | -1.413681 | 1.024180  | 0.875906  | 0.974466  |     |

```

# using the slicers
In [71]: df.loc[:, (slice(None), 'one')]
Out [71]:

```

|        | first     | bar       | baz       | foo       | qux |
|--------|-----------|-----------|-----------|-----------|-----|
| second | one       | one       | one       | one       | one |
| A      | 0.895717  | -1.206412 | 1.431256  | -1.170299 |     |
| B      | 0.410835  | 0.132003  | -0.076467 | 1.130127  |     |
| C      | -1.413681 | 1.024180  | 0.875906  | 0.974466  |     |

`xs()` also allows selection with multiple keys.

```

In [72]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out [72]:

```

|        | first     | bar |
|--------|-----------|-----|
| second | one       |     |
| A      | 0.895717  |     |
| B      | 0.410835  |     |
| C      | -1.413681 |     |

```

# using the slicers
In [73]: df.loc[:, ('bar', 'one')]
Out [73]:
A    0.895717
B    0.410835
C   -1.413681
Name: (bar, one), dtype: float64

```

You can pass `drop_level=False` to `xs()` to retain the level that was selected.

```
In [74]: df.xs('one', level='second', axis=1, drop_level=False)
Out[74]:
```

|        | first     | bar       | baz       | foo       | qux |
|--------|-----------|-----------|-----------|-----------|-----|
| second | one       | one       | one       | one       | one |
| A      | 0.895717  | -1.206412 | 1.431256  | -1.170299 |     |
| B      | 0.410835  | 0.132003  | -0.076467 | 1.130127  |     |
| C      | -1.413681 | 1.024180  | 0.875906  | 0.974466  |     |

Compare the above with the result using `drop_level=True` (the default value).

```
In [75]: df.xs('one', level='second', axis=1, drop_level=True)
Out[75]:
```

|   | first     | bar       | baz       | foo       | qux |
|---|-----------|-----------|-----------|-----------|-----|
| A | 0.895717  | -1.206412 | 1.431256  | -1.170299 |     |
| B | 0.410835  | 0.132003  | -0.076467 | 1.130127  |     |
| C | -1.413681 | 1.024180  | 0.875906  | 0.974466  |     |

### 13.2.3 Advanced reindexing and alignment

The parameter `level` has been added to the `reindex` and `align` methods of pandas objects. This is useful to broadcast values across a level. For instance:

[illegible]

```
In [77]: df = pd.DataFrame(np.random.randn(4,2), index=midx)
```

```
In [78]: df
```

```
Out [78]:
```

|      |   | 0        | 1         |
|------|---|----------|-----------|
| one  | y | 1.519970 | -0.493662 |
|      | x | 0.600178 | 0.274230  |
| zero | y | 0.132885 | -0.023688 |
|      | x | 2.410179 | 1.450520  |

```
In [79]: df2 = df.mean(level=0)
```

```
In [80]: df2
```

```
Out[80]:
```

|      | 0        | 1         |
|------|----------|-----------|
| one  | 1.060074 | -0.109716 |
| zero | 1.271532 | 0.713416  |

```
In [81]: df2.reindex(df.index, level=0)
```

Out

|      |   | 0        | 1         |
|------|---|----------|-----------|
| one  | y | 1.060074 | -0.109716 |
|      | x | 1.060074 | -0.109716 |
| zero | y | 1.271532 | 0.713416  |
|      | x | 1.271532 | 0.713416  |

```
# aligning
```

```
In [82]: df_aligned, df2_aligned = df.align(df2, level=0)
```

(continues on next page)

(continued from previous page)

```
In [83]: df_aligned
Out[83]:
```

|      |   | 0        | 1         |
|------|---|----------|-----------|
| one  | y | 1.519970 | -0.493662 |
|      | x | 0.600178 | 0.274230  |
| zero | y | 0.132885 | -0.023688 |
|      | x | 2.410179 | 1.450520  |

```
In [84]: df2_aligned
////////////////////////////////////
```

|      |   | 0        | 1         |
|------|---|----------|-----------|
| one  | y | 1.060074 | -0.109716 |
|      | x | 1.060074 | -0.109716 |
| zero | y | 1.271532 | 0.713416  |
|      | x | 1.271532 | 0.713416  |

### 13.2.4 Swapping levels with `swaplevel()`

The `swaplevel` function can switch the order of two levels:

```
In [85]: df[:5]
Out[85]:
```

|      |   | 0        | 1         |
|------|---|----------|-----------|
| one  | y | 1.519970 | -0.493662 |
|      | x | 0.600178 | 0.274230  |
| zero | y | 0.132885 | -0.023688 |
|      | x | 2.410179 | 1.450520  |

```
In [86]: df[:5].swaplevel(0, 1, axis=0)
////////////////////////////////////
```

|        |  | 0        | 1         |
|--------|--|----------|-----------|
| y one  |  | 1.519970 | -0.493662 |
| x one  |  | 0.600178 | 0.274230  |
| y zero |  | 0.132885 | -0.023688 |
| x zero |  | 2.410179 | 1.450520  |

### 13.2.5 Reordering levels with `reorder_levels()`

The `reorder_levels` function generalizes the `swaplevel` function, allowing you to permute the hierarchical index levels in one step:

```
In [87]: df[:5].reorder_levels([1,0], axis=0)
Out[87]:
```

|        |  | 0        | 1         |
|--------|--|----------|-----------|
| y one  |  | 1.519970 | -0.493662 |
| x one  |  | 0.600178 | 0.274230  |
| y zero |  | 0.132885 | -0.023688 |
| x zero |  | 2.410179 | 1.450520  |

## 13.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index`.

```
In [88]: import random; random.shuffle(tuples)

In [89]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))

In [90]: s
Out[90]:
foo one    0.206053
qux one   -0.251905
baz two   -2.213588
bar two    1.063327
qux two    1.266143
foo two    0.299368
baz one   -0.863838
bar one    0.408204
dtype: float64

(continued from previous page)

```
qux two 1.266143
dtype: float64
```

You may also pass a level name to `sort_index` if the `MultiIndex` levels are named.

```
In [94]: s.index.set_names(['L1', 'L2'], inplace=True)
```

```
In [95]: s.sort_index(level='L1')
```

```
Out [95]:
```

```
L1 L2
bar one 0.408204
      two 1.063327
baz one -0.863838
      two -2.213588
foo one 0.206053
      two 0.299368
qux one -0.251905
      two 1.266143
dtype: float64
```

```
In [96]: s.sort_index(level='L2')
```

```

////////////////////////////////////
↪
L1 L2
bar one 0.408204
baz one -0.863838
foo one 0.206053
qux one -0.251905
bar two 1.063327
baz two -2.213588
foo two 0.299368
qux two 1.266143
dtype: float64
```

On higher dimensional objects, you can sort any of the other axes by level if they have a `MultiIndex`:

```
In [97]: dfm.T.sort_index(level=1, axis=1)
```

```
Out [97]:
```

```

      one      zero      one      zero
      x      x      y      y
0  0.600178  2.410179  1.519970  0.132885
1  0.274230  1.450520 -0.493662 -0.023688
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```
In [98]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
.....:                      'joe': ['x', 'x', 'z', 'y'],
.....:                      'jolie': np.random.rand(4)})
.....:
```

```
In [99]: dfm = dfm.set_index(['jim', 'joe'])
```

```
In [100]: dfm
```

```
Out [100]:
      jolie
```

(continues on next page)

```
jim joe
0  x  0.490671
   x  0.120248
1  z  0.537020
   y  0.110968
```

## 13.4 Take Methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [108]: index = pd.Index(np.random.randint(0, 1000, 10))

In [109]: index
Out[109]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64',
↳)

In [110]: positions = [0, 9, 3]

In [111]: index[positions]
Out[111]: Int64Index([214, 329, 567], dtype='int64')

In [112]: index.take(positions)
\\Out[112]: Int64Index([214, 329,
↳567], dtype='int64')

In [113]: ser = pd.Series(np.random.randn(10))

In [114]: ser.iloc[positions]
Out[114]:
0    -0.179666
9     1.824375
3     0.392149
dtype: float64

In [115]: ser.take(positions)
\\Out[115]:
0    -0.179666
9     1.824375
3     0.392149
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [116]: frm = pd.DataFrame(np.random.randn(5, 3))

In [117]: frm.take([1, 4, 3])
Out[117]:
      0         1         2
1 -1.237881  0.106854 -1.276829
4  0.629675 -1.425966  1.857704
3  0.979542 -1.633678  0.615855

In [118]: frm.take([0, 2], axis=1)
\\
↳
      0         2
0  0.595974  0.601544
1 -1.237881 -1.276829
2 -0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```

It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```
In [119]: arr = np.random.randn(10)

In [120]: arr.take([False, False, True, True])
Out[120]: array([-1.1935, -1.1935,  0.6775,  0.6775])

In [121]: arr[[0, 1]]
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[121]: array([-1.1935,  0.
↪6775])

In [122]: ser = pd.Series(np.random.randn(10))

In [123]: ser.take([False, False, True, True])
Out[123]:
0    0.233141
0    0.233141
1   -0.223540
1   -0.223540
dtype: float64

In [124]: ser.iloc[[0, 1]]
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[124]: ↵
↪
0    0.233141
1   -0.223540
dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

## 13.5 Index Types

We have discussed `MultiIndex` in the previous sections pretty extensively. `DatetimeIndex` and `PeriodIndex` are shown [here](#), and information about `TimedeltaIndex` is found [here](#).

In the following sub-sections we will highlight some other index types.

### 13.5.1 CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```
In [125]: from pandas.api.types import CategoricalDtype

In [126]: df = pd.DataFrame({'A': np.arange(6),
.....:                      'B': list('aabbca')})
.....:

In [127]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))

In [128]: df
```

---

(continues on next page)

(continued from previous page)

```

Out[128]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [129]: df.dtypes
Out[129]:
A      int64
B      category
dtype: object

In [130]: df.B.cat.categories
Out[130]:
Index(['c', 'a', 'b'], dtype='object')

```

Setting the index will create a CategoricalIndex.

```

In [131]: df2 = df.set_index('B')

In [132]: df2.index
Out[132]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
↳ ordered=False, name='B', dtype='category')

```

Indexing with `__getitem__`/`.iloc`/`.loc` works similarly to an Index with duplicates. The indexers **must** be in the category or the operation will raise a `KeyError`.

```

In [133]: df2.loc['a']
Out[133]:
A
B
a  0
a  1
a  5

```

The CategoricalIndex is **preserved** after indexing:

```

In [134]: df2.loc['a'].index
Out[134]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
↳ name='B', dtype='category')

```

Sorting the index will sort by the order of the categories (recall that we created the index with `CategoricalDtype(list('cab'))`, so the sorted order is cab).

```

In [135]: df2.sort_index()
Out[135]:
A
B
c  4
a  0
a  1
a  5
b  2
b  3

```

Groupby operations on the index will preserve the index nature as well.

```
In [136]: df2.groupby(level=0).sum()
Out[136]:
      A
B
c    4
a    6
b    5

In [137]: df2.groupby(level=0).sum().index
Out[137]: CategoricalIndex(['c', 'a', 'b'],
categories=['c', 'a', 'b'], ordered=False, name='B', dtype='category')
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the **passed** Categorical dtype. This allows one to arbitrarily index these even with values **not** in the categories, similarly to how you can reindex **any** pandas index.

```
In [138]: df2.reindex(['a', 'e'])
Out[138]:
      A
B
a    0.0
a    1.0
a    5.0
e    NaN

In [139]: df2.reindex(['a', 'e']).index
Out[139]: Index(['a', 'a', 'a', 'e'], dtype='object', name='B')

In [140]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
Out[140]:
      A
B
a    0.0
a    1.0
a    5.0
e    NaN

In [141]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index
Out[141]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'],
ordered=False, name='B', dtype='category')
```

**Warning:** Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.

```
In [9]: df3 = pd.DataFrame({'A' : np.arange(6),
                           'B' : pd.Series(list('aabbca')).astype('category')})

In [11]: df3 = df3.set_index('B')

In [11]: df3.index
Out[11]: CategoricalIndex([u'a', u'a', u'b', u'b', u'c', u'a'], categories=[u'a', u'b', u'c'], ordered=False, name='B', dtype='category')
```

```
In [12]: pd.concat([df2, df3])
```

## 13.5.2 Int64Index and RangeIndex

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see [here](#).

`Int64Index` is a fundamental basic index in pandas. This is an Immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the `Int64Index` would provide the default index for all `NDFrame` objects.

`RangeIndex` is a sub-class of `Int64Index` added in version 0.18.0, now providing the default index for all `NDFrame` objects. `RangeIndex` is an optimized version of `Int64Index` that can represent a monotonic ordered set. These are analogous to Python [range types](#).

## 13.5.3 Float64Index

By default a `Float64Index` will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes `[]`, `ix`, `loc` for scalar indexing and slicing work exactly the same.

```
In [142]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])

In [143]: indexf
Out[143]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [144]: sf = pd.Series(range(5), index=indexf)

In [145]: sf
Out[145]:
1.5    0
2.0    1
3.0    2
4.5    3
5.0    4
dtype: int64
```

Scalar selection for `[]`, `.loc` will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [146]: sf[3]
Out[146]: 2

In [147]: sf[3.0]
Out[147]: 2

In [148]: sf.loc[3]
Out[148]: 2

In [149]: sf.loc[3.0]
Out[149]: 2
```

The only positional indexing is via `iloc`.

```
In [150]: sf.iloc[3]
Out[150]: 3
```

A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and **always** positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

```
In [151]: sf[2:4]
Out[151]:
2.0    1
3.0    2
dtype: int64

In [152]: sf.loc[2:4]
Out[152]:
2.0    1
3.0    2
dtype: int64

In [153]: sf.iloc[2:4]
Out[153]:
3.0    2
4.5    3
dtype: int64
```

In float indexes, slicing using floats is allowed.

```
In [154]: sf[2.1:4.6]
Out[154]:
3.0    2
4.5    3
dtype: int64

In [155]: sf.loc[2.1:4.6]
Out[155]:
3.0    2
4.5    3
dtype: int64
```

In non-float indexes, slicing using floats will raise a `TypeError`.

```
In [1]: pd.Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type (Int64Index)

In [1]: pd.Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
(Int64Index)
```

**Warning:** Using a scalar float indexer for `.iloc` has been removed in 0.18.0, so the following will raise a `TypeError`:

```
In [3]: pd.Series(range(5)).iloc[3.0]
TypeError: cannot do positional indexing on <class 'pandas.indexes.range.RangeIndex'> with these indexers [3.0] of <type 'float'>
```

Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could for example be millisecond offsets.

```
In [156]: dfir = pd.concat([pd.DataFrame(np.random.randn(5,2),
.....:                                index=np.arange(5) * 250.0,
.....:                                columns=list('AB')),
.....:                    pd.DataFrame(np.random.randn(6,2),
.....:                                index=np.arange(4,10) * 250.1,
.....:                                columns=list('AB'))])
```

```
In [157]: dfir
```

Out [157]:

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | 0.997289  | -1.693316 |
| 250.0  | -0.179129 | -1.598062 |
| 500.0  | 0.936914  | 0.912560  |
| 750.0  | -1.003401 | 1.632781  |
| 1000.0 | -0.724626 | 0.178219  |
| 1000.4 | 0.310610  | -0.108002 |
| 1250.5 | -0.974226 | -1.147708 |
| 1500.6 | -2.281374 | 0.760010  |
| 1750.7 | -0.742532 | 1.533318  |
| 2000.8 | 2.495362  | -0.432771 |
| 2250.9 | -0.068954 | 0.043520  |

Selection operations then will always work on a value basis, for all selection operators.

```
In [158]: dfir[0:1000.4]
```

Out [158] :

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | 0.997289  | -1.693316 |
| 250.0  | -0.179129 | -1.598062 |
| 500.0  | 0.936914  | 0.912560  |
| 750.0  | -1.003401 | 1.632781  |
| 1000.0 | -0.724626 | 0.178219  |
| 1000.4 | 0.310610  | -0.108002 |

```
In [159]: dfir.loc[0:1001, 'A']
```

```
↔
0.0      0.997289
250.0    -0.179129
500.0     0.936914
750.0    -1.003401
1000.0   -0.724626
1000.4    0.310610
Name: A, dtype: float64
```

```
In [160]: dfir.loc[1000.4]
```

```
↪
A      0.310610
B     -0.108002
Name: 1000.4, dtype: float64
```

You could retrieve the first 1 second (1000 ms) of data as such:

```
In [161]: dfir[0:1000]
Out[161]:
```

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | 0.997289  | -1.693316 |
| 250.0  | -0.179129 | -1.598062 |
| 500.0  | 0.936914  | 0.912560  |
| 750.0  | -1.003401 | 1.632781  |
| 1000.0 | -0.724626 | 0.178219  |

If you need integer based selection, you should use `iloc`:

```
In [162]: dfir.iloc[0:5]
Out[162]:
```

|        | A         | B         |
|--------|-----------|-----------|
| 0.0    | 0.997289  | -1.693316 |
| 250.0  | -0.179129 | -1.598062 |
| 500.0  | 0.936914  | 0.912560  |
| 750.0  | -1.003401 | 1.632781  |
| 1000.0 | -0.724626 | 0.178219  |

### 13.5.4 IntervalIndex

New in version 0.20.0.

*IntervalIndex* together with its own dtype, `interval` as well as the *Interval* scalar type, allow first-class support in pandas for interval notation.

The `IntervalIndex` allows some unique indexing and is also used as a return type for the categories in `cut()` and `qcut()`.

**Warning:** These indexing behaviors are provisional and may change in a future version of pandas.

An `IntervalIndex` can be used in `Series` and in `DataFrame` as the index.

```
In [163]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
.....:                      index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
.....:

In [164]: df
Out[164]:
```

|        | A |
|--------|---|
| (0, 1] | 1 |
| (1, 2] | 2 |
| (2, 3] | 3 |
| (3, 4] | 4 |

Label based indexing via `.loc` along the edges of an interval works as you would expect, selecting that particular interval.

```
In [165]: df.loc[2]
Out[165]:
```

| A |
|---|
| 2 |

Name: (1, 2], dtype: int64

(continues on next page)

(continued from previous page)

```
In [166]: df.loc[[2, 3]]
Out[166]:
      A
(1, 2] 2
(2, 3] 3
```

If you select a label *contained* within an interval, this will also select the interval.

```
In [167]: df.loc[2.5]
Out[167]:
A      3
Name: (2, 3], dtype: int64

In [168]: df.loc[[2.5, 3.5]]
Out[168]:
      A
(2, 3] 3
(3, 4] 4
```

Interval and IntervalIndex are used by cut and qcut:

```
In [169]: c = pd.cut(range(4), bins=2)

In [170]: c
Out[170]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]

In [171]: c.categories
Out[171]:
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]]
              closed='right',
              dtype='interval[float64]')
```

Furthermore, IntervalIndex allows one to bin *other* data with these same bins, with NaN representing a missing value similar to other dtypes.

```
In [172]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[172]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]]
```

### 13.5.4.1 Generating Ranges of Intervals

If we need intervals on a regular frequency, we can use the `interval_range()` function to create an IntervalIndex using various combinations of start, end, and periods. The default frequency for `interval_range` is a 1 for numeric intervals, and calendar day for datetime-like intervals:

```
In [173]: pd.interval_range(start=0, end=5)
Out[173]:
IntervalIndex([ (0, 1], (1, 2], (2, 3], (3, 4], (4, 5]]
              closed='right',
              dtype='interval[int64]')
```

(continues on next page)

(continued from previous page)

```

In [174]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4)
IntervalIndex([(2017-01-01, 2017-01-02], (2017-01-02, 2017-01-03], (2017-01-03, 2017-
01-04], (2017-01-04, 2017-01-05]]
           closed='right',
           dtype='interval[datetime64[ns]]')

In [175]: pd.interval_range(end=pd.Timedelta('3 days'), periods=3)
IntervalIndex([(0 days 00:00:00, 1 days 00:00:00], (1 days 00:00:00, 2 days 00:00:00],
(2 days 00:00:00, 3 days 00:00:00]]
           closed='right',
           dtype='interval[timedelta64[ns]]')

```

The `freq` parameter can be used to specify non-default frequencies, and can utilize a variety of *frequency aliases* with datetime-like intervals:

```

In [176]: pd.interval_range(start=0, periods=5, freq=1.5)
Out[176]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0], (6.0, 7.5]]
           closed='right',
           dtype='interval[float64]')

In [177]: pd.interval_range(start=pd.Timestamp('2017-01-01'), periods=4, freq='W')
IntervalIndex([(2017-01-01, 2017-01-08], (2017-01-08, 2017-01-15], (2017-01-15, 2017-
01-22], (2017-01-22, 2017-01-29]]
           closed='right',
           dtype='interval[datetime64[ns]]')

In [178]: pd.interval_range(start=pd.Timedelta('0 days'), periods=3, freq='9H')
IntervalIndex([(0 days 00:00:00, 0 days 09:00:00], (0 days 09:00:00, 0 days 18:00:00],
(0 days 18:00:00, 1 days 03:00:00]]
           closed='right',
           dtype='interval[timedelta64[ns]]')

```

Additionally, the `closed` parameter can be used to specify which side(s) the intervals are closed on. Intervals are closed on the right side by default.

```

In [179]: pd.interval_range(start=0, end=4, closed='both')
Out[179]:
IntervalIndex([[0, 1], [1, 2], [2, 3], [3, 4]]
           closed='both',
           dtype='interval[int64]')

In [180]: pd.interval_range(start=0, end=4, closed='neither')
IntervalIndex([(0, 1), (1, 2), (2, 3), (3, 4)]
           closed='neither',
           dtype='interval[int64]')

```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced intervals from start to end inclusively, with periods number of elements in the resulting IntervalIndex:

```
In [181]: pd.interval_range(start=0, end=6, periods=4)
Out[181]:
IntervalIndex([(0.0, 1.5], (1.5, 3.0], (3.0, 4.5], (4.5, 6.0]]
              closed='right',
              dtype='interval[float64]')

In [182]: pd.interval_range(pd.Timestamp('2018-01-01'), pd.Timestamp('2018-02-28'),
↪periods=3)
↪
IntervalIndex([(2018-01-01, 2018-01-20 08:00:00], (2018-01-20 08:00:00, 2018-02-08
↪16:00:00], (2018-02-08 16:00:00, 2018-02-28]]
              closed='right',
              dtype='interval[datetime64[ns]]')
```

## 13.6 Miscellaneous indexing FAQ

### 13.6.1 Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index *only* label-based indexing is possible with the standard tools like `.loc`. The following code will generate exceptions:

```
s = pd.Series(range(5))
s[-1]
df = pd.DataFrame(np.random.randn(5, 4))
df
df.loc[-2:]
```

This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

### 13.6.2 Non-monotonic indexes require exact matches

If the index of a Series or DataFrame is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python list. Monotonicity of an index can be tested with the `is_monotonic_increasing` and `is_monotonic_decreasing` attributes.

```
In [183]: df = pd.DataFrame(index=[2,3,3,4,5], columns=['data'], data=list(range(5)))

In [184]: df.index.is_monotonic_increasing
Out[184]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [185]: df.loc[0:4, :]
Out[185]:
data
```

(continues on next page)

(continued from previous page)

```

2      0
3      1
3      2
4      3

# slice is are outside the index, so empty DataFrame is returned
In [186]: df.loc[13:15, :]
Out[186]:
Empty DataFrame
Columns: [data]
Index: []

```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```

In [187]: df = pd.DataFrame(index=[2,3,1,4,3,5], columns=['data'],
↳data=list(range(6)))

In [188]: df.index.is_monotonic_increasing
Out[188]: False

# OK because 2 and 4 are in the index
In [189]: df.loc[2:4, :]
Out[189]:
   data
2     0
3     1
1     2
4     3

```

```

# 0 is not in the index
In [9]: df.loc[0:4, :]
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'

```

`Index.is_monotonic_increasing()` and `Index.is_monotonic_decreasing()` only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with `Index.is_unique()`

```

In [190]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])

In [191]: weakly_monotonic
Out[191]: Index(['a', 'b', 'c', 'c'], dtype='object')

In [192]: weakly_monotonic.is_monotonic_increasing
Out[192]: True

In [193]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[193]: False

```

### 13.6.3 Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas **is inclusive**. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

```
In [194]: s = pd.Series(np.random.randn(6), index=list('abcdef'))

In [195]: s
Out[195]:
a    0.112246
b    0.871721
c   -0.816064
d   -0.784880
e    1.030659
f    0.187483
dtype: float64
```

Suppose we wished to slice from c to e, using integers this would be accomplished as such:

```
In [196]: s[2:5]
Out[196]:
c   -0.816064
d   -0.784880
e    1.030659
dtype: float64
```

However, if you only had c and e, determining the next element in the index can be somewhat complicated. For example, the following does not work:

```
s.loc['c':'e'+1]
```

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design to make label-based slicing include both endpoints:

```
In [197]: s.loc['c':'e']
Out[197]:
c   -0.816064
d   -0.784880
e    1.030659
dtype: float64
```

This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

### 13.6.4 Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [198]: series1 = pd.Series([1, 2, 3])

In [199]: series1.dtype
Out[199]: dtype('int64')

In [200]: res = series1.reindex([0, 4])
```

(continues on next page)

(continued from previous page)

```
In [201]: res.dtype
Out[201]: dtype('float64')

In [202]: res
\\Out[202]:
0      1.0
4      NaN
dtype: float64
```

```
In [203]: series2 = pd.Series([True])

In [204]: series2.dtype
Out[204]: dtype('bool')

In [205]: res = series2.reindex_like(series1)

In [206]: res.dtype
Out[206]: dtype('O')

In [207]: res
\\Out[207]:
0      True
1      NaN
2      NaN
dtype: object
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [this old issue](#) for a more detailed discussion.

## COMPUTATIONAL TOOLS

### 14.1 Statistical Functions

#### 14.1.1 Percent Change

`Series`, `DataFrame`, and `Panel` all have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values *before* computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))
```

```
In [2]: ser.pct_change()
```

```
Out [2]:
```

```
0      NaN
1   -1.602976
2    4.334938
3   -0.247456
4   -2.067345
5   -1.142903
6   -1.688214
7   -9.759729
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))
```

```
In [4]: df.pct_change(periods=3)
```

```
Out [4]:
```

```
      0      1      2      3
0     NaN     NaN     NaN     NaN
1     NaN     NaN     NaN     NaN
2     NaN     NaN     NaN     NaN
3 -0.218320 -1.054001  1.987147 -0.510183
4 -0.439121 -1.816454  0.649715 -4.822809
5 -0.127833 -3.042065 -5.866604 -1.776977
6 -2.596833 -1.959538 -2.111697 -3.798900
7 -0.117826 -2.169058  0.036094 -0.067696
8  2.492606 -1.357320 -1.205802 -1.558697
9 -1.012977  2.324558 -1.003744 -0.371806
```

#### 14.1.2 Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).

```
In [5]: s1 = pd.Series(np.random.randn(1000))

In [6]: s2 = pd.Series(np.random.randn(1000))

In [7]: s1.cov(s2)
Out[7]: 0.00068010881743110871
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See [Estimation of covariance matrices](#) for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e']
↳)

In [9]: frame.cov()
Out[9]:
```

|   | a         | b         | c         | d         | e         |
|---|-----------|-----------|-----------|-----------|-----------|
| a | 1.000882  | -0.003177 | -0.002698 | -0.006889 | 0.031912  |
| b | -0.003177 | 1.024721  | 0.000191  | 0.009212  | 0.000857  |
| c | -0.002698 | 0.000191  | 0.950735  | -0.031743 | -0.005087 |
| d | -0.006889 | 0.009212  | -0.031743 | 1.002983  | -0.047952 |
| e | 0.031912  | 0.000857  | -0.005087 | -0.047952 | 1.042487  |

`DataFrame.cov` also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [11]: frame.loc[frame.index[:5], 'a'] = np.nan

In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [13]: frame.cov()
Out[13]:
```

|   | a         | b         | c        |
|---|-----------|-----------|----------|
| a | 1.123670  | -0.412851 | 0.018169 |
| b | -0.412851 | 1.154141  | 0.305260 |
| c | 0.018169  | 0.305260  | 1.301149 |

```
In [14]: frame.cov(min_periods=12)
↳
```

|   | a        | b        | c        |
|---|----------|----------|----------|
| a | 1.123670 | NaN      | 0.018169 |
| b | NaN      | 1.154141 | 0.305260 |
| c | 0.018169 | 0.305260 | 1.301149 |

### 14.1.3 Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

| Method name          | Description                           |
|----------------------|---------------------------------------|
| pearson<br>(default) | Standard correlation coefficient      |
| kendall              | Kendall Tau correlation coefficient   |
| spearman             | Spearman rank correlation coefficient |

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- [Pearson correlation coefficient](#)
- [Kendall rank correlation coefficient](#)
- [Spearman's rank correlation coefficient](#)

**Note:** Please see the *caveats* associated with this method of calculating correlation matrices in the *covariance section*.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd',
↳ 'e'])

In [16]: frame.iloc[:,2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: 0.013479040400098794

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.0072898851595406371

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
```

|   | a         | b         | c         | d         | e         |
|---|-----------|-----------|-----------|-----------|-----------|
| a | 1.000000  | 0.013479  | -0.049269 | -0.042239 | -0.028525 |
| b | 0.013479  | 1.000000  | -0.020433 | -0.011139 | 0.005654  |
| c | -0.049269 | -0.020433 | 1.000000  | 0.018587  | -0.054269 |
| d | -0.042239 | -0.011139 | 0.018587  | 1.000000  | -0.017060 |
| e | -0.028525 | 0.005654  | -0.054269 | -0.017060 | 1.000000  |

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])

In [21]: frame.loc[frame.index[:5], 'a'] = np.nan

In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan

In [23]: frame.corr()
Out[23]:
```

(continues on next page)

(continued from previous page)

```

      a      b      c
a  1.000000 -0.121111  0.069544
b -0.121111  1.000000  0.051742
c  0.069544  0.051742  1.000000

```

```
In [24]: frame.corr(min_periods=12)
```

```

////////////////////////////////////Out
↪
      a      b      c
a  1.000000    NaN  0.069544
b      NaN  1.000000  0.051742
c  0.069544  0.051742  1.000000

```

A related method `corrwith()` is implemented on `DataFrame` to compute the correlation between like-labeled Series contained in different `DataFrame` objects.

```
In [25]: index = ['a', 'b', 'c', 'd', 'e']
```

```
In [26]: columns = ['one', 'two', 'three', 'four']
```

```
In [27]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
```

```
In [28]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
```

```
In [29]: df1.corrwith(df2)
```

```
Out[29]:
```

```

one      -0.125501
two       -0.493244
three      0.344056
four       0.004183
dtype: float64

```

```
In [30]: df2.corrwith(df1, axis=1)
```

```

////////////////////////////////////Out
↪
a      -0.675817
b       0.458296
c       0.190809
d      -0.186275
e           NaN
dtype: float64

```

### 14.1.4 Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```
In [31]: s = pd.Series(np.random.randn(5), index=list('abcde'))
```

```
In [32]: s['d'] = s['b'] # so there's a tie
```

```
In [33]: s.rank()
```

```

Out[33]:
a      5.0
b      2.5
c      1.0

```

(continues on next page)

(continued from previous page)

```
d    2.5
e    4.0
dtype: float64
```

`rank()` is also a DataFrame method and can rank either the rows (`axis=0`) or the columns (`axis=1`). NaN values are excluded from the ranking.

```
In [34]: df = pd.DataFrame(np.random.randn(10, 6))
```

```
In [35]: df[4] = df[2][:5] # some ties
```

```
In [36]: df
```

```
Out[36]:
```

```
      0         1         2         3         4         5
0 -0.904948 -1.163537 -1.457187  0.135463 -1.457187  0.294650
1 -0.976288 -0.244652 -0.748406 -0.999601 -0.748406 -0.800809
2  0.401965  1.460840  1.256057  1.308127  1.256057  0.876004
3  0.205954  0.369552 -0.669304  0.038378 -0.669304  1.140296
4 -0.477586 -0.730705 -1.129149 -0.601463 -1.129149 -0.211196
5 -1.092970 -0.689246  0.908114  0.204848         NaN  0.463347
6  0.376892  0.959292  0.095572 -0.593740         NaN -0.069180
7 -1.002601  1.957794 -0.120708  0.094214         NaN -1.467422
8 -0.547231  0.664402 -0.519424 -0.073254         NaN -1.263544
9 -0.250277 -0.237428 -1.056443  0.419477         NaN  1.375064
```

```
In [37]: df.rank(1)
```

```

////////////////////////////////////
↪
      0         1         2         3         4         5
0  4.0  3.0  1.5  5.0  1.5  6.0
1  2.0  6.0  4.5  1.0  4.5  3.0
2  1.0  6.0  3.5  5.0  3.5  2.0
3  4.0  5.0  1.5  3.0  1.5  6.0
4  5.0  3.0  1.5  4.0  1.5  6.0
5  1.0  2.0  5.0  3.0  NaN  4.0
6  4.0  5.0  3.0  1.0  NaN  2.0
7  2.0  5.0  3.0  4.0  NaN  1.0
8  2.0  5.0  3.0  4.0  NaN  1.0
9  2.0  3.0  1.0  4.0  NaN  5.0
```

`rank` optionally takes a parameter `ascending` which by default is `true`; when `false`, data is reverse-ranked, with larger values assigned a smaller rank.

`rank` supports different tie-breaking methods, specified with the `method` parameter:

- `average` : average rank of tied group
- `min` : lowest rank in the group
- `max` : highest rank in the group
- `first` : ranks assigned in the order they appear in the array

## 14.2 Window Functions

For working with data, a number of window functions are provided for computing common *window* or *rolling* statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and

kurtosis.

The `rolling()` and `expanding()` functions can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

**Note:** The API for window statistics is quite similar to the way one works with `GroupBy` objects, see the documentation [here](#).

We work with rolling, expanding and exponentially weighted data through the corresponding objects, Rolling, Expanding and EWM.

```
In [38]: s = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000',
↳ periods=1000))

In [39]: s = s.cumsum()

In [40]: s
Out[40]:
2000-01-01    -0.268824
2000-01-02    -1.771855
2000-01-03    -0.818003
2000-01-04    -0.659244
2000-01-05    -1.942133
2000-01-06    -1.869391
2000-01-07     0.563674
...
2002-09-20   -68.233054
2002-09-21   -66.765687
2002-09-22   -67.457323
2002-09-23   -69.253182
2002-09-24   -70.296818
2002-09-25   -70.844674
2002-09-26   -72.475016
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on `Series` and `DataFrame`.

```
In [41]: r = s.rolling(window=60)

In [42]: r
Out[42]: Rolling [window=60,center=False,axis=0]
```

These objects provide tab-completion of the available methods and properties.

```
In [14]: r.
r.agg          r.apply          r.count          r.exclusions  r.max          r.median        r.
↳ name        r.skew          r.sum            r.kurt        r.mean         r.min          r.
r.agg         r.corr          r.cov            r.kurt        r.mean         r.min          r.
↳ quantile    r.std          r.var
```

Generally these methods all have the same interface. They all accept the following arguments:

- `window`: size of moving window
- `min_periods`: threshold of non-null data points to require (otherwise result is NA)
- `center`: boolean, whether to set the labels at the center (default is `False`)

We can then call methods on these rolling objects. These return like-indexed objects:

```
In [43]: r.mean()
```

```
Out [43]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05      NaN
2000-01-06      NaN
2000-01-07      NaN
```

```
...
```

```
2002-09-20    -62.694135
2002-09-21    -62.812190
2002-09-22    -62.914971
2002-09-23    -63.061867
2002-09-24    -63.213876
2002-09-25    -63.375074
2002-09-26    -63.539734
```

```
Freq: D, Length: 1000, dtype: float64
```

```
In [44]: s.plot(style='k--')
```

```
Out [44]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24661e80>
```

```
In [45]: r.mean().plot(style='k')
```

```
Out [45]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24661e80>
```

They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame's columns:

```
In [46]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                    index=pd.date_range('1/1/2000', periods=1000),
.....:                    columns=['A', 'B', 'C', 'D'])
.....:

In [47]: df = df.cumsum()

In [48]: df.rolling(window=60).sum().plot(subplots=True)
Out[48]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x1a24757e48>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1a24780c88>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1a247aae48>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1a247db048>], dtype=object)
```

### 14.2.1 Method Summary

We provide a number of common statistical functions:

| Method                  | Description                                |
|-------------------------|--|
| <code>count()</code>    | Number of non-null observations            |
| <code>sum()</code>      | Sum of values                              |
| <code>mean()</code>     | Mean of values                             |
| <code>median()</code>   | Arithmetic median of values                |
| <code>min()</code>      | Minimum                                    |
| <code>max()</code>      | Maximum                                    |
| <code>std()</code>      | Bessel-corrected sample standard deviation |
| <code>var()</code>      | Unbiased variance                          |
| <code>skew()</code>     | Sample skewness (3rd moment)               |
| <code>kurt()</code>     | Sample kurtosis (4th moment)               |
| <code>quantile()</code> | Sample quantile (value at %)               |
| <code>apply()</code>    | Generic apply                              |
| <code>cov()</code>      | Unbiased covariance (binary)               |
| <code>corr()</code>     | Correlation (binary)                       |

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argument should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [49]: mad = lambda x: np.fabs(x - x.mean()).mean()

In [50]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[50]: <matplotlib.axes._subplots.AxesSubplot at 0x1a24b21630>
```

### 14.2.2 Rolling Windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according to the `win_type`. The following methods are available:

| Method              | Description    |
|---------------------|----------------|
| <code>sum()</code>  | Sum of values  |
| <code>mean()</code> | Mean of values |

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the [scipy.signal window functions](#):

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`

- blackmanharris
- nuttall
- barthann
- kaiser (needs beta)
- gaussian (needs std)
- general\_gaussian (needs power, width)
- slepian (needs width).

```
In [51]: ser = pd.Series(np.random.randn(10), index=pd.date_range('1/1/2000',
↳ periods=10))
```

```
In [52]: ser.rolling(window=5, win_type='triang').mean()
```

```
Out[52]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05   -1.037870
2000-01-06   -0.767705
2000-01-07   -0.383197
2000-01-08   -0.395513
2000-01-09   -0.558440
2000-01-10   -0.672416
Freq: D, dtype: float64
```

Note that the boxcar window is equivalent to `mean()`.

```
In [53]: ser.rolling(window=5, win_type='boxcar').mean()
```

```
Out[53]:
```

```
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05   -0.841164
2000-01-06   -0.779948
2000-01-07   -0.565487
2000-01-08   -0.502815
2000-01-09   -0.553755
2000-01-10   -0.472211
Freq: D, dtype: float64
```

```
In [54]: ser.rolling(window=5).mean()
```

```
////////////////////////////////////
```

```
↳
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05   -0.841164
2000-01-06   -0.779948
2000-01-07   -0.565487
2000-01-08   -0.502815
2000-01-09   -0.553755
2000-01-10   -0.472211
Freq: D, dtype: float64
```

For some windowing functions, additional parameters must be specified:

```
In [55]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out [55]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN
2000-01-05    -1.309989
2000-01-06    -1.153000
2000-01-07     0.606382
2000-01-08    -0.681101
2000-01-09    -0.289724
2000-01-10    -0.996632
Freq: D, dtype: float64
```

---

**Note:** For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

---

### 14.2.3 Time-aware Rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```
In [56]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index=pd.date_range('20130101 09:00:00', periods=5, freq=
↳ 's'))
.....:

In [57]: dft
Out [57]:
                B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  4.0
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [58]: dft.rolling(2).sum()
Out [58]:
                B
2013-01-01 09:00:00  NaN
2013-01-01 09:00:01  1.0
```

(continues on next page)

(continued from previous page)

```

2013-01-01 09:00:02    3.0
2013-01-01 09:00:03    NaN
2013-01-01 09:00:04    NaN

```

```
In [59]: dft.rolling(2, min_periods=1).sum()
```

```

////////////////////////////////////
↪
      B
2013-01-01 09:00:00    0.0
2013-01-01 09:00:01    1.0
2013-01-01 09:00:02    3.0
2013-01-01 09:00:03    2.0
2013-01-01 09:00:04    4.0

```

Specifying an offset allows a more intuitive specification of the rolling frequency.

```
In [60]: dft.rolling('2s').sum()
```

```
Out [60]:
```

```

      B
2013-01-01 09:00:00    0.0
2013-01-01 09:00:01    1.0
2013-01-01 09:00:02    3.0
2013-01-01 09:00:03    2.0
2013-01-01 09:00:04    4.0

```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```

In [61]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
.....:                      index = pd.Index([pd.Timestamp('20130101 09:00:00'),
.....:                                         pd.Timestamp('20130101 09:00:02'),
.....:                                         pd.Timestamp('20130101 09:00:03'),
.....:                                         pd.Timestamp('20130101 09:00:05'),
.....:                                         pd.Timestamp('20130101 09:00:06')],
.....:                                         name='foo'))

```

```
In [62]: dft
```

```
Out [62]:
```

```

      B
foo
2013-01-01 09:00:00    0.0
2013-01-01 09:00:02    1.0
2013-01-01 09:00:03    2.0
2013-01-01 09:00:05    NaN
2013-01-01 09:00:06    4.0

```

```
In [63]: dft.rolling(2).sum()
```

```

////////////////////////////////////
↪
      B
foo
2013-01-01 09:00:00    NaN
2013-01-01 09:00:02    1.0
2013-01-01 09:00:03    3.0
2013-01-01 09:00:05    NaN
2013-01-01 09:00:06    NaN

```

Using the time-specification generates variable windows for this sparse data.

```
In [64]: dft.rolling('2s').sum()
Out[64]:
```

|            |          | B   |
|------------|----------|-----|
| foo        |          |     |
| 2013-01-01 | 09:00:00 | 0.0 |
| 2013-01-01 | 09:00:02 | 1.0 |
| 2013-01-01 | 09:00:03 | 3.0 |
| 2013-01-01 | 09:00:05 | NaN |
| 2013-01-01 | 09:00:06 | 4.0 |

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a `DataFrame`.

```
In [65]: dft = dft.reset_index()
```

```
In [66]: dft
```

```
Out [66]:
```

|   |                     | foo | B |
|---|---------------------|-----|---|
| 0 | 2013-01-01 09:00:00 | 0.0 |   |
| 1 | 2013-01-01 09:00:02 | 1.0 |   |
| 2 | 2013-01-01 09:00:03 | 2.0 |   |
| 3 | 2013-01-01 09:00:05 | NaN |   |
| 4 | 2013-01-01 09:00:06 | 4.0 |   |

```
In [67]: dft.rolling('2s', on='foo').sum()
```

|   |            |          | foo | B |
|---|------------|----------|-----|---|
| 0 | 2013-01-01 | 09:00:00 | 0.0 |   |
| 1 | 2013-01-01 | 09:00:02 | 1.0 |   |
| 2 | 2013-01-01 | 09:00:03 | 3.0 |   |
| 3 | 2013-01-01 | 09:00:05 | NaN |   |
| 4 | 2013-01-01 | 09:00:06 | 4.0 |   |

#### 14.2.4 Rolling Window Endpoints

New in version 0.20.0.

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

| closed  | Description          | Default for        |
|---------|----------------------|--------------------|
| right   | close right endpoint | time-based windows |
| left    | close left endpoint  |                    |
| both    | close both endpoints | fixed windows      |
| neither | open endpoints       |                    |

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

[illegible]

(continues on next page)

(continued from previous page)

```

.....:         pd.Timestamp('20130101 09:00:03'),
.....:         pd.Timestamp('20130101 09:00:04'),
.....:         pd.Timestamp('20130101 09:00:06')]})
.....:

In [69]: df["right"] = df.rolling('2s', closed='right').x.sum() # default

In [70]: df["both"] = df.rolling('2s', closed='both').x.sum()

In [71]: df["left"] = df.rolling('2s', closed='left').x.sum()

In [72]: df["neither"] = df.rolling('2s', closed='neither').x.sum()

In [73]: df
Out[73]:

```

|                     | x | right | both | left | neither |
|---------------------|---|-------|------|------|---------|
| 2013-01-01 09:00:01 | 1 | 1.0   | 1.0  | NaN  | NaN     |
| 2013-01-01 09:00:02 | 1 | 2.0   | 2.0  | 1.0  | 1.0     |
| 2013-01-01 09:00:03 | 1 | 2.0   | 3.0  | 2.0  | 1.0     |
| 2013-01-01 09:00:04 | 1 | 2.0   | 3.0  | 2.0  | 1.0     |
| 2013-01-01 09:00:06 | 1 | 1.0   | 2.0  | 1.0  | NaN     |

Currently, this feature is only implemented for time-based windows. For fixed windows, the `closed` parameter cannot be set and the rolling window will always have both endpoints closed.

### 14.2.5 Time-aware Rolling vs. Resampling

Using `.rolling()` with a time-based index is quite similar to *resampling*. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

### 14.2.6 Centering Windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```

In [74]: ser.rolling(window=5).mean()
Out[74]:
2000-01-01      NaN
2000-01-02      NaN
2000-01-03      NaN
2000-01-04      NaN

```

## 14.2.7 Binary Window Functions

`cov()` and `corr()` can compute moving window statistics about two Series or any combination of DataFrame/Series or DataFrame/DataFrame. Here is the behavior in each case:

- two Series: compute the statistic for the pairing.
- DataFrame/Series: compute the statistics for each column of the DataFrame with the passed Series, thus returning a DataFrame.
- DataFrame/DataFrame: by default compute the statistic for matching column names, returning a DataFrame. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a MultiIndexed DataFrame whose index are the dates in question (see [the next section](#)).

For example:

```

In [76]: df = pd.DataFrame(np.random.randn(1000, 4),
.....:                     index=pd.date_range('1/1/2000', periods=1000),
.....:                     columns=['A', 'B', 'C', 'D'])
.....:

In [77]: df = df.cumsum()

In [78]: df2 = df[:20]

In [79]: df2.rolling(window=5).corr(df2['B'])
Out [79]:
           A      B      C      D
2000-01-01  NaN  NaN  NaN  NaN
2000-01-02  NaN  NaN  NaN  NaN
2000-01-03  NaN  NaN  NaN  NaN
2000-01-04  NaN  NaN  NaN  NaN

```

## 14.2.8 Computing rolling pairwise covariances and correlations

**Warning:** Prior to version 0.20.0 if `pairwise=True` was passed, a `Panel` would be returned. This will now return a 2-level `MultiIndexed DataFrame`, see the [whatsnew here](#).

In financial data analysis and other fields it's common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of `DataFrame` inputs will yield a `MultiIndexed DataFrame` whose index are the dates in question. In the case of a single `DataFrame` argument the `pairwise` argument can even be omitted:

**Note:** Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the [covariance section](#) for *caveats* associated with this method of calculating covariance and correlation matrices.

```

In [80]: covs = df[['B', 'C', 'D']].rolling(window=50).cov(df[['A', 'B', 'C']],
↳ pairwise=True)

```

```

In [81]: covs.loc['2002-09-22':]

```

```

Out[81]:

```

```

          B          C          D

| 2002-09-23 | A   | 1.000000  | 0.134723  | 0.743113  | -0.758758 |
|            | B   | 0.134723  | 1.000000  | 0.124683  | -0.209934 |
|            | C   | 0.743113  | 0.124683  | 1.000000  | -0.719088 |
| ...        | ... | ...       | ...       | ...       | ...       |
| 2002-09-25 | B   | 0.075157  | 1.000000  | 0.064399  | -0.164179 |
|            | C   | 0.731888  | 0.064399  | 1.000000  | -0.704686 |
|            | D   | -0.739160 | -0.164179 | -0.704686 | 1.000000  |
| 2002-09-26 | A   | 1.000000  | 0.087756  | 0.727792  | -0.736562 |
|            | B   | 0.087756  | 1.000000  | 0.079913  | -0.179477 |
|            | C   | 0.727792  | 0.079913  | 1.000000  | -0.692303 |
|            | D   | -0.736562 | -0.179477 | -0.692303 | 1.000000  |

```
[20 rows x 4 columns]
```

You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```
In [84]: correls.unstack(1)[('A', 'C')].plot()
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c25247630>
```

## 14.3 Aggregation

Once the `Rolling`, `Expanding` or `EWM` objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the *aggregating API*, *groupby API*, and *resample API*.

```
In [85]: dfa = pd.DataFrame(np.random.randn(1000, 3),
.....:                     index=pd.date_range('1/1/2000', periods=1000),
.....:                     columns=['A', 'B', 'C'])
.....:

In [86]: r = dfa.rolling(window=60, min_periods=1)

In [87]: r
Out[87]: Rolling [window=60, min_periods=1, center=False, axis=0]
```

We can aggregate by passing a function to the entire `DataFrame`, or select a `Series` (or multiple `Series`) via standard `__getitem__`.

```
In [88]: r.aggregate(np.sum)
Out[88]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | -0.289838 | -0.370545 | -1.284206 |
| 2000-01-02 | -0.216612 | -1.675528 | -1.169415 |

(continues on next page)

(continued from previous page)

2002-09-26   5.093787  -7.074515

```

```
[1000 rows x 2 columns]
```

As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

### 14.3.1 Applying multiple functions

With windowed Series you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```
In [91]: r['A'].agg([np.sum, np.mean, np.std])
```

```
Out [91]:
```

|            | sum       | mean      | std      |
|------------|-----------|-----------|----------|
| 2000-01-01 | -0.289838 | -0.289838 | NaN      |
| 2000-01-02 | -0.216612 | -0.108306 | 0.256725 |
| 2000-01-03 | 1.154661  | 0.384887  | 0.873311 |
| 2000-01-04 | 2.969393  | 0.742348  | 1.009734 |
| 2000-01-05 | 4.690630  | 0.938126  | 0.977914 |
| 2000-01-06 | 3.880630  | 0.646772  | 1.128883 |
| 2000-01-07 | 4.001957  | 0.571708  | 1.049487 |
| ...        | ...       | ...       | ...      |
| 2002-09-20 | 2.652493  | 0.044208  | 1.164919 |
| 2002-09-21 | 0.844497  | 0.014075  | 1.148231 |
| 2002-09-22 | 2.860036  | 0.047667  | 1.132051 |
| 2002-09-23 | 3.510163  | 0.058503  | 1.134296 |
| 2002-09-24 | 6.524983  | 0.108750  | 1.144204 |
| 2002-09-25 | 6.409626  | 0.106827  | 1.142913 |
| 2002-09-26 | 5.093787  | 0.084896  | 1.151416 |

```
[1000 rows x 3 columns]
```

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [92]: r.agg([np.sum, np.mean])
```

```
Out [92]:
```

|            | A         |           | B          |           | C         |           |
|------------|-----------|-----------|------------|-----------|-----------|-----------|
|            | sum       | mean      | sum        | mean      | sum       | mean      |
| 2000-01-01 | -0.289838 | -0.289838 | -0.370545  | -0.370545 | -1.284206 | -1.284206 |
| 2000-01-02 | -0.216612 | -0.108306 | -1.675528  | -0.837764 | -1.169415 | -0.584708 |

```
[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.

### 14.3.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a `DataFrame`:

```
In [93]: r.agg({'A' : np.sum,
.....:         'B' : lambda x: np.std(x, ddof=1)})
.....:
Out [93]:
```

|            | A         | B        |
|------------|-----------|----------|
| 2000-01-01 | -0.289838 | NaN      |
| 2000-01-02 | -0.216612 | 0.660747 |
| 2000-01-03 | 1.154661  | 0.689929 |
| 2000-01-04 | 2.969393  | 1.072199 |
| 2000-01-05 | 4.690630  | 0.939657 |
| 2000-01-06 | 3.880630  | 0.966848 |
| 2000-01-07 | 4.001957  | 1.240137 |
| ...        | ...       | ...      |
| 2002-09-20 | 2.652493  | 1.114814 |
| 2002-09-21 | 0.844497  | 1.113220 |
| 2002-09-22 | 2.860036  | 1.113208 |
| 2002-09-23 | 3.510163  | 1.132381 |
| 2002-09-24 | 6.524983  | 1.080963 |
| 2002-09-25 | 6.409626  | 1.082911 |
| 2002-09-26 | 5.093787  | 1.136199 |

[1000 rows x 2 columns]

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object

```
In [94]: r.agg({'A' : 'sum', 'B' : 'std'})
Out [94]:
```

|            | A         | B        |
|------------|-----------|----------|
| 2000-01-01 | -0.289838 | NaN      |
| 2000-01-02 | -0.216612 | 0.660747 |
| 2000-01-03 | 1.154661  | 0.689929 |
| 2000-01-04 | 2.969393  | 1.072199 |
| 2000-01-05 | 4.690630  | 0.939657 |
| 2000-01-06 | 3.880630  | 0.966848 |
| 2000-01-07 | 4.001957  | 1.240137 |
| ...        | ...       | ...      |
| 2002-09-20 | 2.652493  | 1.114814 |
| 2002-09-21 | 0.844497  | 1.113220 |
| 2002-09-22 | 2.860036  | 1.113208 |
| 2002-09-23 | 3.510163  | 1.132381 |
| 2002-09-24 | 6.524983  | 1.080963 |
| 2002-09-25 | 6.409626  | 1.082911 |
| 2002-09-26 | 5.093787  | 1.136199 |

[1000 rows x 2 columns]

Furthermore you can pass a nested dict to indicate different aggregations on different columns.

```
In [95]: r.agg({'A' : ['sum', 'std'], 'B' : ['mean', 'std'] })
Out [95]:
```

|            | A         |     | B         |     |
|------------|-----------|-----|-----------|-----|
|            | sum       | std | mean      | std |
| 2000-01-01 | -0.289838 | NaN | -0.370545 | NaN |

(continues on next page)

```
[1000 rows x 4 columns]
```

### 14.4.1 Method Summary

| Function                | Description                     |
|-------------------------|---------------------------------|
| <code>count()</code>    | Number of non-null observations |
| <code>sum()</code>      | Sum of values                   |
| <code>mean()</code>     | Mean of values                  |
| <code>median()</code>   | Arithmetic median of values     |
| <code>min()</code>      | Minimum                         |
| <code>max()</code>      | Maximum                         |
| <code>std()</code>      | Unbiased standard deviation     |
| <code>var()</code>      | Unbiased variance               |
| <code>skew()</code>     | Unbiased skewness (3rd moment)  |
| <code>kurt()</code>     | Unbiased kurtosis (4th moment)  |
| <code>quantile()</code> | Sample quantile (value at %)    |
| <code>apply()</code>    | Generic apply                   |
| <code>cov()</code>      | Unbiased covariance (binary)    |
| <code>corr()</code>     | Correlation (binary)            |

Aside from not having a window parameter, these functions have the same interfaces as their `.rolling` counterparts. Like above, the parameters they all accept are:

- `min_periods`: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once `min_periods` non-null data points have been seen.
- `center`: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the `.rolling` and `.expanding` methods do not return a NaN if there are at least `min_periods` non-null values in the current window. For example:

```
In [98]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [99]: sn
Out[99]:
0    1.0
1    2.0
2    NaN
3    3.0
4    NaN
5    4.0
dtype: float64

In [100]: sn.rolling(2).max()
Out[100]:
0    NaN
1    2.0
2    NaN
3    NaN
4    NaN
5    NaN
dtype: float64

In [101]: sn.rolling(2, min_periods=1).max()
Out[101]:
0    1.0
1    2.0
2    3.0
3    3.0
4    4.0
5    4.0
dtype: float64
```

(continues on next page)

(continued from previous page)

```

0    1.0
1    2.0
2    2.0
3    3.0
4    3.0
5    4.0
dtype: float64

```

In case of expanding functions, this differs from `cumsum()`, `cumprod()`, `cummax()`, and `cummin()`, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of `cumsum` with expanding, use `fillna()`:

```
In [102]: sn.expanding().sum()
```

```

Out[102]:
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5   10.0
dtype: float64

```

```
In [103]: sn.cumsum()
```

```

Out[103]:
0    1.0
1    3.0
2    NaN
3    6.0
4    NaN
5   10.0
dtype: float64

```

```
In [104]: sn.cumsum().fillna(method='ffill')
```

```

Out[104]:
0    1.0
1    3.0
2    3.0
3    6.0
4    6.0
5   10.0
dtype: float64

```

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the `mean()` output for the previous time series dataset:

```
In [105]: s.plot(style='k--')
```

```
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x1c254345f8>
```

```
In [106]: s.expanding().mean().plot(style='k')
```

```

Out[106]:
<matplotlib.axes._subplots.AxesSubplot at 0x1c254345f8>

```

## 14.5 Exponentially Weighted Windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

| Function            | Description                  |
|---------------------|------------------------------|
| <code>mean()</code> | EW moving average            |
| <code>var()</code>  | EW moving variance           |
| <code>std()</code>  | EW moving standard deviation |
| <code>corr()</code> | EW moving correlation        |
| <code>cov()</code>  | EW moving covariance         |

In general, a weighted moving average is calculated as

$$y_t = \frac{\sum_{i=0}^t w_i x_{t-i}}{\sum_{i=0}^t w_i},$$

where  $x_t$  is the input,  $y_t$  is the result and the  $w_i$  are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights  $w_i =$

$(1 - \alpha)^i$  which gives

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots + (1 - \alpha)^tx_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots + (1 - \alpha)^t}$$

When `adjust=False` is specified, moving averages are calculated as

$$\begin{aligned} y_0 &= x_0 \\ y_t &= (1 - \alpha)y_{t-1} + \alpha x_t, \end{aligned}$$

which is equivalent to using weights

$$w_i = \begin{cases} \alpha(1 - \alpha)^i & \text{if } i < t \\ (1 - \alpha)^i & \text{if } i = t. \end{cases}$$

---

**Note:** These equations are sometimes written in terms of  $\alpha' = 1 - \alpha$ , e.g.

$$y_t = \alpha' y_{t-1} + (1 - \alpha')x_t.$$

---

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history:

$$y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{1 + (1 - \alpha) + (1 - \alpha)^2 + \dots}$$

Noting that the denominator is a geometric series with initial term equal to 1 and a ratio of  $1 - \alpha$  we have

$$\begin{aligned} y_t &= \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots}{\frac{1}{1 - (1 - \alpha)}} \\ &= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \dots]\alpha \\ &= \alpha x_t + (1 - \alpha)y_{t-1} \end{aligned}$$

which shows the equivalence of the above two variants for infinite series. When `adjust=True` we have  $y_0 = x_0$  and from the last representation above we have  $y_t = \alpha x_t + (1 - \alpha)y_{t-1}$ , therefore there is an assumption that  $x_0$  is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have  $0 < \alpha \leq 1$ , and while since version 0.18.0 it has been possible to pass  $\alpha$  directly, it's often easier to think about either the **span**, **center of mass (com)** or **half-life** of an EW moment:

$$\alpha = \begin{cases} \frac{2}{s+1}, & \text{for span } s \geq 1 \\ \frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\ 1 - \exp^{-\frac{\log 0.5}{h}}, & \text{for half-life } h > 0 \end{cases}$$

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span:  $c = (s - 1)/2$ .
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:

```

In [107]: s.plot(style='k--')
Out[107]: <matplotlib.axes._subplots.AxesSubplot at 0x1a2490e630>

In [108]: s.ewm(span=20).mean().plot(style='k')
Out[108]:
\\Out[108]:
↪<matplotlib.axes._subplots.AxesSubplot at 0x1a2490e630>

```

EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

$$\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.$$

Whereas if `ignore_na=True`, the weighted average would be calculated as

$$\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.$$

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) =`

`ewma(x**2) - ewma(x)**2`; whereas if `bias=False` (the default), the biased variance statistics are scaled by debiasing factors

$$\frac{\left(\sum_{i=0}^t w_i\right)^2}{\left(\sum_{i=0}^t w_i\right)^2 - \sum_{i=0}^t w_i^2}.$$

(For  $w_i = 1$ , this reduces to the usual  $N/(N - 1)$  factor, with  $N = t + 1$ .) See [Weighted Sample Variance](#) on Wikipedia for further details.

## WORKING WITH MISSING DATA

In this section, we will discuss missing (also referred to as NA) values in pandas.

---

**Note:** The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. It differs from the MaskedArray approach of, for example, `scikits.timeseries`. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

---

See the *cookbook* for some advanced strategies.

### 15.1 Missing data basics

#### 15.1.1 When / why does data become missing?

Some might quibble over our usage of *missing*. By “missing” we simply mean **NA** (“not available”) or “not present for whatever reason”. Many data sets simply arrive with missing data, either because it exists and was not collected or it never existed. For example, in a collection of financial time series, some of the time series might start on different dates. Thus, values prior to the start date would generally be marked as missing.

In pandas, one of the most common ways that missing data is **introduced** into a data set is by reindexing. For example:

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
...:                      columns=['one', 'two', 'three'])
...:
...:

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:
```

|   | one       | two       | three     | four | five  |
|---|-----------|-----------|-----------|------|-------|
| a | -0.166778 | 0.501113  | -0.355322 | bar  | False |
| c | -0.337890 | 0.580967  | 0.983801  | bar  | False |
| e | 0.057802  | 0.761948  | -0.712964 | bar  | True  |
| f | -0.443160 | -0.974602 | 1.047704  | bar  | False |
| h | -0.717852 | -1.053898 | -0.019369 | bar  | False |

```
In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
Out[6]:
```

(continues on next page)

(continued from previous page)

|   | one       | two       | three     | four | five  |
|---|-----------|-----------|-----------|------|-------|
| a | -0.166778 | 0.501113  | -0.355322 | bar  | False |
| b | NaN       | NaN       | NaN       | NaN  | NaN   |
| c | -0.337890 | 0.580967  | 0.983801  | bar  | False |
| d | NaN       | NaN       | NaN       | NaN  | NaN   |
| e | 0.057802  | 0.761948  | -0.712964 | bar  | True  |
| f | -0.443160 | -0.974602 | 1.047704  | bar  | False |
| g | NaN       | NaN       | NaN       | NaN  | NaN   |
| h | -0.717852 | -1.053898 | -0.019369 | bar  | False |

### 15.1.2 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python None will arise and we wish to also consider that “missing” or “not available” or “NA”.

---

**Note:** If you want to consider inf and -inf to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

---

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
Out[7]:
a    -0.166778
b         NaN
c    -0.337890
d         NaN
e     0.057802
f    -0.443160
g         NaN
h    -0.717852
Name: one, dtype: float64

In [8]: pd.isna(df2['one'])
Out[8]:
a    False
b     True
c    False
d     True
e    False
f    False
g     True
h    False
Name: one, dtype: bool

In [9]: df2['four'].notna()
Out[9]:
a     True
b    False
```

(continues on next page)

```
c      True
d      False
e      True
f      True
g      False
h      True
Name: four, dtype: bool
```

```

      one      two  three   four   five
a  False  False  False  False  False
b   True   True   True   True   True
c  False  False  False  False  False
d   True   True   True   True   True
e  False  False  False  False  False
f  False  False  False  False  False
g   True   True   True   True   True
h  False  False  False  False  False

```

### 15.3 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [20]: s = pd.Series([1, 2, 3])

In [21]: s.loc[0] = None

In [22]: s
Out[22]:
0      NaN
1      2.0
2      3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [23]: s = pd.Series(["a", "b", "c"])
In [24]: s.loc[0] = None
```

(continues on next page)

(continued from previous page)

```
In [25]: s.loc[1] = np.nan

In [26]: s
Out[26]:
0      None
1      NaN
2         c
dtype: object
```

## 15.4 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

```
In [27]: a
Out[27]:
      one      two
a      NaN  0.501113
c      NaN  0.580967
e  0.057802  0.761948
f -0.443160 -0.974602
h -0.443160 -1.053898
```

```
In [28]: b
↗
      one      two      three
a      NaN  0.501113 -0.355322
c      NaN  0.580967  0.983801
e  0.057802  0.761948 -0.712964
f -0.443160 -0.974602  1.047704
h      NaN -1.053898 -0.019369
```

```
In [29]: a + b
↗
      one  three      two
a      NaN  NaN  1.002226
c      NaN  NaN  1.161935
e  0.115604  NaN  1.523896
f -0.886321  NaN -1.949205
h      NaN  NaN -2.107796
```

The descriptive statistics and computational methods discussed in the [data structure overview](#) (and listed [here](#) and [here](#)) are all written to account for missing data. For example:

- When summing data, NA (missing) values will be treated as zero.
- If the data are all NA, the result will be 0.
- Cumulative methods like `cumsum()` and `cumprod()` ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use `skipna=False`.

```
In [30]: df
Out[30]:
```

(continues on next page)

(continued from previous page)

|   | one       | two       | three     |
|---|-----------|-----------|-----------|

| h | NaN | -0.184472 | 0.943850  |

### 15.4.1 Sum/Prod of Empties/Nans

**Warning:** This behavior is now standard as of v0.22.0 and is consistent with the default in `numpy`; previously `sum/prod` of all-NA or empty `Series/DataFrames` would return `NaN`. See [v0.22.0 whatsnew](#) for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

```
In [35]: pd.Series([np.nan]).sum()
```

Out [35]: 0.0

```
In [36]: pd.Series([]).sum()
```

```
Out[36]: 0.0
```

The product of an empty or all-NA Series or column of a DataFrame is 1.

```
In [37]: pd.Series([np.nan]).prod()
Out[37]: 1.0

In [38]: pd.Series([]).prod()
Out[38]: 1.0
```

## 15.4.2 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```
In [39]: df
Out[39]:
```

|   | one       | two       | three     |
|---|-----------|-----------|-----------|
| a | NaN       | 0.501113  | -0.355322 |
| c | NaN       | 0.580967  | 0.983801  |
| e | 0.057802  | 0.761948  | -0.712964 |
| f | -0.443160 | -0.974602 | 1.047704  |
| h | NaN       | -1.053898 | -0.019369 |

```
In [40]: df.groupby('one').mean()
Out[40]:
```

|           | two       | three     |
|-----------|-----------|-----------|
| one       |           |           |
| -0.443160 | -0.974602 | 1.047704  |
| 0.057802  | 0.761948  | -0.712964 |

See the groupby section [here](#) for more information.

## 15.5 Cleaning / filling missing data

pandas objects are equipped with various data manipulation methods for dealing with missing data.

### 15.5.1 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

**Replace NA with a scalar value**

```
In [41]: df2
Out[41]:
```

|   | one       | two       | three     | four | five  | timestamp  |
|---|-----------|-----------|-----------|------|-------|------------|
| a | NaN       | 0.501113  | -0.355322 | bar  | False | NaT        |
| c | NaN       | 0.580967  | 0.983801  | bar  | False | NaT        |
| e | 0.057802  | 0.761948  | -0.712964 | bar  | True  | 2012-01-01 |
| f | -0.443160 | -0.974602 | 1.047704  | bar  | False | 2012-01-01 |
| h | NaN       | -1.053898 | -0.019369 | bar  | False | NaT        |

```
In [42]: df2.fillna(0)
```

(continues on next page)

(continued from previous page)

```

      one      two      three four   five      timestamp
a  0.000000  0.501113 -0.355322  bar  False              0
c  0.000000  0.580967  0.983801  bar  False              0
e  0.057802  0.761948 -0.712964  bar   True  2012-01-01 00:00:00
f -0.443160 -0.974602  1.047704  bar  False  2012-01-01 00:00:00
h  0.000000 -1.053898 -0.019369  bar  False              0

```

```
In [43]: df2['one'].fillna('missing')
```

```

////////////////////////////////////
↪
a      missing
c      missing
e      0.057802
f     -0.44316
h      missing
Name: one, dtype: object

```

### Fill gaps forward or backward

Using the same filling arguments as [reindexing](#), we can propagate non-NA values forward or backward:

```
In [44]: df
```

```
Out [44]:
```

```

      one      two      three
a      NaN  0.501113 -0.355322
c      NaN  0.580967  0.983801
e  0.057802  0.761948 -0.712964
f -0.443160 -0.974602  1.047704
h      NaN -1.053898 -0.019369

```

```
In [45]: df.fillna(method='pad')
```

```

////////////////////////////////////
↪
      one      two      three
a      NaN  0.501113 -0.355322
c      NaN  0.580967  0.983801
e  0.057802  0.761948 -0.712964
f -0.443160 -0.974602  1.047704
h -0.443160 -1.053898 -0.019369

```

### Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the *limit* keyword:

```
In [46]: df
```

```
Out [46]:
```

```

      one      two      three
a  NaN  0.501113 -0.355322
c  NaN  0.580967  0.983801
e  NaN      NaN      NaN
f  NaN      NaN      NaN
h  NaN -1.053898 -0.019369

```

```
In [47]: df.fillna(method='pad', limit=1)
```

```

////////////////////////////////////
↪
      one      two      three

```

(continues on next page)

(continued from previous page)

```

a  NaN    0.501113 -0.355322
c  NaN    0.580967  0.983801
e  NaN    0.580967  0.983801
f  NaN          NaN          NaN
h  NaN   -1.053898 -0.019369

```

To remind you, these are the available filling methods:

| Method           | Action               |
|------------------|----------------------|
| pad / ffill      | Fill values forward  |
| bfill / backfill | Fill values backward |

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

## 15.5.2 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

```
In [48]: dff = pd.DataFrame(np.random.randn(10,3), columns=list('ABC'))
```

```
In [49]: dff.iloc[3:5,0] = np.nan
```

```
In [50]: dff.iloc[4:6,1] = np.nan
```

```
In [51]: dff.iloc[5:8,2] = np.nan
```

```
In [52]: dff
```

```
Out[52]:
```

```

      A         B         C
0  0.758887  2.340598  0.219039
1 -1.235583  0.031785  0.701683
2 -1.557016 -0.636986 -1.238610
3      NaN -1.002278  0.654052
4      NaN      NaN  1.053999
5  0.651981      NaN      NaN
6  0.109001 -0.533294      NaN
7 -1.037831 -1.150016      NaN
8 -0.687693  1.921056 -0.121113
9 -0.258742 -0.706329  0.402547

```

```
In [53]: dff.fillna(dff.mean())
```

```

////////////////////////////////////

```

```

      A         B         C
0  0.758887  2.340598  0.219039
1 -1.235583  0.031785  0.701683
2 -1.557016 -0.636986 -1.238610
3 -0.407125 -1.002278  0.654052
4 -0.407125  0.033067  1.053999

```

(continues on next page)

(continued from previous page)

|   |           |           |           |
|---|-----------|-----------|-----------|
| 5 | 0.651981  | 0.033067  | 0.238800  |
| 6 | 0.109001  | -0.533294 | 0.238800  |
| 7 | -1.037831 | -1.150016 | 0.238800  |
| 8 | -0.687693 | 1.921056  | -0.121113 |
| 9 | -0.258742 | -0.706329 | 0.402547  |

```
In [54]: dff.fillna(dff.mean()['B':'C'])
```

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| 0 | 0.758887  | 2.340598  | 0.219039  |
| 1 | -1.235583 | 0.031785  | 0.701683  |
| 2 | -1.557016 | -0.636986 | -1.238610 |
| 3 | NaN       | -1.002278 | 0.654052  |
| 4 | NaN       | 0.033067  | 1.053999  |
| 5 | 0.651981  | 0.033067  | 0.238800  |
| 6 | 0.109001  | -0.533294 | 0.238800  |
| 7 | -1.037831 | -1.150016 | 0.238800  |
| 8 | -0.687693 | 1.921056  | -0.121113 |
| 9 | -0.258742 | -0.706329 | 0.402547  |

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

```
In [55]: dff.where(pd.notna(dff), dff.mean(), axis='columns')
```

Out [55] :

|   | A         | B         | C         |
|---|-----------|-----------|-----------|
| 0 | 0.758887  | 2.340598  | 0.219039  |
| 1 | -1.235583 | 0.031785  | 0.701683  |
| 2 | -1.557016 | -0.636986 | -1.238610 |
| 3 | -0.407125 | -1.002278 | 0.654052  |
| 4 | -0.407125 | 0.033067  | 1.053999  |
| 5 | 0.651981  | 0.033067  | 0.238800  |
| 6 | 0.109001  | -0.533294 | 0.238800  |
| 7 | -1.037831 | -1.150016 | 0.238800  |
| 8 | -0.687693 | 1.921056  | -0.121113 |
| 9 | -0.258742 | -0.706329 | 0.402547  |

### 15.5.3 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use `dropna()`:

```
In [56]: df
```

Out [56] :

|   | one | two       | three     |
|---|-----|-----------|-----------|
| a | NaN | 0.501113  | -0.355322 |
| c | NaN | 0.580967  | 0.983801  |
| e | NaN | 0.000000  | 0.000000  |
| f | NaN | 0.000000  | 0.000000  |
| h | NaN | -1.053898 | -0.019369 |

```
In [57]: df.dropna(axis=0)
```

Empty DataFrame

```
Columns: [one, two, three]
```

(continues on next page)

(continued from previous page)

Index: []

```
In [58]: df.dropna(axis=1)
```

|   | two       | three     |
|---|-----------|-----------|
| a | 0.501113  | -0.355322 |
| c | 0.580967  | 0.983801  |
| e | 0.000000  | 0.000000  |
| f | 0.000000  | 0.000000  |
| h | -1.053898 | -0.019369 |

```
In [59]: df['one'].dropna()
```

```
→ Series([], Name: one, dtype: float64)
```

An equivalent `dropna()` is available for Series. `DataFrame.dropna` has considerably more options than `Series.dropna`, which can be examined *in the API*.

### 15.5.4 Interpolation

New in version 0.21.0: The `limit_area` keyword argument was added.

Both Series and DataFrame objects have `interpolate()` that, by default, performs linear interpolation at missing datapoints.

```
In [60]: ts
```

Out [60]:

|            |          |
|------------|----------|
| 2000-01-31 | 0.469112 |
| 2000-02-29 | NaN      |
| 2000-03-31 | NaN      |
| 2000-04-28 | NaN      |
| 2000-05-31 | NaN      |
| 2000-06-30 | NaN      |
| 2000-07-31 | NaN      |

|            |           |
|------------|-----------|
|            | ...       |
| 2007-10-31 | -3.305259 |
| 2007-11-30 | -5.485119 |
| 2007-12-31 | -6.854968 |
| 2008-01-31 | -7.809176 |
| 2008-02-29 | -6.346480 |
| 2008-03-31 | -8.089641 |
| 2008-04-30 | -8.916232 |

Freq: BM, Length: 100, dtype: float64

```
In [61]: ts.count()
```

↪ 61

```
In [62]: ts.interpolate().count()
```

→ 100

```
In [63]: ts.interpolate().plot()
```

```
→<matplotlib.axes._subplots.AxesSubplot at 0x1c38e4a048>
```

Index aware interpolation is available via the `method` keyword:

```
In [64]: ts2
```

Out [64] :

|            |          |
|------------|----------|
| 2000-01-31 | 0.469112 |
|------------|----------|

|            |     |
|------------|-----|
| 2000-02-29 | NaN |
|------------|-----|

|            |           |
|------------|-----------|
| 2002-07-31 | -5.689738 |
|------------|-----------|

|            |     |
|------------|-----|
| 2005-01-31 | NaN |
|------------|-----|

|            |           |
|------------|-----------|
| 2008-04-30 | -8.916232 |
|------------|-----------|

```
dtype: float64
```

```
In [65]: ts2.interpolate()
```

|            |          |
|------------|----------|
| 2000-01-31 | 0.469112 |
|------------|----------|

|            |           |
|------------|-----------|
| 2000-02-29 | -2.610313 |
|------------|-----------|

|            |           |
|------------|-----------|
| 2002-07-31 | -5.689738 |
|------------|-----------|

|            |           |
|------------|-----------|
| 2005-01-31 | -7.302985 |
|------------|-----------|

|            |           |
|------------|-----------|
| 2008-04-30 | -8.916232 |
|------------|-----------|

```
dtype: float64
```

```
In [66]: ts2.interpolate(method='time')
```

////////////////////////////////////

|            |          |
|------------|----------|
| 2000-01-31 | 0.469112 |
|------------|----------|

|            |          |
|------------|----------|
| 2000-01-31 | 0.189112 |
| 2000-02-29 | 0.273272 |

(continues on next page)

(continued from previous page)

```

2002-07-31    -5.689738
2005-01-31    -7.095568
2008-04-30    -8.916232
dtype: float64

```

For a floating-point index, use `method='values'`:

```

In [67]: ser
Out[67]:
0.0      0.0
1.0      NaN
10.0     10.0
dtype: float64

In [68]: ser.interpolate()
Out[68]:
0.0      0.0
1.0      5.0
10.0     10.0
dtype: float64

In [69]: ser.interpolate(method='values')
Out[69]:
0.0      0.0
1.0      1.0
10.0     10.0
dtype: float64

```

You can also interpolate with a DataFrame:

```

In [70]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
.....:                    'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})

In [71]: df
Out[71]:
   A      B
0  1.0  0.25
1  2.1   NaN
2  NaN   NaN
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

In [72]: df.interpolate()
Out[72]:
   A      B
0  1.0  0.25
1  2.1  1.50
2  3.4  2.75
3  4.7  4.00
4  5.6 12.20
5  6.8 14.40

```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the

name of a 1-d interpolation routine to `method`. You'll want to consult the full [scipy interpolation documentation](#) and reference [guide](#) for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require `scipy`.

```
In [73]: df.interpolate(method='barycentric')
```

```
Out[73]:
```

|   | A    | B      |
|---|------|--------|
| 0 | 1.00 | 0.250  |
| 1 | 2.10 | -7.660 |
| 2 | 3.53 | -4.515 |
| 3 | 4.70 | 4.000  |
| 4 | 5.60 | 12.200 |
| 5 | 6.80 | 14.400 |

```
In [74]: df.interpolate(method='pchip')
```

```
////////////////////////////////////
```

```
↪
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | 0.672808  |
| 2 | 3.43454  | 1.928950  |
| 3 | 4.700000 | 4.000000  |
| 4 | 5.600000 | 12.200000 |
| 5 | 6.800000 | 14.400000 |

```
In [75]: df.interpolate(method='akima')
```

```
////////////////////////////////////
```

```
↪
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | -0.873316 |
| 2 | 3.406667 | 0.320034  |
| 3 | 4.700000 | 4.000000  |
| 4 | 5.600000 | 12.200000 |
| 5 | 6.800000 | 14.400000 |

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```
In [76]: df.interpolate(method='spline', order=2)
```

```
Out[76]:
```

|   | A        | B         |
|---|----------|-----------|
| 0 | 1.000000 | 0.250000  |
| 1 | 2.100000 | -0.428598 |
| 2 | 3.404545 | 1.206900  |
| 3 | 4.700000 | 4.000000  |

(continues on next page)

```
In [77]: df.interpolate(method='polynomial', order=2)
```

```
In [79]: ser = pd.Series(np.arange(1, 10.1, .25)**2 + np.random.randn(37))
```

```
In [81]: ser[bad] = np.nan
```

```
In [83]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
```

```
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3702e518>
```

Another use case is interpolation at *new* values. Suppose you have 100 observations from some distribution. And let's suppose that you're particularly interested in what's happening around the middle. You can mix pandas' `reindex` and `interpolate` methods to interpolate at the new values.

```
In [85]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [86]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [87]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [88]: interp_s[49:51]
Out[88]:
49.00    0.471410
49.25    0.476841
49.50    0.481780
49.75    0.485998
50.00    0.489266
50.25    0.491814
50.50    0.493995
50.75    0.495763
51.00    0.497074
dtype: float64
```

### 15.5.4.1 Interpolation Limits

Like other pandas fill methods, `interpolate()` accepts a `limit` keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```
In [89]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.
↳ nan])

# fill all consecutive values in a forward direction
In [90]: ser.interpolate()
Out[90]:
0      NaN
1      NaN
2      5.0
3      7.0
4      9.0
5     11.0
6     13.0
7     13.0
8     13.0
dtype: float64

# fill one consecutive value in a forward direction
In [91]: ser.interpolate(limit=1)
////////////////////////////////////
↳
0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5      NaN
6     13.0
7     13.0
8      NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```
# fill one consecutive value backwards
In [92]: ser.interpolate(limit=1, limit_direction='backward')
Out[92]:
0      NaN
1      5.0
2      5.0
3      NaN
4      NaN
5     11.0
6     13.0
7      NaN
8      NaN
dtype: float64
```

```
# fill one consecutive value in both directions
In [93]: ser.interpolate(limit=1, limit_direction='both')
////////////////////////////////////
↳
```

(continues on next page)

(continued from previous page)

```

0      NaN
1      5.0
2      5.0
3      7.0
4      NaN
5      11.0
6      13.0
7      13.0
8      NaN
dtype: float64

```

```
# fill all consecutive values in both directions
```

```
In [94]: ser.interpolate(limit_direction='both')
```

```

////////////////////////////////////
↪
0      5.0
1      5.0
2      5.0
3      7.0
4      9.0
5      11.0
6      13.0
7      13.0
8      13.0
dtype: float64

```

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the `limit_area` parameter restricts filling to either inside or outside values.

```
# fill one consecutive inside value in both directions
```

```
In [95]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
```

```
Out [95]:
```

```

0      NaN
1      NaN
2      5.0
3      7.0
4      NaN
5      11.0
6      13.0
7      NaN
8      NaN
dtype: float64

```

```
# fill all consecutive outside values backward
```

```
In [96]: ser.interpolate(limit_direction='backward', limit_area='outside')
```

```

////////////////////////////////////
↪
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6      13.0
7      NaN
8      NaN

```

(continues on next page)

(continued from previous page)

```
dtype: float64

# fill all consecutive outside values in both directions
In [97]: ser.interpolate(limit_direction='both', limit_area='outside')
//////////
↪
0      5.0
1      5.0
2      5.0
3      NaN
4      NaN
5      NaN
6     13.0
7     13.0
8     13.0
dtype: float64
```

### 15.5.5 Replacing Generic Values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

```
In [98]: ser = pd.Series([0., 1., 2., 3., 4.])

In [99]: ser.replace(0, 5)
Out[99]:
0    5.0
1    1.0
2    2.0
3    3.0
4    4.0
dtype: float64
```

You can replace a list of values by a list of other values:

```
In [100]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])
Out[100]:
0      4.0
1      3.0
2      2.0
3      1.0
4      0.0
dtype: float64
```

You can also specify a mapping dict:

```
In [101]: ser.replace({0: 10, 1: 100})
Out[101]:
0      10.0
1     100.0
2       2.0
```

(continues on next page)

(continued from previous page)

```
3      3.0
4      4.0
dtype: float64
```

For a DataFrame, you can specify individual values by column:

```
In [102]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})

In [103]: df.replace({'a': 0, 'b': 5}, 100)
Out[103]:
```

|   | a   | b   |
|---|-----|-----|
| 0 | 100 | 100 |
| 1 | 1   | 6   |
| 2 | 2   | 7   |
| 3 | 3   | 8   |
| 4 | 4   | 9   |

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```
In [104]: ser.replace([1, 2, 3], method='pad')
Out[104]:
```

|   |     |
|---|-----|
| 0 | 0.0 |
| 1 | 0.0 |
| 2 | 0.0 |
| 3 | 0.0 |
| 4 | 4.0 |

dtype: float64

## 15.5.6 String/Regular Expression Replacement

---

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\'` == `'\\'`. You should [read about them](#) if this is unclear.

---

Replace the `'.'` with NaN (str -> str):

```
In [105]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}

In [106]: df = pd.DataFrame(d)

In [107]: df.replace('.', np.nan)
Out[107]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```
In [108]: df.replace(r'\s*\.\s*', np.nan, regex=True)
Out[108]:
```

|  | a | b | c |
|--|---|---|---|
|--|---|---|---|

(continues on next page)

(continued from previous page)

|   |   |     |     |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

Replace a few different values (list -> list):

```
In [109]: df.replace(['a', '.'], ['b', np.nan])
```

```
Out [109]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | b   | b   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

list of regex -> list of regex:

```
In [110]: df.replace([r'\.', r'(a)'], ['dot', '\1stuff'], regex=True)
```

```
Out [110]:
```

|   | a | b      | c      |
|---|---|--------|--------|
| 0 | 0 | {stuff | {stuff |
| 1 | 1 | b      | b      |
| 2 | 2 | dot    | NaN    |
| 3 | 3 | dot    | d      |

Only search in column 'b' (dict -> dict):

```
In [111]: df.replace({'b': '.'}, {'b': np.nan})
```

```
Out [111]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [112]: df.replace({'b': r'\s*\.\s*'}, {'b': np.nan}, regex=True)
```

```
Out [112]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [113]: df.replace({'b': {'b': r'.'}}, regex=True)
```

```
Out [113]:
```

|   | a | b | c   |
|---|---|---|-----|
| 0 | 0 | a | a   |
| 1 | 1 | b | b   |
| 2 | 2 | . | NaN |
| 3 | 3 | . | d   |

Alternatively, you can pass the nested dictionary like so:

```
In [114]: df.replace(regex={'b': {r'\s*\.\s*': np.nan}})
Out[114]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

```
In [115]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\1ty'}, regex=True)
Out[115]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | a   | a   |
| 1 | 1 | b   | b   |
| 2 | 2 | .ty | NaN |
| 3 | 3 | .ty | d   |

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

```
In [116]: df.replace([r'\s*\.\s*', r'a|b'], np.nan, regex=True)
Out[116]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | NaN | NaN |
| 1 | 1 | NaN | NaN |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

All of the regular expression examples can also be passed with the `to_replace` argument as the `regex` argument. In this case the `value` argument must be passed explicitly by name or `regex` must be a nested dictionary. The previous example, in this case, would then be:

```
In [117]: df.replace(regex=[r'\s*\.\s*', r'a|b'], value=np.nan)
Out[117]:
```

|   | a | b   | c   |
|---|---|-----|-----|
| 0 | 0 | NaN | NaN |
| 1 | 1 | NaN | NaN |
| 2 | 2 | NaN | NaN |
| 3 | 3 | NaN | d   |

This can be convenient if you do not want to pass `regex=True` every time you want to use a regular expression.

---

**Note:** Anywhere in the above `replace` examples that you see a regular expression a compiled regular expression is valid as well.

---

## 15.5.7 Numeric Replacement

`replace()` is similar to `fillna()`.

```
In [118]: df = pd.DataFrame(np.random.randn(10, 2))
In [119]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5
```

(continues on next page)

Out [120]:

```
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4         NaN         NaN
5         NaN         NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9         NaN         NaN
```

Out [122]:

|   |           |           |
|---|-----------|-----------|
| 0 | a         | -1.02141  |
| 1 | 0.432396  | -0.32358  |
| 2 | 0.423825  | 0.79918   |
| 3 | 1.26261   | 0.751965  |
| 4 | NaN       | NaN       |
| 5 | NaN       | NaN       |
| 6 | -0.498174 | -1.0608   |
| 7 | 0.591667  | -0.183257 |
| 8 | 1.01985   | -1.48247  |
| 9 | NaN       | NaN       |

```
dtype('float64')
```

---

```
TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'
```

\_\_\_\_\_

|    |   |   |   |   |   |   |   |   |
|----|---|---|---|---|---|---|---|---|
| II | 1 | 1 | : | : | 1 | 1 | : | 1 |
|----|---|---|---|---|---|---|---|---|

```
In [125]: s = pd.Series([True, False, True])

In [126]: s.replace('a string', 'another string')
Out[126]:
0      True
1     False
2      True
dtype: bool
```

the original NDFrame object will be returned untouched. We’re working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See [GH6354](#) for more details.

## 15.6 Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

| data type | Cast to |
|-----------|---------|
| integer   | float   |
| boolean   | object  |
| float     | no cast |
| object    | no cast |

For example:

```
In [127]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [128]: s > 0
Out[128]:
0      True
2      True
4      True
6      True
7      True
dtype: bool

In [129]: (s > 0).dtype
Out[129]: dtype('bool')
```

```
In [130]: crit = (s > 0).reindex(list(range(8)))

In [131]: crit
Out[131]:
0      True
1     NaN
2      True
3     NaN
4      True
5     NaN
6      True
```

(continues on next page)

(continued from previous page)

```
7      True
dtype: object
```

```
In [132]: crit.dtype
```

Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```
In [133]: reindexed = s.reindex(list(range(8))).fillna(0)
```

```
In [134]: reindexed[crit]
```

[illegible]

```
<ipython-input-134-0dac417a4890> in <module>()
```

```
----> 1 reindexed[crit]
```

```
~/sandbox/pandas-release/pandas-docs/pandas/core/series.py in __getitem__(self, key)
```

```
805         key = list(key)
```

806

```
--> 807         if com.is_bool_indexer(key):
```

```
808         key = check_bool_indexer(self.index, key)
```

809

```
~/sandbox/pandas-release/pandas-docs/pandas/core/common.py in is_bool_indexer(key)
```

```
105         if not lib.is_bool_array(key):
```

```
106         if isna(key).any():
```

```
--> 107         raise ValueError('cannot index with vector containing '
```

```
108                                     'NA / NaN values')
```

```
109         return False
```

```
ValueError: cannot index with vector containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```
In [135]: reindexed[crit.fillna(False)]
```

Out [135] :

|   |          |

## GROUP BY: SPLIT-APPLY-COMBINE

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to one of the following:

- **Aggregation:** compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.
- **Transformation:** perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.
- **Filtration:** discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.
- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or `itertools`), in which you can write code like:

```
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the [cookbook](#) for some advanced strategies.

## 16.1 Splitting an object into groups

pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```
# default is axis=0
>>> grouped = obj.groupby(key)
>>> grouped = obj.groupby(key, axis=1)
>>> grouped = obj.groupby([key1, key2])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the **keys**. For example, consider the following DataFrame:

---

**Note:** New in version 0.20.

A string passed to `groupby` may refer to either a column or an index level. If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

---

```
In [1]: df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
...:                             'foo', 'bar', 'foo', 'foo'],
...:                      'B' : ['one', 'one', 'two', 'three',
...:                             'two', 'two', 'one', 'three'],
...:                      'C' : np.random.randn(8),
...:                      'D' : np.random.randn(8)})
...:
```

```
In [2]: df
```

```
Out[2]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | 0.469112  | -0.861849 |
| 1 | bar | one   | -0.282863 | -2.104569 |
| 2 | foo | two   | -1.509059 | -0.494929 |
| 3 | bar | three | -1.135632 | 1.071804  |
| 4 | foo | two   | 1.212112  | 0.721555  |
| 5 | bar | two   | -0.173215 | -0.706771 |
| 6 | foo | one   | 0.119209  | -1.039575 |
| 7 | foo | three | -1.044236 | 0.271860  |

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:

```
In [3]: grouped = df.groupby('A')
```

```
In [4]: grouped = df.groupby(['A', 'B'])
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```
In [5]: def get_letter_type(letter):
...:     if letter.lower() in 'aeiou':
...:         return 'vowel'
...:     else:
...:         return 'consonant'
...:
```

```
In [6]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas *Index* objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```
In [7]: lst = [1, 2, 3, 1, 2, 3]
```

```
In [8]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
```

```
In [9]: grouped = s.groupby(level=0)
```

```
In [10]: grouped.first()
```

Out[10]:

```
In [11]: grouped.last()
```

```
1    10
2    20
3    30
dtype: int64
```

```
In [12]: grouped.sum()
```

Note that **no splitting occurs** until it's needed. Creating the `GroupBy` object only verifies that you've passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can't be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.

### 16.1.1 GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```
In [13]: df2 = pd.DataFrame({'X' : ['B', 'B', 'A', 'A'], 'Y' : [1, 2, 3, 4]})
```

```
In [14]: df2.groupby(['X']).sum()
```

Out [14] :

Y

X

A 7

B 3

```
In [15]: df2.groupby(['X'], sort=False).sum()
```

```
\\Out[15]:
```

Y

X

B

A 7

Note that `groupby` will preserve the order in which *observations* are sorted *within* each group. For example, the groups created by `groupby()` below are in the order they appeared in the original `DataFrame`:

```
In [16]: df3 = pd.DataFrame({'X' : ['A', 'B', 'A', 'B'], 'Y' : [1, 4, 3, 2]})
```

```
In [17]: df3.groupby(['X']).get_group('A')
```

Out [17] :

|  | X | Y |
|--|---|---|
|--|---|---|

|   |   |   |
|---|---|---|
| 0 | A | 1 |
|---|---|---|

2 A 3

```
In [18]: df3.groupby(['X']).get_group('B')
```

```
Out[18]:
```

|  | X | Y |
|--|---|---|
|--|---|---|

1 B 4

3 B 2

### 16.1.2 GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```
In [19]: df.groupby('A').groups
```

Out [19] :

```
{'bar': Int64Index([1, 3, 5], dtype='int64'),  
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}
```

```
In [20]: df.groupby(get_letter_type, axis=1).groups
```

////////////////////////////////////

```
{'consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')}
```

Calling the standard Python `len` function on the `GroupBy` object just returns the length of the `groups` dict, so it is largely just a convenience:

```
In [25]: qb = df.groupby('gender')
```

|              |              |            |             |             |              |
|--------------|--------------|------------|-------------|-------------|--------------|
| gb.agg       | gb.boxplot   | gb.cummin  | gb.describe | gb.filter   | gb.get_group |
| ↳ gb.height  | gb.last      | gb.median  | gb.ngroups  | gb.plot     | gb.rank      |
| ↳ gb.std     | gb.transform |            |             |             |              |
| gb.aggregate | gb.count     | gb.cumprod | gb.dtypes   | gb.first    | gb.groups    |
| ↳ gb.hist    | gb.max       | gb.min     | gb.nth      | gb.prod     | gb.resample  |
| ↳ gb.sum     | gb.var       |            |             |             |              |
| gb.apply     | gb.cummax    | gb.cumsum  | gb.fillna   | gb.gender   | gb.head      |
| ↳ gb.indices | gb.mean      | gb.name    | gb.ohlcv    | gb.quantile | gb.size      |
| ↳ gb.tail    | gb.weight    |            |             |             |              |

Let's create a Series with a two-level `MultiIndex`.

```
In [28]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

841

(continued from previous page)

```
In [29]: s = pd.Series(np.random.randn(8), index=index)

In [30]: s
Out[30]:
first second
bar      one    -0.919854
          two    -0.042379
baz      one     1.247642
          two    -0.009920
foo      one     0.290213
          two     0.495767
qux      one     0.362949
          two     1.548106
dtype: float64
```

We can then group by one of the levels in `s`.

```
In [31]: grouped = s.groupby(level=0)

In [32]: grouped.sum()
Out[32]:
first
bar    -0.962232
baz     1.237723
foo     0.785980
qux     1.911055
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```
In [33]: s.groupby(level='second').sum()
Out[33]:
second
one     0.980950
two     1.991575
dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```
In [34]: s.sum(level='second')
Out[34]:
second
one     0.980950
two     1.991575
dtype: float64
```

Grouping with multiple levels is supported.

```
In [35]: s
Out[35]:
first second third
bar      doo    one   -1.131345
          two   -0.089329
baz      bee    one    0.337863
          two   -0.945867
```

(continues on next page)

(continued from previous page)

```

foo    bop    one    -0.932132
        two     1.956030
qux    bop    one     0.017587
        two    -0.016692
dtype: float64

```

```
In [36]: s.groupby(level=['first', 'second']).sum()
```

```

////////////////////////////////////
↪
first  second
bar    doo    -1.220674
baz    bee    -0.608004
foo    bop     1.023898
qux    bop     0.000895
dtype: float64

```

New in version 0.20.

Index level names may be supplied as keys.

```
In [37]: s.groupby(['first', 'second']).sum()
```

```

Out [37]:
first  second
bar    doo    -1.220674
baz    bee    -0.608004
foo    bop     1.023898
qux    bop     0.000895
dtype: float64

```

More on the `sum` function and aggregation later.

### 16.1.4 Grouping DataFrame with Index Levels and Columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as `pd.Grouper` objects.

```
In [38]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
.....:             ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
.....:
```

```
In [39]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
```

```
In [40]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
.....:                     'B': np.arange(8)},
.....:                     index=index)
.....:
```

```
In [41]: df
```

```

Out [41]:
      A  B
first second
bar  one  1  0
     two  1  1
baz  one  1  2
     two  1  3

```

(continues on next page)

(continued from previous page)

|     |     |   |   |
|-----|-----|---|---|
| foo | one | 2 | 4 |
|     | two | 2 | 5 |
| qux | one | 3 | 6 |
|     | two | 3 | 7 |

The following example groups df by the second index level and the A column.

```
In [42]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[42]:
```

|        |   |   |
|--------|---|---|
|        |   | B |
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

Index levels may also be specified by name.

```
In [43]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[43]:
```

|        |   |   |
|--------|---|---|
|        |   | B |
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

New in version 0.20.

Index level names may be specified as keys directly to groupby.

```
In [44]: df.groupby(['second', 'A']).sum()
Out[44]:
```

|        |   |   |
|--------|---|---|
|        |   | B |
| second | A |   |
| one    | 1 | 2 |
|        | 2 | 4 |
|        | 3 | 6 |
| two    | 1 | 4 |
|        | 2 | 5 |
|        | 3 | 7 |

### 16.1.5 DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a DataFrame, you can do:

```
In [45]: grouped = df.groupby(['A'])
In [46]: grouped_C = grouped['C']
In [47]: grouped_D = grouped['D']
```

This is mainly syntactic sugar for the alternative and much more verbose:

```
In [48]: df['C'].groupby(df['A'])
Out[48]: <pandas.core.groupby.groupby.SeriesGroupBy object at 0x1c2adc8390>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

## 16.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [49]: grouped = df.groupby('A')

In [50]: for name, group in grouped:
.....:     print(name)
.....:     print(group)
.....:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 1 | bar | one   | 0.254161  | 1.511763  |
| 3 | bar | three | 0.215897  | -0.990582 |
| 5 | bar | two   | -0.077118 | 1.211526  |

foo

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | -0.575247 | 1.346061  |
| 2 | foo | two   | -1.143704 | 1.627081  |
| 4 | foo | two   | 1.193555  | -0.441652 |
| 6 | foo | one   | -0.408530 | 0.268520  |
| 7 | foo | three | -0.862495 | 0.024580  |

In the case of grouping by multiple keys, the group name will be a tuple:

```
In [51]: for name, group in df.groupby(['A', 'B']):
.....:     print(name)
.....:     print(group)
.....:
```

('bar', 'one')

|   | A   | B   | C        | D        |
|---|-----|-----|----------|----------|
| 1 | bar | one | 0.254161 | 1.511763 |

('bar', 'three')

|   | A   | B     | C        | D         |
|---|-----|-------|----------|-----------|
| 3 | bar | three | 0.215897 | -0.990582 |

('bar', 'two')

|   | A   | B   | C         | D        |
|---|-----|-----|-----------|----------|
| 5 | bar | two | -0.077118 | 1.211526 |

('foo', 'one')

|   | A   | B   | C         | D        |
|---|-----|-----|-----------|----------|
| 0 | foo | one | -0.575247 | 1.346061 |
| 6 | foo | one | -0.408530 | 0.268520 |

('foo', 'three')

|   | A   | B     | C         | D       |
|---|-----|-------|-----------|---------|
| 7 | foo | three | -0.862495 | 0.02458 |

('foo', 'two')

|  | A | B | C | D |
|--|---|---|---|---|
|--|---|---|---|---|

(continues on next page)

(continued from previous page)

```
2  foo  two -1.143704  1.627081
4  foo  two  1.193555 -0.441652
```

It's standard Python-fu but remember you can unpack the tuple in the for loop statement if you wish: `for (k1, k2), group in grouped:`.

## 16.3 Selecting a group

A single group can be selected using `get_group()`:

```
In [52]: grouped.get_group('bar')
Out[52]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 1 | bar | one   | 0.254161  | 1.511763  |
| 3 | bar | three | 0.215897  | -0.990582 |
| 5 | bar | two   | -0.077118 | 1.211526  |

Or for an object grouped on multiple columns:

```
In [53]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[53]:
```

|   | A   | B   | C        | D        |
|---|-----|-----|----------|----------|
| 1 | bar | one | 0.254161 | 1.511763 |

## 16.4 Aggregation

Once the `GroupBy` object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the *aggregating API*, *window functions API*, and *resample API*.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```
In [54]: grouped = df.groupby('A')

In [55]: grouped.agg(np.sum)
Out[55]:
```

|     |  | C         | D        |
|-----|--|-----------|----------|
| A   |  |           |          |
| bar |  | 0.392940  | 1.732707 |
| foo |  | -1.796421 | 2.824590 |

```
In [56]: grouped = df.groupby(['A', 'B'])

In [57]: grouped.agg(np.sum)
Out[57]:
```

|     |       |  | C         | D         |
|-----|-------|--|-----------|-----------|
| A   | B     |  |           |           |
| bar | one   |  | 0.254161  | 1.511763  |
|     | three |  | 0.215897  | -0.990582 |
|     | two   |  | -0.077118 | 1.211526  |
| foo | one   |  | -0.983776 | 1.614581  |
|     | three |  | -0.862495 | 0.024580  |
|     | two   |  | 0.049851  | 1.185429  |

As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a *MultiIndex* by default, though this can be changed by using the `as_index` option:

```
In [58]: grouped = df.groupby(['A', 'B'], as_index=False)
```

```
In [59]: grouped.agg(np.sum)
```

```
Out[59]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | bar | one   | 0.254161  | 1.511763  |
| 1 | bar | three | 0.215897  | -0.990582 |
| 2 | bar | two   | -0.077118 | 1.211526  |
| 3 | foo | one   | -0.983776 | 1.614581  |
| 4 | foo | three | -0.862495 | 0.024580  |
| 5 | foo | two   | 0.049851  | 1.185429  |

```
In [60]: df.groupby('A', as_index=False).sum()
```

```

////////////////////////////////////
↪
      A      C      D
0  bar  0.392940  1.732707
1  foo -1.796421  2.824590

```

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting *MultiIndex*:

```
In [61]: df.groupby(['A', 'B']).sum().reset_index()
```

```
Out[61]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | bar | one   | 0.254161  | 1.511763  |
| 1 | bar | three | 0.215897  | -0.990582 |
| 2 | bar | two   | -0.077118 | 1.211526  |
| 3 | foo | one   | -0.983776 | 1.614581  |
| 4 | foo | three | -0.862495 | 0.024580  |
| 5 | foo | two   | 0.049851  | 1.185429  |

Another simple aggregation example is to compute the size of each group. This is included in *GroupBy* as the `size` method. It returns a *Series* whose index are the group names and whose values are the sizes of each group.

```
In [62]: grouped.size()
```

```
Out[62]:
```

```

A      B
bar  one      1
      three   1
      two     1
foo   one     2
      three   1
      two     2
dtype: int64

```

```
In [63]: grouped.describe()
```

```
Out[63]:
```

|   | C      |          |          |          |          | ... | D        |          |     |  |  |
|---|--------|----------|----------|----------|----------|-----|----------|----------|-----|--|--|
|   | count  | mean     | std      | min      | 25%      | ... | min      | 25%      | 50% |  |  |
| ↪ | count  | mean     | std      | min      | 25%      | ... | min      | 25%      | 50% |  |  |
| ↪ | %      | 75%      | max      |          |          |     |          |          |     |  |  |
| 0 | 1.0    | 0.254161 | NaN      | 0.254161 | 0.254161 | ... | 1.511763 | 1.511763 | 1.  |  |  |
| ↪ | 511763 | 1.511763 | 1.511763 |          |          |     |          |          |     |  |  |

[6 rows x 16 columns]
```

**Note:** Aggregation functions **will not** return the groups that you are aggregating over if they are named *columns*, when `as_index=True`, the default. The grouped columns will be the **indices** of the returned object.

Passing `as_index=False` **will** return the groups that you are aggregating over, if they are named *columns*.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

| Function                | Description  |
|-------------------------|--|
| <code>mean()</code>     | Compute mean of groups                                   |
| <code>sum()</code>      | Compute sum of group values                              |
| <code>size()</code>     | Compute group sizes                                      |
| <code>count()</code>    | Compute count of group                                   |
| <code>std()</code>      | Standard deviation of groups                             |
| <code>var()</code>      | Compute variance of groups                               |
| <code>sem()</code>      | Standard error of the mean of groups                     |
| <code>describe()</code> | Generates descriptive statistics                         |
| <code>first()</code>    | Compute first of group values                            |
| <code>last()</code>     | Compute last of group values                             |
| <code>nth()</code>      | Take <i>nth</i> value, or a subset if <i>n</i> is a list |
| <code>min()</code>      | Compute min of group values                              |
| <code>max()</code>      | Compute max of group values                              |

The aggregating functions above will exclude NA values. Any function which reduces a *Series* to a scalar value is an aggregation function and will work, a trivial example is `df.groupby('A').agg(lambda ser: 1)`. Note that `nth()` can act as a reducer *or* a filter, see [here](#).

### 16.4.1 Applying multiple functions at once

With grouped *Series* you can also pass a list or dict of functions to do aggregation with, outputting a *DataFrame*:

```

In [64]: grouped = df.groupby('A')

In [65]: grouped['C'].agg([np.sum, np.mean, np.std])
Out[65]:
```

|   | sum | mean | std |
|---|-----|------|-----|
| A |     |      |     |

(continues on next page)

(continued from previous page)

```
bar  0.392940  0.130980  0.181231
foo -1.796421 -0.359284  0.912265
```

On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [66]: grouped.agg([np.sum, np.mean, np.std])
Out[66]:
```

|     | C         |           |          | D        |          |          |
|-----|-----------|-----------|----------|----------|----------|----------|
|     | sum       | mean      | std      | sum      | mean     | std      |
| A   |           |           |          |          |          |          |
| bar | 0.392940  | 0.130980  | 0.181231 | 1.732707 | 0.577569 | 1.366330 |
| foo | -1.796421 | -0.359284 | 0.912265 | 2.824590 | 0.564918 | 0.884785 |

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```
In [67]: (grouped['C'].agg([np.sum, np.mean, np.std])
.....:                .rename(columns={'sum': 'foo',
.....:                                'mean': 'bar',
.....:                                'std': 'baz'}))
.....: )
Out[67]:
```

|     | foo       | bar       | baz      |
|-----|-----------|-----------|----------|
| A   |           |           |          |
| bar | 0.392940  | 0.130980  | 0.181231 |
| foo | -1.796421 | -0.359284 | 0.912265 |

For a grouped DataFrame, you can rename in a similar manner:

```
In [68]: (grouped.agg([np.sum, np.mean, np.std])
.....:                .rename(columns={'sum': 'foo',
.....:                                'mean': 'bar',
.....:                                'std': 'baz'}))
.....: )
Out[68]:
```

|     | C         |           |          | D        |          |          |
|-----|-----------|-----------|----------|----------|----------|----------|
|     | foo       | bar       | baz      | foo      | bar      | baz      |
| A   |           |           |          |          |          |          |
| bar | 0.392940  | 0.130980  | 0.181231 | 1.732707 | 0.577569 | 1.366330 |
| foo | -1.796421 | -0.359284 | 0.912265 | 2.824590 | 0.564918 | 0.884785 |

## 16.4.2 Applying different functions to DataFrame columns

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```
In [69]: grouped.agg({'C' : np.sum,
.....:                'D' : lambda x: np.std(x, ddof=1)})
.....:
Out[69]:
```

|   | C | D |
|---|---|---|
| A |   |   |

(continues on next page)

(continued from previous page)

```
bar 0.392940 1.366330
foo -1.796421 0.884785
```

The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via *dispatching*:

```
In [70]: grouped.agg({'C' : 'sum', 'D' : 'std'})
Out[70]:
```

|     | C         | D        |
|-----|-----------|----------|
| A   |           |          |
| bar | 0.392940  | 1.366330 |
| foo | -1.796421 | 0.884785 |

**Note:** If you pass a dict to `aggregate`, the ordering of the output columns is non-deterministic. If you want to be sure the output columns will be in a specific order, you can use an `OrderedDict`. Compare the output of the following two commands:

```
In [71]: grouped.agg({'D': 'std', 'C': 'mean'})
Out[71]:
```

|     | D        | C         |
|-----|----------|-----------|
| A   |          |           |
| bar | 1.366330 | 0.130980  |
| foo | 0.884785 | -0.359284 |

```
In [72]: grouped.agg(OrderedDict([('D', 'std'), ('C', 'mean')]))
////////////////////////////////////
```

|     | D        | C         |
|-----|----------|-----------|
| A   |          |           |
| bar | 1.366330 | 0.130980  |
| foo | 0.884785 | -0.359284 |

### 16.4.3 Cython-optimized aggregation functions

Some common aggregations, currently only `sum`, `mean`, `std`, and `sem`, have optimized Cython implementations:

```
In [73]: df.groupby('A').sum()
Out[73]:
```

|     | C         | D        |
|-----|-----------|----------|
| A   |           |          |
| bar | 0.392940  | 1.732707 |
| foo | -1.796421 | 2.824590 |

```
In [74]: df.groupby(['A', 'B']).mean()
///////////////////////////////////////////////////
↪
```

|     |       | C         | D         |
|-----|-------|-----------|-----------|
| A   | B     |           |           |
| bar | one   | 0.254161  | 1.511763  |
|     | three | 0.215897  | -0.990582 |
|     | two   | -0.077118 | 1.211526  |
| foo | one   | -0.491888 | 0.807291  |

(continues on next page)

|       |           |          |
|-------|-----------|----------|
| three | -0.862495 | 0.024580 |
| two   | 0.024925  | 0.592714 |

```
In [75]: index = pd.date_range('10/1/1999', periods=1100)
In [76]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [77]: ts = ts.rolling(window=100,min_periods=100).mean().dropna()
```

```
2000-01-08    0.779333
2000-01-09    0.778852
2000-01-10    0.786476
2000-01-11    0.782797
2000-01-12    0.798110
Freq: D, dtype: float64
```

```

2002-09-30    0.660294
2002-10-01    0.631095
2002-10-02    0.673601
2002-10-03    0.709213
2002-10-04    0.719369
Freq: D, dtype: float64

```

We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```
# Original Data
In [83]: grouped = ts.groupby(key)

In [84]: grouped.mean()
Out[84]:
2000    0.442441
2001    0.526246
2002    0.459365
dtype: float64

In [85]: grouped.std()
Out[85]:
2000    0.131752
2001    0.210945
2002    0.128753
dtype: float64

# Transformed Data
In [86]: grouped_trans = transformed.groupby(key)

In [87]: grouped_trans.mean()
Out[87]:
2000    1.168208e-15
2001    1.454544e-15
2002    1.726657e-15
dtype: float64

In [88]: grouped_trans.std()
Out[88]:
2000    1.0
2001    1.0
2002    1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```
In [89]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [90]: compare.plot()
Out[90]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2ad9db38>
```

Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

```
In [91]: data_range = lambda x: x.max() - x.min()
```

```
In [92]: ts.groupby(key).transform(data_range)
```

```
Out[92]:
```

```
2000-01-08    0.623893
2000-01-09    0.623893
2000-01-10    0.623893
2000-01-11    0.623893
2000-01-12    0.623893
2000-01-13    0.623893
2000-01-14    0.623893
...
2002-09-28    0.558275
2002-09-29    0.558275
2002-09-30    0.558275
2002-10-01    0.558275
2002-10-02    0.558275
2002-10-03    0.558275
2002-10-04    0.558275
Freq: D, Length: 1001, dtype: float64
```

Alternatively the built-in methods can be used to produce the same outputs

```
In [93]: ts.groupby(key).transform('max') - ts.groupby(key).transform('min')
Out[93]:
2000-01-08    0.623893
2000-01-09    0.623893
2000-01-10    0.623893
2000-01-11    0.623893
2000-01-12    0.623893
2000-01-13    0.623893
2000-01-14    0.623893
...
2002-09-28    0.558275
2002-09-29    0.558275
2002-09-30    0.558275
2002-10-01    0.558275
2002-10-02    0.558275
2002-10-03    0.558275
2002-10-04    0.558275
Freq: D, Length: 1001, dtype: float64
```

Another common data transform is to replace missing data with the group mean.

```
In [94]: data_df
Out[94]:
      A      B      C
0  1.539708 -1.166480  0.533026
1  1.302092 -0.505754    NaN
2 -0.371983  1.104803 -0.651520

[1000 rows x 4 columns]

## 16.5.1 New syntax to window and resample operations

New in version 0.18.1.

Working with the `resample`, `expanding` or `rolling` operations on the `groupby` level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on `groupbys`.

The example below will apply the `rolling()` method on the samples of the column `B` based on the groups of column `A`.

```
In [108]: df_re = pd.DataFrame({'A': [1] * 10 + [5] * 10,
.....:                        'B': np.arange(20)})
.....:

In [109]: df_re
Out[109]:
```

|    | A  | B  |
|----|----|----|
| 0  | 1  | 0  |
| 1  | 1  | 1  |
| 2  | 1  | 2  |
| 3  | 1  | 3  |
| 4  | 1  | 4  |
| 5  | 1  | 5  |
| 6  | 1  | 6  |
| .. | .. | .. |
| 13 | 5  | 13 |
| 14 | 5  | 14 |
| 15 | 5  | 15 |
| 16 | 5  | 16 |
| 17 | 5  | 17 |
| 18 | 5  | 18 |
| 19 | 5  | 19 |

(continues on next page)

(continued from previous page)

[20 rows x 2 columns]

```
In [110]: df_re.groupby('A').rolling(4).B.mean()
```

```

////////////////////////////////////

```

```

↪

```

```

A
1  0      NaN
   1      NaN
   2      NaN
   3      1.5
   4      2.5
   5      3.5
   6      4.5
   ...
5 13     11.5
   14     12.5
   15     13.5
   16     14.5
   17     15.5
   18     16.5
   19     17.5

```

Name: B, Length: 20, dtype: float64

The `expanding()` method will accumulate a given operation (`sum()` in the example) for all the members of each particular group.

```
In [111]: df_re.groupby('A').expanding().sum()
```

```
Out [111]:
```

```

      A      B
A
1  0    1.0    0.0
   1    2.0    1.0
   2    3.0    3.0
   3    4.0    6.0
   4    5.0   10.0
   5    6.0   15.0
   6    7.0   21.0
   ...
5 13   20.0   46.0
   14   25.0   60.0
   15   30.0   75.0
   16   35.0   91.0
   17   40.0  108.0
   18   45.0  126.0
   19   50.0  145.0

```

[20 rows x 2 columns]

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```

In [112]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
.....:                                                  periods=4,
.....:                                                  freq='W'),
.....:                          'group': [1, 1, 2, 2],

```

(continues on next page)

(continued from previous page)

```
.....:                                     'val': [5, 6, 7, 8])).set_index('date')
.....:
```

```
In [113]: df_re
```

```
Out[113]:
```

|            | group | val |
|------------|-------|-----|
| date       |       |     |
| 2016-01-03 | 1     | 5   |
| 2016-01-10 | 1     | 6   |
| 2016-01-17 | 2     | 7   |
| 2016-01-24 | 2     | 8   |

```
In [114]: df_re.groupby('group').resample('1D').ffill()
```

```
////////////////////////////////////
```

|       |            | group | val |
|-------|------------|-------|-----|
| group | date       |       |     |
| 1     | 2016-01-03 | 1     | 5   |
|       | 2016-01-04 | 1     | 5   |
|       | 2016-01-05 | 1     | 5   |
|       | 2016-01-06 | 1     | 5   |
|       | 2016-01-07 | 1     | 5   |
|       | 2016-01-08 | 1     | 5   |
|       | 2016-01-09 | 1     | 5   |
| ...   |            | ...   | ... |
| 2     | 2016-01-18 | 2     | 7   |
|       | 2016-01-19 | 2     | 7   |
|       | 2016-01-20 | 2     | 7   |
|       | 2016-01-21 | 2     | 7   |
|       | 2016-01-22 | 2     | 7   |
|       | 2016-01-23 | 2     | 7   |
|       | 2016-01-24 | 2     | 8   |

```
[16 rows x 2 columns]
```

## 16.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```
In [115]: sf = pd.Series([1, 1, 2, 3, 3, 3])
```

```
In [116]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
```

```
Out[116]:
```

|   |   |
|---|---|
| 3 | 3 |
| 4 | 3 |
| 5 | 3 |

dtype: int64

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`.

Another useful operation is filtering out elements that belong to groups with only a couple members.

```
In [117]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})

In [118]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[118]:
```

|   | A | B |
|---|---|---|
| 2 | 2 | b |
| 3 | 3 | b |
| 4 | 4 | b |
| 5 | 5 | b |

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

```
In [119]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[119]:
```

|   | A   | B   |
|---|-----|-----|
| 0 | NaN | NaN |
| 1 | NaN | NaN |
| 2 | 2.0 | b   |
| 3 | 3.0 | b   |
| 4 | 4.0 | b   |
| 5 | 5.0 | b   |
| 6 | NaN | NaN |
| 7 | NaN | NaN |

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

```
In [120]: dff['C'] = np.arange(8)

In [121]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[121]:
```

|   | A | B | C |
|---|---|---|---|
| 2 | 2 | b | 2 |
| 3 | 3 | b | 3 |
| 4 | 4 | b | 4 |
| 5 | 5 | b | 5 |

**Note:** Some functions when applied to a groupby object will act as a **filter** on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing `as_index=False` will not affect these transformation methods.

For example: `head`, `tail`.

```
In [122]: dff.groupby('B').head(2)
Out[122]:
```

|   | A | B | C |
|---|---|---|---|
| 0 | 0 | a | 0 |
| 1 | 1 | a | 1 |
| 2 | 2 | b | 2 |
| 3 | 3 | b | 3 |
| 6 | 6 | c | 6 |
| 7 | 7 | c | 7 |

## 16.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [123]: grouped = df.groupby('A')

In [124]: grouped.agg(lambda x: x.std())
Out[124]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 0.181231 | 1.366330 |
| foo | 0.912265 | 0.884785 |

But, it's rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```
In [125]: grouped.std()
Out[125]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 0.181231 | 1.366330 |
| foo | 0.912265 | 0.884785 |

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the `std` function). The results are then combined together much in the style of `agg` and `transform` (it actually uses `apply` to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [126]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
.....:                        index=pd.date_range('1/1/2000', periods=1000),
.....:                        columns=['A', 'B', 'C'])
.....:

In [127]: tsdf.iloc[:,2] = np.nan

In [128]: grouped = tsdf.groupby(lambda x: x.year)

In [129]: grouped.fillna(method='pad')
Out[129]:
```

|            | A         | B         | C         |
|------------|-----------|-----------|-----------|
| 2000-01-01 | NaN       | NaN       | NaN       |
| 2000-01-02 | -0.353501 | -0.080957 | -0.876864 |
| 2000-01-03 | -0.353501 | -0.080957 | -0.876864 |
| 2000-01-04 | 0.050976  | 0.044273  | -0.559849 |
| 2000-01-05 | 0.050976  | 0.044273  | -0.559849 |
| 2000-01-06 | 0.030091  | 0.186460  | -0.680149 |
| 2000-01-07 | 0.030091  | 0.186460  | -0.680149 |
| ...        | ...       | ...       | ...       |
| 2002-09-20 | 2.310215  | 0.157482  | -0.064476 |
| 2002-09-21 | 2.310215  | 0.157482  | -0.064476 |
| 2002-09-22 | 0.005011  | 0.053897  | -1.026922 |
| 2002-09-23 | 0.005011  | 0.053897  | -1.026922 |
| 2002-09-24 | -0.456542 | -1.849051 | 1.559856  |
| 2002-09-25 | -0.456542 | -1.849051 | 1.559856  |
| 2002-09-26 | 1.123162  | 0.354660  | 1.128135  |

(continues on next page)

(continued from previous page)

```
[1000 rows x 3 columns]
```

In this example, we chopped the collection of time series into yearly chunks then independently called *fillna* on the groups.

The `nlargest` and `nsmallest` methods work on `Series` style groupbys:

```
In [130]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
```

```
In [131]: g = pd.Series(list('abababab'))
```

```
In [132]: gb = s.groupby(g)
```

```
In [133]: gb.nlargest(3)
```

```
Out[133]:
a  4    19.0
   0     9.0
   2     7.0
b  1     8.0
   3     5.0
   7     3.3
dtype: float64
```

```
In [134]: gb.nsmallest(3)
```

```
Out[134]:
a  6     4.2
   2     7.0
   0     9.0
b  5     1.0
   7     3.3
   3     5.0
dtype: float64
```

## 16.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want `GroupBy` to infer how to combine the results. For these, use the `apply` function, which can be substituted for both `aggregate` and `transform` in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```
In [135]: df
```

```
Out[135]:
   A      B      C      D
0  foo  one -0.575247  1.346061
1  bar  one  0.254161  1.511763
2  foo  two -1.143704  1.627081
3  bar three  0.215897 -0.990582
4  foo  two  1.193555 -0.441652
5  bar  two -0.077118  1.211526
6  foo  one -0.408530  0.268520
7  foo three -0.862495  0.024580
```

(continues on next page)

(continued from previous page)

```
In [136]: grouped = df.groupby('A')

# could also just call .describe()
In [137]: grouped['C'].apply(lambda x: x.describe())
Out[137]:
A
bar  count      3.000000
     mean      0.130980
     std       0.181231
     min      -0.077118
     25%       0.069390
     50%       0.215897
     75%       0.235029
     ...
foo  mean      -0.359284
     std       0.912265
     min      -1.143704
     25%      -0.862495
     50%      -0.575247
     75%      -0.408530
     max       1.193555
Name: C, Length: 16, dtype: float64
```

The dimension of the returned result can also change:

```
In [138]: grouped = df.groupby('A')['C']

In [139]: def f(group):
.....:     return pd.DataFrame({'original' : group,
.....:                          'demeaned' : group - group.mean()})
.....:

In [140]: grouped.apply(f)
Out[140]:
   original  demeaned
0 -0.575247 -0.215962
1  0.254161  0.123181
2 -1.143704 -0.784420
3  0.215897  0.084917
4  1.193555  1.552839
5 -0.077118 -0.208098
6 -0.408530 -0.049245
7 -0.862495 -0.503211
```

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```
In [141]: def f(x):
.....:     return pd.Series([ x, x**2 ], index = ['x', 'x^2'])
.....:

In [142]: s
Out[142]:
0    9.0
1    8.0
2    7.0
```

(continues on next page)

(continued from previous page)

```

3      5.0
4     19.0
5      1.0
6      4.2
7      3.3
dtype: float64

```

```
In [143]: s.apply(f)
```

```

////////////////////////////////////
↪
      x      x^2
0   9.0   81.00
1   8.0   64.00
2   7.0   49.00
3   5.0   25.00
4  19.0  361.00
5   1.0    1.00
6   4.2   17.64
7   3.3   10.89

```

**Note:** `apply` can act as a reducer, transformer, *or* filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped column(s) may be included in the output as well as set the indices.

**Warning:** In the current implementation `apply` calls `func` twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if `func` has side-effects, as they will take effect twice for the first group.

```
In [144]: d = pd.DataFrame({"a": ["x", "y"], "b": [1, 2]})
```

```
In [145]: def identity(df):
.....:     print(df)
.....:     return df
.....:
```

```
In [146]: d.groupby("a").apply(identity)
```

```

a  b
0  x  1
a  b
0  x  1
a  b
1  y  2

```

```
Out[146]:
```

```

a  b
0  x  1
1  y  2

```

## 16.9 Other useful features

### 16.9.1 Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

```
In [147]: df
Out[147]:
```

|   | A   | B     | C         | D         |
|---|-----|-------|-----------|-----------|
| 0 | foo | one   | -0.575247 | 1.346061  |
| 1 | bar | one   | 0.254161  | 1.511763  |
| 2 | foo | two   | -1.143704 | 1.627081  |
| 3 | bar | three | 0.215897  | -0.990582 |
| 4 | foo | two   | 1.193555  | -0.441652 |
| 5 | bar | two   | -0.077118 | 1.211526  |
| 6 | foo | one   | -0.408530 | 0.268520  |
| 7 | foo | three | -0.862495 | 0.024580  |

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [148]: df.groupby('A').std()
Out[148]:
```

|     | C        | D        |
|-----|----------|----------|
| A   |          |          |
| bar | 0.181231 | 1.366330 |
| foo | 0.912265 | 0.884785 |

Note that `df.groupby('A').colname.std().` is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

### 16.9.2 Handling of (un)observed Categorical values

When using a Categorical grouper (as a single grouper, or as part of multiplier groupers), the `observed` keyword controls whether to return a cartesian product of all possible groupers values (`observed=False`) or only those that are observed groupers (`observed=True`).

Show all values:

```
In [149]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b'], observed=False)).count()
Out[149]:
```

|   |   |
|---|---|
| a | 3 |
| b | 0 |

dtype: int64

Show only the observed values:

```
In [150]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b'], observed=True)).count()
Out[150]:
```

(continues on next page)

(continued from previous page)

```
a      3
dtype: int64
```

The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [151]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'],
↳categories=['a', 'b']), observed=False).count()

In [152]: s.index.dtype
Out[152]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

### 16.9.3 NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

### 16.9.4 Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [153]: data = pd.Series(np.random.randn(100))

In [154]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])

In [155]: data.groupby(factor).mean()
Out[155]:
(-2.618, -0.684]    -1.331461
(-0.684, -0.0232]   -0.272816
(-0.0232, 0.541]    0.263607
(0.541, 2.369]      1.166038
dtype: float64
```

### 16.9.5 Grouping with a Grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [156]: import datetime

In [157]: df = pd.DataFrame({
.....:     'Branch' : 'A A A A A A B'.split(),
.....:     'Buyer' : 'Carl Mark Carl Carl Joe Joe Carl'.split(),
.....:     'Quantity': [1,3,5,1,8,1,9,3],
.....:     'Date' : [
.....:         datetime.datetime(2013,1,1,13,0),
.....:         datetime.datetime(2013,1,1,13,5),
.....:         datetime.datetime(2013,10,1,20,0),
.....:         datetime.datetime(2013,10,2,10,0),
.....:         datetime.datetime(2013,10,1,20,0),
```

(continues on next page)

(continued from previous page)

```
.....: datetime.datetime(2013,10,2,10,0),
.....: datetime.datetime(2013,12,2,12,0),
.....: datetime.datetime(2013,12,2,14,0),
.....: ]
.....: })
.....:
```

**In [158]:** df

**Out [158]:**

|   | Branch | Buyer | Quantity | Date                |
|---|--------|-------|----------|---------------------|
| 0 | A      | Carl  | 1        | 2013-01-01 13:00:00 |
| 1 | A      | Mark  | 3        | 2013-01-01 13:05:00 |
| 2 | A      | Carl  | 5        | 2013-10-01 20:00:00 |
| 3 | A      | Carl  | 1        | 2013-10-02 10:00:00 |
| 4 | A      | Joe   | 8        | 2013-10-01 20:00:00 |
| 5 | A      | Joe   | 1        | 2013-10-02 10:00:00 |
| 6 | A      | Joe   | 9        | 2013-12-02 12:00:00 |
| 7 | B      | Carl  | 3        | 2013-12-02 14:00:00 |

Groupby a specific column with the desired frequency. This is like resampling.

```
In [159]: df.groupby([pd.Grouper(freq='1M',key='Date'),'Buyer']).sum()
Out[159]:
```

| Date       | Buyer | Quantity |
|------------|-------|----------|
| 2013-01-31 | Carl  | 1        |
|            | Mark  | 3        |
| 2013-10-31 | Carl  | 6        |
|            | Joe   | 9        |
| 2013-12-31 | Carl  | 3        |
|            | Joe   | 9        |

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```
In [160]: df = df.set_index('Date')

In [161]: df['Date'] = df.index + pd.offsets.MonthEnd(2)

In [162]: df.groupby([pd.Grouper(freq='6M',key='Date'),'Buyer']).sum()
Out[162]:
```

| Date       | Buyer | Quantity |
|------------|-------|----------|
| 2013-02-28 | Carl  | 1        |
|            | Mark  | 3        |
| 2014-02-28 | Carl  | 9        |
|            | Joe   | 18       |

```
In [163]: df.groupby([pd.Grouper(freq='6M',level='Date'),'Buyer']).sum()
////////////////////////////////////
```

↩

| Date       | Buyer | Quantity |
|------------|-------|----------|
| 2013-01-31 | Carl  | 1        |
|            | Mark  | 3        |
| 2014-01-31 | Carl  | 9        |
|            | Joe   | 18       |

```
In [164]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [165]: df
```

Out [165] :

|   | A | B |
|---|---|---|
| 0 | 1 | 2 |
| 1 | 1 | 4 |
| 2 | 5 | 6 |

```
In [166]: g = df.groupby('A')
```

```
In [167]: q.head(1)
```

Out [167] :

|   | A | B |
|---|---|---|
| 0 | 1 | 2 |
| 2 | 5 | 6 |

```
In [168]: q.tail(1)
```

```
Out[168]:
```

|   | A | B |
|---|---|---|
| 1 | 1 | 4 |
| 2 | 5 | 6 |

### 16.9.7 Taking the nth row of each group

```
In [169]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
```

```
In [170]: g = df.groupby('A')
```

```
In [171]: g.nth(0)
```

Out [171] :

|   | B   |
|---|-----|
| A |     |
| 1 | NaN |
| 5 | 6.0 |

```
In [172]: g.nth(-1)
```

```
Out[172]:
```

| A | B   |
|---|-----|
| 1 | 4.0 |
| 5 | 6.0 |

```
In [173]: g.nth(1)
```

↔ B

## 16.9. Other useful features

(continued from previous page)

```
A
1  4.0
```

If you want to select the *nth* not-null item, use the `dropna` kwarg. For a `DataFrame` this should be either `'any'` or `'all'` just like you would pass to `dropna`:

```
# nth(0) is the same as g.first()
In [174]: g.nth(0, dropna='any')
Out[174]:
      B
A
1  4.0
5  6.0

In [175]: g.first()
Out[175]:
      B
A
1  4.0
5  6.0

# nth(-1) is the same as g.last()
In [176]: g.nth(-1, dropna='any') # NaNs denote group exhausted when using dropna
Out[176]:
      B
A
1  4.0
5  6.0

In [177]: g.last()
Out[177]:
      B
A
1  4.0
5  6.0

In [178]: g.B.nth(0, dropna='all')
Out[178]:
A
1  4.0
5  6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```
In [179]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [180]: g = df.groupby('A', as_index=False)
In [181]: g.nth(0)
Out[181]:
   A  B
0  1 NaN
```

(continues on next page)

(continued from previous page)

```
In [182]: g.nth(-1)
\\Out[182]:
```

|   | A | B   |
|---|---|-----|
| 1 | 1 | 4.0 |
| 2 | 5 | 6.0 |

You can also select multiple rows from each group by specifying multiple `nth` values as a list of ints.

```
In [183]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')

In [184]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

# get the first, 4th, and last date index for each month
In [185]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
Out[185]:
```

|      |   | a | b |
|------|---|---|---|
| 2014 | 4 | 1 | 1 |
|      | 4 | 1 | 1 |
|      | 4 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 5 | 1 | 1 |
|      | 6 | 1 | 1 |
|      | 6 | 1 | 1 |
|      | 6 | 1 | 1 |

### 16.9.8 Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```
In [186]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])  
  
In [187]: dfg  
Out[187]:  
   A  
0  a  
1  a  
2  a  
3  b  
4  b  
5  a  
  
In [188]: dfg.groupby('A').cumcount()  
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[188]:  
0    0  
1    1  
2    2  
3    0  
4    1  
5    3  
dtype: int64  
  
In [189]: dfg.groupby('A').cumcount(ascending=False)
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
0      3
1      2
2      1
3      1
4      0
5      0
dtype: int64

```

### 16.9.9 Enumerate groups

New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```

In [190]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [191]: dfg
Out[191]:
   A
0  a
1  a
2  a
3  b
4  b
5  a

In [192]: dfg.groupby('A').ngroup()
Out[192]:
0      0
1      0
2      0
3      1
4      1
5      0
dtype: int64

In [193]: dfg.groupby('A').ngroup(ascending=False)
Out[193]:
0      1
1      1
2      1
3      0
4      0
5      1
dtype: int64

```

### 16.9.10 Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [194]: np.random.seed(1234)

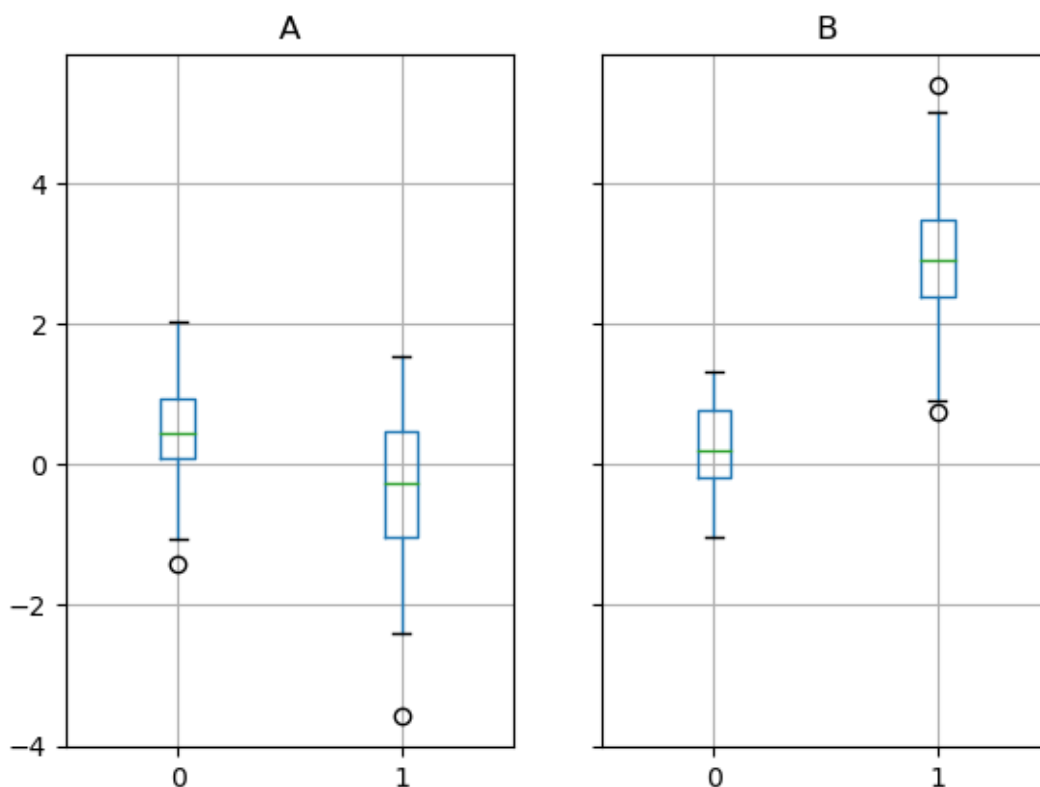

In [195]: df = pd.DataFrame(np.random.randn(50, 2))

In [196]: df['g'] = np.random.choice(['A', 'B'], size=50)

In [197]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [198]: df.groupby('g').boxplot()
Out[198]:
A      AxesSubplot(0.1,0.15;0.363636x0.75)
B      AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the [visualization documentation](#) for more.

**Warning:** For historical reasons, `df.groupby("g").boxplot()` is not equivalent to `df.boxplot(by="g")`. See [here](#) for an explanation.

### 16.9.11 Piping function calls

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We'd like to do a groupwise calculation of *prices* (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```
In [199]: import numpy as np

In [200]: n = 1000

In [201]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
.....:                      'Product': np.random.choice(['Product_1',
.....:                                                    'Product_2'], n),
.....:                      'Revenue': (np.random.random(n)*50+10).round(2),
.....:                      'Quantity': np.random.randint(1, 10, size=n)})
.....:

In [202]: df.head(2)
Out[202]:
```

|   | Store   | Product   | Revenue | Quantity |
|---|---------|-----------|---------|----------|
| 0 | Store_2 | Product_1 | 26.12   | 1        |
| 1 | Store_2 | Product_1 | 28.86   | 1        |

Now, to find prices per store/product, we can simply do:

```
In [203]: (df.groupby(['Store', 'Product'])
.....:      .pipe(lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
.....:      .unstack().round(2))
.....:
Out[203]:
```

|         | Product_1 | Product_2 |
|---------|-----------|-----------|
| Store   |           |           |
| Store_1 | 6.82      | 7.05      |
| Store_2 | 6.30      | 6.64      |

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```
(df.groupby(['Store', 'Product']).pipe(report_func))
```

where `report_func` takes a `GroupBy` object and creates a report from that.

## 16.10 Examples

### 16.10.1 Regrouping by factor

Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.

```
In [204]: df = pd.DataFrame({'a': [1, 0, 0], 'b': [0, 1, 0], 'c': [1, 0, 0], 'd': [2, 3, 4]})

In [205]: df
Out[205]:
```

|   | a | b | c | d |
|---|---|---|---|---|
| 0 | 1 | 0 | 1 | 2 |
| 1 | 0 | 1 | 0 | 3 |
| 2 | 0 | 0 | 0 | 4 |

```
In [206]: df.groupby(df.sum(), axis=1).sum()
Out[206]:
```

|   | 1 | 9 |
|---|---|---|
| 0 | 2 | 2 |
| 1 | 1 | 3 |
| 2 | 0 | 4 |

### 16.10.2 Multi-column factorization

By using `ngroup()`, we can extract information about the groups in a way similar to `factorize()` (as described further in the [reshaping API](#)) but which applies naturally to multiple columns of mixed type and different sources. This can be useful as an intermediate categorical-like step in processing, when the relationships between the group rows are more important than their content, or as input to an algorithm which only accepts the integer encoding. (For more information about support in pandas for full categorical data, see the [Categorical introduction](#) and the [API documentation](#).)

```
In [207]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})

In [208]: dfg
Out[208]:
```

|   | A | B |
|---|---|---|
| 0 | 1 | a |
| 1 | 1 | a |
| 2 | 2 | a |
| 3 | 3 | b |
| 4 | 2 | a |

```
In [209]: dfg.groupby(["A", "B"]).ngroup()
Out[209]:
```

|   | 0 |
|---|---|
| 0 | 0 |
| 1 | 0 |
| 2 | 1 |
| 3 | 2 |
| 4 | 1 |

```
dtype: int64

In [210]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
Out[210]:
```

|   | 0 |
|---|---|
| 0 | 0 |

(continues on next page)

(continued from previous page)

```
1      0
2      1
3      3
4      2
dtype: int64
```

### 16.10.3 Groupby by Indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetime-like, the following procedure can be utilized.

In the following examples, `df.index // 5` returns a binary array which is used to determine what gets selected for the groupby operation.

**Note:** The below example shows how we can downsample by consolidation of samples into fewer samples. Here by using `df.index // 5`, we are aggregating the samples in bins. By applying `std()` function, we aggregate the information contained in many samples into a small subset of values which is their standard deviation thereby reducing the number of samples.

```
In [211]: df = pd.DataFrame(np.random.randn(10,2))
```

```
In [212]: df
```

Out [212] :

|   | 0         | 1         |
|---|-----------|-----------|
| 0 | -0.793893 | 0.321153  |
| 1 | 0.342250  | 1.618906  |
| 2 | -0.975807 | 1.918201  |
| 3 | -0.810847 | -1.405919 |
| 4 | -1.977759 | 0.461659  |
| 5 | 0.730057  | -1.316938 |
| 6 | -0.751328 | 0.528290  |
| 7 | -0.257759 | -1.081009 |
| 8 | 0.505895  | -1.701948 |
| 9 | -1.006349 | 0.020208  |

```
In [213]: df.index // 5
```

[illegible]

```
In [214]: df.groupby(df.index // 5).std()
```

|   | 0        | 1        |
|---|----------|----------|
| 0 | 0.823647 | 1.312912 |
| 1 | 0.760109 | 0.942941 |

#### 16.10.4 Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the

column index name will be used as the name of the inserted column:

```
In [215]: df = pd.DataFrame({
.....:     'a':    [0, 0, 0, 0, 1, 1, 1, 1, 2, 2, 2, 2],
.....:     'b':    [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
.....:     'c':    [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
.....:     'd':    [0, 0, 0, 1, 0, 0, 0, 1, 0, 0, 0, 1],
.....: })

In [216]: def compute_metrics(x):
.....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
.....:     return pd.Series(result, name='metrics')
.....:

In [217]: result = df.groupby('a').apply(compute_metrics)

In [218]: result
Out[218]:
```

|   | metrics                           |
|---|-----------------------------------|
| a |                                   |
| 0 | b_sum      2.0<br>c_mean      0.5 |
| 1 | b_sum      2.0<br>c_mean      0.5 |
| 2 | b_sum      2.0<br>c_mean      0.5 |

```
dtype: float64
```

## MERGE, JOIN, AND CONCATENATE

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

### 17.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
...:                      'B': ['B0', 'B1', 'B2', 'B3'],
...:                      'C': ['C0', 'C1', 'C2', 'C3'],
...:                      'D': ['D0', 'D1', 'D2', 'D3']},
...:                      index=[0, 1, 2, 3])

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
...:                      'B': ['B4', 'B5', 'B6', 'B7'],
...:                      'C': ['C4', 'C5', 'C6', 'C7'],
...:                      'D': ['D4', 'D5', 'D6', 'D7']},
...:                      index=[4, 5, 6, 7])

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
...:                      'B': ['B8', 'B9', 'B10', 'B11'],
...:                      'C': ['C8', 'C9', 'C10', 'C11'],
...:                      'D': ['D8', 'D9', 'D10', 'D11']},
...:                      index=[8, 9, 10, 11])

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```

| df1 |     |     |     |     | Result |     |     |     |     |
|-----|-----|-----|-----|-----|--------|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | 0      | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  | 1      | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  | 2      | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  | 3      | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | 4      | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   | 5      | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  | 6      | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  | 7      | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | df3    |     |     |     |     |
| 7   | A7  | B7  | C7  | D7  |        | A   | B   | C   | D   |
| df3 |     |     |     |     | 8      | A8  | B8  | C8  | D8  |
|     | A   | B   | C   | D   | 9      | A9  | B9  | C9  | D9  |
| 8   | A8  | B8  | C8  | D8  | 10     | A10 | B10 | C10 | D10 |
| 9   | A9  | B9  | C9  | D9  | 11     | A11 | B11 | C11 | D11 |
| 10  | A10 | B10 | C10 | D10 |        |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |     |     |     |     |

Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False,
          keys=None, levels=None, names=None, verify_integrity=False,
          copy=True)
```

- `objs`: a sequence or mapping of Series, DataFrame, or Panel objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a `ValueError` will be raised.
- `axis`: {0, 1, ...}, default 0. The axis to concatenate along.
- `join`: {'inner', 'outer'}, default 'outer'. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index`: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `join_axes`: list of Index objects. Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic.
- `keys`: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels`: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names`: list, default None. Names for the levels in the resulting hierarchical index.
- `verify_integrity`: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.

- `copy` : boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don't make much sense. Let's revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the `keys` argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  |        | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  |        | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  |        | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   |        | 5  | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  |        | 6  | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  |        | 7  | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | z      | 8  | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  |        | 9  | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     |        | 10 | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   |        | 11 | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |    |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

As you can see (if you've read the rest of the documentation), the resulting object's index has a *hierarchical index*. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
```

```
Out [7]:
```

```
   A  B  C  D
4  A4 B4 C4 D4
5  A5 B5 C5 D5
6  A6 B6 C6 D6
7  A7 B7 C7 D7
```

It's not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```

### 17.1.1 Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following three ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.
- Use a specific index, as passed to the `join_axes` argument.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
...:                       'D': ['D2', 'D3', 'D6', 'D7'],
...:                       'F': ['F2', 'F3', 'F6', 'F7']},
...:                       index=[2, 3, 6, 7])

In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

| df1 |    |    |    |    | df4 |    |    |    | Result |     |     |     |     |     |     |     |
|-----|----|----|----|----|-----|----|----|----|--------|-----|-----|-----|-----|-----|-----|-----|
|     | A  | B  | C  | D  |     | B  | D  | F  |        | A   | B   | C   | D   | B   | D   | F   |
| 0   | A0 | B0 | C0 | D0 | 2   | B2 | D2 | F2 | 0      | A0  | B0  | C0  | D0  | NaN | NaN | NaN |
| 1   | A1 | B1 | C1 | D1 | 3   | B3 | D3 | F3 | 1      | A1  | B1  | C1  | D1  | NaN | NaN | NaN |
| 2   | A2 | B2 | C2 | D2 | 6   | B6 | D6 | F6 | 2      | A2  | B2  | C2  | D2  | B2  | D2  | F2  |
| 3   | A3 | B3 | C3 | D3 | 7   | B7 | D7 | F7 | 3      | A3  | B3  | C3  | D3  | B3  | D3  | F3  |
|     |    |    |    |    |     |    |    |    | 6      | NaN | NaN | NaN | NaN | B6  | D6  | F6  |
|     |    |    |    |    |     |    |    |    | 7      | NaN | NaN | NaN | NaN | B7  | D7  | F7  |

**Warning:** Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

| df1 |    |    |    |    | df4 |    |    |    | Result |    |    |    |    |    |    |    |
|-----|----|----|----|----|-----|----|----|----|--------|----|----|----|----|----|----|----|
|     | A  | B  | C  | D  |     | B  | D  | F  |        | A  | B  | C  | D  | B  | D  | F  |
| 0   | A0 | B0 | C0 | D0 | 2   | B2 | D2 | F2 |        |    |    |    |    |    |    |    |
| 1   | A1 | B1 | C1 | D1 | 3   | B3 | D3 | F3 |        |    |    |    |    |    |    |    |
| 2   | A2 | B2 | C2 | D2 | 6   | B6 | D6 | F6 | 2      | A2 | B2 | C2 | D2 | B2 | D2 | F2 |
| 3   | A3 | B3 | C3 | D3 | 7   | B7 | D7 | F7 | 3      | A3 | B3 | C3 | D3 | B3 | D3 | F3 |

Lastly, suppose we just wanted to reuse the *exact index* from the original DataFrame:

```
In [11]: result = pd.concat([df1, df4], axis=1, join_axes=[df1.index])
```

| df1 |    |    |    |    | df4 |    |    |    | Result |    |    |    |    |     |     |     |
|-----|----|----|----|----|-----|----|----|----|--------|----|----|----|----|-----|-----|-----|
|     | A  | B  | C  | D  |     | B  | D  | F  |        | A  | B  | C  | D  | B   | D   | F   |
| 0   | A0 | B0 | C0 | D0 | 2   | B2 | D2 | F2 | 0      | A0 | B0 | C0 | D0 | NaN | NaN | NaN |
| 1   | A1 | B1 | C1 | D1 | 3   | B3 | D3 | F3 | 1      | A1 | B1 | C1 | D1 | NaN | NaN | NaN |
| 2   | A2 | B2 | C2 | D2 | 6   | B6 | D6 | F6 | 2      | A2 | B2 | C2 | D2 | B2  | D2  | F2  |
| 3   | A3 | B3 | C3 | D3 | 7   | B7 | D7 | F7 | 3      | A3 | B3 | C3 | D3 | B3  | D3  | F3  |

### 17.1.2 Concatenating using `append`

A useful shortcut to `concat()` are the `append()` instance methods on Series and DataFrame. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

```
In [12]: result = df1.append(df2)
```

| df1 |    |    |    |    | Result |    |    |    |    |
|-----|----|----|----|----|--------|----|----|----|----|
|     | A  | B  | C  | D  |        | A  | B  | C  | D  |
| 0   | A0 | B0 | C0 | D0 | 0      | A0 | B0 | C0 | D0 |
| 1   | A1 | B1 | C1 | D1 | 1      | A1 | B1 | C1 | D1 |
| 2   | A2 | B2 | C2 | D2 | 2      | A2 | B2 | C2 | D2 |
| 3   | A3 | B3 | C3 | D3 | 3      | A3 | B3 | C3 | D3 |
| df2 |    |    |    |    | 4      | A4 | B4 | C4 | D4 |
|     | A  | B  | C  | D  | 5      | A5 | B5 | C5 | D5 |
| 4   | A4 | B4 | C4 | D4 | 6      | A6 | B6 | C6 | D6 |
| 5   | A5 | B5 | C5 | D5 | 7      | A7 | B7 | C7 | D7 |
| 6   | A6 | B6 | C6 | D6 |        |    |    |    |    |
| 7   | A7 | B7 | C7 | D7 |        |    |    |    |    |

In the case of DataFrame, the indexes must be disjoint but the columns do not need to be:

```
In [13]: result = df1.append(df4)
```

| df1 |    |    |    |    | Result |     |    |     |    |     |
|-----|----|----|----|----|--------|-----|----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B  | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0 | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1 | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2 | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3 | C3  | D3 | NaN |
|     |    |    |    |    | 2      | NaN | B2 | NaN | D2 | F2  |
|     |    |    |    |    | 3      | NaN | B3 | NaN | D3 | F3  |
|     |    |    |    |    | 6      | NaN | B6 | NaN | D6 | F6  |
|     |    |    |    |    | 7      | NaN | B7 | NaN | D7 | F7  |

append may take multiple objects to concatenate:

```
In [14]: result = df1.append([df2, df3])
```

| df1 |    |    |    |    | Result |     |     |     |     |
|-----|----|----|----|----|--------|-----|-----|-----|-----|
|     | A  | B  | C  | D  |        | A   | B   | C   | D   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0  | C0  | D0  |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1  | C1  | D1  |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2  | C2  | D2  |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3  | C3  | D3  |
|     |    |    |    |    | 4      | A4  | B4  | C4  | D4  |
|     |    |    |    |    | 5      | A5  | B5  | C5  | D5  |
|     |    |    |    |    | 6      | A6  | B6  | C6  | D6  |
|     |    |    |    |    | 7      | A7  | B7  | C7  | D7  |
|     |    |    |    |    | 8      | A8  | B8  | C8  | D8  |
|     |    |    |    |    | 9      | A9  | B9  | C9  | D9  |
|     |    |    |    |    | 10     | A10 | B10 | C10 | D10 |
|     |    |    |    |    | 11     | A11 | B11 | C11 | D11 |

**Note:** Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here **does** not modify `df1` and returns its copy with `df2` appended.

### 17.1.3 Ignoring indexes on the concatenation axis

For `DataFrame`s which don't have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```
In [15]: result = pd.concat([df1, df4], ignore_index=True)
```

| df1 |    |    |    |    | Result |     |     |     |    |     |
|-----|----|----|----|----|--------|-----|-----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B   | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0  | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1  | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2  | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3  | C3  | D3 | NaN |
| df4 |    |    |    |    | 4      | NaN | B2  | NaN | D2 | F2  |
|     | B  | D  | F  |    | 5      | NaN | B3  | NaN | D3 | F3  |
| 2   | B2 | D2 | F2 | 6  | NaN    | B6  | NaN | D6  | F6 |     |
| 3   | B3 | D3 | F3 | 7  | NaN    | B7  | NaN | D7  | F7 |     |
| 6   | B6 | D6 | F6 |    |        |     |     |     |    |     |
| 7   | B7 | D7 | F7 |    |        |     |     |     |    |     |

This is also a valid argument to `DataFrame.append()`:

```
In [16]: result = df1.append(df4, ignore_index=True)
```

| df1 |    |    |    |    | Result |     |     |     |    |     |
|-----|----|----|----|----|--------|-----|-----|-----|----|-----|
|     | A  | B  | C  | D  |        | A   | B   | C   | D  | F   |
| 0   | A0 | B0 | C0 | D0 | 0      | A0  | B0  | C0  | D0 | NaN |
| 1   | A1 | B1 | C1 | D1 | 1      | A1  | B1  | C1  | D1 | NaN |
| 2   | A2 | B2 | C2 | D2 | 2      | A2  | B2  | C2  | D2 | NaN |
| 3   | A3 | B3 | C3 | D3 | 3      | A3  | B3  | C3  | D3 | NaN |
| df4 |    |    |    |    | 4      | NaN | B2  | NaN | D2 | F2  |
|     | B  | D  | F  |    | 5      | NaN | B3  | NaN | D3 | F3  |
| 2   | B2 | D2 | F2 | 6  | NaN    | B6  | NaN | D6  | F6 |     |
| 3   | B3 | D3 | F3 | 7  | NaN    | B7  | NaN | D7  | F7 |     |
| 6   | B6 | D6 | F6 |    |        |     |     |     |    |     |
| 7   | B7 | D7 | F7 |    |        |     |     |     |    |     |

### 17.1.4 Concatenating with mixed ndims

You can concatenate a mix of `Series` and `DataFrame`s. The `Series` will be transformed to `DataFrame` with the column name as the name of the `Series`.

```
In [17]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')
```

```
In [18]: result = pd.concat([df1, s1], axis=1)
```

| df1 |    |    |    |    | s1 |    | Result |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|
|     | A  | B  | C  | D  |    | X  |        | A  | B  | C  | D  | X  |
| 0   | A0 | B0 | C0 | D0 | 0  | X0 | 0      | A0 | B0 | C0 | D0 | X0 |
| 1   | A1 | B1 | C1 | D1 | 1  | X1 | 1      | A1 | B1 | C1 | D1 | X1 |
| 2   | A2 | B2 | C2 | D2 | 2  | X2 | 2      | A2 | B2 | C2 | D2 | X2 |
| 3   | A3 | B3 | C3 | D3 | 3  | X3 | 3      | A3 | B3 | C3 | D3 | X3 |

**Note:** Since we're concatenating a Series to a DataFrame, we could have achieved the same result with `DataFrame.assign()`. To concatenate an arbitrary number of pandas objects (DataFrame or Series), use `concat`.

If unnamed Series are passed they will be numbered consecutively.

```
In [19]: s2 = pd.Series(['_0', '_1', '_2', '_3'])
```

```
In [20]: result = pd.concat([df1, s2, s2, s2], axis=1)
```

| df1 |    |    |    |    | s2 |    | Result |    |    |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|----|----|
|     | A  | B  | C  | D  |    |    |        | A  | B  | C  | D  | 0  | 1  | 2  |
| 0   | A0 | B0 | C0 | D0 | 0  | _0 | 0      | A0 | B0 | C0 | D0 | _0 | _0 | _0 |
| 1   | A1 | B1 | C1 | D1 | 1  | _1 | 1      | A1 | B1 | C1 | D1 | _1 | _1 | _1 |
| 2   | A2 | B2 | C2 | D2 | 2  | _2 | 2      | A2 | B2 | C2 | D2 | _2 | _2 | _2 |
| 3   | A3 | B3 | C3 | D3 | 3  | _3 | 3      | A3 | B3 | C3 | D3 | _3 | _3 | _3 |

Passing `ignore_index=True` will drop all name references.

```
In [21]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
```

| df1 |    |    |    |    | s1 |    | Result |    |    |    |    |    |
|-----|----|----|----|----|----|----|--------|----|----|----|----|----|
|     | A  | B  | C  | D  |    | X  |        | 0  | 1  | 2  | 3  | 4  |
| 0   | A0 | B0 | C0 | D0 | 0  | X0 | 0      | A0 | B0 | C0 | D0 | X0 |
| 1   | A1 | B1 | C1 | D1 | 1  | X1 | 1      | A1 | B1 | C1 | D1 | X1 |
| 2   | A2 | B2 | C2 | D2 | 2  | X2 | 2      | A2 | B2 | C2 | D2 | X2 |
| 3   | A3 | B3 | C3 | D3 | 3  | X3 | 3      | A3 | B3 | C3 | D3 | X3 |

### 17.1.5 More concatenating with group keys

A fairly common use of the `keys` argument is to override the column names when creating a new `DataFrame` based on existing `Series`. Notice how the default behaviour consists on letting the resulting `DataFrame` inherit the parent `Series`' name, when these existed.

```
In [22]: s3 = pd.Series([0, 1, 2, 3], name='foo')
```

```
In [23]: s4 = pd.Series([0, 1, 2, 3])
```

```
In [24]: s5 = pd.Series([0, 1, 4, 5])
```

```
In [25]: pd.concat([s3, s4, s5], axis=1)
```

```
Out[25]:
   foo  0  1
0    0  0  0
1    1  1  1
2    2  2  4
3    3  3  5
```

Through the `keys` argument we can override the existing column names.

```
In [26]: pd.concat([s3, s4, s5], axis=1, keys=['red', 'blue', 'yellow'])
```

```
Out[26]:
   red  blue  yellow
0    0    0    0
1    1    1    1
2    2    2    4
3    3    3    5
```

Let's consider a variation of the very first example presented:

```
In [27]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  |        | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  |        | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  |        | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   | y      | 5  | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  | y      | 6  | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  | y      | 7  | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | z      | 8  | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  | z      | 9  | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     | z      | 10 | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   | z      | 11 | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |    |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

```
In [28]: pieces = {'x': df1, 'y': df2, 'z': df3}
```

```
In [29]: result = pd.concat(pieces)
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  |        | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  |        | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  |        | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   |        | 5  | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  |        | 6  | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  |        | 7  | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | z      | 8  | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  |        | 9  | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     |        | 10 | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   |        | 11 | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |    |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

```
In [30]: result = pd.concat(pieces, keys=['z', 'y'])
```

| df1 |     |     |     |     | Result |   |     |     |     |     |
|-----|-----|-----|-----|-----|--------|---|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |   | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | z      | 8 | A8  | B8  | C8  | D8  |
| 1   | A1  | B1  | C1  | D1  |        |   | A9  | B9  | C9  | D9  |
| 2   | A2  | B2  | C2  | D2  |        |   | A10 | B10 | C10 | D10 |
| 3   | A3  | B3  | C3  | D3  |        |   | A11 | B11 | C11 | D11 |
| df2 |     |     |     |     | y      | 4 | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   |        |   | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  |        |   | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  |        |   | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | y      | 5 | A5  | B5  | C5  | D5  |
| 7   | A7  | B7  | C7  | D7  |        |   | A6  | B6  | C6  | D6  |
| df3 |     |     |     |     |        |   | A7  | B7  | C7  | D7  |
|     | A   | B   | C   | D   |        |   |     |     |     |     |
| 8   | A8  | B8  | C8  | D8  | y      | 6 | A6  | B6  | C6  | D6  |
| 9   | A9  | B9  | C9  | D9  |        |   | A7  | B7  | C7  | D7  |
| 10  | A10 | B10 | C10 | D10 |        |   |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |   |     |     |     |     |

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

```
In [31]: result.index.levels
Out[31]: FrozenList([[ 'z', 'y' ], [4, 5, 6, 7, 8, 9, 10, 11]])
```

If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```
In [32]: result = pd.concat(pieces, keys=[ 'x', 'y', 'z' ],
.....:                      levels=[ 'z', 'y', 'x', 'w' ],
.....:                      names=[ 'group_key' ])
.....:
```

| df1 |     |     |     |     | Result |    |     |     |     |     |
|-----|-----|-----|-----|-----|--------|----|-----|-----|-----|-----|
|     | A   | B   | C   | D   |        |    | A   | B   | C   | D   |
| 0   | A0  | B0  | C0  | D0  | x      | 0  | A0  | B0  | C0  | D0  |
| 1   | A1  | B1  | C1  | D1  |        | 1  | A1  | B1  | C1  | D1  |
| 2   | A2  | B2  | C2  | D2  |        | 2  | A2  | B2  | C2  | D2  |
| 3   | A3  | B3  | C3  | D3  |        | 3  | A3  | B3  | C3  | D3  |
| df2 |     |     |     |     | y      | 4  | A4  | B4  | C4  | D4  |
|     | A   | B   | C   | D   |        | 5  | A5  | B5  | C5  | D5  |
| 4   | A4  | B4  | C4  | D4  |        | 6  | A6  | B6  | C6  | D6  |
| 5   | A5  | B5  | C5  | D5  |        | 7  | A7  | B7  | C7  | D7  |
| 6   | A6  | B6  | C6  | D6  | z      | 8  | A8  | B8  | C8  | D8  |
| 7   | A7  | B7  | C7  | D7  |        | 9  | A9  | B9  | C9  | D9  |
| df3 |     |     |     |     |        | 10 | A10 | B10 | C10 | D10 |
|     | A   | B   | C   | D   |        | 11 | A11 | B11 | C11 | D11 |
| 8   | A8  | B8  | C8  | D8  |        |    |     |     |     |     |
| 9   | A9  | B9  | C9  | D9  |        |    |     |     |     |     |
| 10  | A10 | B10 | C10 | D10 |        |    |     |     |     |     |
| 11  | A11 | B11 | C11 | D11 |        |    |     |     |     |     |

```
In [33]: result.index.levels
Out[33]: FrozenList([[ 'z', 'y', 'x', 'w' ], [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]])
```

This is fairly esoteric, but it is actually necessary for implementing things like `GroupBy` where the order of a categorical variable is meaningful.

### 17.1.6 Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a `DataFrame` by passing a `Series` or dict to `append`, which returns a new `DataFrame` as above.

```
In [34]: s2 = pd.Series([ 'X0', 'X1', 'X2', 'X3' ], index=[ 'A', 'B', 'C', 'D' ])
In [35]: result = df1.append(s2, ignore_index=True)
```

| df1 |    |    |    |    | Result |    |    |    |    |
|-----|----|----|----|----|--------|----|----|----|----|
|     | A  | B  | C  | D  |        | A  | B  | C  | D  |
| 0   | A0 | B0 | C0 | D0 | 0      | A0 | B0 | C0 | D0 |
| 1   | A1 | B1 | C1 | D1 | 1      | A1 | B1 | C1 | D1 |
| 2   | A2 | B2 | C2 | D2 | 2      | A2 | B2 | C2 | D2 |
| 3   | A3 | B3 | C3 | D3 | 3      | A3 | B3 | C3 | D3 |

| s2 |   |  |  |    |   |    |    |    |    |
|----|---|--|--|----|---|----|----|----|----|
|    | A |  |  |    |   |    |    |    |    |
|    |   |  |  | X0 | 4 | X0 | X1 | X2 | X3 |
| A  |   |  |  | X0 |   |    |    |    |    |
| B  |   |  |  | X1 |   |    |    |    |    |
| C  |   |  |  | X2 |   |    |    |    |    |
| D  |   |  |  | X3 |   |    |    |    |    |

You should use `ignore_index` with this method to instruct `DataFrame` to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed `DataFrame` and append or concatenate those objects.

You can also pass a list of dicts or `Series`:

```
In [36]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
.....:           {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
.....:

In [37]: result = df1.append(dicts, ignore_index=True)
```

| df1 |       |    |    |     | Result |   |    |    |    |     |     |     |
|-----|-------|----|----|-----|--------|---|----|----|----|-----|-----|-----|
|     | A     | B  | C  | D   |        | A | B  | C  | D  | X   | Y   |     |
| 0   | A0    | B0 | C0 | D0  |        | 0 | A0 | B0 | C0 | D0  | NaN | NaN |
| 1   | A1    | B1 | C1 | D1  |        | 1 | A1 | B1 | C1 | D1  | NaN | NaN |
| 2   | A2    | B2 | C2 | D2  |        | 2 | A2 | B2 | C2 | D2  | NaN | NaN |
| 3   | A3    | B3 | C3 | D3  |        | 3 | A3 | B3 | C3 | D3  | NaN | NaN |
|     | dicts |    |    |     |        | 4 | 1  | 2  | 3  | NaN | 4.0 | NaN |
|     | A     | B  | C  | X   | Y      | 5 | 5  | 6  | 7  | NaN | 8.0 |     |
| 0   | 1     | 2  | 3  | 4.0 | NaN    |   |    |    |    |     |     |     |
| 1   | 5     | 6  | 7  | NaN | 8.0    |   |    |    |    |     |     |     |

## 17.2 Database-style DataFrame joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in `DataFrame`.

See the [cookbook](#) for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a [comparison with SQL](#).

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between `DataFrame` objects:

```
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
         left_index=False, right_index=False, sort=True,
         suffixes=('_x', '_y'), copy=True, indicator=False,
         validate=None)
```

- `left`: A `DataFrame` object.
- `right`: Another `DataFrame` object.
- `on`: Column or index level names to join on. Must be found in both the left and right `DataFrame` objects. If not passed and `left_index` and `right_index` are `False`, the intersection of the columns in the `DataFrames` will be inferred to be the join keys.
- `left_on`: Columns or index levels from the left `DataFrame` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame`.
- `right_on`: Columns or index levels from the right `DataFrame` to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the `DataFrame`.
- `left_index`: If `True`, use the index (row labels) from the left `DataFrame` as its join key(s). In the case of a `DataFrame` with a `MultiIndex` (hierarchical), the number of levels must match the number of join keys from the right `DataFrame`.
- `right_index`: Same usage as `left_index` for the right `DataFrame`.
- `how`: One of `'left'`, `'right'`, `'outer'`, `'inner'`. Defaults to `inner`. See below for more detailed description of each method.
- `sort`: Sort the result `DataFrame` by the join keys in lexicographical order. Defaults to `True`, setting to `False` will improve performance substantially in many cases.
- `suffixes`: A tuple of string suffixes to apply to overlapping columns. Defaults to `('_x', '_y')`.
- `copy`: Always copy data (default `True`) from the passed `DataFrame` objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
- `indicator`: Add a column to the output `DataFrame` called `_merge` with information on the source of each row. `_merge` is Categorical-type and takes on a value of `left_only` for observations whose merge key only appears in `'left'` `DataFrame`, `right_only` for observations whose merge key only appears in `'right'` `DataFrame`, and `both` if the observation's merge key is found in both.
- `validate`: string, default `None`. If specified, checks if merge is of specified type.
  - `"one_to_one"` or `"1:1"`: checks if merge keys are unique in both left and right datasets.
  - `"one_to_many"` or `"1:m"`: checks if merge keys are unique in left dataset.
  - `"many_to_one"` or `"m:1"`: checks if merge keys are unique in right dataset.
  - `"many_to_many"` or `"m:m"`: allowed, but does not result in checks.

New in version 0.21.0.

---

**Note:** Support for specifying index levels as the `on`, `left_on`, and `right_on` parameters was added in version 0.23.0.

---

The return type will be the same as `left`. If `left` is a `DataFrame` and `right` is a subclass of `DataFrame`, the return type will still be `DataFrame`.

`merge` is a function in the pandas namespace, and it is also available as a `DataFrame` instance method `merge()`, with the calling `DataFrame` being implicitly considered the left object in the join.

The related `join()` method, uses `merge` internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use `DataFrame.join` to save yourself some typing.

### 17.2.1 Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (`DataFrame` objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two `DataFrame` objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different `DataFrame`.
- **many-to-many** joins: joining columns on columns.

**Note:** When joining columns on columns (potentially a many-to-many join), any indexes on the passed `DataFrame` objects **will be discarded**.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

```
In [38]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:

In [39]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
.....:                         'C': ['C0', 'C1', 'C2', 'C3'],
.....:                         'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [40]: result = pd.merge(left, right, on='key')
```

| left |     |    |    | right |     |    |    | Result |     |    |    |    |    |
|------|-----|----|----|-------|-----|----|----|--------|-----|----|----|----|----|
|      | key | A  | B  |       | key | C  | D  |        | key | A  | B  | C  | D  |
| 0    | K0  | A0 | B0 | 0     | K0  | C0 | D0 | 0      | K0  | A0 | B0 | C0 | D0 |
| 1    | K1  | A1 | B1 | 1     | K1  | C1 | D1 | 1      | K1  | A1 | B1 | C1 | D1 |
| 2    | K2  | A2 | B2 | 2     | K2  | C2 | D2 | 2      | K2  | A2 | B2 | C2 | D2 |
| 3    | K3  | A3 | B3 | 3     | K3  | C3 | D3 | 3      | K3  | A3 | B3 | C3 | D3 |

Here is a more complicated example with multiple join keys. Only the keys appearing in `left` and `right` are present (the intersection), since `how='inner'` by default.

```
In [41]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1'],
.....:                       'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3']})
.....:
```

(continues on next page)

(continued from previous page)

```
In [42]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K0', 'K0', 'K0'],
.....:                       'C': ['C0', 'C1', 'C2', 'C3'],
.....:                       'D': ['D0', 'D1', 'D2', 'D3']})
.....:

In [43]: result = pd.merge(left, right, on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2 | B2 | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 |        |      |      |    |    |    |    |

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be NA. Here is a summary of the `how` options and their SQL equivalent names:

| Merge method | SQL Join Name    | Description                               |
|--------------|------------------|---|
| left         | LEFT OUTER JOIN  | Use keys from left frame only             |
| right        | RIGHT OUTER JOIN | Use keys from right frame only            |
| outer        | FULL OUTER JOIN  | Use union of keys from both frames        |
| inner        | INNER JOIN       | Use intersection of keys from both frames |

```
In [44]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |     |     |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|-----|-----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C   | D   |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0  | D0  |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K0   | K1   | A1 | B1 | NaN | NaN |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C1  | D1  |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 | 3      | K1   | K0   | A2 | B2 | C2  | D2  |
|      |      |      |    |    |       |      |      |    |    | 4      | K2   | K1   | A3 | B3 | NaN | NaN |

```
In [45]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |     |     |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|-----|-----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A   | B   | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0  | B0  | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2  | B2  | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2  | B2  | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 | 3      | K2   | K0   | NaN | NaN | C3 | D3 |

```
In [46]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |     |     |     |     |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|-----|-----|-----|-----|
|      |      |      |    |    |       |      |      |    |    |        |      |      |     |     |     |     |
|      |      |      |    |    |       |      |      |    |    |        | key1 | key2 | A   | B   | C   | D   |
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  | 0      | K0   | K0   | A0  | B0  | C0  | D0  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 1      | K0   | K1   | A1  | B1  | NaN | NaN |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 2      | K1   | K0   | A2  | B2  | C1  | D1  |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 3      | K1   | K0   | A2  | B2  | C2  | D2  |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 | 4      | K2   | K1   | A3  | B3  | NaN | NaN |
|      |      |      |    |    |       |      |      |    |    | 5      | K2   | K0   | NaN | NaN | C3  | D3  |

```
In [47]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])
```

| left |      |      |    |    | right |      |      |    |    | Result |      |      |    |    |    |    |
|------|------|------|----|----|-------|------|------|----|----|--------|------|------|----|----|----|----|
|      | key1 | key2 | A  | B  |       | key1 | key2 | C  | D  |        | key1 | key2 | A  | B  | C  | D  |
| 0    | K0   | K0   | A0 | B0 | 0     | K0   | K0   | C0 | D0 | 0      | K0   | K0   | A0 | B0 | C0 | D0 |
| 1    | K0   | K1   | A1 | B1 | 1     | K1   | K0   | C1 | D1 | 1      | K1   | K0   | A2 | B2 | C1 | D1 |
| 2    | K1   | K0   | A2 | B2 | 2     | K1   | K0   | C2 | D2 | 2      | K1   | K0   | A2 | B2 | C2 | D2 |
| 3    | K2   | K1   | A3 | B3 | 3     | K2   | K0   | C3 | D3 |        |      |      |    |    |    |    |

Here is another example with duplicate join keys in DataFrames:

```
In [48]: left = pd.DataFrame({'A' : [1,2], 'B' : [2, 2]})
```

```
In [49]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2,2,2]})
```

```
In [50]: result = pd.merge(left, right, on='B', how='outer')
```

| left |   |   | right |   |   | Result |     |   |     |
|------|---|---|-------|---|---|--------|-----|---|-----|
|      | A | B |       | A | B |        | A_x | B | A_y |
| 0    | 1 | 2 | 0     | 4 | 2 | 0      | 1   | 2 | 4   |
| 1    | 2 | 2 | 1     | 5 | 2 | 1      | 1   | 2 | 5   |
|      |   |   | 2     | 6 | 2 | 2      | 1   | 2 | 6   |
|      |   |   |       |   |   | 3      | 2   | 2 | 4   |
|      |   |   |       |   |   | 4      | 2   | 2 | 5   |
|      |   |   |       |   |   | 5      | 2   | 2 | 6   |

**Warning:** Joining / merging on duplicate keys can cause a returned frame that is the multiplication of the row dimensions, which may result in memory overflow. It is the user's responsibility to manage duplicate values in keys before joining large DataFrames.

## 17.2.2 Checking for duplicate keys

New in version 0.21.0.

Users can use the `validate` argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of `B` in the right DataFrame. As this is not a one-to-one merge – as specified in the `validate` argument – an exception will be raised.

```
In [51]: left = pd.DataFrame({'A' : [1,2], 'B' : [1, 2]})
In [52]: right = pd.DataFrame({'A' : [4,5,6], 'B': [2, 2, 2]})
```

```
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the `validate='one_to_many'` argument instead, which will not raise an exception.

```
In [53]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
Out[53]:
```

|   | A_x | B | A_y |
|---|-----|---|-----|
| 0 | 1   | 1 | NaN |
| 1 | 2   | 2 | 4.0 |
| 2 | 2   | 2 | 5.0 |
| 3 | 2   | 2 | 6.0 |

## 17.2.3 The merge indicator

`merge()` accepts the argument `indicator`. If `True`, a Categorical-type column called `_merge` will be added to the output object that takes on values:

| Observation Origin              | _merge value |
|---------------------------------|--------------|
| Merge key only in 'left' frame  | left_only    |
| Merge key only in 'right' frame | right_only   |
| Merge key in both frames        | both         |

```
In [54]: df1 = pd.DataFrame({'coll': [0, 1], 'col_left':['a', 'b']})
In [55]: df2 = pd.DataFrame({'coll': [1, 2, 2], 'col_right':[2, 2, 2]})
In [56]: pd.merge(df1, df2, on='coll', how='outer', indicator=True)
Out[56]:
```

|   | coll | col_left | col_right | _merge     |
|---|------|----------|-----------|------------|
| 0 | 0    | a        | NaN       | left_only  |
| 1 | 1    | b        | 2.0       | both       |
| 2 | 2    | NaN      | 2.0       | right_only |
| 3 | 2    | NaN      | 2.0       | right_only |

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

```
In [57]: pd.merge(df1, df2, on='coll', how='outer', indicator='indicator_column')
Out[57]:
```

|   | coll | col_left | col_right | indicator_column |
|---|------|----------|-----------|------------------|
| 0 | 0    | a        | NaN       | left_only        |
| 1 | 1    | b        | 2.0       | both             |
| 2 | 2    | NaN      | 2.0       | right_only       |
| 3 | 2    | NaN      | 2.0       | right_only       |

## 17.2.4 Merge Dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

```
In [58]: left = pd.DataFrame({'key': [1], 'v1': [10]})
In [59]: left
Out[59]:
```

|   | key | v1 |
|---|-----|----|
| 0 | 1   | 10 |

```
In [60]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})
In [61]: right
Out[61]:
```

|   | key | v1 |
|---|-----|----|
| 0 | 1   | 20 |
| 1 | 2   | 30 |

We are able to preserve the join keys:

```
In [62]: pd.merge(left, right, how='outer')
Out[62]:
```

|  | key | v1 |
|--|-----|----|
|--|-----|----|

(continues on next page)

(continued from previous page)

```

0    1    10
1    1    20
2    2    30

In [63]: pd.merge(left, right, how='outer').dtypes
Out[63]:
key      int64
v1       int64
dtype: object

```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```

In [64]: pd.merge(left, right, how='outer', on='key')
Out[64]:
   key  v1_x  v1_y
0    1  10.0    20
1    2   NaN    30

In [65]: pd.merge(left, right, how='outer', on='key').dtypes
Out[65]:
key      int64
v1_x    float64
v1_y     int64
dtype: object

```

New in version 0.20.0.

Merging will preserve category dtypes of the mergands. See also the section on *categoricals*.

The left frame.

```

In [66]: from pandas.api.types import CategoricalDtype

In [67]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))

In [68]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))

In [69]: left = pd.DataFrame({'X': X,
.....:                       'Y': np.random.choice(['one', 'two', 'three'], size=(10,
.....:                                                ↪))})
.....:

In [70]: left
Out[70]:
   X      Y
0  bar  one
1  foo  one
2  foo three
3  bar three
4  foo  one
5  bar  one
6  bar three
7  bar three
8  bar three
9  foo three

In [71]: left.dtypes

```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
X      category
Y      object
dtype: object

```

The right frame.

```

In [72]: right = pd.DataFrame({
.....:     'X': pd.Series(['foo', 'bar'],
.....:                     dtype=CategoricalDtype(['foo', 'bar'])),
.....:     'Z': [1, 2]
.....: })
.....:

In [73]: right
Out[73]:
   X  Z
0  foo  1
1  bar  2

In [74]: right.dtypes
Out[74]:
X      category
Z      int64
dtype: object

```

The merged result:

```

In [75]: result = pd.merge(left, right, how='outer')

In [76]: result
Out[76]:
   X      Y  Z
0  bar  one  2
1  bar three  2
2  bar  one  2
3  bar three  2
4  bar three  2
5  bar three  2
6  foo  one  1
7  foo three  1
8  foo  one  1
9  foo three  1

In [77]: result.dtypes
Out[77]:
↪
X      category
Y      object
Z      int64
dtype: object

```

**Note:** The category dtypes must be *exactly* the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to object dtype.

**Note:** Merging on category dtypes that are the same can be quite performant compared to object dtype merging.

## 17.2.5 Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```
In [78]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=['K0', 'K1', 'K2'])

In [79]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
.....:                         'D': ['D0', 'D2', 'D3']},
.....:                         index=['K0', 'K2', 'K3'])

In [80]: result = left.join(right)
```

| left |    |    | right |    |    | Result |    |    |     |     |
|------|----|----|-------|----|----|--------|----|----|-----|-----|
|      | A  | B  |       | C  | D  |        | A  | B  | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1 | B1 | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2 | B2 | C2  | D2  |

```
In [81]: result = left.join(right, how='outer')
```

| left |    |    | right |    |    | Result |     |     |     |     |
|------|----|----|-------|----|----|--------|-----|-----|-----|-----|
|      | A  | B  |       | C  | D  |        | A   | B   | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0  | B0  | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1  | B1  | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2  | B2  | C2  | D2  |
|      |    |    |       |    |    | K3     | NaN | NaN | C3  | D3  |

The same as above, but with `how='inner'`.

```
In [82]: result = left.join(right, how='inner')
```

| left |    |    | right |    |    | Result |    |    |    |    |
|------|----|----|-------|----|----|--------|----|----|----|----|
|      | A  | B  |       | C  | D  |        | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K2    | C2 | D2 |        |    |    |    |    |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2 | B2 | C2 | D2 |

The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [83]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')
↳')
```

| left |    |    | right |    |    | Result |     |     |     |     |
|------|----|----|-------|----|----|--------|-----|-----|-----|-----|
|      | A  | B  |       | C  | D  |        | A   | B   | C   | D   |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0  | B0  | C0  | D0  |
| K1   | A1 | B1 | K2    | C2 | D2 | K1     | A1  | B1  | NaN | NaN |
| K2   | A2 | B2 | K3    | C3 | D3 | K2     | A2  | B2  | C2  | D2  |
|      |    |    |       |    |    | K3     | NaN | NaN | C3  | D3  |

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner')
↳');
```

| left |    |    | right |    |    | Result |    |    |    |    |
|------|----|----|-------|----|----|--------|----|----|----|----|
|      | A  | B  |       | C  | D  |        | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | C0 | D0 | K0     | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K2    | C2 | D2 | K2     | A2 | B2 | C2 | D2 |
| K2   | A2 | B2 | K3    | C3 | D3 |        |    |    |    |    |

## 17.2.6 Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed `DataFrame` is to be aligned on that column in the `DataFrame`. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True,
        how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the `DataFrame`'s is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [85]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                      'B': ['B0', 'B1', 'B2', 'B3'],
.....:                      'key': ['K0', 'K1', 'K0', 'K1']})
.....:

In [86]: right = pd.DataFrame({'C': ['C0', 'C1'],
.....:                       'D': ['D0', 'D1']},
.....:                       index=['K0', 'K1'])
.....:

In [87]: result = left.join(right, on='key')
```

| left |    |    |     | right |    |    | Result |    |    |     |    |    |
|------|----|----|-----|-------|----|----|--------|----|----|-----|----|----|
|      | A  | B  | key |       | C  | D  |        | A  | B  | key | C  | D  |
| 0    | A0 | B0 | K0  |       |    |    | 0      | A0 | B0 | K0  | C0 | D0 |
| 1    | A1 | B1 | K1  | K0    | C0 | D0 | 1      | A1 | B1 | K1  | C1 | D1 |
| 2    | A2 | B2 | K0  | K1    | C1 | D1 | 2      | A2 | B2 | K0  | C0 | D0 |
| 3    | A3 | B3 | K1  |       |    |    | 3      | A3 | B3 | K1  | C1 | D1 |

```
In [88]: result = pd.merge(left, right, left_on='key', right_index=True,
.....:                     how='left', sort=False);
.....:
```

| left |    |    |     | right |    |    | Result |    |    |     |    |    |
|------|----|----|-----|-------|----|----|--------|----|----|-----|----|----|
|      | A  | B  | key |       | C  | D  |        | A  | B  | key | C  | D  |
| 0    | A0 | B0 | K0  |       |    |    | 0      | A0 | B0 | K0  | C0 | D0 |
| 1    | A1 | B1 | K1  | K0    | C0 | D0 | 1      | A1 | B1 | K1  | C1 | D1 |
| 2    | A2 | B2 | K0  | K1    | C1 | D1 | 2      | A2 | B2 | K0  | C0 | D0 |
| 3    | A3 | B3 | K1  |       |    |    | 3      | A3 | B3 | K1  | C1 | D1 |

To join on multiple keys, the

passed DataFrame must have a MultiIndex:

```
In [89]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                       'B': ['B0', 'B1', 'B2', 'B3'],
.....:                       'key1': ['K0', 'K0', 'K1', 'K2'],
.....:                       'key2': ['K0', 'K1', 'K0', 'K1']})

In [90]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
.....:                                     ('K2', 'K0'), ('K2', 'K1')])

In [91]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                         'D': ['D0', 'D1', 'D2', 'D3']},
.....:                        index=index)
.....:
```

Now this can be joined by passing the two key column names:

```
In [92]: result = left.join(right, on=['key1', 'key2'])
```

| left |    |    |      |      | right |    |    |    | Result |    |    |      |      |     |     |
|------|----|----|------|------|-------|----|----|----|--------|----|----|------|------|-----|-----|
|      | A  | B  | key1 | key2 |       |    | C  | D  |        | A  | B  | key1 | key2 | C   | D   |
| 0    | A0 | B0 | K0   | K0   | K0    | K0 | C0 | D0 | 0      | A0 | B0 | K0   | K0   | C0  | D0  |
| 1    | A1 | B1 | K0   | K1   | K1    | K0 | C1 | D1 | 1      | A1 | B1 | K0   | K1   | NaN | NaN |
| 2    | A2 | B2 | K1   | K0   | K2    | K0 | C2 | D2 | 2      | A2 | B2 | K1   | K0   | C1  | D1  |
| 3    | A3 | B3 | K2   | K1   | K2    | K1 | C3 | D3 | 3      | A3 | B3 | K2   | K1   | C3  | D3  |

The default for `DataFrame.join` is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which

uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

```
In [93]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

| left |    |    |      |      | right |    |    |    | Result |    |    |      |      |    |    |
|------|----|----|------|------|-------|----|----|----|--------|----|----|------|------|----|----|
|      | A  | B  | key1 | key2 |       |    | C  | D  |        | A  | B  | key1 | key2 | C  | D  |
| 0    | A0 | B0 | K0   | K0   | K0    | K0 | C0 | D0 | 0      | A0 | B0 | K0   | K0   | C0 | D0 |
| 1    | A1 | B1 | K0   | K1   | K1    | K0 | C1 | D1 | 2      | A2 | B2 | K1   | K0   | C1 | D1 |
| 2    | A2 | B2 | K1   | K0   | K2    | K0 | C2 | D2 | 3      | A3 | B3 | K2   | K1   | C3 | D3 |
| 3    | A3 | B3 | K2   | K1   | K2    | K1 | C3 | D3 |        |    |    |      |      |    |    |

As you can see, this drops any rows where there was no match.

### 17.2.7 Joining a single Index to a Multi-index

You can join a singly-indexed DataFrame with a level of a multi-indexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the multi-indexed frame.

```
In [94]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                       'B': ['B0', 'B1', 'B2']},
.....:                       index=pd.Index(['K0', 'K1', 'K2'], name='key'))
.....:
```

```
In [95]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
.....:                                     ('K2', 'Y2'), ('K2', 'Y3')],
.....:                                     names=['key', 'Y'])
.....:
```

```
In [96]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3']},
.....:                        index=index)
.....:
```

```
In [97]: result = left.join(right, how='inner')
```

| left |    |    | right |    |    |    | Result |    |    |    |    |    |
|------|----|----|-------|----|----|----|--------|----|----|----|----|----|
|      | A  | B  |       |    | C  | D  |        |    | A  | B  | C  | D  |
| K0   | A0 | B0 | K0    | Y0 | C0 | D0 | K0     | Y0 | A0 | B0 | C0 | D0 |
| K1   | A1 | B1 | K1    | Y1 | C1 | D1 | K1     | Y1 | A1 | B1 | C1 | D1 |
| K2   | A2 | B2 | K2    | Y2 | C2 | D2 | K2     | Y2 | A2 | B2 | C2 | D2 |
|      |    |    | K2    | Y3 | C3 | D3 | K2     | Y3 | A2 | B2 | C3 | D3 |

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [98]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                      on=['key', 'Y'], how='inner').set_index(['key', 'Y'])
.....:
```

| left |    |    | right |    |    |    | Result |    |    |    |    |    |  |  |
|------|----|----|-------|----|----|----|--------|----|----|----|----|----|--|--|
|      |    |    |       |    | C  | D  |        |    | A  | B  | C  | D  |  |  |
| K0   | A0 | B0 | K0    | Y0 | C0 | D0 | K0     | Y0 | A0 | B0 | C0 | D0 |  |  |
| K1   | A1 | B1 | K1    | Y1 | C1 | D1 | K1     | Y1 | A1 | B1 | C1 | D1 |  |  |
| K2   | A2 | B2 | K2    | Y2 | C2 | D2 | K2     | Y2 | A2 | B2 | C2 | D2 |  |  |
|      |    |    | K2    | Y3 | C3 | D3 | K2     | Y3 | A2 | B2 | C3 | D3 |  |  |

## 17.2.8 Joining with two multi-indexes

This is not implemented via `join` at-the-moment, however it can be done using the following code.

```
In [99]: index = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
.....:                                     ('K1', 'X2')],
.....:                                     names=['key', 'X'])
.....:

In [100]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
.....:                         'B': ['B0', 'B1', 'B2']},
.....:                        index=index)
.....:

In [101]: result = pd.merge(left.reset_index(), right.reset_index(),
.....:                       on=['key'], how='inner').set_index(['key', 'X', 'Y'])
.....:
```

| left |    |    |    | right |    |    |    | Result |    |    |    |    |    |    |  |
|------|----|----|----|-------|----|----|----|--------|----|----|----|----|----|----|--|
|      |    | A  | B  |       |    | C  | D  |        |    |    | A  | B  | C  | D  |  |
| K0   | X0 | A0 | B0 | K0    | Y0 | C0 | D0 | K0     | X0 | Y0 | A0 | B0 | C0 | D0 |  |
| K0   | X1 | A1 | B1 | K1    | Y1 | C1 | D1 | K0     | X1 | Y0 | A1 | B1 | C0 | D0 |  |
| K1   | X2 | A2 | B2 | K2    | Y2 | C2 | D2 | K1     | X2 | Y1 | A2 | B2 | C1 | D1 |  |
|      |    |    |    | K2    | Y3 | C3 | D3 |        |    |    |    |    |    |    |  |

## 17.2.9 Merging on a combination of columns and index levels

New in version 0.22.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```
In [102]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [103]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
.....:                         'B': ['B0', 'B1', 'B2', 'B3'],
.....:                         'key2': ['K0', 'K1', 'K0', 'K1']},
.....:                        index=left_index)
```

(continues on next page)

(continued from previous page)

```

.....:
In [104]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [105]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
.....:                        'D': ['D0', 'D1', 'D2', 'D3'],
.....:                        'key2': ['K0', 'K0', 'K0', 'K1']},
.....:                        index=right_index)
.....:

In [106]: result = left.merge(right, on=['key1', 'key2'])

```

| left |    |    |      | right |    |    |      | Result |    |    |      |    |    |
|------|----|----|------|-------|----|----|------|--------|----|----|------|----|----|
|      | A  | B  | key2 |       | C  | D  | key2 |        | A  | B  | key2 | C  | D  |
| K0   | A0 | B0 | K0   | K0    | C0 | D0 | K0   | K0     | A0 | B0 | K0   | C0 | D0 |
| K0   | A1 | B1 | K1   | K1    | C1 | D1 | K0   | K1     | A2 | B2 | K0   | C1 | D1 |
| K1   | A2 | B2 | K0   | K2    | C2 | D2 | K0   | K2     | A3 | B3 | K1   | C3 | D3 |
| K2   | A3 | B3 | K1   | K2    | C3 | D3 | K1   |        |    |    |      |    |    |

**Note:** When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

**Note:** If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### 17.2.10 Overlapping value columns

The merge `suffixes` argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

```

In [107]: left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})

In [108]: right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})

In [109]: result = pd.merge(left, right, on='k')

```

| left |    |   | right |    |   | Result |    |     |     |
|------|----|---|-------|----|---|--------|----|-----|-----|
|      | k  | v |       | k  | v |        | k  | v_x | v_y |
| 0    | K0 | 1 | 0     | K0 | 4 | 0      | K0 | 1   | 4   |
| 1    | K1 | 2 | 1     | K0 | 5 | 1      | K0 | 1   | 5   |
| 2    | K2 | 3 | 2     | K3 | 6 |        |    |     |     |

```
In [110]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])
```

| left |    |   | right |    |   | Result |    |     |     |
|------|----|---|-------|----|---|--------|----|-----|-----|
|      | k  | v |       | k  | v |        | k  | v_l | v_r |
| 0    | K0 | 1 | 0     | K0 | 4 | 0      | K0 | 1   | 4   |
| 1    | K1 | 2 | 1     | K0 | 5 | 1      | K0 | 1   | 5   |
| 2    | K2 | 3 | 2     | K3 | 6 |        |    |     |     |

`DataFrame.join()` has `lsuffix` and `rsuffix` arguments which behave similarly.

```
In [111]: left = left.set_index('k')
```

```
In [112]: right = right.set_index('k')
```

```
In [113]: result = left.join(right, lsuffix='_l', rsuffix='_r')
```

| left |   | right |   | Result |     |     |
|------|---|-------|---|--------|-----|-----|
|      | v |       | v |        | v_l | v_r |
| K0   | 1 | K0    | 4 | K0     | 1   | 4.0 |
| K1   | 2 | K0    | 5 | K0     | 1   | 5.0 |
| K2   | 3 | K3    | 6 | K1     | 2   | NaN |
|      |   |       |   | K2     | 3   | NaN |

### 17.2.11 Joining multiple DataFrame or Panel objects

A list or tuple of DataFrames can also be passed to `join()` to join them together on their indexes.

```
In [114]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
```

```
In [115]: result = left.join([right, right2])
```

| left |   | right |   | right2 |   | Result |     |     |     |
|------|---|-------|---|--------|---|--------|-----|-----|-----|
|      | v |       | v |        | v |        | v_x | v_y | v   |
| K0   | 1 | K0    | 4 | K1     | 7 | K0     | 1   | 4.0 | NaN |
| K1   | 2 | K0    | 5 | K1     | 8 | K0     | 1   | 5.0 | NaN |
| K2   | 3 | K3    | 6 | K2     | 9 | K1     | 2   | NaN | 7.0 |
|      |   |       |   |        |   | K1     | 2   | NaN | 8.0 |
|      |   |       |   |        |   | K2     | 3   | NaN | 9.0 |

## 17.2.12 Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) `Series` or `DataFrame` objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```
In [116]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
.....:                        [np.nan, 7., np.nan]])
.....:

In [117]: df2 = pd.DataFrame([[ -42.6, np.nan, -8.2], [-5., 1.6, 4]],
.....:                        index=[1, 2])
.....:
```

For this, use the `combine_first()` method:

```
In [118]: result = df1.combine_first(df2)
```

| df1 |      |     |     | df2 |       |     |      | Result |      |     |      |
|-----|------|-----|-----|-----|-------|-----|------|--------|------|-----|------|
|     | 0    | 1   | 2   |     | 0     | 1   | 2    |        | 0    | 1   | 2    |
| 0   | NaN  | 3.0 | 5.0 |     |       |     |      | 0      | NaN  | 3.0 | 5.0  |
| 1   | -4.6 | NaN | NaN | 1   | -42.6 | NaN | -8.2 | 1      | -4.6 | NaN | -8.2 |
| 2   | NaN  | 7.0 | NaN | 2   | -5.0  | 1.6 | 4.0  | 2      | -5.0 | 7.0 | 4.0  |

Note that this method only takes values from the right `DataFrame` if they are missing in the left `DataFrame`. A related method, `update()`, alters non-NA values inplace:

```
In [119]: df1.update(df2)
```

| df1 |      |     |     | df2 |       |     |      | Result |       |     |      |
|-----|------|-----|-----|-----|-------|-----|------|--------|-------|-----|------|
|     | 0    | 1   | 2   |     | 0     | 1   | 2    |        | 0     | 1   | 2    |
| 0   | NaN  | 3.0 | 5.0 |     |       |     |      | 0      | NaN   | 3.0 | 5.0  |
| 1   | -4.6 | NaN | NaN | 1   | -42.6 | NaN | -8.2 | 1      | -42.6 | NaN | -8.2 |
| 2   | NaN  | 7.0 | NaN | 2   | -5.0  | 1.6 | 4.0  | 2      | -5.0  | 1.6 | 4.0  |

## 17.3 Timeseries friendly merging

### 17.3.1 Merging Ordered Data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```
In [120]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
.....:                        'lv': [1, 2, 3, 4],
.....:                        's': ['a', 'b', 'c', 'd']})
.....:

In [121]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
```

(continues on next page)

(continued from previous page)

```

.....:             'rv': [1, 2, 3])
.....:

In [122]: pd.merge_ordered(left, right, fill_method='ffill', left_by='s')
Out[122]:
   k  lv s  rv
0  K0  1.0 a NaN
1  K1  1.0 a  1.0
2  K2  1.0 a  2.0
3  K4  1.0 a  3.0
4  K1  2.0 b  1.0
5  K2  2.0 b  2.0
6  K4  2.0 b  3.0
7  K1  3.0 c  1.0
8  K2  3.0 c  2.0
9  K4  3.0 c  3.0
10 K1  NaN d  1.0
11 K2  4.0 d  2.0
12 K4  4.0 d  3.0

```

## 17.3.2 Merging AsOf

New in version 0.19.0.

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the left DataFrame, we select the last row in the right DataFrame whose on key is less than the left's key. Both DataFrames must be sorted by the key.

Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to asof merge them.

```

In [123]: trades = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                             '20160525 13:30:00.038',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.048']),
.....:     'ticker': ['MSFT', 'MSFT',
.....:                 'GOOG', 'GOOG', 'AAPL'],
.....:     'price': [51.95, 51.95,
.....:               720.77, 720.92, 98.00],
.....:     'quantity': [75, 155,
.....:                  100, 100, 100]},
.....:     columns=['time', 'ticker', 'price', 'quantity'])
.....:

In [124]: quotes = pd.DataFrame({
.....:     'time': pd.to_datetime(['20160525 13:30:00.023',
.....:                             '20160525 13:30:00.023',
.....:                             '20160525 13:30:00.030',
.....:                             '20160525 13:30:00.041',
.....:                             '20160525 13:30:00.048',
.....:                             '20160525 13:30:00.049',
.....:                             '20160525 13:30:00.072'],
.....:

```

(continues on next page)

By default we are taking the asof of the quotes.

We only asof within 2ms between the quote time and the trade time.

(continues on next page)

(continued from previous page)

|   |                         |      |        |     |        |        |
|---|-------------------------|------|--------|-----|--------|--------|
| 0 | 2016-05-25 13:30:00.023 | MSFT | 51.95  | 75  | 51.95  | 51.96  |
| 1 | 2016-05-25 13:30:00.038 | MSFT | 51.95  | 155 | NaN    | NaN    |
| 2 | 2016-05-25 13:30:00.048 | GOOG | 720.77 | 100 | 720.50 | 720.93 |
| 3 | 2016-05-25 13:30:00.048 | GOOG | 720.92 | 100 | 720.50 | 720.93 |
| 4 | 2016-05-25 13:30:00.048 | AAPL | 98.00  | 100 | NaN    | NaN    |

We only asof within 10ms between the quote time and the trade time and we exclude exact matches on time. Note that though we exclude the exact matches (of the quotes), prior quotes **do** propagate to that point in time.

```
In [129]: pd.merge_asof(trades, quotes,
.....:                  on='time',
.....:                  by='ticker',
.....:                  tolerance=pd.Timedelta('10ms'),
.....:                  allow_exact_matches=False)
.....:
```

```
Out [129]:
```

|   | time                    | ticker | price  | quantity | bid   | ask   |
|---|-------------------------|--------|--------|----------|-------|-------|
| 0 | 2016-05-25 13:30:00.023 | MSFT   | 51.95  | 75       | NaN   | NaN   |
| 1 | 2016-05-25 13:30:00.038 | MSFT   | 51.95  | 155      | 51.97 | 51.98 |
| 2 | 2016-05-25 13:30:00.048 | GOOG   | 720.77 | 100      | NaN   | NaN   |
| 3 | 2016-05-25 13:30:00.048 | GOOG   | 720.92 | 100      | NaN   | NaN   |
| 4 | 2016-05-25 13:30:00.048 | AAPL   | 98.00  | 100      | NaN   | NaN   |

## RESHAPING AND PIVOT TABLES

### 18.1 Reshaping by pivoting DataFrame objects

Data is often stored in CSV files or databases in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
```

|    | date       | variable | value     |
|----|------------|----------|-----------|
| 0  | 2000-01-03 | A        | 0.469112  |
| 1  | 2000-01-04 | A        | -0.282863 |
| 2  | 2000-01-05 | A        | -1.509059 |
| 3  | 2000-01-03 | B        | -1.135632 |
| 4  | 2000-01-04 | B        | 1.212112  |
| 5  | 2000-01-05 | B        | -0.173215 |
| 6  | 2000-01-03 | C        | 0.119209  |
| 7  | 2000-01-04 | C        | -1.044236 |
| 8  | 2000-01-05 | C        | -0.861849 |
| 9  | 2000-01-03 | D        | -2.104569 |
| 10 | 2000-01-04 | D        | -0.494929 |
| 11 | 2000-01-05 | D        | 1.071804  |

For the curious here is how the above DataFrame was created:

```
import pandas.util.testing as tm; tm.N = 3
def unpivot(frame):
    N, K = frame.shape
    data = {'value' : frame.values.ravel('F'),
           'variable' : np.asarray(frame.columns).repeat(N),
           'date' : np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])
df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

```
In [2]: df[df['variable'] == 'A']
Out[2]:
```

|   | date       | variable | value     |
|---|------------|----------|-----------|
| 0 | 2000-01-03 | A        | 0.469112  |
| 1 | 2000-01-04 | A        | -0.282863 |
| 2 | 2000-01-05 | A        | -1.509059 |

# Pivot

df

|   | foo | bar | baz | zoo |
|---|-----|-----|-----|-----|
| 0 | one | A   | 1   | x   |
| 1 | one | B   | 2   | y   |
| 2 | one | C   | 3   | z   |
| 3 | two | A   | 4   | q   |
| 4 | two | B   | 5   | w   |
| 5 | two | C   | 6   | t   |

➔

```
df.pivot(index='foo',
          columns='bar',
          values='baz')
```

|     | bar | A | B | C |
|-----|-----|---|---|---|
| foo |     |   |   |   |
| one |     | 1 | 2 | 3 |
| two |     | 4 | 5 | 6 |

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):

```
In [3]: df.pivot(index='date', columns='variable', values='value')
Out[3]:
```

| variable   | A         | B         | C         | D         |
|------------|-----------|-----------|-----------|-----------|
| date       |           |           |           |           |
| 2000-01-03 | 0.469112  | -1.135632 | 0.119209  | -2.104569 |
| 2000-01-04 | -0.282863 | 1.212112  | -1.044236 | -0.494929 |
| 2000-01-05 | -1.509059 | -0.173215 | -0.861849 | 1.071804  |

If the `values` argument is omitted, and the input `DataFrame` has more than one column of values which are not used as column or index inputs to `pivot`, then the resulting “pivoted” `DataFrame` will have *hierarchical columns* whose topmost level indicates the respective value column:

```
In [4]: df['value2'] = df['value'] * 2
In [5]: pivoted = df.pivot('date', 'variable')
In [6]: pivoted
Out[6]:
```

|            | value     |           |           |           | value2    |           |           |           |
|------------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|-----------|
| variable   | A         | B         | C         | D         | A         | B         | C         | D         |
| date       |           |           |           |           |           |           |           |           |
| 2000-01-03 | 0.469112  | -1.135632 | 0.119209  | -2.104569 | 0.938225  | -2.271265 | 0.238417  | -4.209138 |
| 2000-01-04 | -0.282863 | 1.212112  | -1.044236 | -0.494929 | -0.565727 | 2.424224  | -2.088472 | -0.989859 |
| 2000-01-05 | -1.509059 | -0.173215 | -0.861849 | 1.071804  | -3.018117 | -0.346429 | -1.723698 | 2.143608  |

You can then select subsets from the pivoted `DataFrame`:

```
In [7]: pivoted['value2']
Out [7]:
variable          A          B          C          D
date
2000-01-03  0.938225 -2.271265  0.238417 -4.209138
2000-01-04 -0.565727  2.424224 -2.088472 -0.989859
2000-01-05 -3.018117 -0.346429 -1.723698  2.143608
```

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

## 18.2 Reshaping by stacking and unstacking

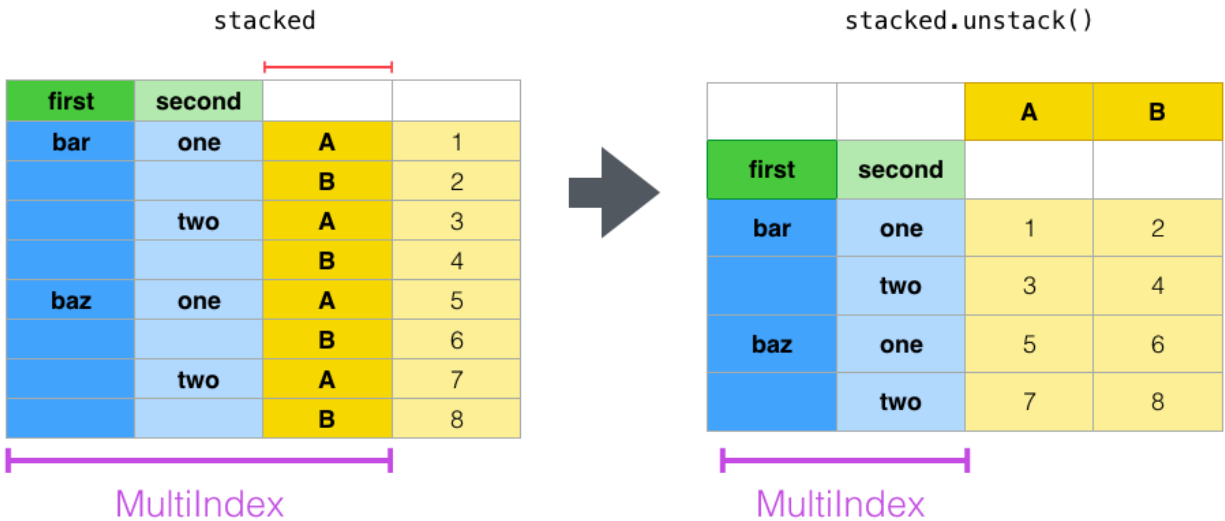

### Stack

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on Series and DataFrame. These methods are designed to work together with MultiIndex objects (see the section on *hierarchical indexing*). Here are essentially what these methods do:

- `stack`: “pivot” a level of the (possibly hierarchical) column labels, returning a DataFrame with an index with a new inner-most level of row labels.
- `unstack`: (inverse operation of `stack`) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped DataFrame with a new inner-most level of column labels.

# Unstack

The clearest way to explain is by example. Let's take a prior example data set from the hierarchical indexing section:

```
In [8]: tuples = list(zip(*(['bar', 'bar', 'baz', 'baz',
...:                        'foo', 'foo', 'qux', 'qux'],
...:                        ['one', 'two', 'one', 'two',
...:                        'one', 'two', 'one', 'two'])))
...:
In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])
In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])
In [11]: df2 = df[:4]
In [12]: df2
Out[12]:
```

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | 0.721555  | -0.706771 |
|       | two    | -1.039575 | 0.271860  |
| baz   | one    | -0.424972 | 0.567020  |
|       | two    | 0.276232  | -1.087401 |

The stack function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:

```
In [13]: stacked = df2.stack()
```

```
In [14]: stacked
```

Out [14]:

```
first  second
bar    one    A    0.721555
        B    -0.706771
        two    A   -1.039575
        B     0.271860
baz    one    A   -0.424972
        B     0.567020
        two    A    0.276232
        B    -1.087401
dtype: float64
```

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is `unstack`, which by default unstacks the **last level**:

```
In [15]: stacked.unstack()
```

Out [15] :

|       |        | A         | B         |
|-------|--------|-----------|-----------|
| first | second |           |           |
| bar   | one    | 0.721555  | -0.706771 |
|       | two    | -1.039575 | 0.271860  |
| baz   | one    | -0.424972 | 0.567020  |
|       | two    | 0.276232  | -1.087401 |

```
In [16]: stacked.unstack(1)
```

```

second      one      two
first
bar  A  0.721555 -1.039575
     B -0.706771  0.271860
baz  A -0.424972  0.276232
     B  0.567020 -1.087401

```

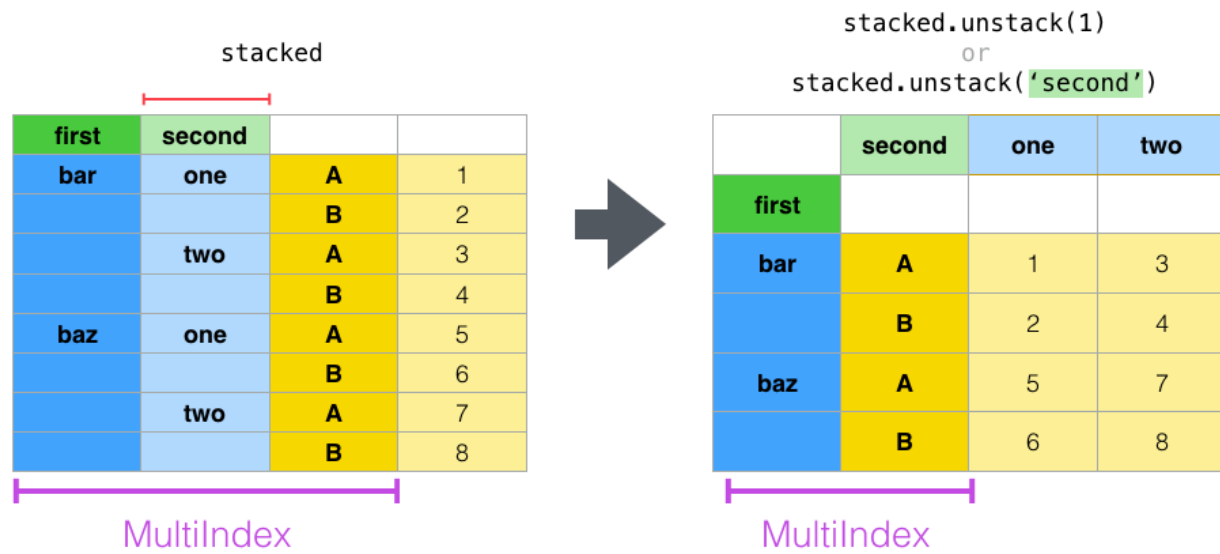

```
In [17]: stacked.unstack(0)
```

```

first      bar      baz
second
one      A      0.721555 -0.424972
          B      -0.706771  0.567020
two      A      -1.039575  0.276232
          B      0.271860 -1.087401

```

## Unstack(1)

If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
second      one      two
first
bar   A  0.721555 -1.039575
      B -0.706771  0.271860
baz   A -0.424972  0.276232
      B  0.567020 -1.087401
```

## Unstack(0)

Notice that the `stack` and `unstack` methods implicitly sort the index levels involved. Hence a call to `stack` and then `unstack`, or vice versa, will result in a **sorted** copy of the original DataFrame or Series:

```
In [19]: index = pd.MultiIndex.from_product([[2,1], ['a', 'b']])
In [20]: df = pd.DataFrame(np.random.randn(4), index=index, columns=['A'])
In [21]: df
Out[21]:
      A
2 a -0.370647
  b -1.157892
1 a -1.344312
  b  0.844885

In [22]: all(df.unstack().stack() == df.sort_index())
Out[22]:
True
```

The above code will raise a `TypeError` if the call to `sort_index` is removed.

### 18.2.1 Multiple Levels

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

```
In [23]: columns = pd.MultiIndex.from_tuples([
....:     ('A', 'cat', 'long'), ('B', 'cat', 'long'),
....:     ('A', 'dog', 'short'), ('B', 'dog', 'short')
....: ],
....:     names=['exp', 'animal', 'hair_length'])
```

(continues on next page)

(continued from previous page)

```

.....: )
.....:

In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)

In [25]: df
Out[25]:
exp          A          B          A          B
animal      cat      cat      dog      dog
hair_length  long      long      short     short
0          1.075770 -0.109050  1.643563 -1.469388
1          0.357021 -0.674600 -1.776904 -0.968914
2         -1.294524  0.413738  0.276662 -0.472035
3         -0.013960 -0.362543 -0.006154 -0.923061

```

```
In [26]: df.stack(level=['animal', 'hair_length'])
```

```

////////////////////////////////////
↪
exp          A          B
animal hair_length
0 cat      long      1.075770 -0.109050
  dog      short     1.643563 -1.469388
1 cat      long      0.357021 -0.674600
  dog      short     -1.776904 -0.968914
2 cat      long     -1.294524  0.413738
  dog      short      0.276662 -0.472035
3 cat      long     -0.013960 -0.362543
  dog      short     -0.006154 -0.923061

```

The list of levels can contain either level names or level numbers (but not a mixture of the two).

```

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [27]: df.stack(level=[1, 2])

```

```

Out[27]:
exp          A          B
animal hair_length
0 cat      long      1.075770 -0.109050
  dog      short     1.643563 -1.469388
1 cat      long      0.357021 -0.674600
  dog      short     -1.776904 -0.968914
2 cat      long     -1.294524  0.413738
  dog      short      0.276662 -0.472035
3 cat      long     -0.013960 -0.362543
  dog      short     -0.006154 -0.923061

```

## 18.2.2 Missing Data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling `sort_index`, of course). Here is a more complex example:

```

In [28]: columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
.....:                                     ('B', 'cat'), ('A', 'dog')],
.....:                                     names=['exp', 'animal'])

```

(continues on next page)

(continued from previous page)

```

.....:
In [29]: index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
.....:                                     ('one', 'two')],
.....:                                     names=['first', 'second'])
.....:

In [30]: df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

In [32]: df2
Out[32]:
exp          A          B          A
animal      cat      dog      cat      dog
first second
bar   one    0.895717  0.805244 -1.206412  2.565646
      two    1.431256  1.340309 -1.170299 -0.226169
baz   one    0.410835  0.813850  0.132003 -0.827317
foo   one   -1.413681  1.607920  1.024180  0.569605
      two    0.875906 -2.211372  0.974466 -2.006747
qux   two   -1.226825  0.769804 -1.281247 -0.727707

```

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

```

In [33]: df2.stack('exp')
Out[33]:
animal      cat      dog
first second exp
bar   one    A    0.895717  2.565646
      two    B   -1.206412  0.805244
      two    A    1.431256 -0.226169
      two    B   -1.170299  1.340309
baz   one    A    0.410835 -0.827317
      two    B    0.132003  0.813850
foo   one    A   -1.413681  0.569605
      two    B    1.024180  1.607920
      two    A    0.875906 -2.006747
      two    B    0.974466 -2.211372
qux   two    A   -1.226825 -0.727707
      two    B   -1.281247  0.769804

In [34]: df2.stack('animal')
//////////
↪
exp          A          B
first second animal
bar   one    cat    0.895717 -1.206412
      two    dog    2.565646  0.805244
      two    cat    1.431256 -1.170299
      two    dog   -0.226169  1.340309
baz   one    cat    0.410835  0.132003
      two    dog   -0.827317  0.813850
foo   one    cat   -1.413681  1.024180
      two    dog    0.569605  1.607920
      two    cat    0.875906  0.974466
      two    dog   -2.006747 -2.211372

```

(continues on next page)

(continued from previous page)

|     |     |     |           |           |
|-----|-----|-----|-----------|-----------|
| qux | two | cat | -1.226825 | -1.281247 |
|     |     | dog | -0.727707 | 0.769804  |

Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, NaN for float, NaT for datetimelike, etc. For integer types, by default data will be converted to float and missing values will be set to NaN.

```
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]
```

```
In [36]: df3
```

```
Out [36]:
```

| exp    |        | B        |           |     |
|--------|--------|----------|-----------|-----|
| animal |        | dog      |           | cat |
| first  | second |          |           |     |
| bar    | one    | 0.805244 | -1.206412 |     |
|        | two    | 1.340309 | -1.170299 |     |
| foo    | one    | 1.607920 | 1.024180  |     |
| qux    | two    | 0.769804 | -1.281247 |     |

```
In [37]: df3.unstack()
```

```

////////////////////////////////////
↪
exp      B
animal   dog      cat
second   one      two      one      two
first
bar      0.805244  1.340309 -1.206412 -1.170299
foo      1.607920      NaN  1.024180      NaN
qux      NaN      0.769804      NaN -1.281247

```

New in version 0.18.0.

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

```
In [38]: df3.unstack(fill_value=-1e9)
```

```
Out [38]:
```

| exp    |  | B             |               |               |               |
|--------|--|---------------|---------------|---------------|---------------|
| animal |  | dog           |               | cat           |               |
| second |  | one           | two           | one           | two           |
| first  |  |               |               |               |               |
| bar    |  | 8.052440e-01  | 1.340309e+00  | -1.206412e+00 | -1.170299e+00 |
| foo    |  | 1.607920e+00  | -1.000000e+09 | 1.024180e+00  | -1.000000e+09 |
| qux    |  | -1.000000e+09 | 7.698036e-01  | -1.000000e+09 | -1.281247e+00 |

## 18.2.3 With a MultiIndex

Unstacking when the columns are a `MultiIndex` is also careful about doing the right thing:

```
In [39]: df[:3].unstack(0)
```

```
Out [39]:
```

| exp    |  | A        |          | B        |         |           |          | A        |           |
|--------|--|----------|----------|----------|---------|-----------|----------|----------|-----------|
| animal |  | cat      |          | dog      |         | cat       |          | dog      |           |
| first  |  | bar      | baz      | bar      | baz     | bar       | baz      | bar      | baz       |
| second |  |          |          |          |         |           |          |          |           |
| one    |  | 0.895717 | 0.410835 | 0.805244 | 0.81385 | -1.206412 | 0.132003 | 2.565646 | -0.827317 |

(continues on next page)

(continued from previous page)

```

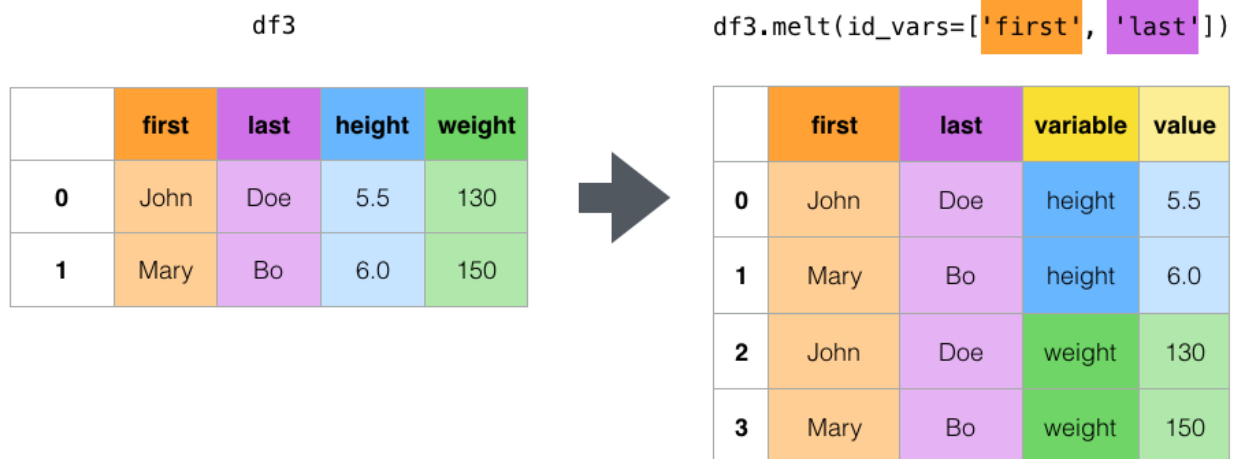

two      1.431256      NaN  1.340309      NaN -1.170299      NaN -0.226169      NaN

```

## 18.3 Reshaping by Melt

### Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a `DataFrame` into a format where one or more columns are *identifier variables*, while all other columns, considered *measured variables*, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```

In [41]: cheese = pd.DataFrame({'first' : ['John', 'Mary'],
.....:                        'last'  : ['Doe', 'Bo'],
.....:                        'height' : [5.5, 6.0],
.....:                        'weight' : [130, 150]})
.....:

In [42]: cheese
Out [42]:

```

(continues on next page)

(continued from previous page)

```

    first last  height  weight
0   John   Doe     5.5    130
1   Mary    Bo     6.0    150

In [43]: cheese.melt(id_vars=['first', 'last'])
Out[43]:
↪
   first last  variable  value
0   John   Doe    height     5.5
1   Mary    Bo    height     6.0
2   John   Doe   weight   130.0
3   Mary    Bo   weight   150.0

In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')
Out[44]:
↪
   first last quantity  value
0   John   Doe    height     5.5
1   Mary    Bo    height     6.0
2   John   Doe   weight   130.0
3   Mary    Bo   weight   150.0

```

Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```

In [45]: dft = pd.DataFrame({"A1970" : {0 : "a", 1 : "b", 2 : "c"},
.....:                      "A1980" : {0 : "d", 1 : "e", 2 : "f"},
.....:                      "B1970" : {0 : 2.5, 1 : 1.2, 2 : .7},
.....:                      "B1980" : {0 : 3.2, 1 : 1.3, 2 : .1},
.....:                      "X"      : dict(zip(range(3), np.random.randn(3)))
.....:                      })

In [46]: dft["id"] = dft.index

In [47]: dft
Out[47]:
   A1970 A1980  B1970  B1980         X  id
0      a      d    2.5    3.2 -0.121306  0
1      b      e    1.2    1.3 -0.097883  1
2      c      f    0.7    0.1  0.695775  2

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
Out[48]:
↪

## 18.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic `Series` and `DataFrame` statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
Out[49]:
```

|        |        | A         |           | B         |           |
|--------|--------|-----------|-----------|-----------|-----------|
| exp    |        | cat       | dog       | cat       | dog       |
| animal |        |           |           |           |           |

## 18.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the [cookbook](#) for some advanced strategies.

It takes a number of arguments:

- `data`: a `DataFrame` object.
- `values`: a column or a list of columns to aggregate.
- `index`: a column, `Grouper`, array which has the same length as data, or list of them. Keys to group by on the pivot table index. If an array is passed, it is being used as the same manner as column values.
- `columns`: a column, `Grouper`, array which has the same length as data, or list of them. Keys to group by on the pivot table column. If an array is passed, it is being used as the same manner as column values.
- `aggfunc`: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```

In [54]: import datetime

In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
.....:                    'B': ['A', 'B', 'C'] * 8,
.....:                    'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
.....:                    'D': np.random.randn(24),
.....:                    'E': np.random.randn(24),
.....:                    'F': [datetime.datetime(2013, i, 1) for i in range(1,
↪13)] +
.....:                    [datetime.datetime(2013, i, 15) for i in range(1,
↪13)]})

In [56]: df
Out[56]:
   A  B  C         D         E         F
0  one A  foo  0.341734 -0.317441 2013-01-01
1  one B  foo  0.959726 -1.236269 2013-02-01
2  two C  foo -1.110336  0.896171 2013-03-01
3 three A  bar -0.619976 -0.487602 2013-04-01
4  one B  bar  0.149748 -0.082240 2013-05-01
5  one C  bar -0.732339 -2.182937 2013-06-01
6  two A  foo  0.687738  0.380396 2013-07-01
..  ..  ..  ...  ...  ...
17 one C  bar -0.345352  0.206053 2013-06-15
18 two A  foo  1.314232 -0.251905 2013-07-15

```

(continues on next page)

(continued from previous page)

```

19  three  B  foo  0.690579 -2.213588 2013-08-15
20   one   C  foo  0.995761  1.063327 2013-09-15
21   one   A  bar  2.396780  1.266143 2013-10-15
22   two   B  bar  0.014871  0.299368 2013-11-15
23  three   C  bar  3.357427 -0.863838 2013-12-15

```

```
[24 rows x 6 columns]
```

We can produce pivot tables from this data very easily:

```
In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
```

```
Out[57]:
```

```

C          bar          foo
A  B
one A  1.120915 -0.514058
    B -0.338421  0.002759
    C -0.538846  0.699535
three A -1.181568      NaN
      B      NaN  0.433512
      C  0.588783      NaN
two   A      NaN  1.000985
      B  0.158248      NaN
      C      NaN  0.176180

```

```
In [58]: pd.pivot_table(df, values='D', index=['B'], columns=['A', 'C'], aggfunc=np.
→sum)
```

```

////////////////////////////////////
→
A      one          three          two
C      bar          foo          bar          foo          bar          foo

C -1.077692  1.399070  1.177566      NaN      NaN  0.352360

```

```
In [59]: pd.pivot_table(df, values=['D', 'E'], index=['B'], columns=['A', 'C'],
→aggfunc=np.sum)
```

```

////////////////////////////////////
→
      D          ...          E
→
A      one          three          two          ...          one          three
→
C      bar          foo          bar          foo          bar          ...          foo          bar
→  foo          bar          foo
B
→
A  2.241830 -1.028115 -2.363137      NaN      NaN          ... -0.043211  1.922577
→  NaN          NaN  0.128491
B -0.676843  0.005518      NaN  0.867024  0.316495          ... -1.103384      NaN -2.
→128743 -0.194294      NaN
C -1.077692  1.399070  1.177566      NaN      NaN          ...  1.495717 -0.263660
→  NaN          NaN  0.872482

```

```
[3 rows x 12 columns]
```

The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values

column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
Out [60]:
```

|       |   | D         |           | E         |           |
|-------|---|-----------|-----------|-----------|-----------|
| C     |   | bar       | foo       | bar       | foo       |
| one   | A | 1.120915  | -0.514058 | 1.393057  | -0.021605 |
|       | B | -0.338421 | 0.002759  | 0.684140  | -0.551692 |
|       | C | -0.538846 | 0.699535  | -0.988442 | 0.747859  |
| three | A | -1.181568 | NaN       | 0.961289  | NaN       |
|       | B | NaN       | 0.433512  | NaN       | -1.064372 |
|       | C | 0.588783  | NaN       | -0.131830 | NaN       |
| two   | A | NaN       | 1.000985  | NaN       | 0.064245  |
|       | B | 0.158248  | NaN       | -0.097147 | NaN       |
|       | C | NaN       | 0.176180  | NaN       | 0.436241  |

Also, you can use `Grouper` for index and columns keywords. For detail of `Grouper`, see [Grouping with a Grouper specification](#).

```
In [61]: pd.pivot_table(df, values='D', index=pd.Grouper(freq='M', key='F'), columns=
→ 'C')
```

```
Out [61]:
```

| C          |  | bar       | foo       |
|------------|--|-----------|-----------|
| F          |  |           |           |
| 2013-01-31 |  | NaN       | -0.514058 |
| 2013-02-28 |  | NaN       | 0.002759  |
| 2013-03-31 |  | NaN       | 0.176180  |
| 2013-04-30 |  | -1.181568 | NaN       |
| 2013-05-31 |  | -0.338421 | NaN       |
| 2013-06-30 |  | -0.538846 | NaN       |
| 2013-07-31 |  | NaN       | 1.000985  |
| 2013-08-31 |  | NaN       | 0.433512  |
| 2013-09-30 |  | NaN       | 0.699535  |
| 2013-10-31 |  | 1.120915  | NaN       |
| 2013-11-30 |  | 0.158248  | NaN       |
| 2013-12-31 |  | 0.588783  | NaN       |

You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```

```
In [63]: print(table.to_string(na_rep=''))
```

|       |   | D         |           | E         |           |
|-------|---|-----------|-----------|-----------|-----------|
| C     |   | bar       | foo       | bar       | foo       |
| one   | A | 1.120915  | -0.514058 | 1.393057  | -0.021605 |
|       | B | -0.338421 | 0.002759  | 0.684140  | -0.551692 |
|       | C | -0.538846 | 0.699535  | -0.988442 | 0.747859  |
| three | A | -1.181568 |           | 0.961289  |           |
|       | B |           | 0.433512  |           | -1.064372 |
|       | C | 0.588783  |           | -0.131830 |           |
| two   | A |           | 1.000985  |           | 0.064245  |
|       | B | 0.158248  |           | -0.097147 |           |
|       | C |           | 0.176180  |           | 0.436241  |

Note that `pivot_table` is also available as an instance method on `DataFrame`, i.e. `DataFrame.pivot_table()`.

*DataFrame.*

### 18.5.1 Adding margins

If you pass `margins=True` to `pivot_table`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
Out [64]:
```

|       |   | D        |          |          | E        |          |          |
|-------|---|----------|----------|----------|----------|----------|----------|
| C     |   | bar      | foo      | All      | bar      | foo      | All      |
| one   | A | 1.804346 | 1.210272 | 1.569879 | 0.179483 | 0.418374 | 0.858005 |
|       | B | 0.690376 | 1.353355 | 0.898998 | 1.083825 | 0.968138 | 1.101401 |
|       | C | 0.273641 | 0.418926 | 0.771139 | 1.689271 | 0.446140 | 1.422136 |
| three | A | 0.794212 | NaN      | 0.794212 | 2.049040 | NaN      | 2.049040 |
|       | B | NaN      | 0.363548 | 0.363548 | NaN      | 1.625237 | 1.625237 |
|       | C | 3.915454 | NaN      | 3.915454 | 1.035215 | NaN      | 1.035215 |
| two   | A | NaN      | 0.442998 | 0.442998 | NaN      | 0.447104 | 0.447104 |
|       | B | 0.202765 | NaN      | 0.202765 | 0.560757 | NaN      | 0.560757 |
|       | C | NaN      | 1.819408 | 1.819408 | NaN      | 0.650439 | 0.650439 |
| All   |   | 1.556686 | 0.952552 | 1.246608 | 1.250924 | 0.899904 | 1.059389 |

## 18.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments

- `index`: array-like, values to group by in the rows.
- `columns`: array-like, values to group by in the columns.
- `values`: array-like, optional, array of values to aggregate according to the factors.
- `aggfunc`: function, optional, If no values array is passed, computes a frequency table.
- `rownames`: sequence, default `None`, must match number of row arrays passed.
- `colnames`: sequence, default `None`, if passed, must match number of column arrays passed.
- `margins`: boolean, default `False`, Add row/column margins (subtotals)
- `normalize`: boolean, {'all', 'index', 'columns'}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any `Series` passed will have their name attributes used unless row or column names for the cross-tabulation are specified

For example:

```
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'

In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)

In [67]: b = np.array([one, one, two, one, two, one], dtype=object)

In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)

In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```

(continues on next page)

(continued from previous page)

```
Out [69]:
b      one      two
c  dull shiny dull shiny
a
bar      1      0      0      1
foo      2      1      1      0
```

If `crosstab` receives only two Series, it will provide a frequency table.

```
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4],
.....:                    'C': [1, 1, np.nan, 1, 1]})
.....:
```

```
In [71]: df
```

```
Out [71]:
   A  B    C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
4  2  4  1.0
```

```
In [72]: pd.crosstab(df.A, df.B)
```

```
Out [72]:
B  3  4
A
1  1  0
2  1  3
```

Any input passed containing Categorical data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

```
In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
```

```
In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
```

```
In [75]: pd.crosstab(foo, bar)
```

```
Out [75]:
col_0  d  e
row_0
a      1  0
b      0  1
```

## 18.6.1 Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```
In [76]: pd.crosstab(df.A, df.B, normalize=True)
```

```
Out [76]:
B      3      4
A
1  0.2  0.0
2  0.2  0.6
```

`normalize` can also normalize values within each row or within each column:

```
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out[77]:
B      3      4
A
1    0.5    0.0
2    0.5    1.0
```

`crosstab` can also be passed a third Series and an aggregation function (`aggfunc`) that will be applied to the values of the third Series within each group defined by the first two Series:

```
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out[78]:
B      3      4
A
1    1.0    NaN
2    1.0    2.0
```

## 18.6.2 Adding Margins

Finally, one can also add margins or normalize this output.

```
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True,
.....:               margins=True)
Out[79]:
B      3      4    All
A
1    0.25  0.0  0.25
2    0.25  0.5  0.75
All  0.50  0.5  1.00
```

## 18.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])

In [81]: pd.cut(ages, bins=3)
Out[81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.
→95, 26.667], (26.667, 43.333], (43.333, 60.0], (43.333, 60.0]]
Categories (3, interval[float64]): [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.
→0]]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])

In [83]: c
Out[83]:
```

(continues on next page)

(continued from previous page)

```
[ (0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70] ]
Categories (3, interval[int64]): [(0, 18] < (18, 35] < (35, 70]]
```

## New in version 0.20.0.

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data.:

```
pd.cut([25, 20, 50], bins=c.categories)
```

## 18.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has k distinct values, can derive a DataFrame containing k columns of 1s and 0s using `get_dummies()`:

```
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})
```

```
In [85]: pd.get_dummies(df['key'])
```

Out [85] :

|   | a | b | c |
|---|---|---|---|
| 0 | 0 | 1 | 0 |
| 1 | 0 | 1 | 0 |
| 2 | 1 | 0 | 0 |
| 3 | 0 | 0 | 1 |
| 4 | 1 | 0 | 0 |
| 5 | 0 | 1 | 0 |

Sometimes it's useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')
```

```
In [87]: dummies
```

Out [87] :

|   | key_a | key_b | key_c |
|---|-------|-------|-------|
| 0 | 0     | 1     | 0     |
| 1 | 0     | 1     | 0     |
| 2 | 1     | 0     | 0     |
| 3 | 0     | 0     | 1     |
| 4 | 1     | 0     | 0     |
| 5 | 0     | 1     | 0     |

```
In [88]: df[['data1']].join(dummies)
```

|   | data1 | key_a | key_b | key_c |
|---|-------|-------|-------|-------|
| 0 | 0     | 0     | 1     | 0     |
| 1 | 1     | 0     | 1     | 0     |
| 2 | 2     | 1     | 0     | 0     |
| 3 | 3     | 0     | 0     | 1     |
| 4 | 4     | 1     | 0     | 0     |
| 5 | 5     | 0     | 1     | 0     |

This function is often used along with discretization functions like `cut`:

```
In [89]: values = np.random.randn(10)

In [90]: values
Out[90]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29   ,
        0.0824, -0.0558,  0.5366])

In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]

In [92]: pd.get_dummies(pd.cut(values, bins))
Out[92]:
```

|   | (0.0, 0.2] | (0.2, 0.4] | (0.4, 0.6] | (0.6, 0.8] | (0.8, 1.0] |
|---|------------|------------|------------|------------|------------|
| 0 | 0          | 0          | 1          | 0          | 0          |
| 1 | 0          | 0          | 0          | 0          | 0          |
| 2 | 0          | 0          | 0          | 0          | 0          |
| 3 | 0          | 0          | 0          | 0          | 0          |
| 4 | 1          | 0          | 0          | 0          | 0          |
| 5 | 0          | 0          | 0          | 0          | 0          |
| 6 | 0          | 0          | 0          | 0          | 0          |
| 7 | 1          | 0          | 0          | 0          | 0          |
| 8 | 0          | 0          | 0          | 0          | 0          |
| 9 | 0          | 0          | 1          | 0          | 0          |

See also `Series.str.get_dummies`.

`get_dummies()` also accepts a `DataFrame`. By default all categorical variables (categorical in the statistical sense, those with `object` or `categorical` dtype) are encoded as dummy variables.

```
In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
.....:                    'C': [1, 2, 3]})
.....:

In [94]: pd.get_dummies(df)
Out[94]:
```

|   | C | A_a | A_b | B_b | B_c |
|---|---|-----|-----|-----|-----|
| 0 | 1 | 1   | 0   | 0   | 1   |
| 1 | 2 | 0   | 1   | 0   | 1   |
| 2 | 3 | 1   | 0   | 1   | 0   |

All non-object columns are included untouched in the output. You can control the columns that are encoded with the `columns` keyword.

```
In [95]: pd.get_dummies(df, columns=['A'])
Out[95]:
```

|   | B | C | A_a | A_b |
|---|---|---|-----|-----|
| 0 | c | 1 | 1   | 0   |
| 1 | c | 2 | 0   | 1   |
| 2 | b | 3 | 1   | 0   |

Notice that the `B` column is still included in the output, it just hasn't been encoded. You can drop `B` before calling `get_dummies` if you don't want to include it in the output.

As with the `Series` version, you can pass values for the `prefix` and `prefix_sep`. By default the column name is used as the prefix, and `'_'` as the prefix separator. You can specify `prefix` and `prefix_sep` in 3 ways:

- string: Use the same value for `prefix` or `prefix_sep` for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')

In [97]: simple
Out[97]:
```

|   | C | new_prefix_a | new_prefix_b | new_prefix_b | new_prefix_c |
|---|---|--------------|--------------|--------------|--------------|
| 0 | 1 | 1            | 0            | 0            | 1            |
| 1 | 2 | 0            | 1            | 0            | 1            |
| 2 | 3 | 1            | 0            | 1            | 0            |

```
In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])

In [99]: from_list
Out[99]:
```

|   | C | from_A_a | from_A_b | from_B_b | from_B_c |
|---|---|----------|----------|----------|----------|
| 0 | 1 | 1        | 0        | 0        | 1        |
| 1 | 2 | 0        | 1        | 0        | 1        |
| 2 | 3 | 1        | 0        | 1        | 0        |

```
In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})

In [101]: from_dict
Out[101]:
```

|   | C | from_A_a | from_A_b | from_B_b | from_B_c |
|---|---|----------|----------|----------|----------|
| 0 | 1 | 1        | 0        | 0        | 1        |
| 1 | 2 | 0        | 1        | 0        | 1        |
| 2 | 3 | 1        | 0        | 1        | 0        |

New in version 0.18.0.

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```
In [102]: s = pd.Series(list('abcaa'))

In [103]: pd.get_dummies(s)
Out[103]:
```

|   | a | b | c |
|---|---|---|---|
| 0 | 1 | 0 | 0 |
| 1 | 0 | 1 | 0 |
| 2 | 0 | 0 | 1 |
| 3 | 1 | 0 | 0 |
| 4 | 1 | 0 | 0 |

```
In [104]: pd.get_dummies(s, drop_first=True)
Out[104]:
```

|   | b | c |
|---|---|---|
| 0 | 0 | 0 |
| 1 | 1 | 0 |
| 2 | 0 | 1 |
| 3 | 0 | 0 |
| 4 | 0 | 0 |

When a column contains only one level, it will be omitted in the result.

```
In [105]: df = pd.DataFrame({'A':list('aaaaa'), 'B':list('ababc')})

In [106]: pd.get_dummies(df)
```

(continues on next page)

(continued from previous page)

**Out [106]:**

|   | A_a | B_a | B_b | B_c |
|---|-----|-----|-----|-----|
| 0 | 1   | 1   | 0   | 0   |
| 1 | 1   | 0   | 1   | 0   |
| 2 | 1   | 1   | 0   | 0   |
| 3 | 1   | 0   | 1   | 0   |
| 4 | 1   | 0   | 0   | 1   |

**In [107]:** `pd.get_dummies(df, drop_first=True)`

```

////////////////////////////////////
→
   B_b  B_c
0    0    0
1    1    0
2    0    0
3    1    0
4    0    1

```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the “dtype” argument:

**In [108]:** `df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})`**In [109]:** `pd.get_dummies(df, dtype=bool).dtypes`**Out [109]:**

```

B          float64
A_a         bool
A_b         bool
A_c         bool
dtype: object

```

New in version 0.23.0.

## 18.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

**In [110]:** `x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])`**In [111]:** `x`**Out [111]:**

```

0      A
1      A
2    NaN
3      B
4    3.14
5     inf
dtype: object

```

**In [112]:** `labels, uniques = pd.factorize(x)`**In [113]:** `labels`**Out [113]:** `array([ 0, 0, -1, 1, 2, 3])`**In [114]:** `uniques`

(continues on next page)

(continued from previous page)

```
Out[114]: Index(['A', 'B', 3.14, inf],  
dtype='object')
```

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

**Note:** The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also [here](#).

```
In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2,  2, -1,  3,  0,  1]),
 Index([3.14, inf, u'A', u'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]: (array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))
```

**Note:** If you just want to handle one column as a categorical variable (like R's factor), you can use `df["cat_col"] = pd.Categorical(df["col"])` or `df["cat_col"] = df["col"].astype("category")`. For full docs on *Categorical*, see the *Categorical introduction* and the *API documentation*.

## TIME SERIES / DATE FUNCTIONALITY

pandas has proven very successful as a tool for working with time series data, especially in the financial data analysis space. Using the NumPy `datetime64` and `timedelta64` dtypes, we have consolidated a large number of features from other Python libraries like `scikits.timeseries` as well as created a tremendous amount of new functionality for manipulating time series data.

In working with time series data, we will frequently seek to:

- generate sequences of fixed-frequency dates and time spans
- conform or convert time series to a particular frequency
- compute “relative” dates based on various non-standard time increments (e.g. 5 business days before the last business day of the year), or “roll” dates forward or backward

pandas provides a relatively compact and self-contained set of tools for performing the above tasks.

Create a range of dates:

```
# 72 hours starting with midnight Jan 1st, 2011
In [1]: rng = pd.date_range('1/1/2011', periods=72, freq='H')

In [2]: rng[:5]
Out[2]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 01:00:00',
               '2011-01-01 02:00:00', '2011-01-01 03:00:00',
               '2011-01-01 04:00:00'],
              dtype='datetime64[ns]', freq='H')
```

Index pandas objects with dates:

```
In [3]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [4]: ts.head()
Out[4]:
2011-01-01 00:00:00    0.469112
2011-01-01 01:00:00   -0.282863
2011-01-01 02:00:00   -1.509059
2011-01-01 03:00:00   -1.135632
2011-01-01 04:00:00    1.212112
Freq: H, dtype: float64
```

Change frequency and fill gaps:

```
# to 45 minute frequency and forward fill
In [5]: converted = ts.asfreq('45Min', method='pad')
```

(continues on next page)

(continued from previous page)

```
In [6]: converted.head()
Out [6]:
2011-01-01 00:00:00    0.469112
2011-01-01 00:45:00    0.469112
2011-01-01 01:30:00   -0.282863
2011-01-01 02:15:00   -1.509059
2011-01-01 03:00:00   -1.135632
Freq: 45T, dtype: float64
```

Resample the series to a daily frequency:

```
# Daily means
In [7]: ts.resample('D').mean()
Out [7]:
2011-01-01    -0.319569
2011-01-02    -0.337703
2011-01-03     0.117258
Freq: D, dtype: float64
```

## 19.1 Overview

The following table shows the type of time-related classes pandas can handle and how to create them.

| Class         | Remarks                        | How to create                                       |
|---------------|--------------------------------|---|
| Timestamp     | Represents a single times-tamp | to_datetime, Timestamp                              |
| DatetimeIndex | Index of Timestamp             | to_datetime, date_range, bdate_range, DatetimeIndex |
| Period        | Represents a single time span  | Period  |
| PeriodIndex   | Index of Period                | period_range, PeriodIndex                           |

## 19.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```
In [8]: pd.Timestamp(datetime(2012, 5, 1))
Out [8]: Timestamp('2012-05-01 00:00:00')

In [9]: pd.Timestamp('2012-05-01')
Out [9]: Timestamp('2012-05-01 00:00:00')

In [10]: pd.Timestamp(2012, 5, 1)
Out [10]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:

```
In [11]: pd.Period('2011-01')
Out[11]: Period('2011-01', 'M')

In [12]: pd.Period('2012-05', freq='D')
Out[12]: Period('2012-05-01', 'D')
```

*Timestamp* and *Period* can serve as an index. Lists of *Timestamp* and *Period* are automatically coerced to *DatetimeIndex* and *PeriodIndex* respectively.

```
In [13]: dates = [pd.Timestamp('2012-05-01'), pd.Timestamp('2012-05-02'), pd.
↳Timestamp('2012-05-03')]

In [14]: ts = pd.Series(np.random.randn(3), dates)

In [15]: type(ts.index)
Out[15]: pandas.core.indexes.datetimes.DatetimeIndex

In [16]: ts.index
Out[16]: DatetimeIndex(['2012-05-
↳01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [17]: ts
Out[17]:
2012-05-01    -0.410001
2012-05-02    -0.078638
2012-05-03     0.545952
dtype: float64

In [18]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]

In [19]: ts = pd.Series(np.random.randn(3), periods)

In [20]: type(ts.index)
Out[20]: pandas.core.indexes.period.PeriodIndex

In [21]: ts.index
Out[21]: PeriodIndex(['2012-01',
↳'2012-02', '2012-03'], dtype='period[M]', freq='M')

In [22]: ts
Out[22]:
2012-01    -1.219217
2012-02    -1.226825
2012-03     0.769804
Freq: M, dtype: float64
```

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of *Timestamp* and sequences of timestamps using instances of *DatetimeIndex*. For regular time spans, pandas uses *Period* objects for scalar values and *PeriodIndex* for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

## 19.3 Converting to Timestamps

To convert a *Series* or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a *Series*, this returns a *Series* (with the same index), while a list-like is converted to a *DatetimeIndex*:

```
In [23]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[23]:
0    2009-07-31
1    2010-01-10
2         NaT
dtype: datetime64[ns]

In [24]: pd.to_datetime(['2005/11/23', '2010.12.31'])
Out[24]:
DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [25]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[25]: DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)

In [26]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
Out[26]:
DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

**Warning:** You see in the above example that `dayfirst` isn't strict, so if a date can't be parsed with the day being first it will be parsed as if `dayfirst` were `False`.

If you pass a single string to `to_datetime`, it returns a single *Timestamp*. *Timestamp* can also accept string input, but it doesn't accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [27]: pd.to_datetime('2010/11/12')
Out[27]: Timestamp('2010-11-12 00:00:00')

In [28]: pd.Timestamp('2010/11/12')
Out[28]: Timestamp('2010-11-12 00:00:00')
```

### 19.3.1 Providing a Format Argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [29]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[29]: Timestamp('2010-11-12 00:00:00')

In [30]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
Out[30]: Timestamp('2010-11-12 00:00:00')
```

For more information on the choices available when specifying the `format` option, see the [Python datetime documentation](#).

### 19.3.2 Assembling Datetime from Multiple DataFrame Columns

New in version 0.18.1.

You can also pass a `DataFrame` of integer or string columns to assemble into a `Series` of `Timestamps`.

```
In [31]: df = pd.DataFrame({'year': [2015, 2016],
.....:                    'month': [2, 3],
.....:                    'day': [4, 5],
.....:                    'hour': [2, 3]})
.....:
```

```
In [32]: pd.to_datetime(df)
```

```
Out[32]:
0    2015-02-04 02:00:00
1    2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
```

```
Out[33]:
0    2015-02-04
1    2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- required: year, month, day
- optional: hour, minute, second, millisecond, microsecond, nanosecond

### 19.3.3 Invalid Data

The default behavior, `errors='raise'`, is to raise when unparseable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparseable:

```
In [34]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[34]: array(['2009/07/31', 'asd'], dtype=object)
```

Pass `errors='coerce'` to convert unparseable data to `NaT` (not a time):

```
In [35]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[35]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

### 19.3.4 Epoch Timestamps

pandas supports converting integer or float epoch times to `Timestamp` and `DatetimeIndex`. The default unit is nanoseconds, since that is how `Timestamp` objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.

```
In [36]: pd.to_datetime([1349720105, 1349806505, 1349892905,
.....:                  1349979305, 1350065705], unit='s')
.....:

Out[36]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
              '2012-10-10 18:15:05', '2012-10-11 18:15:05',
              '2012-10-12 18:15:05'],
              dtype='datetime64[ns]', freq=None)

In [37]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300,
.....:                  1349720105400, 1349720105500 ], unit='ms')
.....:

#####
↪
DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000',
              '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000',
              '2012-10-08 18:15:05.500000'],
              dtype='datetime64[ns]', freq=None)
```

**Note:** Epoch times will be rounded to the nearest nanosecond.

**Warning:** Conversion of float epoch times can lead to inaccurate and unexpected results. `Python floats` have about 15 digits precision in decimal. Rounding during conversion from float to high precision `Timestamp` is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an `int64`).

[illegible]

**See also:**

### Using the origin Parameter

### 19.3.5 From Timestamps to Epoch

To invert the operation from above, namely, to convert from a `Timestamp` to a ‘unix’ epoch:

```
In [40]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [41]: stamps
Out[41]:
DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05',
              '2012-10-10 18:15:05', '2012-10-11 18:15:05'],
              dtype='datetime64[ns]', freq='D')
```

We subtract the epoch (midnight at January 1, 1970 UTC) and then floor divide by the “unit” (1 second).

```
In [42]: (stamps - pd.Timestamp("1970-01-01")) // pd.Timedelta('1s')
Out[42]: Int64Index([1349720105, 1349806505, 1349892905, 1349979305], dtype='int64')
```

### 19.3.6 Using the `origin` Parameter

New in version 0.20.0.

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```
In [43]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[43]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```
In [44]: pd.to_datetime([1, 2, 3], unit='D')
Out[44]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype=
↳ 'datetime64[ns]', freq=None)
```

## 19.4 Generating Ranges of Timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```
In [45]: dates = [datetime(2012, 5, 1), datetime(2012, 5, 2), datetime(2012, 5, 3)]

# Note the frequency information
In [46]: index = pd.DatetimeIndex(dates)

In [47]: index
Out[47]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↳ 'datetime64[ns]', freq=None)

# Automatically converted to DatetimeIndex
In [48]: index = pd.Index(dates)

In [49]: index
Out[49]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype=
↳ 'datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a **calendar day** while the default for `bdate_range` is a **business day**:

```
In [50]: start = datetime(2011, 1, 1)

In [51]: end = datetime(2012, 1, 1)

In [52]: index = pd.date_range(start, end)

In [53]: index
Out[53]:
DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03', '2011-01-04',
                '2011-01-05', '2011-01-06', '2011-01-07', '2011-01-08',
                '2011-01-09', '2011-01-10',
```

(continues on next page)

(continued from previous page)

```

...
'2011-12-23', '2011-12-24', '2011-12-25', '2011-12-26',
'2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30',
'2011-12-31', '2012-01-01'],
dtype='datetime64[ns]', length=366, freq='D')

In [54]: index = pd.bdate_range(start, end)

In [55]: index
Out[55]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
               '2011-01-13', '2011-01-14',
               ...
               '2011-12-19', '2011-12-20', '2011-12-21', '2011-12-22',
               '2011-12-23', '2011-12-26', '2011-12-27', '2011-12-28',
               '2011-12-29', '2011-12-30'],
              dtype='datetime64[ns]', length=260, freq='B')

```

Convenience functions like `date_range` and `bdate_range` can utilize a variety of *frequency aliases*:

```

In [56]: pd.date_range(start, periods=1000, freq='M')
Out[56]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-30',
               '2011-05-31', '2011-06-30', '2011-07-31', '2011-08-31',
               '2011-09-30', '2011-10-31',
               ...
               '2093-07-31', '2093-08-31', '2093-09-30', '2093-10-31',
               '2093-11-30', '2093-12-31', '2094-01-31', '2094-02-28',
               '2094-03-31', '2094-04-30'],
              dtype='datetime64[ns]', length=1000, freq='M')

In [57]: pd.bdate_range(start, periods=250, freq='BQS')
↪
DatetimeIndex(['2011-01-03', '2011-04-01', '2011-07-01', '2011-10-03',
               '2012-01-02', '2012-04-02', '2012-07-02', '2012-10-01',
               '2013-01-01', '2013-04-01',
               ...
               '2071-01-01', '2071-04-01', '2071-07-01', '2071-10-01',
               '2072-01-01', '2072-04-01', '2072-07-01', '2072-10-03',
               '2073-01-02', '2073-04-03'],
              dtype='datetime64[ns]', length=250, freq='BQS-JAN')

```

`date_range` and `bdate_range` make it easy to generate a range of dates using various combinations of parameters like `start`, `end`, `periods`, and `freq`. The start and end dates are strictly inclusive, so dates outside of those specified will not be generated:

```

In [58]: pd.date_range(start, end, freq='BM')
Out[58]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')

In [59]: pd.date_range(start, end, freq='W')

```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
DatetimeIndex(['2011-01-02', '2011-01-09', '2011-01-16', '2011-01-23',
               '2011-01-30', '2011-02-06', '2011-02-13', '2011-02-20',
               '2011-02-27', '2011-03-06', '2011-03-13', '2011-03-20',
               '2011-03-27', '2011-04-03', '2011-04-10', '2011-04-17',
               '2011-04-24', '2011-05-01', '2011-05-08', '2011-05-15',
               '2011-05-22', '2011-05-29', '2011-06-05', '2011-06-12',
               '2011-06-19', '2011-06-26', '2011-07-03', '2011-07-10',
               '2011-07-17', '2011-07-24', '2011-07-31', '2011-08-07',
               '2011-08-14', '2011-08-21', '2011-08-28', '2011-09-04',
               '2011-09-11', '2011-09-18', '2011-09-25', '2011-10-02',
               '2011-10-09', '2011-10-16', '2011-10-23', '2011-10-30',
               '2011-11-06', '2011-11-13', '2011-11-20', '2011-11-27',
               '2011-12-04', '2011-12-11', '2011-12-18', '2011-12-25',
               '2012-01-01'],
              dtype='datetime64[ns]', freq='W-SUN')

```

```
In [60]: pd.bdate_range(end=end, periods=20)
```

```

////////////////////////////////////
↪
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-12', '2011-12-13', '2011-12-14',
               '2011-12-15', '2011-12-16', '2011-12-19', '2011-12-20',
               '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-26',
               '2011-12-27', '2011-12-28', '2011-12-29', '2011-12-30'],
              dtype='datetime64[ns]', freq='B')

```

```
In [61]: pd.bdate_range(start=start, periods=20)
```

```

////////////////////////////////////
↪
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07', '2011-01-10', '2011-01-11', '2011-01-12',
               '2011-01-13', '2011-01-14', '2011-01-17', '2011-01-18',
               '2011-01-19', '2011-01-20', '2011-01-21', '2011-01-24',
               '2011-01-25', '2011-01-26', '2011-01-27', '2011-01-28'],
              dtype='datetime64[ns]', freq='B')

```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced dates from start to end inclusively, with periods number of elements in the resulting DatetimeIndex:

```
In [62]: pd.date_range('2018-01-01', '2018-01-05', periods=5)
```

```
Out [62]:
```

```

DatetimeIndex(['2018-01-01', '2018-01-02', '2018-01-03', '2018-01-04',
               '2018-01-05'],
              dtype='datetime64[ns]', freq=None)

```

```
In [63]: pd.date_range('2018-01-01', '2018-01-05', periods=10)
```

```

////////////////////////////////////
↪
DatetimeIndex(['2018-01-01 00:00:00', '2018-01-01 10:40:00',

               '2018-01-02 18:40:00', '2018-01-03 05:20:00',
               '2018-01-03 16:00:00', '2018-01-04 02:40:00',
               '2018-01-04 13:20:00', '2018-01-05 00:00:00'],
              dtype='datetime64[ns]', freq=None)

```

(continues on next page)

(continued from previous page)

```
dtype='datetime64[ns]', freq=None)
```

## 19.4.1 Custom Frequency Ranges

**Warning:** This functionality was originally exclusive to `cdate_range`, which is deprecated as of version 0.21.0 in favor of `bdate_range`. Note that `cdate_range` only utilizes the `weekmask` and `holidays` parameters when custom business day, 'C', is passed as the frequency string. Support has been expanded with `bdate_range` to work with any custom frequency string.

New in version 0.21.0.

`bdate_range` can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```
In [64]: weekmask = 'Mon Wed Fri'

In [65]: holidays = [datetime(2011, 1, 5), datetime(2011, 3, 14)]

In [66]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out [66]:
DatetimeIndex(['2011-01-03', '2011-01-07', '2011-01-10', '2011-01-12',
               '2011-01-14', '2011-01-17', '2011-01-19', '2011-01-21',

## 19.5 Timestamp Limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```
In [68]: pd.Timestamp.min
Out [68]: Timestamp('1677-09-21 00:12:43.145225')

In [69]: pd.Timestamp.max
Out [69]: Timestamp('2262-04-11 23:47:16.854775807')
```

(continues on next page)

(continued from previous page)

**See also:***Representing Out-of-Bounds Spans*

## 19.6 Indexing

One of the main uses for `DatetimeIndex` is as an index for pandas objects. The `DatetimeIndex` class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

**See also:***Reindexing methods*

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```
In [70]: rng = pd.date_range(start, end, freq='BM')

In [71]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [72]: ts.index
Out[72]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31', '2011-06-30', '2011-07-29', '2011-08-31',
               '2011-09-30', '2011-10-31', '2011-11-30', '2011-12-30'],
              dtype='datetime64[ns]', freq='BM')

In [73]: ts[:5].index
Out[73]:
DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31', '2011-04-29',
               '2011-05-31'],
              dtype='datetime64[ns]', freq='BM')

In [74]: ts[::2].index
Out[74]:
DatetimeIndex(['2011-01-31', '2011-03-31', '2011-05-31', '2011-07-29',
               '2011-09-30', '2011-11-30'],
              dtype='datetime64[ns]', freq='BMS')
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2011-01-31', '2011-03-31', '2011-05-31', '2011-07-29',
               '2011-09-30', '2011-11-30'],
              dtype='datetime64[ns]', freq='2BM')
```

## 19.6.1 Partial String Indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```
In [75]: ts['1/31/2011']
Out[75]: -1.2812473076599531

In [76]: ts[datetime(2011, 12, 25):]
Out[76]:
2011-12-30    0.687738
Freq: BM, dtype: float64

In [77]: ts['10/31/2011':'12/31/2011']
Out[77]:
2011-10-31    0.149748
2011-11-30   -0.732339
2011-12-30    0.687738
Freq: BM, dtype: float64
```

To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [78]: ts['2011']
Out[78]:
2011-01-31   -1.281247
2011-02-28   -0.727707
2011-03-31   -0.121306
2011-04-29   -0.097883
2011-05-31    0.695775
2011-06-30    0.341734
2011-07-29    0.959726
2011-08-31   -1.110336
2011-09-30   -0.619976
2011-10-31    0.149748
2011-11-30   -0.732339
2011-12-30    0.687738
Freq: BM, dtype: float64

In [79]: ts['2011-6']
Out[79]:
2011-06-30    0.341734
Freq: BM, dtype: float64
```

This type of slicing will work on a `DataFrame` with a `DatetimeIndex` as well. Since the partial string selection is a form of label slicing, the endpoints **will be** included. This would include matching times on an included date:

```
In [80]: dft = pd.DataFrame(randn(100000, 1),
.....:                      columns=['A'],
.....:                      index=pd.date_range('20130101', periods=100000, freq='T'))
```

(continues on next page)

(continued from previous page)

**In [81]:** dft**Out [81]:**

```

[751 rows x 1 columns]
```

New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [87]: dft2 = pd.DataFrame(np.random.randn(20, 1),
    ....:                    columns=['A'],
    ....:                    index=pd.MultiIndex.from_product([pd.date_range('20130101',
↳ ',
    ....:
↳ periods=10,
    ....:
    ....:                    freq='12H
↳ '),
    ....:                    ['a', 'b']]))
    ....:
```

```
In [88]: dft2
Out[88]:
```

```

          A

## 19.6.2 Slice vs. Exact Match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```

In [93]: series_minute = pd.Series([1, 2, 3],
.....:                             pd.DatetimeIndex(['2011-12-31 23:59:00',
.....:                                                  '2012-01-01 00:00:00',
.....:                                                  '2012-01-01 00:02:00']))
.....:

In [94]: series_minute.index.resolution
Out[94]: 'minute'

```

A timestamp string less accurate than a minute gives a `Series` object.

```

In [95]: series_minute['2011-12-31 23']
Out[95]:
2011-12-31 23:59:00    1
dtype: int64

```

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```

In [96]: series_minute['2011-12-31 23:59']
Out[96]: 1

In [97]: series_minute['2011-12-31 23:59:00']
Out[97]: 1

```

If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```
In [98]: series_second = pd.Series([1, 2, 3],
.....:                             pd.DatetimeIndex(['2011-12-31 23:59:59',
.....:                                                  '2012-01-01 00:00:00',
.....:                                                  '2012-01-01 00:00:01']))
.....:

In [99]: series_second.index.resolution
Out[99]: 'second'

In [100]: series_second['2011-12-31 23:59']
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[100]:
2011-12-31 23:59:59      1
dtype: int64
```

If the timestamp string is treated as a slice, it can be used to index DataFrame with `[]` as well.

```
In [101]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
.....:                               index=series_minute.index)
.....:

In [102]: dft_minute['2011-12-31 23']
Out[102]:
```

|                     | a | b |
|---------------------|---|---|
| 2011-12-31 23:59:00 | 1 | 4 |

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame's `[]` will be column-wise and not row-wise, see [Indexing Basics](#). For example `dft_minute['2011-12-31 23:59']` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```
In [103]: dft_minute.loc['2011-12-31 23:59']
Out[103]:
```

|                     | a | b |
|---------------------|---|---|
| 2011-12-31 23:59:00 | 1 | 4 |

Name: 2011-12-31 23:59:00, dtype: int64

Note also that `DatetimeIndex` resolution cannot be less precise than day.

```
In [104]: series_monthly = pd.Series([1, 2, 3],
.....:                               pd.DatetimeIndex(['2011-12',
.....:                                                  '2012-01',
.....:                                                  '2012-02']))
.....:

In [105]: series_monthly.index.resolution
Out[105]: 'day'

In [106]: series_monthly['2011-12'] # returns Series
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[106]:
2011-12-01      1
dtype: int64
```

### 19.6.3 Exact Indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of *including both endpoints*.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
In [107]: dft[datetime(2013, 1, 1):datetime(2013,2,28)]
Out[107]:
```

|                     | A         |
|---------------------|-----------|
| 2013-01-01 00:00:00 | 0.176444  |
| 2013-01-01 00:01:00 | 0.403310  |
| 2013-01-01 00:02:00 | -0.154951 |
| 2013-01-01 00:03:00 | 0.301624  |
| 2013-01-01 00:04:00 | -2.179861 |
| 2013-01-01 00:05:00 | -1.369849 |
| 2013-01-01 00:06:00 | -0.954208 |
| ...                 | ...       |
| 2013-02-27 23:54:00 | 0.897051  |
| 2013-02-27 23:55:00 | -0.309230 |
| 2013-02-27 23:56:00 | 1.944713  |
| 2013-02-27 23:57:00 | 0.369265  |
| 2013-02-27 23:58:00 | 0.053071  |
| 2013-02-27 23:59:00 | -0.019734 |
| 2013-02-28 00:00:00 | 1.388189  |

[83521 rows x 1 columns]

With no defaults.

```
In [108]: dft[datetime(2013, 1, 1, 10, 12, 0):datetime(2013, 2, 28, 10, 12, 0)]
Out[108]:
```

|                     | A         |
|---------------------|-----------|
| 2013-01-01 10:12:00 | -0.246733 |
| 2013-01-01 10:13:00 | -1.429225 |
| 2013-01-01 10:14:00 | -1.265339 |
| 2013-01-01 10:15:00 | 0.710986  |
| 2013-01-01 10:16:00 | -0.818200 |
| 2013-01-01 10:17:00 | 0.543542  |
| 2013-01-01 10:18:00 | 1.577713  |
| ...                 | ...       |
| 2013-02-28 10:06:00 | 0.311249  |
| 2013-02-28 10:07:00 | 2.366080  |
| 2013-02-28 10:08:00 | -0.490372 |
| 2013-02-28 10:09:00 | 0.373340  |
| 2013-02-28 10:10:00 | 0.638442  |
| 2013-02-28 10:11:00 | 1.330135  |
| 2013-02-28 10:12:00 | -0.945450 |

[83521 rows x 1 columns]

## 19.6.4 Truncating & Fancy Indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [109]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
```

```
In [110]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
```

```
In [111]: ts2.truncate(before='2011-11', after='2011-12')
```

```
Out[111]:
```

```
2011-11-06    -0.773743
2011-11-13     0.247216
2011-11-20     0.591308
2011-11-27     2.228500
Freq: W-SUN, dtype: float64
```

```
In [112]: ts2['2011-11':'2011-12']
```

```
////////////////////////////////////
```

```
↪
2011-11-06    -0.773743
2011-11-13     0.247216
2011-11-20     0.591308
2011-11-27     2.228500
2011-12-04     0.838769
2011-12-11     0.658538
2011-12-18     0.567353
2011-12-25    -1.076735
Freq: W-SUN, dtype: float64
```

Even complicated fancy indexing that breaks the `DatetimeIndex` frequency regularity will result in a `DatetimeIndex`, although frequency is lost:

```
In [113]: ts2[[0, 2, 6]].index
```

```
Out[113]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype=
↪ 'datetime64[ns]', freq=None)
```

## 19.7 Time/Date Components

There are several time/date properties that one can access from `Timestamp` or a collection of timestamps like a `DatetimeIndex`.

| Property         | Description   |
|------------------|---|
| year             | The year of the datetime  |
| month            | The month of the datetime   |
| day              | The days of the datetime  |
| hour             | The hour of the datetime  |
| minute           | The minutes of the datetime                                       |
| second           | The seconds of the datetime                                       |
| microsecond      | The microseconds of the datetime                                  |
| nanosecond       | The nanoseconds of the datetime                                   |
| date             | Returns datetime.date (does not contain timezone information)     |
| time             | Returns datetime.time (does not contain timezone information)     |
| dayofyear        | The ordinal day of year   |
| weekofyear       | The week ordinal of the year                                      |
| week             | The week ordinal of the year                                      |
| dayofweek        | The number of the day of the week with Monday=0, Sunday=6         |
| weekday          | The number of the day of the week with Monday=0, Sunday=6         |
| weekday_name     | The name of the day in a week (ex: Friday)                        |
| quarter          | Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.               |
| days_in_month    | The number of days in the month of the datetime                   |
| is_month_start   | Logical indicating if first day of month (defined by frequency)   |
| is_month_end     | Logical indicating if last day of month (defined by frequency)    |
| is_quarter_start | Logical indicating if first day of quarter (defined by frequency) |
| is_quarter_end   | Logical indicating if last day of quarter (defined by frequency)  |
| is_year_start    | Logical indicating if first day of year (defined by frequency)    |
| is_year_end      | Logical indicating if last day of year (defined by frequency)     |
| is_leap_year     | Logical indicating if the date belongs to a leap year             |

Furthermore, if you have a `Series` with datetimelike values, then you can access these properties via the `.dt` accessor, as detailed in the section on [.dt accessors](#).

## 19.8 DateOffset Objects

In the preceding examples, we created `DatetimeIndex` objects at various frequencies by passing in *frequency strings* like ‘M’, ‘W’, and ‘BM’ to the `freq` keyword. Under the hood, these frequency strings are being translated into an instance of `DateOffset`, which represents a regular frequency increment. Specific offset logic like “month”, “business day”, or “one hour” is represented in its various subclasses.

| Class name                   | Description  |
|------------------------------|--|
| <code>DateOffset</code>      | Generic offset class, defaults to 1 calendar day   |
| <code>BDay</code>            | business day (weekday)                             |
| <code>CDay</code>            | custom business day                                |
| <code>Week</code>            | one week, optionally anchored on a day of the week |
| <code>WeekOfMonth</code>     | the x-th day of the y-th week of each month        |
| <code>LastWeekOfMonth</code> | the x-th day of the last week of each month        |
| <code>MonthEnd</code>        | calendar month end                                 |
| <code>MonthBegin</code>      | calendar month begin                               |
| <code>BMonthEnd</code>       | business month end                                 |
| <code>BMonthBegin</code>     | business month begin                               |
| <code>CBMonthEnd</code>      | custom business month end                          |

Continued on next page

Table 1 – continued from previous page

| Class name         | Description   |
|--------------------|---|
| CBMonthBegin       | custom business month begin                           |
| SemiMonthEnd       | 15th (or other day_of_month) and calendar month end   |
| SemiMonthBegin     | 15th (or other day_of_month) and calendar month begin |
| QuarterEnd         | calendar quarter end                                  |
| QuarterBegin       | calendar quarter begin                                |
| BQuarterEnd        | business quarter end                                  |
| BQuarterBegin      | business quarter begin                                |
| FY5253Quarter      | retail (aka 52-53 week) quarter                       |
| YearEnd            | calendar year end                                     |
| YearBegin          | calendar year begin                                   |
| BYearEnd           | business year end                                     |
| BYearBegin         | business year begin                                   |
| FY5253             | retail (aka 52-53 week) year                          |
| BusinessHour       | business hour   |
| CustomBusinessHour | custom business hour                                  |
| Hour               | one hour  |
| Minute             | one minute  |
| Second             | one second  |
| Milli              | one millisecond                                       |
| Micro              | one microsecond                                       |
| Nano               | one nanosecond  |

The basic `DateOffset` takes the same arguments as `dateutil.relativedelta`, which works as follows:

```
In [114]: d = datetime(2008, 8, 18, 9, 0)

In [115]: d + relativedelta(months=4, days=5)
Out[115]: datetime.datetime(2008, 12, 23, 9, 0)
```

We could have done the same thing with `DateOffset`:

```
In [116]: from pandas.tseries.offsets import *

In [117]: d + DateOffset(months=4, days=5)
Out[117]: Timestamp('2008-12-23 09:00:00')
```

The key features of a `DateOffset` object are:

- It can be added / subtracted to/from a datetime object to obtain a shifted date.
- It can be multiplied by an integer (positive or negative) so that the increment will be applied multiple times.
- It has `rollforward()` and `rollback()` methods for moving a date forward or backward to the next or previous “offset date”.

Subclasses of `DateOffset` define the `apply` function which dictates custom date increment logic, such as adding business days:

```
class BDay(DateOffset):
    """DateOffset increments between business days"""
    def apply(self, other):
        ...
```

```
In [118]: d - 5 * BDay()
Out[118]: Timestamp('2008-08-11 09:00:00')

In [119]: d + BMonthEnd()
Out[119]: Timestamp('2008-08-29 09:00:00')
```

The `rollforward` and `rollback` methods do exactly what you would expect:

[illegible]

It's definitely worth exploring the `pandas.tseries.offsets` module and the various docstrings for the classes.

These operations (apply, rollforward and rollback) preserve time (hour, minute, etc) information by default. To reset time, use `normalize=True` when creating the offset instance. If `normalize=True`, the result is normalized after the function is applied.

```
In [124]: day = Day()

In [125]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[125]: Timestamp('2014-01-02 09:00:00')

In [126]: day = Day(normalize=True)

In [127]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[127]: Timestamp('2014-01-02 00:00:00')

In [128]: hour = Hour()

In [129]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[129]: Timestamp('2014-01-01 23:00:00')

In [130]: hour = Hour(normalize=True)

In [131]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[131]: Timestamp('2014-01-01 00:00:00')

In [132]: hour.apply(pd.Timestamp('2014-01-01 23:00'))
Out[132]: Timestamp('2014-01-02 00:00:00')
```

### 19.8.1 Parametric Offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```
In [133]: d
Out[133]: datetime.datetime(2008, 8, 18, 9, 0)
```

(continues on next page)

(continued from previous page)

```

In [134]: d + Week()
Out[134]: Timestamp('2008-08-25 09:00:00')

In [135]: d + Week(weekday=4)
Out[135]: Timestamp('2008-08-22 09:00:00')

In [136]: (d + Week(weekday=4)).weekday()
Out[136]: 4

In [137]: d - Week()
Out[137]: Timestamp('2008-08-11 09:00:00')

```

The `normalize` option will be effective for addition and subtraction.

```

In [138]: d + Week(normalize=True)
Out[138]: Timestamp('2008-08-25 00:00:00')

In [139]: d - Week(normalize=True)
Out[139]: Timestamp('2008-08-11 00:00:00')

```

Another example is parameterizing `YearEnd` with the specific ending month:

```

In [140]: d + YearEnd()
Out[140]: Timestamp('2008-12-31 09:00:00')

In [141]: d + YearEnd(month=6)
Out[141]: Timestamp('2009-06-30 09:00:00')

```

## 19.8.2 Using Offsets with Series / DatetimeIndex

Offsets can be used with either a `Series` or `DatetimeIndex` to apply the offset to each element.

```

In [142]: rng = pd.date_range('2012-01-01', '2012-01-03')

In [143]: s = pd.Series(rng)

In [144]: rng
Out[144]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')

In [145]: rng + DateOffset(months=2)
Out[145]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq='D')

In [146]: s + DateOffset(months=2)
Out[146]:
0    2012-03-01
1    2012-03-02

```

(continues on next page)

(continued from previous page)

```
2    2012-03-03
dtype: datetime64[ns]

In [147]: s - DateOffset(months=2)
//////////
0    2011-11-01
1    2011-11-02
2    2011-11-03
dtype: datetime64[ns]
```

If the offset class maps directly to a `Timedelta` (Day, Hour, Minute, Second, Micro, Milli, Nano) it can be used exactly like a `Timedelta` - see the [Timedelta section](#) for more examples.

```
In [148]: s - Day(2)
Out[148]:
0    2011-12-30
1    2011-12-31
2    2012-01-01
dtype: datetime64[ns]

In [149]: td = s - pd.Series(pd.date_range('2011-12-29', '2011-12-31'))

In [150]: td
Out[150]:
0    3 days
1    3 days
2    3 days
dtype: timedelta64[ns]

In [151]: td + Minute(15)
Out[151]:
0    3 days 00:15:00
1    3 days 00:15:00
2    3 days 00:15:00
dtype: timedelta64[ns]
```

Note that some offsets (such as `BQuarterEnd`) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a `PerformanceWarning`

```
In [152]: rng + BQuarterEnd()
Out[152]: DatetimeIndex(['2012-03-30', '2012-03-30', '2012-03-30'], dtype=
↳ 'datetime64[ns]', freq='D')
```

### 19.8.3 Custom Business Days

The `CDay` or `CustomBusinessDay` class provides a parametric `BusinessDay` class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let's look at Egypt where a Friday-Saturday weekend is observed.

```
In [153]: from pandas.tseries.offsets import CustomBusinessDay

In [154]: weekmask_egypt = 'Sun Mon Tue Wed Thu'
```

(continues on next page)

(continued from previous page)

```
# They also observe International Workers' Day so let's
# add that for a couple of years
In [155]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01')]

In [156]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [157]: dt = datetime(2013, 4, 30)

In [158]: dt + 2 * bday_egypt
Out[158]: Timestamp('2013-05-05 00:00:00')
```

Let's map to the weekday names:

```
In [159]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [160]: pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat Sun'.
↳split()))
Out[160]:
2013-04-30    Tue
2013-05-02    Thu
2013-05-05    Sun
2013-05-06    Mon
2013-05-07    Tue
Freq: C, dtype: object
```

Holiday calendars can be used to provide the list of holidays. See the [holiday calendar](#) section for more information.

```
In [161]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [162]: bday_us = CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [163]: dt = datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [164]: dt + bday_us
Out[164]: Timestamp('2014-01-21 00:00:00')
```

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

```
In [165]: from pandas.tseries.offsets import CustomBusinessMonthBegin

In [166]: bmth_us = CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [167]: dt = datetime(2013, 12, 17)

In [168]: dt + bmth_us
Out[168]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [169]: pd.DatetimeIndex(start='20100101', end='20120101', freq=bmth_us)
Out[169]:
DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
                '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
                '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
                '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01',
```

(continues on next page)

(continued from previous page)

```
'2011-05-02', '2011-06-01', '2011-07-01', '2011-08-01',
'2011-09-01', '2011-10-03', '2011-11-01', '2011-12-01'],
dtype='datetime64[ns]', freq='CBMS')
```

**Note:** The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

## 19.8.4 Business Hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [170]: bh = BusinessHour()

In [171]: bh
Out[171]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [172]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[172]: 4

In [173]: pd.Timestamp('2014-08-01 10:00') + bh
Out[173]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [174]: pd.Timestamp('2014-08-01 08:00') + bh
Out[174]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [175]: pd.Timestamp('2014-08-01 16:00') + bh
Out[175]: Timestamp('2014-08-04 09:00:00')

# Remainings are added to the next day
In [176]: pd.Timestamp('2014-08-01 16:30') + bh
Out[176]: Timestamp('2014-08-04 09:30:00')

# Adding 2 business hours
In [177]: pd.Timestamp('2014-08-01 10:00') + BusinessHour(2)
Out[177]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
```

(continues on next page)

(continued from previous page)

```
In [178]: pd.Timestamp('2014-08-01 10:00') + BusinessHour(-3)
\\Out[178]: Timestamp('2014-07-31 15:00:00')
```

You can also specify start and end time by keywords. The argument must be a `str` with an `hour:minute` representation or a `datetime.time` instance. Specifying seconds, microseconds and nanoseconds as business hour results in `ValueError`.

```
In [179]: bh = BusinessHour(start='11:00', end=time(20, 0))

In [180]: bh
Out[180]: <BusinessHour: BH=11:00-20:00>

In [181]: pd.Timestamp('2014-08-01 13:00') + bh
\\Out[181]: Timestamp('2014-08-01 14:00:00')

In [182]: pd.Timestamp('2014-08-01 09:00') + bh
\\Out[182]: Timestamp('2014-08-01 12:00:00')

In [183]: pd.Timestamp('2014-08-01 18:00') + bh
\\Out[183]: Timestamp('2014-08-01 19:00:00')
```

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid `BusinessDay`.

```
In [184]: bh = BusinessHour(start='17:00', end='09:00')

In [185]: bh
Out[185]: <BusinessHour: BH=17:00-09:00>

In [186]: pd.Timestamp('2014-08-01 17:00') + bh
\\Out[186]: Timestamp('2014-08-01 18:00:00')

In [187]: pd.Timestamp('2014-08-01 23:00') + bh
\\Out[187]: Timestamp('2014-08-02 00:00:00')

# Although 2014-08-02 is Saturday,
# it is valid because it starts from 08-01 (Friday).
In [188]: pd.Timestamp('2014-08-02 04:00') + bh
\\Out[188]: Timestamp('2014-08-02 05:00:00')

# Although 2014-08-04 is Monday,
# it is out of business hours because it starts from 08-03 (Sunday).
In [189]: pd.Timestamp('2014-08-04 04:00') + bh
\\Out[189]: Timestamp('2014-08-04 18:00:00')
```

Applying `BusinessHour.rollforward` and `rollback` to out of business hours results in the next business hour start or previous day's end. Different from other offsets, `BusinessHour.rollforward` may output different results from apply by definition.

This is because one day's business hour end is equal to next day's business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04

09:00.

```
# This adjusts a Timestamp to business hour edge
In [190]: BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[190]: Timestamp('2014-08-01 17:00:00')

In [191]: BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
\\Out[191]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [192]: BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
\\Out[192]:
↪Timestamp('2014-08-04 10:00:00')

# BusinessDay results (for reference)
In [193]: BusinessHour().rollforward(pd.Timestamp('2014-08-02'))
\\
↪Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessDay().apply(pd.Timestamp('2014-08-01'))
# The result is the same as rollforward because BusinessDay never overlap.
In [194]: BusinessHour().apply(pd.Timestamp('2014-08-02'))
\\
↪Timestamp('2014-08-04 10:00:00')
```

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

## 19.8.5 Custom Business Hour

New in version 0.18.1.

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

```
In [195]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [196]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [197]: dt = datetime(2014, 1, 17, 15)

In [198]: dt + bhour_us
Out[198]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [199]: dt + bhour_us * 2
\\Out[199]: Timestamp('2014-01-21 09:00:00')
```

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

```
In [200]: bhour_mon = CustomBusinessHour(start='10:00', weekmask='Tue Wed Thu Fri')

# Monday is skipped because it's a holiday, business hour starts from 10:00
```

(continues on next page)

(continued from previous page)

```
In [201]: dt + bhour_mon * 2
Out [201]: Timestamp('2014-01-21 10:00:00')
```

## 19.8.6 Offset Aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as *offset aliases*.

| Alias    | Description                                      |
|----------|--|
| B        | business day frequency                           |
| C        | custom business day frequency                    |
| D        | calendar day frequency                           |
| W        | weekly frequency                                 |
| M        | month end frequency                              |
| SM       | semi-month end frequency (15th and end of month) |
| BM       | business month end frequency                     |
| CBM      | custom business month end frequency              |
| MS       | month start frequency                            |
| SMS      | semi-month start frequency (1st and 15th)        |
| BMS      | business month start frequency                   |
| CBMS     | custom business month start frequency            |
| Q        | quarter end frequency                            |
| BQ       | business quarter end frequency                   |
| QS       | quarter start frequency                          |
| BQS      | business quarter start frequency                 |
| A, Y     | year end frequency                               |
| BA, BY   | business year end frequency                      |
| AS, YS   | year start frequency                             |
| BAS, BYS | business year start frequency                    |
| BH       | business hour frequency                          |
| H        | hourly frequency                                 |
| T, min   | minutely frequency                               |
| S        | secondly frequency                               |
| L, ms    | milliseconds                                     |
| U, us    | microseconds                                     |
| N        | nanoseconds                                      |

## 19.8.7 Combining Aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

```
In [202]: pd.date_range(start, periods=5, freq='B')
Out [202]:
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07'],
              dtype='datetime64[ns]', freq='B')

In [203]: pd.date_range(start, periods=5, freq=BDay())
//////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
```

(continues on next page)

(continued from previous page)

```
DatetimeIndex(['2011-01-03', '2011-01-04', '2011-01-05', '2011-01-06',
               '2011-01-07'],
              dtype='datetime64[ns]', freq='B')
```

You can combine together day and intraday offsets:

```
In [204]: pd.date_range(start, periods=10, freq='2h20min')
```

```
Out[204]:
```

```
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
               '2011-01-01 04:40:00', '2011-01-01 07:00:00',
               '2011-01-01 09:20:00', '2011-01-01 11:40:00',
               '2011-01-01 14:00:00', '2011-01-01 16:20:00',
               '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
              dtype='datetime64[ns]', freq='140T')
```

```
In [205]: pd.date_range(start, periods=10, freq='1D10U')
```

```
DatetimeIndex([
    '2011-01-01 00:00:00', '2011-01-02 00:00:00.000010',
    '2011-01-03 00:00:00.000020', '2011-01-04 00:00:00.000030',
    '2011-01-05 00:00:00.000040', '2011-01-06 00:00:00.000050',
    '2011-01-07 00:00:00.000060', '2011-01-08 00:00:00.000070',
    '2011-01-09 00:00:00.000080', '2011-01-10 00:00:00.000090'],
              dtype='datetime64[ns]', freq='86400000010U')
```

### 19.8.8 Anchored Offsets

For some frequencies you can specify an anchoring suffix:

| Alias       | Description   |
|-------------|---|
| W-SUN       | weekly frequency (Sundays). Same as 'W'                 |
| W-MON       | weekly frequency (Mondays)                              |
| W-TUE       | weekly frequency (Tuesdays)                             |
| W-WED       | weekly frequency (Wednesdays)                           |
| W-THU       | weekly frequency (Thursdays)                            |
| W-FRI       | weekly frequency (Fridays)                              |
| W-SAT       | weekly frequency (Saturdays)                            |
| (B)Q(S)-DEC | quarterly frequency, year ends in December. Same as 'Q' |
| (B)Q(S)-JAN | quarterly frequency, year ends in January               |
| (B)Q(S)-FEB | quarterly frequency, year ends in February              |
| (B)Q(S)-MAR | quarterly frequency, year ends in March                 |
| (B)Q(S)-APR | quarterly frequency, year ends in April                 |
| (B)Q(S)-MAY | quarterly frequency, year ends in May                   |
| (B)Q(S)-JUN | quarterly frequency, year ends in June                  |

Continued on next page

Table 2 – continued from previous page

| Alias       | Description   |
|-------------|---|
| (B)Q(S)-JUL | quarterly frequency, year ends in July                  |
| (B)Q(S)-AUG | quarterly frequency, year ends in August                |
| (B)Q(S)-SEP | quarterly frequency, year ends in September             |
| (B)Q(S)-OCT | quarterly frequency, year ends in October               |
| (B)Q(S)-NOV | quarterly frequency, year ends in November              |
| (B)A(S)-DEC | annual frequency, anchored end of December. Same as 'A' |
| (B)A(S)-JAN | annual frequency, anchored end of January               |
| (B)A(S)-FEB | annual frequency, anchored end of February              |
| (B)A(S)-MAR | annual frequency, anchored end of March                 |
| (B)A(S)-APR | annual frequency, anchored end of April                 |
| (B)A(S)-MAY | annual frequency, anchored end of May                   |
| (B)A(S)-JUN | annual frequency, anchored end of June                  |
| (B)A(S)-JUL | annual frequency, anchored end of July                  |
| (B)A(S)-AUG | annual frequency, anchored end of August                |
| (B)A(S)-SEP | annual frequency, anchored end of September             |
| (B)A(S)-OCT | annual frequency, anchored end of October               |
| (B)A(S)-NOV | annual frequency, anchored end of November              |

These can be used as arguments to `date_range`, `bdate_range`, constructors for `DatetimeIndex`, as well as various other timeseries-related functions in pandas.

### 19.8.9 Anchored Offset Semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When `n` is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved `|n| - 1` additional steps forwards or backwards.

```
In [206]: pd.Timestamp('2014-01-02') + MonthBegin(n=1)
Out[206]: Timestamp('2014-02-01 00:00:00')
```

```
In [207]: pd.Timestamp('2014-01-02') + MonthEnd(n=1)
Out[207]: Timestamp('2014-01-31 00:00:00')
```

(continues on next page)

(continued from previous page)

```
In [208]: pd.Timestamp('2014-01-02') - MonthBegin(n=1)
Out[208]:
↳Timestamp('2014-01-01 00:00:00')
```

```
In [209]: pd.Timestamp('2014-01-02') - MonthEnd(n=1)
↳Timestamp('2013-12-31 00:00:00')
```

```
In [210]: pd.Timestamp('2014-01-02') + MonthBegin(n=4)
↳Timestamp('2014-05-01 00:00:00')
```

```
In [211]: pd.Timestamp('2014-01-02') - MonthBegin(n=4)
↳Timestamp('2013-10-01 00:00:00')
```

If the given date *is* on an anchor point, it is moved  $|n|$  points forwards or backwards.

```
In [212]: pd.Timestamp('2014-01-01') + MonthBegin(n=1)
Out[212]: Timestamp('2014-02-01 00:00:00')
```

```
In [213]: pd.Timestamp('2014-01-31') + MonthEnd(n=1)
Out[213]: Timestamp('2014-02-28 00:00:00')
```

```
In [214]: pd.Timestamp('2014-01-01') - MonthBegin(n=1)
Out[214]: Timestamp('2013-12-01 00:00:00')
```

```
In [215]: pd.Timestamp('2014-01-31') - MonthEnd(n=1)
Out[215]: Timestamp('2013-12-31 00:00:00')
```

```
In [216]: pd.Timestamp('2014-01-01') + MonthBegin(n=4)
Out[216]: Timestamp('2014-05-01 00:00:00')
```

```
In [217]: pd.Timestamp('2014-01-31') - MonthBegin(n=4)
Out[217]: Timestamp('2013-10-01 00:00:00')
```

For the case when  $n=0$ , the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.

```
In [218]: pd.Timestamp('2014-01-02') + MonthBegin(n=0)
Out[218]: Timestamp('2014-02-01 00:00:00')

In [219]: pd.Timestamp('2014-01-02') + MonthEnd(n=0)
Out[219]: Timestamp('2014-01-31 00:00:00')

In [220]: pd.Timestamp('2014-01-01') + MonthBegin(n=0)
Out[220]: Timestamp('2014-01-01 00:00:00')

In [221]: pd.Timestamp('2014-01-31') + MonthEnd(n=0)
Out[221]: Timestamp('2014-01-31 00:00:00')
```

## 19.8.10 Holidays / Holiday Calendars

Holidays and calendars provide a simple way to define holiday rules to be used with `CustomBusinessDay` or in other analysis that requires a predefined set of holidays. The `AbstractHolidayCalendar` class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the `start_date` and `end_date` class attributes determine over what date range holidays are generated. These should be overwritten on the `AbstractHolidayCalendar` class to have the range apply to all calendar subclasses. `USFederalHolidayCalendar` is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

| Rule                                | Description  |
|-------------------------------------|--|
| <code>nearest_workday</code>        | move Saturday to Friday and Sunday to Monday         |
| <code>sunday_to_monday</code>       | move Sunday to following Monday                      |
| <code>next_monday_or_tuesday</code> | move Saturday to Monday and Sunday/Monday to Tuesday |
| <code>previous_friday</code>        | move Saturday and Sunday to previous Friday          |
| <code>next_monday</code>            | move Saturday and Sunday to following Monday         |

An example of how holidays and holiday calendars are defined:

```
In [222]: from pandas.tseries.holiday import Holiday, USMemorialDay, \
.....:      AbstractHolidayCalendar, nearest_workday, MO
.....:

In [223]: class ExampleCalendar(AbstractHolidayCalendar):
.....:     rules = [
.....:         USMemorialDay,
.....:         Holiday('July 4th', month=7, day=4, observance=nearest_workday),
.....:         Holiday('Columbus Day', month=10, day=1,
.....:             offset=DateOffset(weekday=MO(2))), #same as 2*Week(weekday=2)
.....:     ]
.....:

In [224]: cal = ExampleCalendar()

In [225]: cal.holidays(datetime(2012, 1, 1), datetime(2012, 12, 31))
Out[225]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype=
->'datetime64[ns]', freq=None)
```

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the `ExampleCalendar`. Like any other offset, it can be used to create a `DatetimeIndex` or added to `datetime` or `Timestamp` objects.

```
In [226]: from pandas.tseries.offsets import CDay

In [227]: pd.DatetimeIndex(start='7/1/2012', end='7/10/2012',
.....:     freq=CDay(calendar=cal)).to_pydatetime()
.....:
Out[227]:
array([datetime.datetime(2012, 7, 2, 0, 0),
       datetime.datetime(2012, 7, 3, 0, 0),
       datetime.datetime(2012, 7, 5, 0, 0),
       datetime.datetime(2012, 7, 6, 0, 0),
       datetime.datetime(2012, 7, 9, 0, 0),
```

(continues on next page)

(continued from previous page)

[illegible]

Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [233]: AbstractHolidayCalendar.start_date
Out[233]: Timestamp('1970-01-01 00:00:00')
```

```
In [234]: AbstractHolidayCalendar.end_date
Out[234]: Timestamp('2030-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as datetime/Timestamp/string.

```
In [235]: AbstractHolidayCalendar.start_date = datetime(2012, 1, 1)

In [236]: AbstractHolidayCalendar.end_date = datetime(2012, 12, 31)

In [237]: cal.holidays()
Out[237]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype=
↳ 'datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [238]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory, \
.....:      USLaborDay
.....:

In [239]: cal = get_calendar('ExampleCalendar')

In [240]: cal.rules
Out[240]:
[Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x1c36e47158>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]

In [241]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)
```

(continues on next page)

(continued from previous page)

```
In [242]: new_cal.rules
Out [242]:
[Holiday: Labor Day (month=9, day=1, offset=<DateOffset: weekday=MO(+1)>),
 Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
 Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x1c36e47158>),
 Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
```

## 19.9 Time Series-Related Instance Methods

### 19.9.1 Shifting / Lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is `shift()`, which is available on all of the pandas objects.

```
In [243]: ts = ts[:5]

In [244]: ts.shift(1)
Out [244]:
2011-01-31      NaN
2011-02-28    -1.281247
2011-03-31    -0.727707
2011-04-29    -0.121306
2011-05-31    -0.097883
Freq: BM, dtype: float64
```

The `shift` method accepts an `freq` argument which can accept a `DateOffset` class or other `timedelta`-like object or also an *offset alias*:

```
In [245]: ts.shift(5, freq=offsets.BDay())
Out [245]:
2011-02-07    -1.281247
2011-03-07    -0.727707
2011-04-07    -0.121306
2011-05-06    -0.097883
2011-06-07     0.695775
dtype: float64

In [246]: ts.shift(5, freq='BM')
Out [246]:
2011-06-30    -1.281247
2011-07-29    -0.727707
2011-08-31    -0.121306
2011-09-30    -0.097883
2011-10-31     0.695775
Freq: BM, dtype: float64
```

Rather than changing the alignment of the data and the index, `DataFrame` and `Series` objects also have a `tshift()` convenience method that changes all the dates in the index by a specified number of offsets:

```
In [247]: ts.tshift(5, freq='D')
Out [247]:
```

(continues on next page)

(continued from previous page)

```
2011-02-05    -1.281247
2011-03-05    -0.727707
2011-04-05    -0.121306
2011-05-04    -0.097883
2011-06-05     0.695775
dtype: float64
```

Note that with `tshift`, the leading entry is no longer NaN because the data is not being realigned.

## 19.9.2 Frequency Conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```
In [248]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * offsets.BDay())
```

```
In [249]: ts = pd.Series(randn(3), index=dr)
```

```
In [250]: ts
```

Out [250] :

```
2010-01-01    0.155932
2010-01-06    1.486218
2010-01-11   -2.148675
Freq: 3B, dtype: float64
```

```
In [251]: ts.asfreq(BDay())
```

```

↔
2010-01-01    0.155932
2010-01-04         NaN
2010-01-05         NaN
2010-01-06    1.486218
2010-01-07         NaN
2010-01-08         NaN
2010-01-11   -2.148675
Freq: B, dtype: float64

```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```
In [252]: ts.asfreq(BDay(), method='pad')
```

Out [252] :

```
2010-01-01    0.155932
2010-01-04    0.155932
2010-01-05    0.155932
2010-01-06    1.486218
2010-01-07    1.486218
2010-01-08    1.486218
2010-01-11   -2.148675
Freq: B, dtype: float64
```

### 19.9.3 Filling Forward / Backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the *missing data section*.

## 19.9.4 Converting to Python Datetimes

`DatetimeIndex` can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

## 19.10 Resampling

**Warning:** The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the [whatsnew docs](#) for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some [cookbook examples](#) for some advanced strategies.

Starting in version 0.18.1, the `resample()` function can be used directly from `DataFrameGroupBy` objects, see the [groupby docs](#).

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion [here](#).

### 19.10.1 Basics

```
In [253]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [254]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [255]: ts.resample('5Min').sum()
Out[255]:
2012-01-01    25653
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via [dispatching](#) is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [256]: ts.resample('5Min').mean()
Out[256]:
2012-01-01    256.53
Freq: 5T, dtype: float64

In [257]: ts.resample('5Min').ohlc()
Out[257]:
\\Out[257]:
      open  high  low  close
2012-01-01   296   496    6   449

In [258]: ts.resample('5Min').max()
```

(continues on next page)

(continued from previous page)

```

2012-01-01      496
Freq: 5T, dtype: int64

```

For downsampling, `closed` can be set to 'left' or 'right' to specify which end of the interval is closed:

```
In [259]: ts.resample('5Min', closed='right').mean()
Out[259]:
2011-12-31 23:55:00    296.000000
2012-01-01 00:00:00    256.131313
Freq: 5T, dtype: float64

In [260]: ts.resample('5Min', closed='left').mean()
////////////////////////////////////
↪
2012-01-01    256.53
Freq: 5T, dtype: float64
```

Parameters like `label` and `loffset` are used to manipulate the resulting labels. `label` specifies whether the result is labeled with the beginning or the end of the interval. `loffset` performs a time adjustment on the output labels.

```
In [261]: ts.resample('5Min').mean() # by default label='left'
Out[261]:
2012-01-01    256.53
Freq: 5T, dtype: float64

In [262]: ts.resample('5Min', label='left').mean()
Out[262]:
2012-01-01    256.53
Freq: 5T, dtype: float64

In [263]: ts.resample('5Min', label='left', loffset='1s').mean()
Out[263]:
2012-01-01 00:00:01    256.53
dtype: float64
```

**Note:** The default values for `label` and `closed` is 'left' for all frequency offsets except for 'M', 'A', 'Q', 'BM', 'BA', 'BQ', and 'W' which all have a default of 'right'.

```
In [264]: rng2 = pd.date_range('1/1/2012', end='3/31/2012', freq='D')

In [265]: ts2 = pd.Series(range(len(rng2)), index=rng2)

# default: label='right', closed='right'
In [266]: ts2.resample('M').max()
Out[266]:
2012-01-31    30
2012-02-29    59
2012-03-31    90
Freq: M, dtype: int64

# default: label='left', closed='left'
In [267]: ts2.resample('SM').max()
```

(continues on next page)

(continued from previous page)

```

\\Out [267]:
↪
2011-12-31      13
2012-01-15      29
2012-01-31      44
2012-02-15      58
2012-02-29      73
2012-03-15      89
2012-03-31      90
Freq: SM-15, dtype: int64

In [268]: ts2.resample('SM', label='right', closed='right').max()
\\
↪
2012-01-15      14.0
2012-01-31      30.0
2012-02-15      45.0
2012-02-29      59.0
2012-03-15      74.0
2012-03-31      90.0
2012-04-15       NaN
Freq: SM-15, dtype: float64

```

The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`.

`kind` can be set to `'timestamp'` or `'period'` to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation.

`convention` can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

## 19.10.2 Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```
# from secondly to every 250 milliseconds
```

```
In [269]: ts[:2].resample('250L').asfreq()
```

Out [269] :

```
2012-01-01 00:00:00.000    296.0
2012-01-01 00:00:00.250      NaN
2012-01-01 00:00:00.500      NaN
2012-01-01 00:00:00.750      NaN
2012-01-01 00:00:01.000    199.0
Freq: 250L, dtype: float64
```

```
In [270]: ts[:2].resample('250L').ffill()
```

```

2012-01-01 00:00:00.000    296
2012-01-01 00:00:00.250    296
2012-01-01 00:00:00.500    296
2012-01-01 00:00:00.750    296
2012-01-01 00:00:01.000    199
Freq: 250L, dtype: int64

```

(continues on next page)

(continued from previous page)

```
In [271]: ts[:2].resample('250L').ffill(limit=2)
```

```

////////////////////////////////////
↪
2012-01-01 00:00:00.000    296.0
2012-01-01 00:00:00.250    296.0
2012-01-01 00:00:00.500    296.0
2012-01-01 00:00:00.750     NaN
2012-01-01 00:00:01.000    199.0
Freq: 250L, dtype: float64

```

### 19.10.3 Sparse Resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don't want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```
In [272]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
```

```
In [273]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```
In [274]: ts.resample('3T').sum()
```

```
Out[274]:
```

```

2014-01-01 00:00:00    0
2014-01-01 00:03:00    0
2014-01-01 00:06:00    0
2014-01-01 00:09:00    0
2014-01-01 00:12:00    0
2014-01-01 00:15:00    0
2014-01-01 00:18:00    0
..
2014-04-09 23:42:00    0
2014-04-09 23:45:00    0
2014-04-09 23:48:00    0
2014-04-09 23:51:00    0
2014-04-09 23:54:00    0
2014-04-09 23:57:00    0
2014-04-10 00:00:00    99
Freq: 3T, Length: 47521, dtype: int64

```

We can instead only resample those groups where we have points as follows:

```
In [275]: from functools import partial
```

```
In [276]: from pandas.tseries.frequencies import to_offset
```

```

In [277]: def round(t, freq):
.....:     freq = to_offset(freq)
.....:     return pd.Timestamp((t.value // freq.delta.value) * freq.delta.value)

```

(continues on next page)

(continued from previous page)

```

.....:
In [278]: ts.groupby(partial(round, freq='3T')).sum()
Out[278]:
2014-01-01      0
2014-01-02      1
2014-01-03      2
2014-01-04      3
2014-01-05      4
2014-01-06      5
2014-01-07      6
..
2014-04-04     93
2014-04-05     94
2014-04-06     95
2014-04-07     96
2014-04-08     97
2014-04-09     98
2014-04-10     99
Length: 100, dtype: int64

```

### 19.10.4 Aggregation

Similar to the *aggregating API*, *groupby API*, and the *window functions API*, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

```

In [279]: df = pd.DataFrame(np.random.randn(1000, 3),
.....:                      index=pd.date_range('1/1/2012', freq='S', periods=1000),
.....:                      columns=['A', 'B', 'C'])
.....:

In [280]: r = df.resample('3T')

In [281]: r.mean()
Out[281]:
              A              B              C
2012-01-01 00:00:00 -0.038580 -0.085117 -0.024750
2012-01-01 00:03:00  0.052387 -0.061477  0.029548
2012-01-01 00:06:00  0.121377 -0.010630 -0.043691

2012-01-01 00:15:00  0.060486 -0.057602 -0.106213

```

We can select a specific column or columns using standard getitem.

```

In [282]: r['A'].mean()
Out[282]:
2012-01-01 00:00:00 -0.038580
2012-01-01 00:03:00  0.052387
2012-01-01 00:06:00  0.121377
2012-01-01 00:09:00 -0.106814
2012-01-01 00:12:00  0.032560
2012-01-01 00:15:00  0.060486

```

(continues on next page)

(continued from previous page)

Freq: 3T, Name: A, dtype: float64

**In [283]:** r[['A', 'B']].mean()

```

////////////////////////////////////
↪

```

|                     | A         | B         |
|---------------------|-----------|-----------|
| 2012-01-01 00:00:00 | -0.038580 | -0.085117 |
| 2012-01-01 00:03:00 | 0.052387  | -0.061477 |
| 2012-01-01 00:06:00 | 0.121377  | -0.010630 |
| 2012-01-01 00:09:00 | -0.106814 | -0.053819 |
| 2012-01-01 00:12:00 | 0.032560  | 0.080543  |
| 2012-01-01 00:15:00 | 0.060486  | -0.057602 |

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

**In [284]:** r['A'].agg([np.sum, np.mean, np.std])**Out[284]:**

|                     | sum        | mean      | std      |
|---------------------|------------|-----------|----------|
| 2012-01-01 00:00:00 | -6.944481  | -0.038580 | 0.985150 |
| 2012-01-01 00:03:00 | 9.429707   | 0.052387  | 1.078022 |
| 2012-01-01 00:06:00 | 21.847876  | 0.121377  | 0.996365 |
| 2012-01-01 00:09:00 | -19.226593 | -0.106814 | 0.914070 |
| 2012-01-01 00:12:00 | 5.860874   | 0.032560  | 1.100055 |
| 2012-01-01 00:15:00 | 6.048588   | 0.060486  | 1.001532 |

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

**In [285]:** r.agg([np.sum, np.mean])**Out[285]:**

|                     | A          |           | B          |           | C          |           |
|---------------------|------------|-----------|------------|-----------|------------|-----------|
|                     | sum        | mean      | sum        | mean      | sum        | mean      |
| 2012-01-01 00:00:00 | -6.944481  | -0.038580 | -15.320993 | -0.085117 | -4.454941  | -0.024750 |
| 2012-01-01 00:03:00 | 9.429707   | 0.052387  | -11.065916 | -0.061477 | 5.318688   | 0.029548  |
| 2012-01-01 00:06:00 | 21.847876  | 0.121377  | -1.913420  | -0.010630 | -7.864429  | -0.043691 |
| 2012-01-01 00:09:00 | -19.226593 | -0.106814 | -9.687468  | -0.053819 | 17.499920  | 0.097222  |
| 2012-01-01 00:12:00 | 5.860874   | 0.032560  | 14.497725  | 0.080543  | 30.128432  | 0.167380  |
| 2012-01-01 00:15:00 | 6.048588   | 0.060486  | -5.760208  | -0.057602 | -10.621260 | -0.106213 |

By passing a dict to aggregate you can apply a different aggregation to the columns of a DataFrame:

```

In [286]: r.agg({'A' : np.sum,
.....:          'B' : lambda x: np.std(x, ddof=1)})
.....:

```

**Out[286]:**

|                     | A          | B        |
|---------------------|------------|----------|
| 2012-01-01 00:00:00 | -6.944481  | 1.087752 |
| 2012-01-01 00:03:00 | 9.429707   | 1.014552 |
| 2012-01-01 00:06:00 | 21.847876  | 0.954588 |
| 2012-01-01 00:09:00 | -19.226593 | 1.027990 |
| 2012-01-01 00:12:00 | 5.860874   | 1.021503 |
| 2012-01-01 00:15:00 | 6.048588   | 1.004984 |

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:

```
In [287]: r.agg({'A' : 'sum', 'B' : 'std'})
Out[287]:
```

|                     | A          | B        |
|---------------------|------------|----------|
| 2012-01-01 00:00:00 | -6.944481  | 1.087752 |
| 2012-01-01 00:03:00 | 9.429707   | 1.014552 |
| 2012-01-01 00:06:00 | 21.847876  | 0.954588 |
| 2012-01-01 00:09:00 | -19.226593 | 1.027990 |
| 2012-01-01 00:12:00 | 5.860874   | 1.021503 |
| 2012-01-01 00:15:00 | 6.048588   | 1.004984 |

Furthermore, you can also specify multiple aggregation functions for each column separately.

```
In [288]: r.agg({'A' : ['sum', 'std'], 'B' : ['mean', 'std'] })
Out[288]:
```

|                     | A          |          | B         |          |
|---------------------|------------|----------|-----------|----------|
|                     | sum        | std      | mean      | std      |
| 2012-01-01 00:00:00 | -6.944481  | 0.985150 | -0.085117 | 1.087752 |
| 2012-01-01 00:03:00 | 9.429707   | 1.078022 | -0.061477 | 1.014552 |
| 2012-01-01 00:06:00 | 21.847876  | 0.996365 | -0.010630 | 0.954588 |
| 2012-01-01 00:09:00 | -19.226593 | 0.914070 | -0.053819 | 1.027990 |
| 2012-01-01 00:12:00 | 5.860874   | 1.100055 | 0.080543  | 1.021503 |
| 2012-01-01 00:15:00 | 6.048588   | 1.001532 | -0.057602 | 1.004984 |

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can be passed to the `on` keyword.

```
In [289]: df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
.....:                      'a': np.arange(5)},
.....:                      index=pd.MultiIndex.from_arrays([
.....:                          [1,2,3,4,5],
.....:                          pd.date_range('2015-01-01', freq='W',
.....:                                          periods=5)],
.....:                      names=['v', 'd']))
```

```
In [290]: df
Out[290]:
```

|     | date                  | a |
|-----|-----------------------|---|
| v d |                       |   |
| 1   | 2015-01-04 2015-01-04 | 0 |
| 2   | 2015-01-11 2015-01-11 | 1 |
| 3   | 2015-01-18 2015-01-18 | 2 |
| 4   | 2015-01-25 2015-01-25 | 3 |
| 5   | 2015-02-01 2015-02-01 | 4 |

```
In [291]: df.resample('M', on='date').sum()
```

```

////////////////////////////////////
↪
a
date
2015-01-31  6
2015-02-28  4
```

Similarly, if you instead want to resample by a datetimelike level of `MultiIndex`, its name or location can be passed to the `level` keyword.

```
In [292]: df.resample('M', level='d').sum()
```

(continues on next page)

(continued from previous page)

```
Out [292]:
          a
d
2015-01-31  6
2015-02-28  4
```

## 19.11 Time Span Representation

Regular intervals of time are represented by `Period` objects in pandas while sequences of `Period` objects are collected in a `PeriodIndex`, which can be created with the convenience function `period_range`.

### 19.11.1 Period

A `Period` represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via `freq` keyword using a frequency alias like below. Because `freq` represents a span of `Period`, it cannot be negative like “-3D”.

```
In [293]: pd.Period('2012', freq='A-DEC')
Out [293]: Period('2012', 'A-DEC')

In [294]: pd.Period('2012-1-1', freq='D')
Out [294]: Period('2012-01-01', 'D')

In [295]: pd.Period('2012-1-1 19:00', freq='H')
Out [295]: Period('2012-01-01 19:00', 'H')

In [296]: pd.Period('2012-1-1 19:00', freq='5H')
Out [296]: Period('2012-01-01 19:00', '5H')
```

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between `Period` with different `freq` (span).

```
In [297]: p = pd.Period('2012', freq='A-DEC')

In [298]: p + 1
Out [298]: Period('2013', 'A-DEC')

In [299]: p - 3
Out [299]: Period('2009', 'A-DEC')

In [300]: p = pd.Period('2012-01', freq='2M')

In [301]: p + 2
Out [301]: Period('2012-05', '2M')

In [302]: p - 1
Out [302]: Period('2011-11', '2M')

In [303]: p == pd.Period('2012-01', freq='3M')
Out [303]:
IncompatibleFrequency                                Traceback (most recent call last)
```

(continues on next page)

(continued from previous page)

```
<ipython-input-303-4b67dc0b596c> in <module>()
----> 1 p == pd.Period('2012-01', freq='3M')

~/sandbox/pandas-release/pandas-docs/pandas/_libs/tslibs/period.pyx in pandas._libs.
↳tslibs.period._Period.__richcmp__()

IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)
```

If Period freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, ValueError will be raised.

[illegible]

```
In [1]: p + Minute(5)
Traceback
...
ValueError: Input has different freq from Period(freq=H)
```

If `Period` has other freqs, only the same offsets can be added. Otherwise, `ValueError` will be raised.

```
In [308]: p = pd.Period('2014-07', freq='M')

In [309]: p + MonthEnd(3)
Out[309]: Period('2014-10', 'M')
```

```
In [1]: p + MonthBegin(3)
Traceback
...
ValueError: Input has different freq from Period(freq=M)
```

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

```
In [310]: pd.Period('2012', freq='A-DEC') - pd.Period('2002', freq='A-DEC')
Out[310]: 10
```

### 19.11.2 PeriodIndex and period\_range

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

```
In [311]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')
In [312]: prng
```

(continues on next page)

(continued from previous page)

```
Out [312]:
PeriodIndex(['2011-01', '2011-02', '2011-03', '2011-04', '2011-05', '2011-06',
            '2011-07', '2011-08', '2011-09', '2011-10', '2011-11', '2011-12',
            '2012-01'],
            dtype='period[M]', freq='M')
```

The PeriodIndex constructor can also be used directly:

```
In [313]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out [313]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of Period which has multiplied span.

```
In [314]: pd.PeriodIndex(start='2014-01', freq='3M', periods=4)
Out [314]: PeriodIndex(['2014-01', '2014-04', '2014-07', '2014-10'], dtype='period[3M]',
                        freq='3M')
```

If start or end are Period objects, they will be used as anchor endpoints for a PeriodIndex with frequency matching that of the PeriodIndex constructor.

```
In [315]: pd.PeriodIndex(start=pd.Period('2017Q1', freq='Q'),
                        .....: end=pd.Period('2017Q2', freq='Q'), freq='M')
Out [315]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]',
                        freq='M')
```

Just like DatetimeIndex, a PeriodIndex can also be used to index pandas objects:

```
In [316]: ps = pd.Series(np.random.randn(len(prng)), prng)

In [317]: ps
Out [317]:
2011-01    0.258318
2011-02   -2.503700
2011-03   -0.303053
2011-04    0.270509
2011-05    1.004841
2011-06   -0.129044
2011-07   -1.406335
2011-08   -1.310412
2011-09    0.769439
2011-10   -0.542325
2011-11    2.010541
2011-12    1.001558
2012-01   -0.087453
Freq: M, dtype: float64
```

PeriodIndex supports addition and subtraction with the same rule as Period.

```
In [318]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')

In [319]: idx
Out [319]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
            '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')
```

(continues on next page)

(continued from previous page)

PeriodIndex has its own dtype named `period`, refer to *Period Dtypes*.

### 19.11.3 Period Dtypes

New in version 0.19.0.

`PeriodIndex` has a custom `period` dtype. This is a pandas extension dtype similar to the *timezone aware dtype* (`datetime64[ns, tz]`).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using *frequency strings*.

```
In [324]: pi = pd.period_range('2016-01-01', periods=3, freq='M')

In [325]: pi
Out[325]: PeriodIndex(['2016-01', '2016-02', '2016-03'], dtype='period[M]', freq='M')

In [326]: pi.dtype
\\Out[326]: period[M]
```

The period dtype can be used in `.astype(...)`. It allows one to change the `freq` of a `PeriodIndex` like `.asfreq()` and convert a `DatetimeIndex` to `PeriodIndex` like `to_period()`:

```
# change monthly freq to daily freq
In [327]: pi.astype('period[D]')
Out[327]: PeriodIndex(['2016-01-31', '2016-02-29', '2016-03-31'], dtype='period[D]',
→freq='D')

# convert to DatetimeIndex
In [328]: pi.astype('datetime64[ns]')
Out[328]: DatetimeIndex(['2016-01-01', '2016-02-01', '2016-03-01'], dtype='datetime64[ns]',
→freq='MS')

# convert to PeriodIndex
In [329]: dti = pd.date_range('2011-01-01', freq='M', periods=3)
```

(continues on next page)

(continued from previous page)

```
In [330]: dti
Out[330]: DatetimeIndex(['2011-01-31', '2011-02-28', '2011-03-31'], dtype=
↳ 'datetime64[ns]', freq='M')

In [331]: dti.astype('period[M]')
////////////////////////////////////
↳ PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

#### 19.11.4 PeriodIndex Partial String Indexing

You can pass in dates and strings to `Series` and `DataFrame` with `PeriodIndex`, in the same manner as `DatetimeIndex`. For details, refer to [DatetimeIndex Partial String Indexing](#).

```
In [332]: ps['2011-01']
Out[332]: 0.25831819727391592

In [333]: ps[datetime(2011, 12, 25):]
Out[333]:
2011-12      1.001558
2012-01     -0.087453
Freq: M, dtype: float64

In [334]: ps['10/31/2011':'12/31/2011']
Out[334]:
↔
2011-10     -0.542325
2011-11      2.010541
2011-12      1.001558
Freq: M, dtype: float64
```

Passing a string representing a lower frequency than `PeriodIndex` returns partial sliced data.

```
In [335]: ps['2011']
Out[335]:
2011-01    0.258318
2011-02   -2.503700
2011-03   -0.303053
2011-04    0.270509
2011-05    1.004841
2011-06   -0.129044
2011-07   -1.406335
2011-08   -1.310412
2011-09    0.769439
2011-10   -0.542325
2011-11    2.010541
2011-12    1.001558
Freq: M, dtype: float64

In [336]: dfp = pd.DataFrame(np.random.randn(600,1),
.....:                        columns=['A'],

### 19.11.5 Frequency Conversion and Resampling with PeriodIndex

The frequency of `Period` and `PeriodIndex` can be converted via the `asfreq` method. Let's start with the fiscal year 2011, ending in December:

```

In [340]: p = pd.Period('2011', freq='A-DEC')

In [341]: p
Out[341]: Period('2011', 'A-DEC')

```

We can convert it to a monthly frequency. Using the `how` parameter, we can specify whether to return the starting or ending month:

```

In [342]: p.asfreq('M', how='start')
Out[342]: Period('2011-01', 'M')

In [343]: p.asfreq('M', how='end')
Out[343]: Period('2011-12', 'M')

```

The shorthands 's' and 'e' are provided for convenience:

```

In [344]: p.asfreq('M', 's')
Out[344]: Period('2011-01', 'M')

In [345]: p.asfreq('M', 'e')
Out[345]: Period('2011-12', 'M')

```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```

In [346]: p = pd.Period('2011-12', freq='M')

In [347]: p.asfreq('A-NOV')
Out[347]: Period('2012', 'A-NOV')

```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q-JAN through Q-DEC.

Q-DEC define regular calendar quarters:

```
In [351]: p = pd.Period('2011Q4', freq='Q-MAR')

In [352]: p.asfreq('D', 's')
Out[352]: Period('2011-01-01', 'D')

In [353]: p.asfreq('D', 'e')
Out[353]: Period('2011-03-31', 'D')
```

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [354]: rng = pd.date_range('1/1/2012', periods=5, freq='M')

In [355]: ts = pd.Series(np.random.randn(len(rng)), index=rng)

In [356]: ts
Out[356]:
2012-01-31    -0.898547
2012-02-29    -1.332247
2012-03-31    -0.741645
2012-04-30     0.094321
2012-05-31    -0.438813
Freq: M, dtype: float64

In [357]: ps = ts.to_period()

In [358]: ps
Out[358]:
2012-01    -0.898547
2012-02    -1.332247
2012-03    -0.741645
2012-04     0.094321
2012-05    -0.438813
Freq: M, dtype: float64

In [359]: ps.to_timestamp()
```

↪

```
2012-01-01    -0.898547
2012-02-01    -1.332247
2012-03-01    -0.741645
2012-04-01     0.094321
```

## 19.12. Converting Between Representations

(continued from previous page)

```
2012-05-01    -0.438813
Freq: MS, dtype: float64
```

Remember that 's' and 'e' can be used to return the timestamps at the start or end of the period:

```
In [360]: ps.to_timestamp('D', how='s')
Out[360]:
2012-01-01    -0.898547
2012-02-01    -1.332247
2012-03-01    -0.741645
2012-04-01     0.094321
2012-05-01    -0.438813
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [361]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')

In [362]: ts = pd.Series(np.random.randn(len(prng)), prng)

In [363]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9

In [364]: ts.head()
Out[364]:
1990-03-01 09:00    -0.564874
1990-06-01 09:00    -1.426510
1990-09-01 09:00     1.295437
1990-12-01 09:00     1.124017
1991-03-01 09:00     0.840428
Freq: H, dtype: float64
```

## 19.13 Representing Out-of-Bounds Spans

If you have data that is outside of the Timestamp bounds, see [Timestamp limitations](#), then you can use a PeriodIndex and/or Series of Periods to do computations.

```
In [365]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')

In [366]: span
Out[366]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
            '1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
            '1215-01-09', '1215-01-10',
            ...,
            '1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
            '1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
            '1380-12-31', '1381-01-01'],
            dtype='period[D]', length=60632, freq='D')
```

To convert from an int64 based YYYYMMDD representation.

[illegible]

These can easily be converted to a `PeriodIndex`:

```
In [372]: span = pd.PeriodIndex(s.apply(conv))

In [373]: span
Out[373]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'], dtype='period[D]',
    freq='D')
```

## 19.14 Time Zone Handling

Pandas provides rich support for working with timestamps in different time zones using `pytz` and `dateutil` libraries. `dateutil` currently is only supported for fixed offset and `tzfile` zones. The default library is `pytz`. Support for `dateutil` is provided for compatibility with other applications e.g. if you use `dateutil` in other Python packages.

### 19.14.1 Working with Time Zones

By default, pandas objects are time zone unaware:

```
In [374]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')

In [375]: rng.tz is None
Out[375]: True
```

To supply the time zone, you can use the `tz` keyword to `date_range` and other functions. Dateutil time zone strings are distinguished from `pytz` time zones by starting with `dateutil/`.

- In `pytz` you can find a list of common (and less common) time zones using `from pytz import common_timezones, all_timezones`.

- `dateutil` uses the OS timezones so there isn't a fixed list available. For common zones, the names are the same as `pytz`.

```
# pytz
In [376]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                             tz='Europe/London')
.....:

In [377]: rng_pytz.tz
Out[377]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [378]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                                 tz='dateutil/Europe/London')
.....:

In [379]: rng_dateutil.tz
Out[379]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [380]: rng_utc = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                             tz=dateutil.tz.tzutc())
.....:

In [381]: rng_utc.tz
Out[381]: tzutc()
```

Note that the UTC timezone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other timezones explicitly first, which gives you more control over which time zone is used:

```
# pytz
In [382]: tz_pytz = pytz.timezone('Europe/London')

In [383]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                             tz=tz_pytz)
.....:

In [384]: rng_pytz.tz == tz_pytz
Out[384]: True

# dateutil
In [385]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [386]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
.....:                                 tz=tz_dateutil)
.....:

In [387]: rng_dateutil.tz == tz_dateutil
Out[387]: True
```

Timestamps, like Python's `datetime.datetime` object can be either time zone naive or time zone aware. Naive time series and `DatetimeIndex` objects can be *localized* using `tz_localize`:

```
In [388]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [389]: ts_utc = ts.tz_localize('UTC')
```

(continues on next page)

(continued from previous page)

```
In [390]: ts_utc
Out[390]:
2012-03-06 00:00:00+00:00    0.037206
2012-03-07 00:00:00+00:00    2.313998
2012-03-08 00:00:00+00:00    1.458296
2012-03-09 00:00:00+00:00   -0.620431
2012-03-10 00:00:00+00:00   -0.000111
2012-03-11 00:00:00+00:00   -0.342783
2012-03-12 00:00:00+00:00   -0.664322
2012-03-13 00:00:00+00:00    0.654814
2012-03-14 00:00:00+00:00    1.550680
2012-03-15 00:00:00+00:00    0.174511
2012-03-16 00:00:00+00:00    1.360491
2012-03-17 00:00:00+00:00    0.799737
2012-03-18 00:00:00+00:00    0.449149
2012-03-19 00:00:00+00:00    0.111346
2012-03-20 00:00:00+00:00   -0.435531
Freq: D, dtype: float64
```

Again, you can explicitly construct the timezone object first. You can use the `tz_convert` method to convert pandas objects to convert tz-aware data to another time zone:

```
In [391]: ts_utc.tz_convert('US/Eastern')
Out[391]:
2012-03-05 19:00:00-05:00    0.037206
2012-03-06 19:00:00-05:00    2.313998
2012-03-07 19:00:00-05:00    1.458296
2012-03-08 19:00:00-05:00   -0.620431
2012-03-09 19:00:00-05:00   -0.000111
2012-03-10 19:00:00-05:00   -0.342783
2012-03-11 20:00:00-04:00   -0.664322
2012-03-12 20:00:00-04:00    0.654814
2012-03-13 20:00:00-04:00    1.550680
2012-03-14 20:00:00-04:00    0.174511
2012-03-15 20:00:00-04:00    1.360491
2012-03-16 20:00:00-04:00    0.799737
2012-03-17 20:00:00-04:00    0.449149
2012-03-18 20:00:00-04:00    0.111346
2012-03-19 20:00:00-04:00   -0.435531
Freq: D, dtype: float64
```

**Warning:** Be wary of conversions between libraries. For some zones `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual timezones than for ‘standard’ zones like US/Eastern.

**Warning:** Be aware that a timezone definition across versions of timezone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** It is incorrect to pass a timezone directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=timezone('US/Eastern'))`). Instead, the `datetime` needs

to be localized using the localize method on the timezone.

Under the hood, all timestamps are stored in UTC. Scalar values from a `DatetimeIndex` with a time zone will have their fields (day, hour, minute) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```
In [392]: rng_eastern = rng_utc.tz_convert('US/Eastern')

In [393]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')

In [394]: rng_eastern[5]
Out[394]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')

In [395]: rng_berlin[5]
Out[395]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')

In [396]: rng_eastern[5] == rng_berlin[5]
Out[396]: True
```

Like `Series`, `DataFrame`, and `DatetimeIndex`, `Timestamp`'s can be converted to other time zones using `tz_convert`:

```
In [397]: rng_eastern[5]
Out[397]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')

In [398]: rng_berlin[5]
Out[398]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')

In [399]: rng_eastern[5].tz_convert('Europe/Berlin')
Out[399]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin')
```

Localization of `Timestamp` functions just like `DatetimeIndex` and `Series`:

```
In [400]: rng[5]
Out[400]: Timestamp('2012-03-11 00:00:00', freq='D')

In [401]: rng[5].tz_localize('Asia/Shanghai')
Out[401]: Timestamp('2012-03-11 00:00:00+0800', tz='Asia/Shanghai')
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```
In [402]: eastern = ts_utc.tz_convert('US/Eastern')

In [403]: berlin = ts_utc.tz_convert('Europe/Berlin')

In [404]: result = eastern + berlin

In [405]: result
Out[405]:
2012-03-06 00:00:00+00:00    0.074412
```

(continues on next page)

(continued from previous page)

```

DatetimeIndex(['2012-03-06', '2012-03-07', '2012-03-08', '2012-03-09',
              '2012-03-10', '2012-03-11', '2012-03-12', '2012-03-13',
              '2012-03-14', '2012-03-15', '2012-03-16', '2012-03-17',
              '2012-03-18', '2012-03-19', '2012-03-20'],
              dtype='datetime64[ns, UTC]', freq='D')

```

To remove timezone from tz-aware DatetimeIndex, use `tz_localize(None)` or `tz_convert(None)`. `tz_localize(None)` will remove timezone holding local time representations. `tz_convert(None)` will remove timezone after converting to UTC time.

```
In [407]: didx = pd.DatetimeIndex(start='2014-08-01 09:00', freq='H', periods=10, tz=
      ↪ 'US/Eastern')
```

```
In [408]: didx
```

```

### 19.14.2 Ambiguous Times when Localizing

In some cases, localize cannot determine the DST and non-DST hours when there are duplicates. This often happens when reading files or database records that simply duplicate the hours. Passing `ambiguous='infer'` into `tz_localize` will attempt to determine the right offset. Below the top example will fail as it contains ambiguous times and the bottom will infer the right offset.

```

In [412]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00',
.....:                                '11/06/2011 01:00', '11/06/2011 02:00',
.....:                                '11/06/2011 03:00'])
.....:

```

This will fail as there are ambiguous times

```

In [2]: rng_hourly.tz_localize('US/Eastern')
AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try_
↪ using the 'ambiguous' argument

```

Infer the ambiguous times

```

In [413]: rng_hourly_eastern = rng_hourly.tz_localize('US/Eastern', ambiguous='infer')

In [414]: rng_hourly_eastern.tolist()
Out[414]:
[Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0400', tz='US/Eastern'),
 Timestamp('2011-11-06 01:00:00-0500', tz='US/Eastern'),
 Timestamp('2011-11-06 02:00:00-0500', tz='US/Eastern'),
 Timestamp('2011-11-06 03:00:00-0500', tz='US/Eastern')]

```

In addition to ‘infer’, there are several other arguments supported. Passing an array-like of bools or 0s/1s where True represents a DST hour and False a non-DST hour, allows for distinguishing more than one DST transition (e.g., if you have multiple records in a database each with their own DST transition). Or passing ‘NaT’ will fill in transition times with not-a-time values. These methods are available in the `DatetimeIndex` constructor as well as `tz_localize`.

```

In [415]: rng_hourly_dst = np.array([1, 1, 0, 0, 0])

In [416]: rng_hourly.tz_localize('US/Eastern', ambiguous=rng_hourly_dst).tolist()

```

(continues on next page)

(continued from previous page)

```

Out[416]:

### 19.14.3 TZ Aware Dtypes

Series/DatetimeIndex with a timezone **naive** value are represented with a dtype of `datetime64[ns]`.

```
In [423]: s_naive = pd.Series(pd.date_range('20130101', periods=3))

In [424]: s_naive
Out[424]:
0    2013-01-01
1    2013-01-02
2    2013-01-03
dtype: datetime64[ns]
```

Series/DatetimeIndex with a timezone **aware** value are represented with a dtype of `datetime64[ns, tz]`.

```
In [425]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))

In [426]: s_aware
Out[426]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series can be manipulated via the `.dt` accessor, see [here](#).

For example, to localize and convert a naive stamp to timezone aware.

```
In [427]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[427]:
0    2012-12-31 19:00:00-05:00
1    2013-01-01 19:00:00-05:00
2    2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Further more you can `.astype(...)` timezone aware (and naive). This operation is effectively a localize AND convert on a naive stamp, and a convert on an aware stamp.

```
# localize and convert a naive timezone
In [428]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[428]:
0    2012-12-31 19:00:00-05:00
1    2013-01-01 19:00:00-05:00
2    2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
In [429]: s_aware.astype('datetime64[ns]')
Out[429]:
0    2013-01-01 05:00:00
1    2013-01-02 05:00:00
```

(continues on next page)

(continued from previous page)

```

2    2013-01-03 05:00:00
dtype: datetime64[ns]

# convert to a new timezone
In [430]: s_aware.astype('datetime64[ns, CET]')
///////////////////////////////////////////////////
↪
0    2013-01-01 06:00:00+01:00
1    2013-01-02 06:00:00+01:00
2    2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]

```

**Note:** Using the `.values` accessor on a `Series`, returns an NumPy array of the data. These values are converted to UTC, as NumPy does not currently support timezones (even though it is *printing* in the local timezone!).

```

In [431]: s_naive.values
Out[431]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [432]: s_aware.values
///////////////////////////////////////////////////
↪
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')

```

Further note that once converted to a NumPy array these would lose the tz tenor.

```

In [433]: pd.Series(s_aware.values)
Out[433]:
0    2013-01-01 05:00:00
1    2013-01-02 05:00:00
2    2013-01-03 05:00:00
dtype: datetime64[ns]

```

However, these can be easily converted:

```

In [434]: pd.Series(s_aware.values).dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[434]:
0    2013-01-01 00:00:00-05:00
1    2013-01-02 00:00:00-05:00
2    2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]

```

## TIME DELTAS

Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of `datetime.timedelta`, and behaves in a similar manner, but allows compatibility with `np.timedelta64` types as well as a host of custom representation, parsing, and attributes.

### 20.1 Parsing

You can construct a `Timedelta` scalar through various arguments:

```
# strings
In [1]: pd.Timedelta('1 days')
Out[1]: Timedelta('1 days 00:00:00')

In [2]: pd.Timedelta('1 days 00:00:00')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 2 hours')
Out[3]: Timedelta('1 days 02:00:00')

In [4]: pd.Timedelta('-1 days 2 min 3us')
Out[4]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [5]: pd.Timedelta(days=1, seconds=1)
Out[5]: Timedelta('1 days 00:00:01')

# integers with a unit
In [6]: pd.Timedelta(1, unit='d')
Out[6]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [7]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[7]: Timedelta('1 days 00:00:01')

In [8]: pd.Timedelta(np.timedelta64(1, 'ms'))
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪Timedelta('0 days 00:00:00.001000')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [9]: pd.Timedelta('-1us')
////////////////////////////////////
↪Timedelta('-1 days +23:59:59.999999')

# a NaT
In [10]: pd.Timedelta('nan')
////////////////////////////////////
↪NaT

In [11]: pd.Timedelta('nat')
////////////////////////////////////
↪NaT

# ISO 8601 Duration strings
In [12]: pd.Timedelta('P0DT0H1M0S')
////////////////////////////////////
↪Timedelta('0 days 00:01:00')

In [13]: pd.Timedelta('P0DT0H0M0.000000123S')
////////////////////////////////////
↪Timedelta('0 days 00:00:00.000000')

```

New in version 0.23.0: Added constructor for [ISO 8601 Duration strings](#)

*DateOffsets* (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

```

In [14]: pd.Timedelta(Second(2))
Out [14]: Timedelta('0 days 00:00:02')

```

Further, operations among the scalars yield another scalar `Timedelta`.

```

In [15]: pd.Timedelta(Day(2)) + pd.Timedelta(Second(2)) + pd.Timedelta('00:00:00.
↪000123')
Out [15]: Timedelta('2 days 00:00:02.000123')

```

### 20.1.1 to\_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or `Series` from a recognized `timedelta` format / value into a `Timedelta` type. It will construct `Series` if the input is a `Series`, a scalar if the input is scalar-like, otherwise it will output a `TimedeltaIndex`.

You can parse a single string to a `Timedelta`:

```

In [16]: pd.to_timedelta('1 days 06:05:01.00003')
Out [16]: Timedelta('1 days 06:05:01.000030')

In [17]: pd.to_timedelta('15.5us')
////////////////////////////////////Out [17]: Timedelta('0 days 00:00:00.
↪000015')

```

or a list/array of strings:

```
In [18]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[18]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
↳dtype='timedelta64[ns]', freq=None)
```

The unit keyword argument specifies the unit of the Timedelta:

```
In [19]: pd.to_timedelta(np.arange(5), unit='s')
Out[19]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
↳dtype='timedelta64[ns]', freq=None)

In [20]: pd.to_timedelta(np.arange(5), unit='d')
////////////////////////////////////Out[20]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
↳'timedelta64[ns]', freq=None)
```

### 20.1.2 Timedelta limitations

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

```
In [21]: pd.Timedelta.min
Out[21]: Timedelta('-106752 days +00:12:43.145224')

In [22]: pd.Timedelta.max
////////////////////////////////////Out[22]: Timedelta('106751 days
↳23:47:16.854775')
```

## 20.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

```
In [23]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [24]: td = pd.Series([ pd.Timedelta(days=i) for i in range(3) ])

In [25]: df = pd.DataFrame(dict(A = s, B = td))

In [26]: df
Out[26]:
      A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [27]: df['C'] = df['A'] + df['B']

In [28]: df
Out[28]:
      A      B      C
0 2012-01-01 0 days 2012-01-01

dtype: datetime64[ns]

```

Operations with scalars from a `timedelta64[ns]` series:**In [35]:** y = s - s[0]**In [36]:** y**Out[36]:**

```

0    0 days
1    1 days

```

(continues on next page)

(continued from previous page)

```
2    2 days
dtype: timedelta64[ns]
```

Series of timedeltas with NaT values are supported:

```
In [37]: y = s - s.shift()

In [38]: y
Out[38]:
0      NaT
1    1 days
2    1 days
dtype: timedelta64[ns]
```

Elements can be set to NaT using `np.nan` analogously to datetimes:

```
In [39]: y[1] = np.nan

In [40]: y
Out[40]:
0      NaT
1      NaT
2    1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```
In [41]: s.max() - s
Out[41]:
0    2 days
1    1 days
2    0 days
dtype: timedelta64[ns]

In [42]: datetime.datetime(2011, 1, 1, 3, 5) - s
Out[42]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

In [43]: datetime.datetime(2012, 1, 1, 0, 5) + s
Out[43]:
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]
```

`min`, `max` and the corresponding `idxmin`, `idxmax` operations are supported on frames:

```
In [44]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [45]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [46]: df = pd.DataFrame(dict(A=A, B=B))
```

(continues on next page)

(continued from previous page)

```
In [47]: df
Out[47]:
```

|   | A                 | B       |
|---|-------------------|---------|
| 0 | -1 days +23:54:55 | -1 days |
| 1 | 0 days 23:54:55   | -1 days |
| 2 | 1 days 23:54:55   | -1 days |

```
In [48]: df.min()
Out[48]:
A    -1 days +23:54:55
B    -1 days +00:00:00
dtype: timedelta64[ns]
```

```
In [49]: df.min(axis=1)
Out[49]:
0    -1 days
1    -1 days
2    -1 days
dtype: timedelta64[ns]
```

```
In [50]: df.idxmin()
Out[50]:
A    0
B    0
dtype: int64
```

```
In [51]: df.idxmax()
Out[51]:
A    2
B    0
dtype: int64
```

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

```
In [52]: df.min().max()
Out[52]: Timedelta('-1 days +23:54:55')

In [53]: df.min(axis=1).min()
Out[53]: Timedelta('-1 days +00:00:00')
```

```
In [54]: df.min().idxmax()
Out[54]: 'A'
```

```
In [55]: df.min(axis=1).idxmin()
Out[55]: 0
```

You can fillna on timedeltas. Integers will be interpreted as seconds. You can pass a timedelta to get a particular value.

```
In [56]: y.fillna(0)
Out[56]:
```

(continues on next page)

(continued from previous page)

```

0    0 days
1    0 days
2    1 days
dtype: timedelta64[ns]

In [57]: y.fillna(10)
Out[57]:
0    0 days 00:00:10
1    0 days 00:00:10
2    1 days 00:00:00
dtype: timedelta64[ns]

In [58]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
Out[58]:
0    -1 days +00:00:05
1    -1 days +00:00:05
2     1 days 00:00:00
dtype: timedelta64[ns]

```

You can also negate, multiply and use abs on Timedeltas:

```

In [59]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')

In [60]: td1
Out[60]: Timedelta('-2 days +21:59:57')

In [61]: -1 * td1
Out[61]: Timedelta('1 days 02:00:03')

In [62]: -td1
Out[62]: Timedelta('1 days 02:00:03')

In [63]: abs(td1)
Out[63]: Timedelta('1 days 02:00:03')

```

## 20.3 Reductions

Numeric reduction operation for `timedelta64[ns]` will return `Timedelta` objects. As usual `NaT` are skipped during evaluation.

```

In [64]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat', '-1 days_
Out[64]:
0    -1 days +00:00:05
1         NaT
2    -1 days +00:00:05
3     1 days 00:00:00
dtype: timedelta64[ns]

```

(continues on next page)

(continued from previous page)

[illegible][illegible]

## 20.4 Frequency Conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```
In [70]: td = pd.Series(pd.date_range('20130101', periods=4)) - \
.....:     pd.Series(pd.date_range('20121201', periods=4))
.....:
```

```
In [71]: td[2] += datetime.timedelta(minutes=5, seconds=3)
```

```
In [72]: td[3] = np.nan
```

```
In [73]: td
```

Out [73]:

```
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3              NaT
dtype: timedelta64[ns]
```

```
# to days
```

```
In [74]: td / np.timedelta64(1, 'D')
```

```
0      31.000000
1      31.000000
2      31.003507
3           NaN
dtype: float64
```

```
In [75]: td.astype('timedelta64[D]')
```

|   |      |
|---|------|
|   |      |
| ↔ |      |
| 0 | 31.0 |
| 1 | 31.0 |
| 2 | 31.0 |

(continues on next page)

```
# to seconds
```

```
In [77]: td.astype('timedelta64[s]')
```

```
# to months (these are constant months)
```

Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

```
In [80]: td * pd.Series([1, 2, 3, 4])
```

Rounded division (floor-division) of a `timedelta64[ns]` Series by a scalar `Timedelta` gives a series of integers.

---

(continues on next page)

(continued from previous page)

```

0    9.0
1    9.0
2    9.0
3    NaN
dtype: float64

In [82]: pd.Timedelta(days=3, hours=4) // td
Out[82]:
0    0.0
1    0.0
2    0.0
3    NaN
dtype: float64

```

The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

```

In [83]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[83]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [84]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[84]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [85]: divmod(pd.Timedelta(hours=25), 864000000000000)
Out[85]: (Timedelta('0 days 00:00:00.000000'), Timedelta('0 days 01:00:00'))

```

## 20.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes `days`, `seconds`, `microseconds`, `nanoseconds`. These are identical to the values returned by `datetime.timedelta`, in that, for example, the `.seconds` attribute represents the number of seconds  $\geq 0$  and  $< 1$  day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the `.dt` property of the Series as well.

**Note:** Note that the attributes are NOT the displayed values of the Timedelta. Use `.components` to retrieve the displayed values.

For a Series:

```

In [86]: td.dt.days
Out[86]:
0    31.0
1    31.0
2    31.0
3    NaN
dtype: float64

In [87]: td.dt.seconds

```

(continues on next page)

```
Out[87]:
0      0.0
1      0.0
2     303.0
3      NaN
dtype: float64
```

Using `TimedeltaIndex` you can pass string-like, `Timedelta`, `timedelta`, or `np.timedelta64` objects. Passing `np.nan/pd.NaT/nat` will represent missing values.

```
In [95]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
.....:                      np.timedelta64(2, 'D'), datetime.timedelta(days=2,
↳seconds=2)])
.....:
Out[95]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
               '2 days 00:00:02'],
               dtype='timedelta64[ns]', freq=None)
```

### 20.6.1 Generating Ranges of Time Deltas

Similar to `date_range()`, you can construct regular ranges of a `TimedeltaIndex` using `timedelta_range()`. The default frequency for `timedelta_range` is calendar day:

```
In [96]: pd.timedelta_range(start='1 days', periods=5)
Out[96]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↳ 'timedelta64[ns]', freq='D')
```

Various combinations of `start`, `end`, and `periods` can be used with `timedelta_range`:

```
In [97]: pd.timedelta_range(start='1 days', end='5 days')
Out[97]: TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'], dtype=
↳ 'timedelta64[ns]', freq='D')

In [98]: pd.timedelta_range(end='10 days', periods=4)
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳ TimedeltaIndex(['7 days', '8 days', '9 days', '10 days'], dtype='timedelta64[ns]
↳ freq='D')
```

The `freq` parameter can be passed a variety of *frequency aliases*:

```
In [99]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
Out[99]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:30:00', '1 days 01:00:00',
                '1 days 01:30:00', '1 days 02:00:00', '1 days 02:30:00',
                '1 days 03:00:00', '1 days 03:30:00', '1 days 04:00:00',
                '1 days 04:30:00', '1 days 05:00:00', '1 days 05:30:00',
                '1 days 06:00:00', '1 days 06:30:00', '1 days 07:00:00',
                '1 days 07:30:00', '1 days 08:00:00', '1 days 08:30:00',
                '1 days 09:00:00', '1 days 09:30:00', '1 days 10:00:00',
                '1 days 10:30:00', '1 days 11:00:00', '1 days 11:30:00',
                '1 days 12:00:00', '1 days 12:30:00', '1 days 13:00:00',
                '1 days 13:30:00', '1 days 14:00:00', '1 days 14:30:00',
                '1 days 15:00:00', '1 days 15:30:00', '1 days 16:00:00',
                '1 days 16:30:00', '1 days 17:00:00', '1 days 17:30:00',
                '1 days 18:00:00', '1 days 18:30:00', '1 days 19:00:00',
                '1 days 19:30:00', '1 days 20:00:00', '1 days 20:30:00',
                '1 days 21:00:00', '1 days 21:30:00', '1 days 22:00:00',
                '1 days 22:30:00', '1 days 23:00:00', '1 days 23:30:00',
                '2 days 00:00:00'],
                dtype='timedelta64[ns]', freq='30T')

In [100]: pd.timedelta_range(start='1 days', periods=5, freq='2D5H')
```

(continues on next page)

(continued from previous page)

```

////////////////////////////////////
↪
TimedeltaIndex(['1 days 00:00:00', '3 days 05:00:00', '5 days 10:00:00',
               '7 days 15:00:00', '9 days 20:00:00'],
              dtype='timedelta64[ns]', freq='53H')

```

New in version 0.23.0.

Specifying start, end, and periods will generate a range of evenly spaced timesteps from start to end inclusively, with periods number of elements in the resulting `TimedeltaIndex`:

```

In [101]: pd.timedelta_range('0 days', '4 days', periods=5)
Out[101]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype=
↪ 'timedelta64[ns]', freq=None)

In [102]: pd.timedelta_range('0 days', '4 days', periods=10)
////////////////////////////////////
↪
TimedeltaIndex(['0 days 00:00:00', '0 days 10:40:00', '0 days 21:20:00',
               '1 days 08:00:00', '1 days 18:40:00', '2 days 05:20:00',
               '2 days 16:00:00', '3 days 02:40:00', '3 days 13:20:00',
               '4 days 00:00:00'],
              dtype='timedelta64[ns]', freq=None)

```

## 20.6.2 Using the `TimedeltaIndex`

Similarly to other of the datetime-like indices, `DatetimeIndex` and `PeriodIndex`, you can use `TimedeltaIndex` as the index of pandas objects.

```

In [103]: s = pd.Series(np.arange(100),
.....:                  index=pd.timedelta_range('1 days', periods=100, freq='h'))
.....:

In [104]: s
Out[104]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
..
4 days 21:00:00   93
4 days 22:00:00   94
4 days 23:00:00   95
5 days 00:00:00   96
5 days 01:00:00   97
5 days 02:00:00   98
5 days 03:00:00   99
Freq: H, Length: 100, dtype: int64

```

Selections work similarly, with coercion on string-likes and slices:

```
In [105]: s['1 day':'2 day']
Out[105]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
..
2 days 17:00:00   41
2 days 18:00:00   42
2 days 19:00:00   43
2 days 20:00:00   44
2 days 21:00:00   45
2 days 22:00:00   46
2 days 23:00:00   47
Freq: H, Length: 48, dtype: int64
```

```
In [106]: s['1 day 01:00:00']
```

```

////////////////////////////////////
↪1
```

```
In [107]: s[pd.Timedelta('1 day 1h')]
```

```

////////////////////////////////////
↪1
```

Furthermore you can use partial string selection and the range will be inferred:

```
In [108]: s['1 day':'1 day 5 hours']
Out[108]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```

### 20.6.3 Operations

Finally, the combination of `TimedeltaIndex` with `DatetimeIndex` allow certain combination operations that are NaT preserving:

```
In [109]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [110]: tdi.tolist()
Out[110]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [111]: dti = pd.date_range('20130101', periods=3)

In [112]: dti.tolist()
Out[112]: [Timestamp('2013-01-01 00:00:00', freq='D'),
Timestamp('2013-01-02 00:00:00', freq='D'),
Timestamp('2013-01-03 00:00:00', freq='D')]
```

(continues on next page)

(continued from previous page)

```

In [113]: (dti + tdi).tolist()
\\Out[113]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [114]: (dti - tdi).tolist()
\\Out[114]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]

```

## 20.6.4 Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

```

In [115]: tdi / np.timedelta64(1, 's')
Out[115]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

In [116]: tdi.astype('timedelta64[s]')
\\Out[116]: Float64Index([86400.0, nan, 172800.0], dtype='float64')

```

Scalars type ops work as well. These can potentially return a *different* type of index.

```

# adding or timedelta and date -> datelike
In [117]: tdi + pd.Timestamp('20130101')
Out[117]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]', freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [118]: (pd.Timestamp('20130101') - tdi).tolist()
\\Out[118]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [119]: tdi + pd.Timedelta('10 days')
\\Out[119]: TimedeltaIndex(['11 days', 'NaT', '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
In [120]: tdi / 2
\\Out[120]: TimedeltaIndex(['0 days 12:00:00', 'NaT', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)

# or a Float64Index if the divisor is a Timedelta
In [121]: tdi / tdi[0]
\\Out[121]: Float64Index([1.0, nan, 2.0], dtype='float64')

```

## 20.7 Resampling

Similar to *timeseries resampling*, we can resample with a TimedeltaIndex.

```
In [122]: s.resample('D').mean()
Out[122]:
1 days    11.5
2 days    35.5
3 days    59.5
4 days    83.5
5 days    97.5
Freq: D, dtype: float64
```

## CATEGORICAL DATA

This is an introduction to pandas categorical data type, including a short comparison with R's `factor`.

*Categoricals* are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (*categories*; *levels* in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. 'strongly agree' vs 'agree' or 'first observation' vs. 'second observation'), but numerical operations (additions, divisions, ...) are not possible.

All values of categorical data are either in *categories* or *np.nan*. Order is defined by the order of *categories*, not lexical order of the values. Internally, the data structure consists of a *categories* array and an integer array of *codes* which point to the real value in the *categories* array.

The categorical data type is useful in the following cases:

- A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see [here](#).
- The lexical order of a variable is not the same as the logical order ("one", "two", "three"). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see [here](#).
- As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the [API docs on categoricals](#).

## 21.1 Object Creation

### 21.1.1 Series Creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying `dtype="category"` when constructing a Series:

```
In [1]: s = pd.Series(["a", "b", "c", "a"], dtype="category")

In [2]: s
Out[2]:
0      a
1      b
2      c
3      a
```

(continues on next page)

(continued from previous page)

```
dtype: category
Categories (3, object): [a, b, c]
```

By converting an existing Series or column to a category dtype:

```
In [3]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})

In [4]: df["B"] = df["A"].astype('category')

In [5]: df
Out[5]:
   A B
0  a a
1  b b
2  c c
3  a a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the [example on tiling](#) in the docs.

```
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})

In [7]: labels = ["{0} - {1}".format(i, i + 9) for i in range(0, 100, 10)]

In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)

In [9]: df.head(10)
Out[9]:
   value  group
0     65  60 - 69
1     49  40 - 49
2     56  50 - 59
3     43  40 - 49
4     43  40 - 49
5     91  90 - 99
6     32  30 - 39
7     87  80 - 89
8     36  30 - 39
9      8   0 - 9
```

By passing a `pandas.Categorical` object to a Series or assigning it to a DataFrame.

```
In [10]: raw_cat = pd.Categorical(["a", "b", "c", "a"], categories=["b", "c", "d"],
....:                             ordered=False)
....:

In [11]: s = pd.Series(raw_cat)

In [12]: s
Out[12]:
0    NaN
1     b
2     c
3    NaN
dtype: category
Categories (3, object): [b, c, d]
```

(continues on next page)

(continued from previous page)

```
In [13]: df = pd.DataFrame({"A": ["a", "b", "c", "a"]})
In [14]: df["B"] = raw_cat
In [15]: df
Out[15]:
   A    B
0  a  NaN
1  b    b
2  c    c
3  a  NaN
```

Categorical data has a specific category *dtype*:

```
In [16]: df.dtypes
Out[16]:
A      object
B    category
dtype: object
```

## 21.1.2 DataFrame Creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying `dtype="category"` in the DataFrame constructor:

```
In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")
In [18]: df.dtypes
Out[18]:
A    category
B    category
dtype: object
```

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

```
In [19]: df['A']
Out[19]:
0    a
1    b
2    c
3    a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df['B']
Out[20]:
0    b
1    c
2    c
3    d
```

(continues on next page)

(continued from previous page)

```
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

New in version 0.23.0.

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A      category
B      category
dtype: object
```

This conversion is likewise done column by column:

```
In [24]: df_cat['A']
Out[24]:
0      a
1      b
2      c
3      a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [25]: df_cat['B']
Out[25]:
0      b
1      c
2      c
3      d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

### 21.1.3 Controlling Behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing `'category'`, use an instance of `CategoricalDtype`.

```
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(["a", "b", "c", "a"])
In [28]: cat_type = CategoricalDtype(categories=["b", "c", "d"],
.....:                                     ordered=True)
.....:
```

(continues on next page)

### 21.1.4 Regaining Original Data

To get back to the original Series or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```
In [38]: s = pd.Series(["a", "b", "c", "a"])

In [39]: s
Out[39]:
0    a
1    b
2    c
3    a
dtype: object

In [40]: s2 = s.astype('category')

In [41]: s2
Out[41]:
0    a
1    b
2    c
3    a
dtype: category
Categories (3, object): [a, b, c]

In [42]: s2.astype(str)
Out[42]:
0    a
1    b
2    c
3    a
dtype: object

In [43]: np.asarray(s2)
array(['a', 'b', 'c', 'a'], dtype=object)
```

---

**Note:** In contrast to R's *factor* function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

---

---

**Note:** In contrast to R's *factor* function, there is currently no way to assign/change labels at creation time. Use *categories* to change the categories after creation time.

---

## 21.2 CategoricalDtype

Changed in version 0.21.0.

A categorical's type is fully described by

1. `categories`: a sequence of unique values and no missing values

2. `ordered`: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```
In [44]: from pandas.api.types import CategoricalDtype

In [45]: CategoricalDtype(['a', 'b', 'c'])
Out[45]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=None)

In [46]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)

In [47]: CategoricalDtype()
Out[47]: CategoricalDtype(categories=None, ordered=None)
```

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the Series constructor.

**Note:** As a convenience, you can use the string `'category'` in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

### 21.2.1 Equality Semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```
In [48]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)

# Equal, since order is not considered when ordered=False
In [49]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[49]: True

# Unequal, since the second CategoricalDtype is ordered
In [50]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[50]: False
```

All instances of `CategoricalDtype` compare equal to the string `'category'`.

```
In [51]: c1 == 'category'
Out[51]: True
```

**Warning:** Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to `'category'`, all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of categories or ordered.

## 21.3 Description

Using `describe()` on categorical data will produce similar output to a Series or DataFrame of type string.

```
In [52]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])

In [53]: df = pd.DataFrame({"cat":cat, "s":["a", "c", "c", np.nan]})

In [54]: df.describe()
Out[54]:
```

|        | cat | s |
|--------|-----|---|
| count  | 3   | 3 |
| unique | 2   | 2 |
| top    | c   | c |
| freq   | 2   | 2 |

```
In [55]: df["cat"].describe()
Out[55]:
```

|        |   |
|--------|---|
| count  | 3 |
| unique | 2 |
| top    | c |
| freq   | 2 |

```
Name: cat, dtype: object
```

## 21.4 Working with categories

Categorical data has a *categories* and a *ordered* property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don't manually specify categories and ordering, they are inferred from the passed arguments.

```
In [56]: s = pd.Series(["a","b","c","a"], dtype="category")

In [57]: s.cat.categories
Out[57]: Index(['a', 'b', 'c'], dtype='object')

In [58]: s.cat.ordered
Out[58]: False
```

It's also possible to pass in the categories in a specific order:

```
In [59]: s = pd.Series(pd.Categorical(["a", "b", "c", "a"], categories=["c", "b", "a"]))
In [60]: s.cat.categories
Out[60]: Index(['c', 'b', 'a'], dtype='object')

In [61]: s.cat.ordered
Out[61]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`.

```

////////////////////////////////////////
↪
[b, a, c]
Categories (3, object): [b, a, c]

```

```
\\Out[64]:
```

```
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

1019

(continued from previous page)

```
In [70]: s.cat.rename_categories([1,2,3])
```

```

////////////////////////////////////
↪
0      1
1      2
2      3
3      1
dtype: category
Categories (3, int64): [1, 2, 3]
```

```
In [71]: s
```

```

////////////////////////////////////
↪
0      Group a
1      Group b
2      Group c
3      Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

```
# You can also pass a dict-like object to map the renaming
```

```
In [72]: s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})
```

```

////////////////////////////////////
↪
0      Group a
1      Group b
2      Group c
3      Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

```
In [73]: s
```

```

////////////////////////////////////
↪
0      Group a
1      Group b
2      Group c
3      Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

---

**Note:** In contrast to R's *factor*, categorical data can have categories of other types than string.

---

---

**Note:** Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

---

Categories must be unique or a `ValueError` is raised:

```
In [74]: try:
....:     s.cat.categories = [1,1,1]
....: except ValueError as e:
....:     print("ValueError: " + str(e))
....:
```

(continues on next page)

(continued from previous page)

```
ValueError: Categorical categories must be unique
```

Categories must also not be NaN or a *ValueError* is raised:

```
In [75]: try:
.....:     s.cat.categories = [1,2,np.nan]
.....: except ValueError as e:
.....:     print("ValueError: " + str(e))
.....:
ValueError: Categorical categories cannot be null
```

## 21.4.2 Appending new categories

Appending categories can be done by using the `add_categories()` method:

```
In [76]: s = s.cat.add_categories([4])

In [77]: s.cat.categories
Out[77]: Index(['Group a', 'Group b', 'Group c', 4], dtype='object')

In [78]: s
Out[78]:
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (4, object): [Group a, Group b, Group c, 4]
```

## 21.4.3 Removing categories

Removing categories can be done by using the `remove_categories()` method. Values which are removed are replaced by `np.nan`:

```
In [79]: s = s.cat.remove_categories([4])

In [80]: s
Out[80]:
0    Group a
1    Group b
2    Group c
3    Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

## 21.4.4 Removing unused categories

Removing unused categories can also be done:

```
In [81]: s = pd.Series(pd.Categorical(["a","b","a"], categories=["a","b","c","d"]))
```

(continues on next page)

(continued from previous page)

```

In [82]: s
Out[82]:
0      a
1      b
2      a
dtype: category
Categories (4, object): [a, b, c, d]

In [83]: s.cat.remove_unused_categories()
Out[83]:
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]

```

### 21.4.5 Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```

In [84]: s = pd.Series(["one", "two", "four", "-"], dtype="category")

In [85]: s
Out[85]:
0      one
1      two
2      four
3      -
dtype: category
Categories (4, object): [-, four, one, two]

In [86]: s = s.cat.set_categories(["one", "two", "three", "four"])

In [87]: s
Out[87]:
0      one
1      two
2      four
3      NaN
dtype: category
Categories (4, object): [one, two, three, four]

```

**Note:** Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!

[illegible]

```
In [94]: s.cat.as_ordered()
Out[94]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a < b < c]

In [95]: s.cat.as_unordered()
Out[95]:
0      a
3      a
1      b
2      c
dtype: category
Categories (3, object): [a, b, c]
```

```
In [96]: s = pd.Series([1,2,3,1], dtype="category")
In [97]: s = s.cat.set_categories([2,3,1], ordered=True)
```

1023

(continued from previous page)

[illegible]

### 21.5.1 Reordering

Reordering the categories is possible via the `Categorical.reorder_categories()` and the `Categorical.set_categories()` methods. For `Categorical.reorder_categories()`, all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

```
In [102]: s = pd.Series([1,2,3,1], dtype="category")

In [103]: s = s.cat.reorder_categories([2,3,1], ordered=True)

In [104]: s
Out[104]:
0    1
1    2
2    3
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [105]: s.sort_values(inplace=True)

In [106]: s
Out[106]:
1    2
2    3
0    1
3    1
dtype: category
Categories (3, int64): [2 < 3 < 1]
```

(continues on next page)

(continued from previous page)

```
In [107]: s.min(), s.max()
\\Out[107]:
↪ (2, 1)
```

**Note:** Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the `Series`, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the `Series` are changed.

**Note:** If the `Categorical` is not ordered, `Series.min()` and `Series.max()` will raise `TypeError`. Numeric operations like `+`, `-`, `*`, `/` and operations based on them (e.g. `Series.median()`, which would need to compute the mean between two values if the length of an array is even) do not work and raise a `TypeError`.

## 21.5.2 Multi Column Sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

```
In [108]: dfs = pd.DataFrame({'A' : pd.Categorical(list('bbeebbaa'), categories=['e',
↪ 'a', 'b'], ordered=True),
.....:                      'B' : [1,2,1,2,2,1,2,1] })
.....:

In [109]: dfs.sort_values(by=['A', 'B'])
Out[109]:
   A  B
2  e  1
3  e  2
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
```

Reordering the categories changes a future sort.

```
In [110]: dfs['A'] = dfs['A'].cat.reorder_categories(['a', 'b', 'e'])

In [111]: dfs.sort_values(by=['A', 'B'])
Out[111]:
   A  B
7  a  1
6  a  2
0  b  1
5  b  1
1  b  2
4  b  2
2  e  1
3  e  2
```

## 21.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (`==` and `!=`) to a list-like object (list, Series, array, ...) of the same length as the categorical data.
- All comparisons (`==`, `!=`, `>`, `>=`, `<`, and `<=`) of categorical data to another categorical Series, when `ordered==True` and the *categories* are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a `TypeError`.

**Note:** Any “non-equality” comparisons of categorical data with a `Series`, `np.array`, `list` or categorical data with different categories or ordering will raise a `TypeError` because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```
In [112]: cat = pd.Series([1,2,3]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [113]: cat_base = pd.Series([2,2,2]).astype(
.....:     CategoricalDtype([3, 2, 1], ordered=True)
.....: )
.....:

In [114]: cat_base2 = pd.Series([2,2,2]).astype(
.....:     CategoricalDtype(ordered=True)
.....: )
.....:

In [115]: cat
Out[115]:
0    1
1    2
2    3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [116]: cat_base
Out[116]:
0    2
1    2
2    2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base2
Out[117]:
0    2
1    2
```

(continues on next page)

```
In [124]: base = np.array([1,2,3])  
  
In [125]: try:  
.....:     cat > base  
.....: except TypeError as e:  
.....:     print("TypeError: " + str(e))  
.....:  
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'  
↳ '>'.  
If you want to compare values, use 'np.asarray(cat) <op> other'.  
  
In [126]: np.asarray(cat) > base  
/////////////////////////////////////  
↳ array([False, False, False], dtype=bool)
```

When you compare two unordered categoricals with the same categories, the order is not considered:

```
In [127]: c1 = pd.Categorical(['a', 'b'], categories=['a', 'b'], ordered=False)
In [128]: c2 = pd.Categorical(['a', 'b'], categories=['b', 'a'], ordered=False)
In [129]: c1 == c2
Out[129]: array([ True,  True], dtype=bool)
```

## 21.7 Operations

Apart from `Series.min()`, `Series.max()` and `Series.mode()`, the following operations are possible with categorical data:

Series methods like `Series.value_counts()` will use all categories, even if some categories are not present in the data:

```
In [130]: s = pd.Series(pd.Categorical(["a", "b", "c", "c"], categories=["c", "a", "b", "d"
↳ ""]))

In [131]: s.value_counts()
Out[131]:
c      2
b      1
a      1
d      0
dtype: int64
```

Groupby will also show “unused” categories:

```
In [132]: cats = pd.Categorical(["a", "b", "b", "b", "c", "c", "c"], categories=["a", "b", "c", "d"])
In [133]: df = pd.DataFrame({"cats": cats, "values": [1, 2, 2, 2, 3, 4, 5]})
In [134]: df.groupby("cats").mean()
Out[134]:
```

|      | values |
|------|--------|
| cats |        |
| a    | 1.0    |

(continues on next page)

(continued from previous page)

```

b      2.0
c      4.0
d      NaN

In [135]: cats2 = pd.Categorical(["a","a","b","b"], categories=["a","b","c"])

In [136]: df2 = pd.DataFrame({"cats":cats2,"B":["c","d","c","d"], "values":[1,2,3,4]})

In [137]: df2.groupby(["cats","B"]).mean()
Out[137]:
      values
cats B
a     c     1.0
     d     2.0
b     c     3.0
     d     4.0
c     c     NaN
     d     NaN

```

Pivot tables:

```

In [138]: raw_cat = pd.Categorical(["a","a","b","b"], categories=["a","b","c"])

In [139]: df = pd.DataFrame({"A":raw_cat,"B":["c","d","c","d"], "values":[1,2,3,4]})

In [140]: pd.pivot_table(df, values='values', index=['A', 'B'])
Out[140]:
      values
A B
a c         1
  d         2
b c         3
  d         4

```

## 21.8 Data munging

The optimized pandas data access methods `.loc`, `.iloc`, `.at`, and `.iat`, work as normal. The only difference is the return type (for getting) and that only values already in *categories* can be assigned.

### 21.8.1 Getting

If the slicing operation returns either a `DataFrame` or a column of type `Series`, the `category` dtype is preserved.

```

In [141]: idx = pd.Index(["h","i","j","k","l","m","n",])

In [142]: cats = pd.Series(["a","b","b","b","c","c","c"], dtype="category", index=idx)

In [143]: values= [1,2,2,2,3,4,5]

In [144]: df = pd.DataFrame({"cats":cats,"values":values}, index=idx)

In [145]: df.iloc[2:4,:]
Out[145]:

```

(continues on next page)

(continued from previous page)

```

   cats  values
j      b      2
k      b      2

```

```
In [146]: df.iloc[2:4,:].dtypes
```

```

////////////////////////////////////Out[146]:
cats      category
values      int64
dtype: object

```

```
In [147]: df.loc["h":"j", "cats"]
```

```

////////////////////////////////////
↪
h      a
i      b
j      b
Name: cats, dtype: category
Categories (3, object): [a, b, c]

```

```
In [148]: df[df["cats"] == "b"]
```

```

////////////////////////////////////
↪
   cats  values
i      b      2
j      b      2
k      b      2

```

An example where the category type is not preserved is if you take one single row: the resulting `Series` is of dtype `object`:

```
# get the complete "h" row as a Series
```

```
In [149]: df.loc["h", :]
```

```

Out[149]:
cats      a
values      1
Name: h, dtype: object

```

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

```
In [150]: df.iat[0,0]
```

```
Out[150]: 'a'
```

```
In [151]: df["cats"].cat.categories = ["x", "y", "z"]
```

```
In [152]: df.at["h", "cats"] # returns a string
```

```
Out[152]: 'x'
```

---

**Note:** This is in contrast to R’s `factor` function, where `factor(c(1, 2, 3))[1]` returns a single value *factor*.

---

To get a single value `Series` of type `category`, you pass in a list with a single value:

```
In [153]: df.loc[["h"], "cats"]
```

```
Out[153]:
```

```
h      x
```

(continues on next page)

(continued from previous page)

```
Name: cats, dtype: category
Categories (3, object): [x, y, z]
```

## 21.8.2 String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```
In [154]: str_s = pd.Series(list('aabb'))

In [155]: str_cat = str_s.astype('category')

In [156]: str_cat
Out[156]:
0    a
1    a
2    b
3    b
dtype: category
Categories (2, object): [a, b]

In [157]: str_cat.str.contains("a")
Out[157]:
0    True
1    True
2   False
3   False
dtype: bool

In [158]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))

In [159]: date_cat = date_s.astype('category')

In [160]: date_cat
Out[160]:
0    2015-01-01
1    2015-01-02
2    2015-01-03
3    2015-01-04
4    2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, 2015-01-05]

In [161]: date_cat.dt.day
Out[161]:
0    1
1    2
2    3
3    4
4    5
dtype: int64
```

**Note:** The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.`

<method> on a Series of that type (and not of type *category*!).

---

That means, that the returned values from methods and properties on the accessors of a *Series* and the returned values from methods and properties on the accessors of this *Series* transformed to one of type *category* will be equal:

```
In [162]: ret_s = str_s.str.contains("a")

In [163]: ret_cat = str_cat.str.contains("a")

In [164]: ret_s.dtype == ret_cat.dtype
Out[164]: True

In [165]: ret_s == ret_cat
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[165]:
0      True
1      True
2      True
3      True
dtype: bool
```

---

**Note:** The work is done on the *categories* and then a new *Series* is constructed. This has some performance implication if you have a *Series* of type string, where lots of elements are repeated (i.e. the number of unique elements in the *Series* is a lot smaller than the length of the *Series*). In this case it can be faster to convert the original *Series* to one of type *category* and use `.str.<method>` or `.dt.<property>` on that.

---

### 21.8.3 Setting

Setting values in a categorical column (or *Series*) works as long as the value is included in the *categories*:

```
In [166]: idx = pd.Index(["h", "i", "j", "k", "l", "m", "n"])

In [167]: cats = pd.Categorical(["a", "a", "a", "a", "a", "a", "a"], categories=["a", "b"])

In [168]: values = [1, 1, 1, 1, 1, 1, 1]

In [169]: df = pd.DataFrame({"cats": cats, "values": values}, index=idx)

In [170]: df.iloc[2:4, :] = [["b", 2], ["b", 2]]

In [171]: df
Out[171]:
   cats  values
h     a        1
i     a        1
j     b        2
k     b        2
l     a        1
m     a        1
n     a        1

In [172]: try:
.....:     df.iloc[2:4, :] = [["c", 3], ["c", 3]]
```

(continues on next page)

(continued from previous page)

```

.....: except ValueError as e:
.....:     print("ValueError: " + str(e))
.....:
////////////////////////////////////
↪Cannot setitem on a Categorical with a new category, set the categories first

```

Setting values by assigning categorical data will also check that the *categories* match:

```

In [173]: df.loc["j":"k", "cats"] = pd.Categorical(["a", "a"], categories=["a", "b"])

In [174]: df
Out[174]:
   cats  values
h     a        1
i     a        1
j     a        2
k     a        2
l     a        1
m     a        1
n     a        1

In [175]: try:
.....:     df.loc["j":"k", "cats"] = pd.Categorical(["b", "b"], categories=["a", "b",
↪ "c"])
.....: except ValueError as e:
.....:     print("ValueError: " + str(e))
.....:
////////////////////////////////////
↪Cannot set a Categorical with another, without identical categories

```

Assigning a Categorical to parts of a column of other types will use the values:

```

In [176]: df = pd.DataFrame({"a": [1, 1, 1, 1, 1], "b": ["a", "a", "a", "a", "a"]})

In [177]: df.loc[1:2, "a"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [178]: df.loc[2:3, "b"] = pd.Categorical(["b", "b"], categories=["a", "b"])

In [179]: df
Out[179]:
   a  b
0  1  a
1  b  a
2  b  b
3  1  b
4  1  a

In [180]: df.dtypes
Out[180]:
a    object
b    object
dtype: object

```

## 21.8.4 Merging

You can concat two DataFrames containing categorical data together, but the categories of these categoricals need to be the same:

```
In [181]: cat = pd.Series(["a", "b"], dtype="category")

In [182]: vals = [1, 2]

In [183]: df = pd.DataFrame({"cats": cat, "vals": vals})

In [184]: res = pd.concat([df, df])

In [185]: res
Out[185]:
   cats  vals
0     a     1
1     b     2
0     a     1
1     b     2

In [186]: res.dtypes
Out[186]:
cats      category
vals      int64
dtype: object
```

In this case the categories are not the same, and therefore an error is raised:

```
In [187]: df_different = df.copy()

In [188]: df_different["cats"].cat.categories = ["c", "d"]

In [189]: try:
.....:     pd.concat([df, df_different])
.....: except ValueError as e:
.....:     print("ValueError: " + str(e))
.....:
```

The same applies to `df.append(df_different)`.

See also the section on *merge dtypes* for notes about preserving merge dtypes and performance.

## 21.8.5 Unioning

New in version 0.19.0.

If you want to combine categoricals that do not necessarily have the same categories, the `union_categoricals()` function will combine a list-like of categoricals. The new categories will be the union of the categories being combined.

```
In [190]: from pandas.api.types import union_categoricals

In [191]: a = pd.Categorical(["b", "c"])

In [192]: b = pd.Categorical(["a", "b"])

In [193]: union_categoricals([a, b])
```

(continues on next page)

(continued from previous page)

```
Out [193]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexicographically sorted, use `sort_categories=True` argument.

```
In [194]: union_categoricals([a, b], sort_categories=True)
Out [194]:
[b, c, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```
In [195]: a = pd.Categorical(["a", "b"], ordered=True)
In [196]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [197]: union_categoricals([a, b])
Out [197]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out [3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```
In [198]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [199]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [200]: union_categoricals([a, b], ignore_order=True)
Out [200]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```
In [201]: a = pd.Series(["b", "c"], dtype='category')
In [202]: b = pd.Series(["a", "b"], dtype='category')
In [203]: union_categoricals([a, b])
Out [203]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```
In [204]: c1 = pd.Categorical(["b", "c"])

In [205]: c2 = pd.Categorical(["a", "b"])

In [206]: c1
Out[206]:
[b, c]
Categories (2, object): [b, c]

# "b" is coded to 0
In [207]: c1.codes
Out[207]: array([0, 1], dtype=int8)

In [208]: c2
Out[208]:
[a, b]
Categories (2, object): [a, b]

# "b" is coded to 1
In [209]: c2.codes
Out[209]: array([0, 1], dtype=int8)

In [210]: c = union_categoricals([c1, c2])

In [211]: c
Out[211]:
[b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [212]: c.codes
Out[212]: array([0, 1, 2, 0], dtype=int8)
```

## 21.8.6 Concatenation

This section describes concatenations specific to `category` dtype. See *Concatenating objects* for general description.

By default, `Series` or `DataFrame` concatenation which contains the same categories results in `category` dtype, otherwise results in `object` dtype. Use `.astype` or `union_categoricals` to get category result.

```
# same categories
In [213]: s1 = pd.Series(['a', 'b'], dtype='category')

In [214]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')

In [215]: pd.concat([s1, s2])
Out[215]:
0      a
```

(continues on next page)

(continued from previous page)

```

1      b
0      a
1      b
2      a
dtype: category
Categories (2, object): [a, b]

# different categories
In [216]: s3 = pd.Series(['b', 'c'], dtype='category')

In [217]: pd.concat([s1, s3])
Out[217]:
0      a
1      b
0      b
1      c
dtype: object

In [218]: pd.concat([s1, s3]).astype('category')
\\Out[218]:
0      a
1      b
0      b
1      c
dtype: category
Categories (3, object): [a, b, c]

In [219]: union_categoricals([s1.values, s3.values])
\\
↪
[a, b, b, c]
Categories (3, object): [a, b, c]

```

Following table summarizes the results of `Categoricals` related concatenations.

| arg1     | arg2   | result                     |
|----------|--|----------------------------|
| category | category (identical categories)                        | category                   |
| category | category (different categories, both not ordered)      | object (dtype is inferred) |
| category | category (different categories, either one is ordered) | object (dtype is inferred) |
| category | not category   | object (dtype is inferred) |

## 21.9 Getting Data In/Out

You can write data that contains `category` dtypes to a `HDFStore`. See [here](#) for an example and caveats.

It is also possible to write data to and reading data from *Stata* format files. See [here](#) for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to `category` and assign the right categories and categories ordering.

```

In [220]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories

```

(continues on next page)

(continued from previous page)

```

In [221]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [223]: df = pd.DataFrame({"cats":s, "vals":[1,2,3,4,5,6]})

In [224]: csv = StringIO()

In [225]: df.to_csv(csv)

In [226]: df2 = pd.read_csv(StringIO(csv.getvalue()))

In [227]: df2.dtypes
Out[227]:
Unnamed: 0      int64
cats           object
vals           int64
dtype: object

In [228]: df2["cats"]
Out[228]:
↪
0      very good
1         good
2         good
3      very good
4      very good
5         bad
Name: cats, dtype: object

# Redo the category
In [229]: df2["cats"] = df2["cats"].astype("category")

In [230]: df2["cats"].cat.set_categories(["very bad", "bad", "medium", "good", "very
↪good"],
.....:                                     inplace=True)
.....:

In [231]: df2.dtypes
Out[231]:
Unnamed: 0      int64
cats           category
vals           int64
dtype: object

In [232]: df2["cats"]
Out[232]:
↪
0      very good
1         good
2         good
3      very good
4      very good
5         bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

```

The same holds for writing to a SQL database with `to_sql`.

## 21.10 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the [Missing Data section](#).

Missing values should **not** be included in the Categorical's `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical's `codes`, missing values will always have a code of `-1`.

```
In [233]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [234]: s
Out[234]:
0      a
1      b
2     NaN
3      a
dtype: category
Categories (2, object): [a, b]

In [235]: s.cat.codes
Out[235]:
0      0
1      1
2     -1
3      0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```
In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [237]: s
Out[237]:
0      a
1      b
2     NaN
dtype: category
Categories (2, object): [a, b]

In [238]: pd.isna(s)
Out[238]:
0    False
1    False
2     True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0      a
```

(continues on next page)

(continued from previous page)

```
1      b
2      a
dtype: category
Categories (2, object): [a, b]
```

## 21.11 Differences to R's *factor*

The following differences to R's factor functions can be observed:

- R's *levels* are named *categories*.
- R's *levels* are always of type string, while *categories* in pandas can be of any dtype.
- It's not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R's *factor* function, using categorical data as the sole input to create a new categorical series will *not* remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its *levels* (pandas' *categories*). Pandas does not allow *NaN* categories, but missing values can still be in the *values*.

## 21.12 Gotchas

### 21.12.1 Memory Usage

The memory usage of a `Categorical` is proportional to the number of categories plus the length of the data. In contrast, an `object` dtype is a constant times the length of the data.

```
In [240]: s = pd.Series(['foo', 'bar']*1000)

# object dtype
In [241]: s.nbytes
Out[241]: 16000

# category dtype
In [242]: s.astype('category').nbytes
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[242]: 2016
```

---

**Note:** If the number of categories approaches the length of the data, the `Categorical` will use nearly the same or more memory than an equivalent `object` dtype representation.

```
In [243]: s = pd.Series(['foo%04d' % i for i in range(2000)])

# object dtype
In [244]: s.nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype('category').nbytes
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[245]: 20000
```

### 21.12.2 *Categorical* is not a *numpy* array

Currently, categorical data and the underlying `Categorical` is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn't know about the new *dtype*:

```
In [246]: try:
.....:     np.dtype("category")
.....: except TypeError as e:
.....:     print("TypeError: " + str(e))
.....:
TypeError: data type "category" not understood

In [247]: dtype = pd.Categorical(["a"]).dtype

In [248]: try:
.....:     np.dtype(dtype)
.....: except TypeError as e:
.....:     print("TypeError: " + str(e))
.....:
TypeError: data type not understood
```

Dtype comparisons work:

```
In [249]: dtype == np.str_
Out[249]: False

In [250]: np.str_ == dtype
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[250]: False
```

To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:

```
In [251]: hasattr(pd.Series(['a'], dtype='category'), 'cat')
Out[251]: True

In [252]: hasattr(pd.Series(['a']), 'cat')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[252]: False
```

Using NumPy functions on a Series of type category should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [253]: s = pd.Series(pd.Categorical([1,2,3,4]))

In [254]: try:
.....:     np.sum(s)
.....: except TypeError as e:
.....:     print("TypeError: " + str(e))
.....:
TypeError: Categorical cannot perform the operation sum
```

---

**Note:** If such a function works, please file a bug at <https://github.com/pandas-dev/pandas!>

---

### 21.12.3 dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a *Series* of *object* dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object.

```
In [255]: df = pd.DataFrame({"a": [1, 2, 3, 4],
.....:                       "b": ["a", "b", "c", "d"],
.....:                       "cats": pd.Categorical([1, 2, 3, 2])})
.....:
```

```
In [256]: df.apply(lambda row: type(row["cats"]), axis=1)
```

```
Out [256]:
0    <class 'int'>
1    <class 'int'>
2    <class 'int'>
3    <class 'int'>
dtype: object
```

```
In [257]: df.apply(lambda col: col.dtype, axis=0)
```

### 21.12.4 Categorical Index

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements. See the [advanced indexing docs](#) for a more detailed explanation.

Setting the index will create a `CategoricalIndex`:

```
In [258]: cats = pd.Categorical([1,2,3,4], categories=[4,2,3,1])
```

```
In [259]: strings = ["a", "b", "c", "d"]
```

```
In [260]: values = [4, 2, 3, 1]
```

```
In [261]: df = pd.DataFrame({"strings":strings, "values":values}, index=cats)
```

```
In [262]: df.index
```

```
Out [262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False,
dtype='category')
```

```
# This now sorts by the categories order
```

```
In [263]: df.sort_index()
```

```

\\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\ \\
↪
strings  values
4        d        1
2        b        2
3        c        3
1        a        4

```

### 21.12.5 Side Effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```
In [264]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])

In [265]: s = pd.Series(cat, name="cat")

In [266]: cat
Out[266]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [267]: s.iloc[0:2] = 10

In [268]: cat
Out[268]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [269]: df = pd.DataFrame(s)

In [270]: df["cat"].cat.categories = [1,2,3,4,5]

In [271]: cat
Out[271]:
[5, 5, 3, 5]
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use `copy=True` to prevent such a behaviour or simply don't reuse Categoricals:

```
In [272]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])

In [273]: s = pd.Series(cat, name="cat", copy=True)

In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]

In [275]: s.iloc[0:2] = 10

In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

**Note:** This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. `np.array([1,2,3,4])`) will exhibit the same behavior, while using a string array (e.g. `np.array(["a","b","c","a"])`) will not.

## VISUALIZATION

We use the standard convention for referencing the matplotlib API:

```
In [1]: import matplotlib.pyplot as plt
```

We provide the basics in pandas to easily create decent looking plots. See the *ecosystem* section for visualization libraries that go beyond the basics documented here.

---

**Note:** All calls to `np.random` are seeded with 123456.

---

### 22.1 Basic Plotting: `plot`

We will demonstrate the basics, see the *cookbook* for some advanced strategies.

The `plot` method on `Series` and `DataFrame` is just a simple wrapper around `plt.plot()`:

```
In [2]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000',
↳ periods=1000))

In [3]: ts = ts.cumsum()

In [4]: ts.plot()
Out[4]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2e3b0ba8>
```

If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On `DataFrame`, `plot()` is a convenience to plot all of the columns with labels:

```
In [5]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list('ABCD
↳'))

In [6]: df = df.cumsum()

In [7]: plt.figure(); df.plot();
```

You can plot one column versus another using the *x* and *y* keywords in `plot()`:

```
In [8]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [9]: df3['A'] = pd.Series(list(range(len(df))))
In [10]: df3.plot(x='A', y='B')
Out[10]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38114e10>
```

---

**Note:** For more formatting and styling options, see *formatting* below.

---

## 22.2 Other Plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `'bar'` or `'barh'` for bar plots
- `'hist'` for histogram
- `'box'` for boxplot
- `'kde'` or `'density'` for density plots
- `'area'` for area plots
- `'scatter'` for scatter plots
- `'hexbin'` for hexagonal bin plots
- `'pie'` for pie plots

For example, a bar plot can be created the following way:

```
In [11]: plt.figure();
In [12]: df.iloc[5].plot(kind='bar');
```

You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [13]: df = pd.DataFrame()

In [14]: df.plot.<TAB>
df.plot.area      df.plot.barh      df.plot.density  df.plot.hist      df.plot.line
↳ df.plot.scatter
df.plot.bar        df.plot.box        df.plot.hexbin   df.plot.kde        df.plot.pie
```

In addition to these kinds, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several *plotting functions* in `pandas.plotting` that take a *Series* or *DataFrame* as an argument. These include:

- *Scatter Matrix*
- *Andrews Curves*
- *Parallel Coordinates*
- *Lag Plot*

- *Autocorrelation Plot*
- *Bootstrap Plot*
- *RadViz*

Plots may also be adorned with *errorbars* or *tables*.

## 22.2.1 Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```
In [15]: plt.figure();  
In [16]: df.iloc[5].plot.bar(); plt.axhline(0, color='k')  
Out[16]: <matplotlib.lines.Line2D at 0x1c33f082e8>
```

Calling a DataFrame's `plot.bar()` method produces a multiple bar plot:

```
In [17]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])  
In [18]: df2.plot.bar();
```

To produce a stacked bar plot, pass `stacked=True`:

```
In [19]: df2.plot.bar(stacked=True);
```

To get horizontal bar plots, use the `barh` method:

```
In [20]: df2.plot.barh(stacked=True);
```

### 22.2.2 Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

```
In [21]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.
↳randn(1000),
      ....:                  'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])
      ....:

In [22]: plt.figure();

In [23]: df4.plot.hist(alpha=0.5)
Out[23]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36abc470>
```

A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [24]: plt.figure();  
  
In [25]: df4.plot.hist(stacked=True, bins=20)  
Out[25]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36ac4940>
```

You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [26]: plt.figure();  
  
In [27]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)  
Out[27]: <matplotlib.axes._subplots.AxesSubplot at 0x1c369362b0>
```

See the [hist](#) method and the [matplotlib hist documentation](#) for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```
In [28]: plt.figure();  
  
In [29]: df['A'].diff().hist()  
Out[29]: <matplotlib.axes._subplots.AxesSubplot at 0x1c388ceeb8>
```

`DataFrame.hist()` plots the histograms of the columns on multiple subplots:

```
In [30]: plt.figure()
Out[30]: <Figure size 640x480 with 0 Axes>

In [31]: df.diff().hist(color='k', alpha=0.5, bins=50)
Out[31]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c2a6eda20>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c37637860>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x1c3764ab70>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c37d4be80>]],
      dtype=object)
```

The `by` keyword can be specified to plot grouped histograms:

```
In [32]: data = pd.Series(np.random.randn(1000))

In [33]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
Out[33]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c36be2d30>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1c2efde940>],
      [<matplotlib.axes._subplots.AxesSubplot object at 0x1c2f002e48>,
      <matplotlib.axes._subplots.AxesSubplot object at 0x1c33d2c198>]],
      dtype=object)
```

### 22.2.3 Box Plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on  $[0,1)$ .

```
In [34]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
In [35]: df.plot.box()
Out[35]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38838f98>
```

Boxplot can be colored by passing `color` keyword. You can pass a dict whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the dict, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```
In [36]: color = dict(boxes='DarkGreen', whiskers='DarkOrange',
.....:               medians='DarkBlue', caps='Gray')
.....:

In [37]: df.plot.box(color=color, sym='r+')
Out [37]: <matplotlib.axes._subplots.AxesSubplot at 0x1c378c4198>
```

Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [38]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out [38]: <matplotlib.axes._subplots.AxesSubplot at 0x1c36a6ae10>
```

See the [boxplot](#) method and the [matplotlib boxplot documentation](#) for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```
In [39]: df = pd.DataFrame(np.random.rand(10, 5))
```

```
In [40]: plt.figure();
```

```
In [41]: bp = df.boxplot()
```

You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [42]: df = pd.DataFrame(np.random.rand(10,2), columns=['Col1', 'Col2'] )
In [43]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [44]: plt.figure();
In [45]: bp = df.boxplot(by='X')
```

You can also pass a subset of columns to plot, as well as group by multiple columns:

```
In [46]: df = pd.DataFrame(np.random.rand(10,3), columns=['Col1', 'Col2', 'Col3'])
In [47]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [48]: df['Y'] = pd.Series(['A','B','A','B','A','B','A','B','A','B'])
In [49]: plt.figure();
In [50]: bp = df.boxplot(column=['Col1','Col2'], by=['X','Y'])
```

**Warning:** The default changed from 'dict' to 'axes' in version 0.19.0.

In `boxplot`, the return type can be controlled by the `return_type`, keyword. The valid choices are {"axes", "dict", "both", None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

| return_type= | Faceted | Output type                |
|--------------|---------|----------------------------|
| None         | No      | axes                       |
| None         | Yes     | 2-D ndarray of axes        |
| 'axes'       | No      | axes                       |
| 'axes'       | Yes     | Series of axes             |
| 'dict'       | No      | dict of artists            |
| 'dict'       | Yes     | Series of dicts of artists |
| 'both'       | No      | namedtuple                 |
| 'both'       | Yes     | Series of namedtuples      |

`Groupby.boxplot` always returns a `Series` of `return_type`.

```
In [51]: np.random.seed(1234)
In [52]: df_box = pd.DataFrame(np.random.randn(50, 2))
```

(continues on next page)

(continued from previous page)

```
In [53]: df_box['g'] = np.random.choice(['A', 'B'], size=50)
```

```
In [54]: df_box.loc[df_box['g'] == 'B', 1] += 3
```

```
In [55]: bp = df_box.boxplot(by='g')
```

The subplots above are split by the numeric columns first, then the value of the `g` column. Below the subplots are first split by the value of `g`, then by the numeric columns.

```
In [56]: bp = df_box.groupby('g').boxplot()
```

### 22.2.4 Area Plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains *NaN*, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```
In [57]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [58]: df.plot.area();
```

To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [59]: df.plot.area(stacked=False);
```

### 22.2.5 Scatter Plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the `x` and `y` keywords.

```
In [60]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
```

```
In [61]: df.plot.scatter(x='a', y='b');
```

To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [62]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');  
In [63]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```

The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [64]: df.plot.scatter(x='a', y='b', c='c', s=50);
```

You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the `DataFrame` as the bubble size.

```
In [65]: df.plot.scatter(x='a', y='b', s=df['c']*200);
```

See the `scatter` method and the [matplotlib scatter documentation](#) for more.

### 22.2.6 Hexagonal Bin Plot

You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```
In [66]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])  
In [67]: df['b'] = df['b'] + np.arange(1000)  
In [68]: df.plot.hexbin(x='a', y='b', gridsize=25)  
Out[68]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d4c09b0>
```

A useful keyword argument is `gridsize`; it controls the number of hexagons in the x-direction, and defaults to 100. A larger `gridsize` means more, smaller bins.

By default, a histogram of the counts around each  $(x, y)$  point is computed. You can specify alternative aggregations by passing values to the `C` and `reduce_C_function` arguments. `C` specifies the value at each  $(x, y)$  point and `reduce_C_function` is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns `a` and `b`, while the value is given by column `z`. The bins are aggregated with NumPy's `max` function.

```
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])

In [70]: df['b'] = df['b'] + np.arange(1000)

In [71]: df['z'] = np.random.uniform(0, 3, 1000)

In [72]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max,
.....:                 gridsize=25)
.....:
Out[72]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d567dd8>
```

See the `hexbin` method and the `matplotlib hexbin` documentation for more.

### 22.2.7 Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any `NaN`, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```
In [73]: series = pd.Series(3 * np.random.rand(4), index=['a', 'b', 'c', 'd'], name=
↳ 'series')

In [74]: series.plot.pie(figsize=(6, 6))
Out [74]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d85c5f8>
```

For pie plots it's best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [75]: df = pd.DataFrame(3 * np.random.rand(4, 2), index=['a', 'b', 'c', 'd'],
↳ columns=['x', 'y'])

In [76]: df.plot.pie(subplots=True, figsize=(8, 4))
Out[76]: array([<matplotlib.axes._subplots.AxesSubplot object at 0x1c3d8c5940>,
<matplotlib.axes._subplots.AxesSubplot object at 0x1c3da4bd30>], dtype=object)
```

You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```
In [77]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'],
.....:                  autopct='%0.2f', fontsize=20, figsize=(6, 6))
.....:
Out [77]: <matplotlib.axes._subplots.AxesSubplot at 0x121551ba8>
```

If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

```
In [78]: series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')
```

```
In [79]: series.plot.pie(figsize=(6, 6))
```

```
Out [79]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3d8b22b0>
```

See the [matplotlib pie documentation](#) for more.

## 22.3 Plotting with Missing Data

Pandas tries to be pragmatic about plotting `DataFrames` or `Series` that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.

| Plot Type      | NaN Handling            |
|----------------|-------------------------|
| Line           | Leave gaps at NaNs      |
| Line (stacked) | Fill 0's                |
| Bar            | Fill 0's                |
| Scatter        | Drop NaNs               |
| Histogram      | Drop NaNs (column-wise) |
| Box            | Drop NaNs (column-wise) |
| Area           | Fill 0's                |
| KDE            | Drop NaNs (column-wise) |
| Hexbin         | Drop NaNs               |
| Pie            | Fill 0's                |

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.

## 22.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a *Series* or *DataFrame* as an argument.

### 22.4.1 Scatter Matrix Plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```
In [80]: from pandas.plotting import scatter_matrix

In [81]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [82]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
Out[82]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c381e89e8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c37c4da20>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c3781c898>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c376d50f0>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x1c33b56320>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c33b56518>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c2f046550>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c2bdcf780>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x1c370c6400>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c25a6a710>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c2f082a20>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c36ac3668>],
        [<matplotlib.axes._subplots.AxesSubplot object at 0x1c33c43cf8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c37d01cc0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c383a0358>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c38115470>]],
        dtype=object)
```

### 22.4.2 Density Plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```
In [83]: ser = pd.Series(np.random.randn(1000))  
  
In [84]: ser.plot.kde()  
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3842c908>
```

### 22.4.3 Andrews Curves

Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the [Wikipedia entry](#) for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

**Note:** The “Iris” dataset is available [here](#).

```
In [85]: from pandas.plotting import andrews_curves

In [86]: data = pd.read_csv('data/iris.data')

In [87]: plt.figure()
Out[87]: <Figure size 640x480 with 0 Axes>

In [88]: andrews_curves(data, 'Name')
Out[88]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c38f27da0>
```

#### 22.4.4 Parallel Coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the [Wikipedia entry](#) for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```
In [89]: from pandas.plotting import parallel_coordinates

In [90]: data = pd.read_csv('data/iris.data')

In [91]: plt.figure()
Out[91]: <Figure size 640x480 with 0 Axes>

In [92]: parallel_coordinates(data, 'Name')
Out[92]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c38e62b38>
```

### 22.4.5 Lag Plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The `lag` argument may be passed, and when `lag=1` the plot is essentially `data[:-1]` vs. `data[1:]`.

```
In [93]: from pandas.plotting import lag_plot

In [94]: plt.figure()
Out[94]: <Figure size 640x480 with 0 Axes>

In [95]: data = pd.Series(0.1 * np.random.rand(1000) +
.....:     0.9 * np.sin(np.linspace(-99 * np.pi, 99 * np.pi, num=1000)))
.....:

In [96]: lag_plot(data)
Out[96]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2b26e208>
```

### 22.4.6 Autocorrelation Plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the [Wikipedia entry](#) for more about autocorrelation plots.

```
In [97]: from pandas.plotting import autocorrelation_plot

In [98]: plt.figure()
Out[98]: <Figure size 640x480 with 0 Axes>

In [99]: data = pd.Series(0.7 * np.random.rand(1000) +
.....:     0.3 * np.sin(np.linspace(-9 * np.pi, 9 * np.pi, num=1000)))
.....:

In [100]: autocorrelation_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37dd3588>
```

### 22.4.7 Bootstrap Plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```
In [101]: from pandas.plotting import bootstrap_plot
In [102]: data = pd.Series(np.random.rand(1000))
In [103]: bootstrap_plot(data, size=50, samples=500, color='grey')
Out[103]: <Figure size 640x480 with 6 Axes>
```

## 22.4.8 RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs to it will be colored differently. See the R package [Radviz](#) for more information.

**Note:** The “Iris” dataset is available [here](#).

```
In [104]: from pandas.plotting import radviz

In [105]: data = pd.read_csv('data/iris.data')

In [106]: plt.figure()
Out[106]: <Figure size 640x480 with 0 Axes>

In [107]: radviz(data, 'Name')
Out[107]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c3747f470>
```

## 22.5 Plot Formatting

### 22.5.1 Setting the plot style

From version 1.5 and up, matplotlib offers a range of preconfigured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it's very easy to try them out.

### 22.5.2 General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```
In [108]: plt.figure(); ts.plot(style='k--', label='Series');
```

For each kind of plot (e.g. *line*, *bar*, *scatter*) any additional arguments keywords are passed along to the corresponding matplotlib function (`ax.plot()`, `ax.bar()`, `ax.scatter()`). These can be used to control additional styling, beyond what pandas provides.

### 22.5.3 Controlling the Legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [109]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list(
↳ 'ABCD'))

In [110]: df = df.cumsum()

In [111]: df.plot(legend=False)
Out[111]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2a823fd0>
```

### 22.5.4 Scales

You may pass `logy` to get a log-scale Y axis.

```
In [112]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000',  
↳periods=1000))  
  
In [113]: ts = np.exp(ts.cumsum())  
  
In [114]: ts.plot(logy=True)  
Out[114]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2f026080>
```

See also the `logx` and `loglog` keyword arguments.

### 22.5.5 Plotting on a Secondary Y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [115]: df.A.plot()
Out[115]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37e6c7f0>

In [116]: df.B.plot(secondary_y=True, style='g')
Out[116]:
<matplotlib.axes._subplots.AxesSubplot at 0x1c38758ef0>
```

To plot some columns in a DataFrame, give the column names to the `secondary_y` keyword:

```
In [117]: plt.figure()
Out[117]: <Figure size 640x480 with 0 Axes>

In [118]: ax = df.plot(secondary_y=['A', 'B'])

In [119]: ax.set_ylabel('CD scale')
Out[119]: Text(0,0.5,'CD scale')

In [120]: ax.right_ax.set_ylabel('AB scale')
Out[120]: Text(0,0.5,'AB scale')
```

Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```
In [121]: plt.figure()
Out[121]: <Figure size 640x480 with 0 Axes>

In [122]: df.plot(secondary_y=['A', 'B'], mark_right=False)
Out[122]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c265d6f28>
```

### 22.5.6 Suppressing Tick Resolution Adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created `twinx`), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>

In [124]: df.A.plot()
Out[124]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c31f58a58>
```

Using the `x_compat` parameter, you can suppress this behavior:

```
In [125]: plt.figure()
Out[125]: <Figure size 640x480 with 0 Axes>

In [126]: df.A.plot(x_compat=True)
Out[126]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c3aba2208>
```

If you have more than one plot that needs to be suppressed, the use method in `pandas.plotting.plot_params` can be used in a *with statement*:

```
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>

In [128]: with pd.plotting.plot_params.use('x_compat', True):
.....:     df.A.plot(color='r')
.....:     df.B.plot(color='g')
.....:     df.C.plot(color='b')
.....:
```

### 22.5.7 Automatic Date Tick Adjustment

New in version 0.20.0.

`TimedeltaIndex` now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the [matplotlib documentation](#) for more.

### 22.5.8 Subplots

Each Series in a DataFrame can be plotted on a different axis with the `subplots` keyword:

```
In [129]: df.plot(subplots=True, figsize=(6, 6));
```

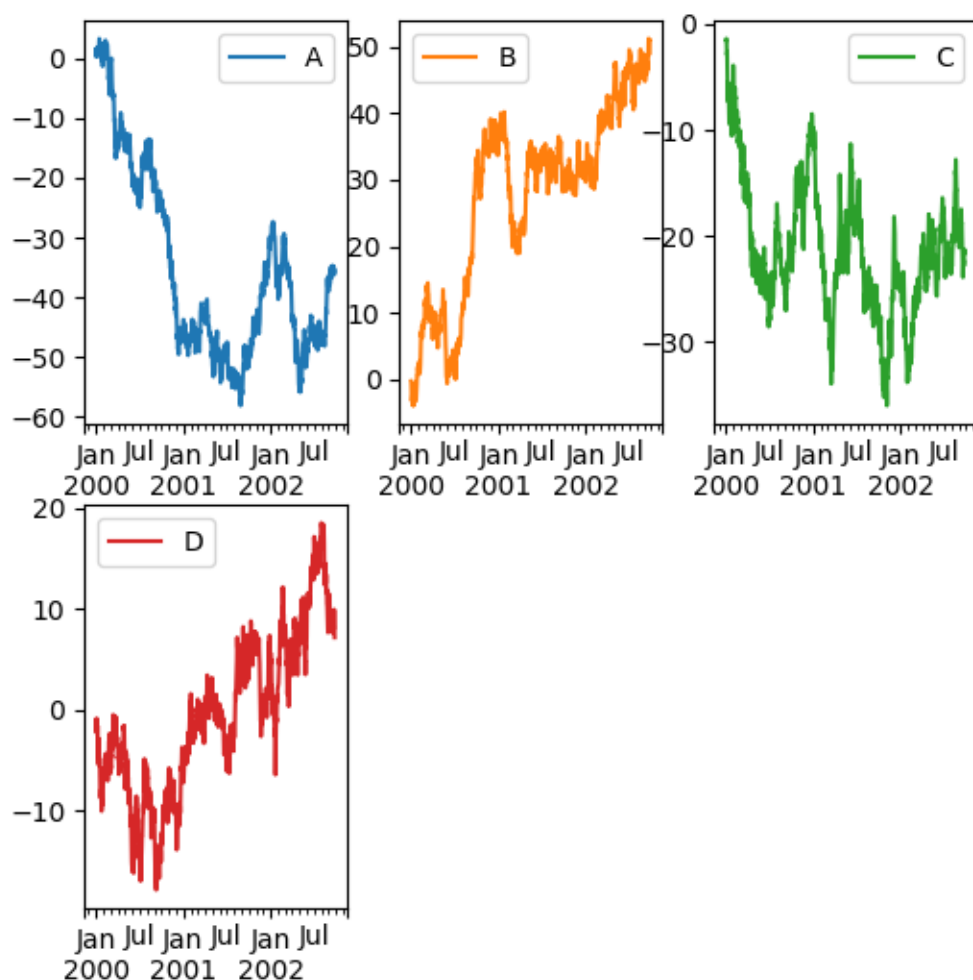

### 22.5.9 Using Layout and Targeting Multiple Axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by `rows x columns` specified by `layout` must be larger than the number of required subplots. If `layout` can contain more axes than required, blank axes are not drawn. Similar to a NumPy array's `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [130]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```

The above example is identical to using:

```
In [131]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don't affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [132]: fig, axes = plt.subplots(4, 4, figsize=(6, 6));
```

```
In [133]: plt.subplots_adjust(wspace=0.5, hspace=0.5);
```

```
In [134]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
```

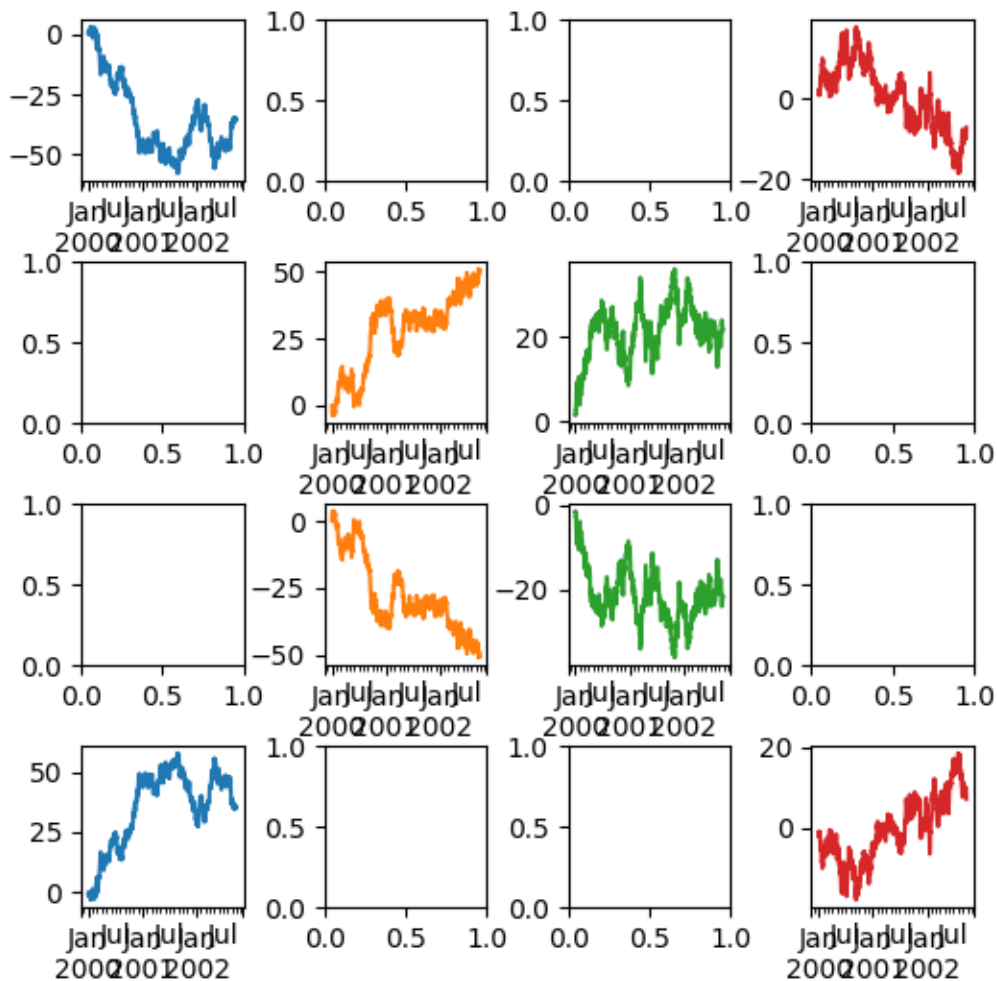

(continues on next page)

(continued from previous page)

```
In [135]: target2 = [axes[3][0], axes[2][1], axes[1][2], axes[0][3]]

In [136]: df.plot(subplots=True, ax=target1, legend=False, sharex=False,
↳sharey=False);

In [137]: (-df).plot(subplots=True, ax=target2, legend=False, sharex=False,
↳sharey=False);
```

Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```
In [138]: fig, axes = plt.subplots(nrows=2, ncols=2)

In [139]: df['A'].plot(ax=axes[0,0]); axes[0,0].set_title('A');

In [140]: df['B'].plot(ax=axes[0,1]); axes[0,1].set_title('B');
```

(continues on next page)

(continued from previous page)

```
In [141]: df['C'].plot(ax=axes[1,0]); axes[1,0].set_title('C');
In [142]: df['D'].plot(ax=axes[1,1]); axes[1,1].set_title('D');
```

### 22.5.10 Plotting With Error Bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or dict of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (list, tuple, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a `M` length `Series`, a `Mx2` array should be provided indicating lower and upper (or left and right) errors. For a `MxN` `DataFrame`, asymmetrical errors should be in a `Mx2xN` array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.

```
# Generate the data
In [143]: ix3 = pd.MultiIndex.from_arrays([[ 'a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'], [
↳ 'foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']], names=[ 'letter', 'word'])

In [144]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2], 'data2': [6, 5, 7, 5,
↳ 4, 5, 6, 5]}, index=ix3)

# Group by index labels and take the means and standard deviations for each group
In [145]: gp3 = df3.groupby(level=( 'letter', 'word'))

In [146]: means = gp3.mean()

In [147]: errors = gp3.std()

In [148]: means
Out[148]:
```

|        |      | data1 | data2 |
|--------|------|-------|-------|
| letter | word |       |       |
| a      | bar  | 3.5   | 6.0   |
|        | foo  | 2.5   | 5.5   |
| b      | bar  | 2.5   | 5.5   |
|        | foo  | 3.0   | 4.5   |

```

In [149]: errors
\\////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////////
↳

```

|        |      | data1    | data2    |
|--------|------|----------|----------|
| letter | word |          |          |
| a      | bar  | 0.707107 | 1.414214 |
|        | foo  | 0.707107 | 0.707107 |
| b      | bar  | 0.707107 | 0.707107 |
|        | foo  | 1.414214 | 0.707107 |

```

# Plot
In [150]: fig, ax = plt.subplots()

In [151]: means.plot.bar(yerr=errors, ax=ax)
Out[151]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3f1fd208>

```

### 22.5.11 Plotting Tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [152]: fig, ax = plt.subplots(1, 1)

In [153]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [154]: ax.get_xaxis().set_visible(False)    # Hide Ticks

In [155]: df.plot(table=True, ax=ax)
Out[155]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e719550>
```

Also, you can pass a different `DataFrame` or `Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [156]: fig, ax = plt.subplots(1, 1)

In [157]: ax.get_xaxis().set_visible(False)    # Hide Ticks

In [158]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3e23f320>
```

There also exists a helper function `pandas.plotting.table`, which creates a table from *DataFrame* or *Series*, and adds it to an `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` table has.

```
In [159]: from pandas.plotting import table

In [160]: fig, ax = plt.subplots(1, 1)

In [161]: table(ax, np.round(df.describe(), 2),
.....:         loc='upper right', colWidths=[0.2, 0.2, 0.2])
.....:
Out[161]: <matplotlib.table.Table at 0x1c382b3630>

In [162]: df.plot(ax=ax, ylim=(0, 2), legend=None)
Out[162]: <matplotlib.axes._
↳subplots.AxesSubplot at 0x1c382b48d0>
```

**Note:** You can get table instances on the axes using `axes.tables` property for further decorations. See the [matplotlib table documentation](#) for more.

## 22.5.12 Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, `DataFrame` plotting supports the use of the `colormap` argument, which accepts either a Matplotlib [colormap](#) or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available [here](#).

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the `DataFrame`. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the `cubehelix` colormap, we can pass `colormap='cubehelix'`.

```
In [163]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [164]: df = df.cumsum()
In [165]: plt.figure()
Out[165]: <Figure size 640x480 with 0 Axes>
In [166]: df.plot(colormap='cubehelix')
Out[166]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c38057208> (continues on next page)
```

(continued from previous page)

Alternatively, we can pass the colormap itself:

```
In [167]: from matplotlib import cm

In [168]: plt.figure()
Out[168]: <Figure size 640x480 with 0 Axes>

In [169]: df.plot(colormap=cm.cubehelix)
Out[169]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c3e0b20f0>
```

Colormaps can also be used other plot types, like bar charts:

```
In [170]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [171]: dd = dd.cumsum()
In [172]: plt.figure()
Out[172]: <Figure size 640x480 with 0 Axes>

In [173]: dd.plot.bar(colormap='Greens')
Out[173]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c3e7c6b38>
```

Parallel coordinates charts:

```
In [174]: plt.figure()
Out[174]: <Figure size 640x480 with 0 Axes>

In [175]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
Out[175]: <matplotlib.axes._subplots.
AxesSubplot at 0x1c3e3f3240>
```

```
In [176]: plt.figure()
Out[176]: <Figure size 640x480 with 0 Axes>

In [177]: andrews_curves(data, 'Name', colormap='winter')
Out[177]: <matplotlib.axes._subplots.
↳ AxesSubplot at 0x1c3ded0080>
```

## 22.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. `Series` and `DataFrame` objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```
In [178]: price = pd.Series(np.random.randn(150).cumsum(),
.....:                      index=pd.date_range('2000-1-1', periods=150, freq='B'))
.....:

In [179]: ma = price.rolling(20).mean()

In [180]: mstd = price.rolling(20).std()

In [181]: plt.figure()
Out[181]: <Figure size 640x480 with 0 Axes>

In [182]: plt.plot(price.index, price, 'k')
Out[182]: [<matplotlib.lines.Line2D at 0x1c3fc4f710>]
```

(continues on next page)

(continued from previous page)

```
In [183]: plt.plot(ma.index, ma, 'b')
```

```
\\Out[183]: <matplotlib.lines.Line2D at 0x1c3fc6aef0>
```

```
In [184]: plt.fill_between(mstd.index, ma-2*mstd, ma+2*mstd, color='b', alpha=0.2)
```

```

## 22.7 Trellis plotting interface

**Warning:** The `rplot` trellis plotting interface has been **removed**. Please use external packages like [seaborn](#) for similar but more refined functionality and refer to our 0.18.1 documentation [here](#) for how to convert to using it.

## STYLING

*New in version 0.17.1*

*Provisional: This is a new feature and still under development. We'll be adding features and possibly making breaking changes in future releases. We'd love to hear your feedback.*

This document is written as a Jupyter Notebook, and can be viewed or downloaded [here](#).

You can apply **conditional formatting**, the visual styling of a DataFrame depending on the data within, by using the `DataFrame.style` property. This is a property that returns a `Styler` object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return *like-indexed* DataFrames or Series with CSS “attribute: value” pairs for the values. These functions can be incrementally passed to the `Styler` which collects the styles before rendering.

### 23.1 Building Styles

Pass your style functions into one of the following methods:

- `Styler.applymap`: elementwise
- `Styler.apply`: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. `Styler.applymap` works through the DataFrame elementwise. `Styler.apply` passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the `axis` keyword argument. For columnwise use `axis=0`, rowwise use `axis=1`, and for the entire table at once use `axis=None`.

For `Styler.applymap` your function should take a scalar and return a single string with the CSS attribute-value pair.

For `Styler.apply` your function should take a Series or DataFrame (depending on the `axis` parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let's see some examples.

```
In [2]: import pandas as pd
import numpy as np

np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))],
               axis=1)
df.iloc[0, 2] = np.nan
```

Here's a boring example of rendering a DataFrame, without any (visible) styles:

```
In [3]: df.style
```

```
Out[3]: <pandas.io.formats.style.Styler at 0x1119c4f98>
```

*Note:* The `DataFrame.style` attribute is a property that returns a `Styler` object. `Styler` has a `_repr_html_` method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the `.render()` method which returns a string.

The above output looks very similar to the standard `DataFrame` HTML representation. But we've done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the `.render` method.

```
In [4]: df.style.highlight_null().render().split('\n')[10]
```

```
Out[4]: ['<style  type="text/css" >',
        '#T_2baa851c_80a0_11e8_ae45_186590cd1c87row0_col2 {',
        '    background-color:  red;',
        '}</style> ',
        '<table id="T_2baa851c_80a0_11e8_ae45_186590cd1c87" > ',
        '<thead>    <tr> ',
        '        <th class="blank level0" ></th> ',
        '        <th class="col_heading level0 col0" >A</th> ',
        '        <th class="col_heading level0 col1" >B</th> ',
        '        <th class="col_heading level0 col2" >C</th> ']
```

The `row0_col2` is the identifier for that particular cell. We've also prepended each row/column identifier with a UUID unique to each `DataFrame` so that the style from one doesn't collide with the styling from another within the same notebook or page (you can set the `uuid` if you'd like to tie together the styling of two `DataFrames`).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let's write a simple style function that will color negative numbers red and positive numbers black.

```
In [5]: def color_negative_red(val):
        """
        Takes a scalar and returns a string with
        the css property `color: red` for negative
        strings, black otherwise.
        """
        color = 'red' if val < 0 else 'black'
        return 'color: %s' % color
```

In this case, the cell's style depends only on it's own value. That means we should use the `Styler.applymap` method which works elementwise.

```
In [6]: s = df.style.applymap(color_negative_red)
        s
```

```
Out[6]: <pandas.io.formats.style.Styler at 0x113d34048>
```

Notice the similarity with the standard `df.applymap`, which operates on `DataFrames` elementwise. We want you to be able to reuse your existing knowledge of how to interact with `DataFrames`.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a `<style>` tag. This will be a common theme.

Finally, the input shapes matched. `Styler.applymap` calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can't use `.applymap` anymore since that operated elementwise. Instead, we'll turn to `.apply` which operates columnwise (or rowwise using the `axis` keyword). Later on we'll see that something like `highlight_max` is already defined on `Styler` so you wouldn't need to write this yourself.

```
In [7]: def highlight_max(s):
        '''
        highlight the maximum in a Series yellow.
        '''
        is_max = s == s.max()
        return ['background-color: yellow' if v else '' for v in is_max]
```

```
In [8]: df.style.apply(highlight_max)
```

```
Out[8]: <pandas.io.formats.style.Styler at 0x113cec9e8>
```

In this case the input is a Series, one column at a time. Notice that the output shape of `highlight_max` matches the input shape, an array with `len(s)` items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

```
In [9]: df.style.\
        applymap(color_negative_red).\
        apply(highlight_max)
```

```
Out[9]: <pandas.io.formats.style.Styler at 0x113cec160>
```

Above we used `Styler.apply` to pass in each column one at a time.

*Debugging Tip:* If you're having trouble writing your style function, try just passing it into `DataFrame.apply`. Internally, `Styler.apply` uses `DataFrame.apply` so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use `.apply(function, axis=None)` to indicate that your function wants the entire table, not one column or row at a time. Let's try that next.

We'll rewrite our `highlight_max` to handle either Series (from `.apply(axis=0 or 1)`) or DataFrames (from `.apply(axis=None)`). We'll also allow the color to be adjustable, to demonstrate that `.apply`, and `.applymap` pass along keyword arguments.

```
In [10]: def highlight_max(data, color='yellow'):
        '''
        highlight the maximum in a Series or DataFrame
        '''
        attr = 'background-color: {}'.format(color)
        if data.ndim == 1: # Series from .apply(axis=0) or axis=1
            is_max = data == data.max()
            return [attr if v else '' for v in is_max]
        else: # from .apply(axis=None)
            is_max = data == data.max().max()
            return pd.DataFrame(np.where(is_max, attr, ''),
                               index=data.index, columns=data.columns)
```

When using `Styler.apply(func, axis=None)`, the function must return a DataFrame with the same index and column labels.

```
In [11]: df.style.apply(highlight_max, color='darkorange', axis=None)
```

```
Out[11]: <pandas.io.formats.style.Styler at 0x113d214e0>
```

### 23.1.1 Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- `Styler.applymap(func)` for elementwise styles
- `Styler.apply(func, axis=0)` for columnwise styles
- `Styler.apply(func, axis=1)` for rowwise styles

- `Styler.apply(func, axis=None)` for tablewise styles

And crucially the input and output shapes of `func` must match. If `x` is the input then `func(x).shape == x.shape`.

## 23.2 Finer Control: Slicing

Both `Styler.apply`, and `Styler.applymap` accept a `subset` keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your `style` function.

The value passed to `subset` behaves similar to slicing a `DataFrame`.

- A scalar is treated as a column label
- A list (or series or numpy array)
- A tuple is treated as `(row_indexer, column_indexer)`

Consider using `pd.IndexSlice` to construct the tuple for the last one.

```
In [12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
```

```
Out[12]: <pandas.io.formats.style.Styler at 0x113d217b8>
```

For row and column slicing, any valid indexer to `.loc` will work.

```
In [13]: df.style.applymap(color_negative_red,
                          subset=pd.IndexSlice[2:5, ['B', 'D']])
```

```
Out[13]: <pandas.io.formats.style.Styler at 0x113d21a20>
```

Only label-based slicing is supported right now, not positional.

If your style function uses a `subset` or `axis` keyword argument, consider wrapping your function in a `functools.partial`, partialing out that keyword.

```
my_func2 = functools.partial(my_func, subset=42)
```

## 23.3 Finer Control: Display Values

We distinguish the *display* value from the *actual* value in `Styler`. To control the display value, the text is printed in each cell, use `Styler.format`. Cells can be formatted according to a *format spec string* or a callable that takes a single value and returns a string.

```
In [14]: df.style.format("{:.2%}")
```

```
Out[14]: <pandas.io.formats.style.Styler at 0x113d21dd8>
```

Use a dictionary to format specific columns.

```
In [15]: df.style.format({'B': "{:0<4.0f}", 'D': '{:+.2f}'})
```

```
Out[15]: <pandas.io.formats.style.Styler at 0x113d214a8>
```

Or pass in a callable (or dictionary of callables) for more flexible handling.

```
In [16]: df.style.format({"B": lambda x: "±{:.2f}".format(abs(x))})
```

```
Out[16]: <pandas.io.formats.style.Styler at 0x113d21b38>
```

## 23.4 Builtin Styles

Finally, we expect certain styling functions to be common enough that we’ve included a few “built-in” to the `Styler`, so you don’t have to write them yourself.

```
In [17]: df.style.highlight_null(null_color='red')
Out[17]: <pandas.io.formats.style.Styler at 0x113d216d8>
```

You can create “heatmaps” with the `background_gradient` method. These require `matplotlib`, and we’ll use `Seaborn` to get a nice colormap.

```
In [18]: import seaborn as sns

        cm = sns.light_palette("green", as_cmap=True)

        s = df.style.background_gradient(cmap=cm)
        s

/Users/taugspurger/miniconda3/envs/travis-36-doc/lib/python3.6/site-packages/matplotlib/colors.py:504:
  xa[xa < 0] = -1
```

```
Out[18]: <pandas.io.formats.style.Styler at 0x113d21198>
```

`Styler.background_gradient` takes the keyword arguments `low` and `high`. Roughly speaking these extend the range of your data by `low` and `high` percent so that when we convert the colors, the colormap’s entire range isn’t used. This is useful so that you can actually read the text still.

```
In [19]: # Uses the full color range
        df.loc[:4].style.background_gradient(cmap='viridis')

/Users/taugspurger/miniconda3/envs/travis-36-doc/lib/python3.6/site-packages/matplotlib/colors.py:504:
  xa[xa < 0] = -1
```

```
Out[19]: <pandas.io.formats.style.Styler at 0x113d21a58>
```

```
In [20]: # Compress the color range
        (df.loc[:4]
         .style
         .background_gradient(cmap='viridis', low=.5, high=0)
         .highlight_null('red'))
```

```
/Users/taugspurger/miniconda3/envs/travis-36-doc/lib/python3.6/site-packages/matplotlib/colors.py:504:
  xa[xa < 0] = -1
```

```
Out[20]: <pandas.io.formats.style.Styler at 0x1a15a64940>
```

There’s also `.highlight_min` and `.highlight_max`.

```
In [21]: df.style.highlight_max(axis=0)
Out[21]: <pandas.io.formats.style.Styler at 0x113d215c0>
```

Use `Styler.set_properties` when the style doesn’t actually depend on the values.

```
In [22]: df.style.set_properties(**{'background-color': 'black',
                                   'color': 'lawngreen',
                                   'border-color': 'white'})
```

```
Out[22]: <pandas.io.formats.style.Styler at 0x1a15a64908>
```

### 23.4.1 Bar charts

You can include “bar charts” in your `DataFrame`.

```
In [23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
```

```
Out[23]: <pandas.io.formats.style.Styler at 0x1a15aea4e0>
```

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here's how you can change the above with the new `align='mid'` option:

```
In [24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
```

```
Out[24]: <pandas.io.formats.style.Styler at 0x1a15bbbe10>
```

The following example aims to give a highlight of the behavior of the new align options:

```
In [25]: import pandas as pd
         from IPython.display import HTML

         # Test series
         test1 = pd.Series([-100,-60,-30,-20], name='All Negative')
         test2 = pd.Series([10,20,50,100], name='All Positive')
         test3 = pd.Series([-10,-5,0,90], name='Both Pos and Neg')

         head = """
         <table>
             <thead>
                 <th>Align</th>
                 <th>All Negative</th>
                 <th>All Positive</th>
                 <th>Both Neg and Pos</th>
             </thead>
             </tbody>

         """

         aligns = ['left', 'zero', 'mid']
         for align in aligns:
             row = "<tr><th>{}</th>".format(align)
             for serie in [test1, test2, test3]:
                 s = serie.copy()
                 s.name = ' '
                 row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                                     color=['#d65f5f', '#5fba7d'],
