pandas: powerful Python data analysis toolkit

Release 0.23.0rc1

Wes McKinney & PyData Development Team

May 02, 2018
1 What’s New
1.1 v0.23.0 ................................................. 3
  1.1.1 New features ........................................ 3
    1.1.1.1 DataFrame.interpolate has gained the limit_area kwarg .... 3
    1.1.1.2 get_dummies now supports dtype argument .............. 4
    1.1.1.3 Rolling/Expanding.apply() accepts a raw keyword to pass a Series to the function 5
    1.1.1.4 Merging on a combination of columns and index levels .......... 6
    1.1.1.5 Sorting by a combination of columns and index levels .......... 6
    1.1.1.6 Timedelta mod method ................................ 7
    1.1.1.7 .rank() handles inf values when NaN are present .......... 7
    1.1.1.8 JSON read/write round-trippable with orient='table' .......... 8
    1.1.1.9 .assign() accepts dependent arguments .............. 10
    1.1.1.10 Series.str.cat has gained the join kwarg .......... 11
    1.1.1.11 DataFrame.astype performs column-wise conversion to Categorical .... 11
    1.1.1.12 Extending Pandas with Custom Types (Experimental) ............ 12
    1.1.1.13 Categorical Groupers has gained an observed keyword .......... 13
    1.1.1.14 Other Enhancements ................................ 15
  1.1.2 Backwards incompatible API changes .......................... 17
    1.1.2.1 Dependencies have increased minimum versions .......... 17
    1.1.2.2 Instantation from dicts preserves dict insertion order for python 3.6+ .... 17
    1.1.2.3 Deprecate Panel ..................................... 18
    1.1.2.4 pandas.core.common removals ............................ 19
    1.1.2.5 Changes to make output of DataFrame.apply consistent .......... 19
    1.1.2.6 Concatenation will no longer sort .................... 21
    1.1.2.7 Build Changes ....................................... 22
    1.1.2.8 Index Division By Zero Fills Correctly .................. 22
    1.1.2.9 Extraction of matching patterns from strings ............ 23
    1.1.2.10 Default value for the ordered parameter of CategoricalDtype .... 23
    1.1.2.11 Better pretty-printing of DataFrames in a terminal .......... 24
    1.1.2.12 Datetimelike API Changes ................................ 26
    1.1.2.13 Other API Changes .................................. 27
  1.1.3 Deprecations ........................................ 29
  1.1.4 Removal of prior version deprecations/changes .................. 30
  1.1.5 Performance Improvements ................................ 31
  1.1.6 Documentation Changes .................................. 32
  1.1.7 Bug Fixes ............................................ 32
    1.1.7.1 Categorical .......................................... 32
    1.1.7.2 Datetimelike ........................................ 33
    1.1.7.3 Timedelta ........................................... 34
    1.1.7.4 Timezones .......................................... 35
# 1.2 v0.22.0 (December 29, 2017)

- **Backwards incompatible API changes**
  - Arithmetic Operations
  - Grouping by a Categorical
  - Resample
  - Rolling and Expanding
- **Compatibility**

# 1.3 v0.21.1 (December 12, 2017)

- **New features**
  - Improvements to the Parquet IO functionality
  - Other Enhancements
- **Deprecations**
- **Performance Improvements**

# 1.4 v0.21.0 (October 27, 2017)

- **New features**
  - Integration with Apache Parquet file format
  - infer_objects type conversion
  - Improved warnings when attempting to create columns
  - drop now also accepts index/columns keywords
  - rename, reindex now also accept axis keyword
  - CategoricalDtype for specifying categoricals
  - GroupBy objects now have a pipe method
  - Categorical.rename_categories accepts a dict-like
  - Other Enhancements
- **Backwards incompatible API changes**
  - Dependencies have increased minimum versions
  - Sun/Prod of all-NaN or empty Series/DataFrames is now consistently NaN
  - Indexing with a list with missing labels is Deprecated
  - NA naming Changes
  - Iteration of Series/Index will now return Python scalars
  - Indexing with a Boolean Index
  - PeriodIndex resampling
1.7.1.6 Pickle file I/O now supports compression
1.7.1.7 UInt64 Support Improved
1.7.1.8 GroupBy on Categoricals
1.7.1.9 Table Schema Output
1.7.1.10 SciPy sparse matrix from/to SparseDataFrame
1.7.1.11 Excel output for styled DataFrames
1.7.1.12 IntervalIndex
1.7.1.13 Other Enhancements

1.7.2 Backwards incompatible API changes
1.7.2.1 Possible incompatibility for HDF5 formats created with pandas < 0.13.0
1.7.2.2 Map on Index types now return other Index types
1.7.2.3 Accessing datetime fields of Index now return Index
1.7.2.4 pd.unique will now be consistent with extension types
1.7.2.5 S3 File Handling
1.7.2.6 Partial String Indexing Changes
1.7.2.7 Concat of different float dtypes will not automatically upcast
1.7.2.8 Pandas Google BigQuery support has moved
1.7.2.9 Memory Usage for Index is more Accurate
1.7.2.10 DataFrame.sort_index changes
1.7.2.11 Groupby Describe Formatting
1.7.2.12 Window Binary Corr/Cov operations return a MultiIndex DataFrame
1.7.2.13 HDFStore where string comparison
1.7.2.14 Index.intersection and inner join now preserve the order of the left Index
1.7.2.15 Pivot Table always returns a DataFrame
1.7.2.16 Other API Changes

1.7.3 Reorganization of the library: Privacy Changes
1.7.3.1 Modules Privacy Has Changed
1.7.3.2 pandas.errors
1.7.3.3 pandas.testing
1.7.3.4 pandas.plotting
1.7.3.5 Other Development Changes

1.7.4 Deprecations
1.7.4.1 Deprecate .ix
1.7.4.2 Deprecate Panel
1.7.4.3 Deprecate groupby.agg() with a dictionary when renaming
1.7.4.4 Deprecate .plotting
1.7.4.5 Other Deprecations

1.7.5 Removal of prior version deprecations/changes

1.7.6 Performance Improvements

1.7.7 Bug Fixes
1.7.7.1 Conversion
1.7.7.2 Indexing
1.7.7.3 I/O
1.7.7.4 Plotting
1.7.7.5 Groupby/Resample/Rolling
1.7.7.6 Sparse
1.7.7.7 Reshaping
1.7.7.8 Numeric
1.7.7.9 Other

1.8 v0.19.2 (December 24, 2016)
1.8.1 Enhancements
1.8.2 Performance Improvements
1.8.3 Bug Fixes

1.9 v0.19.1 (November 3, 2016)
1.10.1 New features

1.10.1.1 merge_asof for asof-style time-series joining ........................................ 125
1.10.1.2 .rolling() is now time-series aware ..................................................... 128
1.10.1.3 read_csv has improved support for duplicate column names ..................... 130
1.10.1.4 read_csv supports parsing Categorical directly .................................... 130
1.10.1.5 Categorical Concatenation ................................................................. 131
1.10.1.6 Semi-Month Offsets ............................................................... 132
1.10.1.7 New Index methods .......................................................... 133
1.10.1.8 Google BigQuery Enhancements ..................................................... 134
1.10.1.9 Fine-grained numpy errstate ......................................................... 134
1.10.1.10 get_dummies now returns integer dtypes ............................................. 134
1.10.1.11 Downcast values to smallest possible dtype in to_numeric .................. 135
1.10.1.12 pandas development API .................................................. 135
1.10.1.13 Other enhancements .............................................................. 136

1.10.2 API changes .......................................................... 139

1.10.2.1 Series.tolist() will now return Python types ........................................ 139
1.10.2.2 Series operators for different indexes ............................................. 139
1.10.2.3 Series type promotion on assignment ............................................. 142
1.10.2.4 to_datetime() changes ............................................................. 143
1.10.2.5 Merging changes .......................................................... 143
1.10.2.6 describe() changes ............................................................ 145
1.10.2.7 Period changes .......................................................... 146
1.10.2.8 Index +/- no longer used for set operations .................................. 148
1.10.2.9 Index.difference and symmetric_difference changes ......................... 149
1.10.2.10 Index.unique consistently returns Index ........................................ 149
1.10.2.11 MultiIndex constructors, groupby and set_index preserve categorical dtypes 150
1.10.2.12 read_csv will progressively enumerate chunks .................................. 151
1.10.2.13 Sparse Changes .............................................................. 152
1.10.2.14 Indexer dtype changes ......................................................... 154
1.10.2.15 Other API Changes .......................................................... 155

1.10.3 Deprecations .......................................................... 156

1.10.4 Removal of prior version deprecations/changes .................................. 157

1.10.5 Performance Improvements ..................................................... 158

1.10.6 Bug Fixes .............................................................. 158

1.11 v0.18.1 (May 3, 2016) ...................................................... 164

1.11.1 New features .............................................................. 165

1.11.1.1 Custom Business Hour ......................................................... 165
1.11.1.2 .groupby(...) syntax with window and resample operations ................. 165
1.11.1.3 Method chaining improvements ............................................. 168
1.11.1.4 Partial string indexing on DateTimeIndex when part of a MultiIndex .... 169
1.11.1.5 Assembling Datetimes ..................................................... 171
1.11.1.6 Other Enhancements .............................................................. 171

1.11.2 Sparse changes .............................................................. 172

1.11.3 API changes .............................................................. 173

1.11.3.1 .groupby(...) .nth() changes ..................................................... 173
1.11.3.2 numpy function compatibility ..................................................... 175
1.11.3.3 Using .apply on groupby resampling ........................................ 176
1.11.3.4 Changes in read_csv exceptions ............................................. 176
1.11.3.5 to_datetime error changes ..................................................... 177
1.11.3.6 Other API changes .............................................................. 178
1.11.3.7 Deprecations .............................................................. 178
1.14  New features ............................................................. 219
  1.14.1  Datetime with TZ ................................................. 219
  1.14.2  Releasing the GIL ............................................. 220
  1.14.3  Plot submethods ............................................... 220
  1.14.4  Additional methods for dt accessor ......................... 221
  1.14.5  Period Frequency Enhancement .............................. 223
  1.14.6  Support for SAS XPORT files ............................... 223
  1.14.7  Support for Math Functions in .eval() ................... 224
  1.14.8  Changes to Excel with MultiIndex ......................... 224
  1.14.9  Google BigQuery Enhancements .............................. 225
  1.14.10 Display Alignment with Unicode East Asian Width .... 226
  1.14.11 Other enhancements ......................................... 226

1.14.2  Backwards incompatible API changes ......................... 230
  1.14.2.1  Changes to sorting API ................................ 230
  1.14.2.2  Changes to to_datetime and to_timedelta ............ 231

1.13  New features ......................................................... 212
  1.13.1  Conditional HTML Formatting ................................ 212
  1.13.2  Enhancements .................................................. 212
  1.13.3  API changes ................................................... 214
  1.13.4  Performance Improvements .................................. 214
  1.13.5  Bug Fixes ....................................................... 215

1.12  v0.18.0 (March 13, 2016) ........................................ 181
  1.12.1  New features .................................................. 183
  1.12.2  Backwards incompatible API changes ......................... 194
  1.12.3  Performance Improvements .................................. 194
  1.12.4  Bug Fixes ....................................................... 208
  1.12.5  Bug Fixes ....................................................... 208
  1.12.6  API changes ................................................... 208
  1.12.7  API changes ................................................... 208
  1.12.8  API changes ................................................... 208
  1.12.9  API changes ................................................... 208
  1.12.10 API changes .................................................. 208
  1.12.11 API changes .................................................. 208
  1.12.12 API changes .................................................. 208
  1.12.13 API changes .................................................. 208

1.11  v0.17.0 (November 21, 2015) ................................... 211
  1.11.1  New features .................................................. 212
  1.11.2  New features .................................................. 212
  1.11.3  New features .................................................. 212
  1.11.4  New features .................................................. 212
  1.11.5  New features .................................................. 212
  1.11.6  New features .................................................. 212

v0.17.0 (October 9, 2015) ........................................... 178
  1.11.4  Performance Improvements .................................. 178
  1.11.5  Bug Fixes ....................................................... 179

1.10  v0.16.0 (October 9, 2015) ....................................... 175
  1.10.1  New features .................................................. 177
  1.10.2  New features .................................................. 177
  1.10.3  New features .................................................. 177
  1.10.4  New features .................................................. 177
  1.10.5  New features .................................................. 177

1.9  v0.15.0 (September 9, 2015) ..................................... 172
  1.9.1  New features .................................................. 174
  1.9.2  New features .................................................. 174
  1.9.3  New features .................................................. 174
  1.9.4  New features .................................................. 174
  1.9.5  New features .................................................. 174

1.8  v0.14.0 (August 17, 2015) ....................................... 169
  1.8.1  New features .................................................. 171
  1.8.2  New features .................................................. 171
  1.8.3  New features .................................................. 171
  1.8.4  New features .................................................. 171
  1.8.5  New features .................................................. 171

1.7  v0.13.0 (July 13, 2015) ........................................... 166
  1.7.1  New features .................................................. 168
  1.7.2  New features .................................................. 168
  1.7.3  New features .................................................. 168
  1.7.4  New features .................................................. 168
  1.7.5  New features .................................................. 168

1.6  v0.12.0 (June 14, 2015) .......................................... 162
  1.6.1  New features .................................................. 164
  1.6.2  New features .................................................. 164
  1.6.3  New features .................................................. 164
  1.6.4  New features .................................................. 164
  1.6.5  New features .................................................. 164

1.5  v0.11.0 (May 14, 2015) .......................................... 158
  1.5.1  New features .................................................. 160
  1.5.2  New features .................................................. 160
  1.5.3  New features .................................................. 160
  1.5.4  New features .................................................. 160
  1.5.5  New features .................................................. 160

1.4  v0.10.0 (April 15, 2015) ......................................... 154
  1.4.1  New features .................................................. 156
  1.4.2  New features .................................................. 156
  1.4.3  New features .................................................. 156
  1.4.4  New features .................................................. 156
  1.4.5  New features .................................................. 156

1.3  v0.9.0 (March 10, 2015) ......................................... 149
  1.3.1  New features .................................................. 151
  1.3.2  New features .................................................. 151
  1.3.3  New features .................................................. 151
  1.3.4  New features .................................................. 151
  1.3.5  New features .................................................. 151

1.2  v0.8.0 (February 18, 2015) ................................... 145
  1.2.1  New features .................................................. 147
  1.2.2  New features .................................................. 147
  1.2.3  New features .................................................. 147
  1.2.4  New features .................................................. 147
  1.2.5  New features .................................................. 147

1.1  v0.7.0 (January 15, 2015) ..................................... 140
  1.1.1  New features .................................................. 142
  1.1.2  New features .................................................. 142
  1.1.3  New features .................................................. 142
  1.1.4  New features .................................................. 142
  1.1.5  New features .................................................. 142

1.23 v0.13.1 (February 3, 2014) ............................... 348
  1.23.1 Output Formatting Enhancements ....................... 349
  1.23.2 API changes ........................................ 350
  1.23.3 Prior Version Deprecations/Changes ................... 352
  1.23.4 Deprecations ....................................... 352
  1.23.5 Enhancements ....................................... 352
  1.23.6 Performance ....................................... 355
  1.23.7 Experimental ..................................... 356
  1.23.8 Bug Fixes ........................................... 356
1.24 v0.13.0 (January 3, 2014) ................................. 356
  1.24.1 API changes ........................................ 356
  1.24.2 Prior Version Deprecations/Changes ................... 359
  1.24.3 Deprecations ....................................... 359
  1.24.4 Indexing API Changes .................................. 359
  1.24.5 Float64Index API Change ............................. 361
  1.24.6 HDFStore API Changes ................................. 363
  1.24.7 DataFrame repr Changes ............................... 365
1.24.8 Enhancements .................................................. 366
1.24.9 Experimental .................................................. 373
1.24.10 Internal Refactoring ......................................... 377
1.24.11 Bug Fixes ....................................................... 379
1.25 v0.12.0 (July 24, 2013) ........................................... 379
  1.25.1 API changes .................................................. 379
  1.25.2 I/O Enhancements .......................................... 383
  1.25.3 Other Enhancements ....................................... 385
  1.25.4 Experimental Features .................................... 387
  1.25.5 Bug Fixes ..................................................... 388
1.26 v0.11.0 (April 22, 2013) ......................................... 390
  1.26.1 Selection Choices .......................................... 391
  1.26.2 Selection Deprecations ..................................... 391
  1.26.3 Dtypes ....................................................... 392
  1.26.4 Dtype Conversion ......................................... 393
  1.26.5 Dtype Gotchas ............................................. 394
  1.26.6 Datetimes Conversion ...................................... 396
  1.26.7 API changes ............................................... 398
  1.26.8 Enhancements .............................................. 398
1.27 v0.10.1 (January 22, 2013) ..................................... 400
  1.27.1 API changes ............................................... 400
  1.27.2 New features .............................................. 401
  1.27.3 HDFStore .................................................. 401
1.28 v0.10.0 (December 17, 2012) .................................. 406
  1.28.1 File parsing new features ................................ 406
  1.28.2 API changes ............................................... 407
  1.28.3 New features .............................................. 412
  1.28.4 Wide DataFrame Printing .................................. 412
  1.28.5 Updated PyTables Support ............................... 414
  1.28.6 N Dimensional Panels (Experimental) .................... 417
1.29 v0.9.1 (November 14, 2012) .................................. 418
  1.29.1 New features .............................................. 418
  1.29.2 API changes .............................................. 421
1.30 v0.9.0 (October 7, 2012) ...................................... 422
  1.30.1 New features .............................................. 422
  1.30.2 API changes .............................................. 422
1.31 v0.8.1 (July 22, 2012) ........................................ 424
  1.31.1 New features .............................................. 424
  1.31.2 Performance improvements .............................. 424
1.32 v0.8.0 (June 29, 2012) ........................................ 424
  1.32.1 Support for non-unique indexes .......................... 424
  1.32.2 NumPy datetime64 dtype and 1.6 dependency .......... 425
  1.32.3 Time series changes and improvements .................. 425
  1.32.4 Other new features ....................................... 426
  1.32.5 New plotting methods .................................... 427
  1.32.6 Other API changes ....................................... 427
  1.32.7 Potential porting issues for pandas <= 0.7.3 users .... 427
1.33 v0.7.3 (April 12, 2012) ........................................ 429
  1.33.1 New features .............................................. 430
  1.33.2 NA Boolean Comparison API Change ...................... 431
  1.33.3 Other API Changes ....................................... 432
1.34 v0.7.2 (March 16, 2012) ....................................... 433
  1.34.1 New features .............................................. 433
  1.34.2 Performance improvements .............................. 433
1.35 v.0.7.1 (February 29, 2012) .................................................. 433
1.35.1 New features ............................................................... 434
1.35.2 Performance improvements ......................................... 434
1.36 v.0.7.0 (February 9, 2012) .................................................. 434
1.36.1 New features ............................................................... 434
1.36.2 API Changes to integer indexing ................................. 435
1.36.3 API tweaks regarding label-based slicing .................... 437
1.36.4 Changes to Series [] operator ..................................... 438
1.36.5 Other API Changes .................................................... 439
1.36.6 Performance improvements ......................................... 439
1.37 v.0.6.1 (December 13, 2011) ............................................. 440
1.37.1 New features ............................................................... 440
1.37.2 Performance improvements ......................................... 440
1.38 v.0.6.0 (November 25, 2011) ............................................. 440
1.38.1 New Features ............................................................... 440
1.38.2 Performance Enhancements ......................................... 442
1.39 v.0.5.0 (October 24, 2011) ................................................ 442
1.39.1 New Features ............................................................... 442
1.39.2 Performance Enhancements ......................................... 443
1.40 v.0.4.3 through v0.4.1 (September 25 - October 9, 2011) ...... 443
1.40.1 New Features ............................................................... 443
1.40.2 Performance Enhancements ......................................... 444

2 Installation ............................................................................ 445
2.1 Plan for dropping Python 2.7 .............................................. 445
2.2 Python version support ..................................................... 445
2.3 Installing pandas ............................................................. 445
2.3.1 Installing with Anaconda ............................................. 445
2.3.2 Installing with Miniconda ............................................ 446
2.3.3 Installing from PyPI ..................................................... 447
2.3.4 Installing with ActivePython ....................................... 447
2.3.5 Installing using your Linux distribution’s package manager. 447
2.3.6 Installing from source .................................................. 447
2.4 Running the test suite ....................................................... 447
2.5 Dependencies ............................................................... 448
2.5.1 Recommended Dependencies ..................................... 448
2.5.2 Optional Dependencies ............................................... 448

3 Contributing to pandas ......................................................... 451
3.1 Where to start? ............................................................... 452
3.2 Bug reports and enhancement requests ............................... 452
3.3 Working with the code ...................................................... 453
3.3.1 Version control, Git, and GitHub .................................. 453
3.3.2 Getting started with Git ............................................. 453
3.3.3 Forking ................................................................. 453
3.3.4 Creating a development environment .......................... 453
3.3.4.1 Installing a C Compiler ........................................ 454
3.3.4.2 Creating a Python Environment .............................. 454
3.3.4.3 Creating a Python Environment (pip) ....................... 455
3.3.5 Creating a branch ....................................................... 455
3.4 Contributing to the documentation .................................... 456
3.4.1 About the pandas documentation .................................. 456
3.4.1.1 pandas docstring guide ........................................ 456
3.4.2 How to build the pandas documentation ....................... 472
## 8 Intro to Data Structures 551

### 8.1 Series 551
- **8.1.1** Series is ndarray-like 553
- **8.1.2** Series is dict-like 554
- **8.1.3** Vectorized operations and label alignment with Series 555
- **8.1.4** Name attribute 556

### 8.2 DataFrame 556
- **8.2.1** From dict of Series or dicts 557
- **8.2.2** From dict of ndarrays / lists 558
- **8.2.3** From structured or record array 558
- **8.2.4** From a list of dicts 559
- **8.2.5** From a dict of tuples 559
- **8.2.6** From a Series 559
- **8.2.7** Alternate Constructors 559
- **8.2.8** Column selection, addition, deletion 560
- **8.2.9** Assigning New Columns in Method Chains 562
- **8.2.10** Indexing / Selection 564
- **8.2.11** Data alignment and arithmetic 565
- **8.2.12** Transposing 568
- **8.2.13** DataFrame interoperability with NumPy functions 568
- **8.2.14** Console display 569
- **8.2.15** DataFrame column attribute access and IPython completion 572

### 8.3 Panel 572
- **8.3.1** From 3D ndarray with optional axis labels 573
- **8.3.2** From dict of DataFrame objects 573
- **8.3.3** From DataFrame using `to_panel` method 574
- **8.3.4** Item selection / addition / deletion 575
- **8.3.5** Transposing 575
- **8.3.6** Indexing / Selection 575
- **8.3.7** Squeezing 576
- **8.3.8** Conversion to DataFrame 576

### 8.4 Deprecate Panel 577

## 9 Essential Basic Functionality 581

### 9.1 Head and Tail 581

### 9.2 Attributes and the raw ndarray(s) 582

### 9.3 Accelerated operations 583

### 9.4 Flexible binary operations 583
- **9.4.1** Matching / broadcasting behavior 584
- **9.4.2** Missing data / operations with fill values 587
- **9.4.3** Flexible Comparisons 588
- **9.4.4** Boolean Reductions 588
- **9.4.5** Comparing if objects are equivalent 590
- **9.4.6** Comparing array-like objects 590
10.2.3 Concatenating a Series and something array-like into a Series ........................................ 657
10.2.4 Concatenating a Series and an indexed object into a Series, with alignment .......................... 658
10.2.5 Concatenating a Series and many objects into a Series .................................................. 660
10.3 Indexing with .str ................................................................................................................. 662
10.4 Extracting Substrings ........................................................................................................... 663
10.4.1 Extract first match in each subject (extract) ........................................................................ 663
10.4.2 Extract all matches in each subject (extractall) ................................................................. 665
10.5 Testing for Strings that Match or Contain a Pattern ............................................................. 666
10.6 Creating Indicator Variables ............................................................................................... 667
10.7 Method Summary .................................................................................................................. 668
10.8 Table Schema Display ......................................................................................................... 682
10.9 Indexing with list with missing labels is Deprecated ............................................................ 701
10.10 Selecting Random Samples ................................................................................................. 703
10.11 Setting Startup Options in python/ipython Environment ...................................................... 673
10.12 Getting and Setting Options ............................................................................................... 672
10.13 Available Options ................................................................................................................ 673
10.14 Frequently Used Options ...................................................................................................... 674
10.15 Setting Startup Options in python/ipython Environment ...................................................... 673
10.16 Dictionary-like method ........................................................................................................ 679
10.17 Duplicate Data ...................................................................................................................... 725
10.18 Dictionary-like get() method ............................................................................................... 728
10.19 The lookup() Method ......................................................................................................... 729
10.20 Index objects ....................................................................................................................... 729
10.20.1 Setting metadata .............................................................................................................. 730
10.20.2 Set operations on Index objects ..................................................................................... 731
11 Options and Settings ............................................................................................................... 671
11.1 Overview .............................................................................................................................. 671
11.2 Getting and Setting Options ............................................................................................... 672
11.3 Setting Startup Options in python/ipython Environment ...................................................... 673
11.4 Frequently Used Options ...................................................................................................... 673
11.5 Available Options ................................................................................................................ 679
11.6 Number Formatting .............................................................................................................. 680
11.7 Unicode Formatting .............................................................................................................. 681
11.8 Table Schema Display ......................................................................................................... 682
12 Indexing and Selecting Data .................................................................................................. 683
12.1 Different Choices for Indexing ............................................................................................. 683
12.2 Basics .................................................................................................................................. 684
12.3 Attribute Access ................................................................................................................... 687
12.4 Slicing ranges ....................................................................................................................... 689
12.5 Selection By Label ............................................................................................................... 690
12.5.1 Slicing with labels .......................................................................................................... 693
12.6 Selection By Position .......................................................................................................... 694
12.7 Selection By Callable .......................................................................................................... 698
12.8 IX Indexer is Deprecated .................................................................................................... 700
12.9 Indexing with list with missing labels is Deprecated ............................................................ 701
12.9.1 Reindexing ..................................................................................................................... 702
12.10 Selecting Random Samples ............................................................................................... 703
12.11 Setting With Enlargement ................................................................................................... 705
12.12 Fast scalar value getting and setting ................................................................................... 706
12.13 Boolean indexing ................................................................................................................. 707
12.14 Indexing with isin ............................................................................................................... 708
12.15 The where() Method and Masking .................................................................................... 711
12.15.1 Mask ............................................................................................................................... 714
12.16 The query() Method .......................................................................................................... 715
12.16.1 MultiIndex query() Syntax ............................................................................................. 717
12.16.2 query() Use Cases ........................................................................................................ 718
12.16.3 query() Python versus pandas Syntax Comparison ....................................................... 719
12.16.4 The in and not in operators ........................................................................................... 720
12.16.5 Special use of the == operator with list objects ............................................................. 722
12.16.6 Boolean Operators ........................................................................................................ 724
12.16.7 Performance of query() ................................................................................................. 725
12.17 Duplicate Data .................................................................................................................... 725
12.18 Dictionary-like get() method ............................................................................................. 728
12.19 The lookup() Method ....................................................................................................... 729
12.20 Index objects ...................................................................................................................... 729
16 Group By: split-apply-combine 827
16.1 Splitting an object into groups 828
   16.1.1 GroupBy sorting 830
   16.1.2 GroupBy object attributes 830
   16.1.3 GroupBy with MultiIndex 831
   16.1.4 Grouping DataFrame with Index Levels and Columns 833
   16.1.5 DataFrame column selection in GroupBy 834
16.2 Iterating through groups 835
16.3 Selecting a group 836
16.4 Aggregation 836
   16.4.1 Applying multiple functions at once 838
   16.4.2 Applying different functions to DataFrame columns 839
   16.4.3 Cython-optimized aggregation functions 840
16.5 Transformation 841
   16.5.1 New syntax to window and resample operations 846
16.6 Filtration 848
16.7 Dispatching to instance methods 850
16.8 Flexible apply 851
16.9 Other useful features 854
   16.9.1 Automatic exclusion of “nuisance” columns 854
   16.9.2 Handling of (un)observed Categorical values 854
   16.9.3 NA and NaT group handling 855
   16.9.4 Grouping with ordered factors 855
   16.9.5 Grouping with a Grouper specification 855
   16.9.6 Taking the first rows of each group 857
   16.9.7 Taking the nth row of each group 857
   16.9.8 Enumerate group items 859
   16.9.9 Enumerate groups 860
   16.9.10 Plotting 861
   16.9.11 Piping function calls 862
16.10 Examples 863
| 16.10.1 | Regrouping by factor | 863 |
| 16.10.2 | Multi-column factorization | 863 |
| 16.10.3 | Groupby by Indexer to ‘resample’ data | 864 |
| 16.10.4 | Returning a Series to propagate names | 864 |

| 17 | Merge, join, and concatenate | 867 |
| 17.1 | Concatenating objects | 867 |
| 17.1.1 | Set logic on the other axes | 870 |
| 17.1.2 | Concatenating using `append` | 871 |
| 17.1.3 | Ignoring indexes on the concatenation axis | 873 |
| 17.1.4 | Concatenating with mixed ndims | 873 |
| 17.1.5 | More concatenating with group keys | 875 |
| 17.1.6 | Appending rows to a DataFrame | 878 |
| 17.2 | Database-style DataFrame joining/merging | 879 |
| 17.2.1 | Brief primer on merge methods (relational algebra) | 881 |
| 17.2.2 | Checking for duplicate keys | 884 |
| 17.2.3 | The merge indicator | 884 |
| 17.2.4 | Merge Dtypes | 885 |
| 17.2.5 | Joining on index | 888 |
| 17.2.6 | Joining key columns on an index | 889 |
| 17.2.7 | Joining a single Index to a Multi-index | 891 |
| 17.2.8 | Joining with two multi-indexes | 892 |
| 17.2.9 | Merging on a combination of columns and index levels | 892 |
| 17.2.10 | Overlapping value columns | 893 |
| 17.2.11 | Joining multiple DataFrame or Panel objects | 894 |
| 17.2.12 | Merging together values within Series or DataFrame columns | 895 |

| 17.3 | Timeseries friendly merging | 895 |
| 17.3.1 | Merging Ordered Data | 895 |
| 17.3.2 | Merging AsOf | 896 |

| 18 | Reshaping and Pivot Tables | 899 |
| 18.1 | Reshaping by pivoting DataFrame objects | 899 |
| 18.2 | Reshaping by stacking and unstacking | 900 |
| 18.2.1 | Multiple Levels | 902 |
| 18.2.2 | Missing Data | 903 |
| 18.2.3 | With a MultiIndex | 905 |
| 18.3 | Reshaping by Melt | 906 |
| 18.4 | Combining with stats and GroupBy | 907 |
| 18.5 | Pivot tables | 908 |
| 18.5.1 | Adding margins | 911 |
| 18.6 | Cross tabulations | 912 |
| 18.6.1 | Normalization | 913 |
| 18.6.2 | Adding Margins | 914 |
| 18.7 | Tiling | 914 |
| 18.8 | Computing indicator / dummy variables | 914 |
| 18.9 | Factorizing values | 918 |

| 19 | Time Series / Date functionality | 921 |
| 19.1 | Overview | 922 |
| 19.2 | Timestamps vs. Time Spans | 922 |
| 19.3 | Converting to Timestamps | 924 |
| 19.3.1 | Providing a Format Argument | 924 |
| 19.3.2 | Assembling Datetime from Multiple DataFrame Columns | 925 |
| 19.3.3 | Invalid Data | 925 |
# Categorical Data

## Object Creation

### Series Creation

### DataFrame Creation

### Controlling Behavior

### Regaining Original Data

## CategoricalDtype

### Equality Semantics

## Description

## Working with categories

### Renaming categories

### Appending new categories

### Removing categories

### Removing unused categories

### Setting categories

## Sorting and Order

### Reordering

### Multi Column Sorting

## Comparisons

## Operations

## Data munging

### Getting

### String and datetime accessors

### Setting

### Merging

### Unioning

### Concatenation

## Getting Data In/Out

## Missing Data

## Differences to R's `factor`

## Gotchas

### Memory Usage

### `Categorical` is not a `numpy` array

### `dtype` in apply

### Categorical Index

### Side Effects

# Visualization

## Basic Plotting: `plot`

## Other Plots

### Bar plots

### Histograms

### Box Plots

### Area Plot

### Scatter Plot

### Hexagonal Bin Plot

### Pie plot

pandas is a Python package providing fast, flexible, and expressive data structures designed to make working with “relational” or “labeled” data both easy and intuitive. It aims to be the fundamental high-level building block for doing practical, real world data analysis in Python. Additionally, it has the broader goal of becoming the most powerful and flexible open source data analysis / manipulation tool available in any language. It is already well on its way toward this goal.

pandas is well suited for many different kinds of data:

- Tabular data with heterogeneously-typed columns, as in an SQL table or Excel spreadsheet
- Ordered and unordered (not necessarily fixed-frequency) time series data.
- Arbitrary matrix data (homogeneously typed or heterogeneous) with row and column labels
- Any other form of observational / statistical data sets. The data actually need not be labeled at all to be placed into a pandas data structure

The two primary data structures of pandas, Series (1-dimensional) and DataFrame (2-dimensional), handle the vast majority of typical use cases in finance, statistics, social science, and many areas of engineering. For R users, DataFrame provides everything that R’s data.frame provides and much more. pandas is built on top of NumPy and is intended to integrate well within a scientific computing environment with many other 3rd party libraries.

Here are just a few of the things that pandas does well:

- Easy handling of missing data (represented as NaN) in floating point as well as non-floating point data
- Size mutability: columns can be inserted and deleted from DataFrame and higher dimensional objects
- Automatic and explicit data alignment: objects can be explicitly aligned to a set of labels, or the user can simply ignore the labels and let Series, DataFrame, etc. automatically align the data for you in computations
- Powerful, flexible group by functionality to perform split-apply-combine operations on data sets, for both aggregating and transforming data
- Make it easy to convert ragged, differently-indexed data in other Python and NumPy data structures into DataFrame objects
- Intelligent label-based slicing, fancy indexing, and subsetting of large data sets
- Intuitive merging and joining data sets
- Flexible reshaping and pivoting of data sets
- Hierarchical labeling of axes (possible to have multiple labels per tick)
- Robust IO tools for loading data from flat files (CSV and delimited), Excel files, databases, and saving / loading data from the ultrafast HDF5 format
- Time series-specific functionality: date range generation and frequency conversion, moving window statistics, moving window linear regressions, date shifting and lagging, etc.
Many of these principles are here to address the shortcomings frequently experienced using other languages / scientific research environments. For data scientists, working with data is typically divided into multiple stages: munging and cleaning data, analyzing / modeling it, then organizing the results of the analysis into a form suitable for plotting or tabular display. pandas is the ideal tool for all of these tasks.

Some other notes

- pandas is fast. Many of the low-level algorithmic bits have been extensively tweaked in Cython code. However, as with anything else generalization usually sacrifices performance. So if you focus on one feature for your application you may be able to create a faster specialized tool.

- pandas is a dependency of statsmodels, making it an important part of the statistical computing ecosystem in Python.

- pandas has been used extensively in production in financial applications.

Note: This documentation assumes general familiarity with NumPy. If you haven’t used NumPy much or at all, do invest some time in learning about NumPy first.

See the package overview for more detail about what’s in the library.
These are new features and improvements of note in each release.

## 1.1 v0.23.0

This is a major release from 0.22.0 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** Starting January 1, 2019, pandas feature releases will support Python 3 only. See *Plan for dropping Python 2.7* for more.

### 1.1.1 New features

#### 1.1.1.1 DataFrame.interpolate has gained the limit_area kwarg

*DataFrame.interpolate()* has gained a *limit_area* parameter to allow further control of which NaNs are replaced. Use *limit_area='inside'* to fill only NaNs surrounded by valid values or use *limit_area='outside'* to fill only NaNs outside the existing valid values while preserving those inside. ([GH16284](https://github.com/pandas-dev/pandas/issues/16284)) See the *full documentation here*.  

```python
In [1]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])

In [2]: ser
Out[2]:
0   NaN
1   NaN
2    5.0
3   NaN
4   NaN
5   NaN
6   13.0
7   NaN
8   NaN
dtype: float64
```

Fill one consecutive inside value in both directions
Fill all consecutive outside values backward

```
In [4]: ser.interpolate(limit_direction='backward', limit_area='outside')
Out[4]:
0   5.0
1   5.0
2   5.0
3   NaN
4   NaN
5   NaN
6  13.0
7   NaN
8   NaN
dtype: float64
```

Fill all consecutive outside values in both directions

```
In [5]: ser.interpolate(limit_direction='both', limit_area='outside')
Out[5]:
0   5.0
1   5.0
2   5.0
3   NaN
4   NaN
5   NaN
6  13.0
7  13.0
8  13.0
dtype: float64
```

### 1.1.1.2 `get_dummies` now supports dtype argument

The `get_dummies()` now accepts a `dtype` argument, which specifies a dtype for the new columns. The default remains `uint8`. (GH18330)

```
In [6]: df = pd.DataFrame({'a': [1, 2], 'b': [3, 4], 'c': [5, 6]})
In [7]: pd.get_dummies(df, columns=['c']).dtypes
Out[7]:
a     int64
b     int64
c_5   uint8
c_6   uint8
```

(continues on next page)
1.1.3 Rolling/Expanding.apply() accepts a raw keyword to pass a Series to the function

Series.rolling().apply(), DataFrame.rolling().apply(), Series.expanding().apply(), and DataFrame.expanding().apply() have gained a raw=None parameter. This is similar to DataFrame.apply(). This parameter, if True allows one to send a np.ndarray to the applied function. If False a Series will be passed. The default is None, which preserves backward compatibility, so this will default to True, sending an np.ndarray. In a future version the default will be changed to False, sending a Series. (GH5071, GH20584)

Pass a Series:

```python
In [11]: s.rolling(2, min_periods=1).apply(lambda x: x.iloc[-1], raw=False)
Out[11]:
0  0.0
1  1.0
2  2.0
3  3.0
4  4.0
dtype: float64
```

Mimic the original behavior of passing a ndarray:

```python
In [12]: s.rolling(2, min_periods=1).apply(lambda x: x[-1], raw=True)
Out[12]:
0  0.0
1  1.0
2  2.0
3  3.0
4  4.0
dtype: float64
```
1.1.1.4 Merging on a combination of columns and index levels

Strings passed to `DataFrame.merge()` as the on, left_on, and right_on parameters may now refer to either column names or index level names. This enables merging DataFrame instances on a combination of index levels and columns without resetting indexes. See the *Merge on columns and levels* documentation section. (GH14355)

```python
In [13]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [14]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                      ....:                      'B': ['B0', 'B1', 'B2', 'B3'],
                      ....:                      'key2': ['K0', 'K1', 'K0', 'K1'],
                      ....:                      index=left_index)

In [15]: right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

In [16]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                         ....:                         'D': ['D0', 'D1', 'D2', 'D3'],
                         ....:                         'key2': ['K0', 'K0', 'K0', 'K1'],
                         ....:                         index=right_index)

In [17]: left.merge(right, on=['key1', 'key2'])
Out[17]:
   key1  A  B  C  D
0    K0  A0  B0  C0  D0
1    K1  A2  B2  C1  D1
2    K2  A3  B3  C3  D3
```

1.1.1.5 Sorting by a combination of columns and index levels

Strings passed to `DataFrame.sort_values()` as the by parameter may now refer to either column names or index level names. This enables sorting DataFrame instances by a combination of index levels and columns without resetting indexes. See the *Sorting by Indexes and Values* documentation section. (GH14353)

```python
# Build MultiIndex
In [18]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                      ....:                                   ('b', 2), ('b', 1), ('b', 1)])
                      ....:                      

In [19]: idx.names = ['first', 'second']

# Build DataFrame
In [20]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1),
                          ....:                          index=idx})

In [21]: df_multi
Out[21]:
   first  second
a   1     6
     2     5
     2     4
b   2     3
```
# Sort by 'second' (index) and 'A' (column)

```python
In [22]: df_multi.sort_values(by=['second', 'A'])
Out[22]:
    first  second  A
b    1       1   1
b    1       2   2
a    1       6   3
b    2       3   4
a    2       4   5
```

## 1.1.6 Timedelta mod method

The `mod (%)` and `divmod` operations are now defined on `Timedelta` objects when operating with either timedelta-like or with numeric arguments. See the [documentation here](https://pandas.pydata.org/pandas-docs/stable/reference/api/pandas.Timedelta.html). (GH19365)

```python
In [23]: td = pd.Timedelta(hours=37)
In [24]: td % pd.Timedelta(minutes=45)
Out[24]: Timedelta('0 days 00:15:00')
```

### 1.1.7 .rank() handles inf values when NaN are present

In previous versions, `.rank()` would assign `inf` elements `NaN` as their ranks. Now ranks are calculated properly. (GH6945)

```python
In [25]: s = pd.Series([-np.inf, 0, 1, np.nan, np.inf])
In [26]: s
Out[26]:
0   -inf
1  0.000000
2  1.000000
3    NaN
4    inf
dtype: float64
```

**Previous Behavior:**

```python
In [11]: s.rank()
Out[11]:
0   1.0
1   2.0
2   3.0
3   NaN
4   NaN
dtype: float64
```

**Current Behavior:**

```python
In [ ]:
Out[ ]:```
Furthermore, previously if you rank $\text{inf}$ or $-\text{inf}$ values together with NaN values, the calculation won’t distinguish NaN from infinity when using ‘top’ or ‘bottom’ argument.

```python
In [28]: s = pd.Series([np.nan, np.nan, -np.inf, -np.inf])
In [29]: s
Out[29]:
0    NaN
1    NaN
2  -inf
3  -inf
dtype: float64
```

Previous Behavior:

```python
In [15]: s.rank(na_option='top')
Out[15]:
0    2.5
1    2.5
2    2.5
3    2.5
dtype: float64
```

Current Behavior:

```python
In [30]: s.rank(na_option='top')
Out[30]:
0    1.5
1    1.5
2    3.5
3    3.5
dtype: float64
```

These bugs were squashed:

- Bug in `DataFrame.rank()` and `Series.rank()` when `method='dense'` and `pct=True` in which percentile ranks were not being used with the number of distinct observations (GH15630)
- Bug in `Series.rank()` and `DataFrame.rank()` when `ascending='False'` failed to return correct ranks for infinity if NaN were present (GH19538)
- Bug in `DataFrameGroupBy.rank()` where ranks were incorrect when both infinity and NaN were present (GH20561)

1.1.1.8 JSON read/write round-trippable with `orient='table'`

A `DataFrame` can now be written to and subsequently read back via JSON while preserving metadata through usage of the `orient='table'` argument (see GH18912 and GH9146). Previously, none of the available `orient` values guaranteed the preservation of dtypes and index names, amongst other metadata.
In [31]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
                        'bar': ['a', 'b', 'c', 'd'],
                        'baz': pd.date_range('2018-01-01', freq='d', periods=4),
                        'qux': pd.Categorical(['a', 'b', 'c', 'c'])}, index=pd.Index(range(4), name='idx'))

In [32]: df
Out[32]:
   foo  bar       baz          qux
idx
0  1   a 2018-01-01    a
1  2   b 2018-01-02    b
2  3   c 2018-01-03    c
3  4   d 2018-01-04    c

In [33]: df.dtypes
Out[33]:
foo    int64
bar   object
baz  datetime64[ns]
qux   category
dtype: object

In [34]: df.to_json('test.json', orient='table')

In [35]: new_df = pd.read_json('test.json', orient='table')

In [36]: new_df
Out[36]:
   foo  bar       baz          qux
idx
0  1   a 2018-01-01    a
1  2   b 2018-01-02    b
2  3   c 2018-01-03    c
3  4   d 2018-01-04    c

In [37]: new_df.dtypes
Out[37]:
foo    int64
bar   object
baz  datetime64[ns]
qux   category
dtype: object

Please note that the string index is not supported with the round trip format, as it is used by default in write_json to indicate a missing index name.

In [38]: df.index.name = 'index'

In [39]: df.to_json('test.json', orient='table')

In [40]: new_df = pd.read_json('test.json', orient='table')

In [41]: new_df

(continues on next page)
1.1.1.9 .assign() accepts dependent arguments

The DataFrame.assign() now accepts dependent keyword arguments for python version later than 3.6 (see also PEP 468). Later keyword arguments may now refer to earlier ones if the argument is a callable. See the documentation here (GH14207)
In [46]: df.assign(A=df.A+1, C=lambda df: df.A* -1)
Out[46]:
   A  C
0  2 -2
1  3 -3
2  4 -4

1.1.1.10 Series.str.cat has gained the join kwarg

Previously, Series.str.cat() did not – in contrast to most of pandas – align Series on their index before concatenation (see GH18657). The method has now gained a keyword join to control the manner of alignment, see examples below and in here.

In v.0.23 join will default to None (meaning no alignment), but this default will change to 'left' in a future version of pandas.

In [47]: s = pd.Series(['a', 'b', 'c', 'd'])
In [48]: t = pd.Series(['b', 'd', 'e', 'c'], index=[1, 3, 4, 2])
In [49]: s.str.cat(t)
Out[49]:
0  ab
1  bd
2  ce
3  dc
dtype: object

In [50]: s.str.cat(t, join='left', na_rep='\n')
Out[50]:
0  a-
1  bb
2  cc
3  dd
dtype: object

Furthermore, method Series.str.cat now works for CategoricalIndex as well (previously raised a ValueError; see GH20842).

1.1.1.11 DataFrame.astype performs column-wise conversion to Categorical

DataFrame.astype() can now perform column-wise conversion to Categorical by supplying the string 'category' or a CategoricalDtype. Previously, attempting this would raise a NotImplementedError. See the Object Creation section of the documentation for more details and examples. (GH12860, GH18099)

Supplying the string 'category' performs column-wise conversion, with only labels appearing in a given column set as categories:

In [51]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))
In [52]: df = df.astype('category')
In [53]: df['A'].dtype

(continues on next page)
Out[53]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=False)

In [54]: df['B'].dtype
Out[54]: CategoricalDtype(categories=['b', 'c', 'd'], ordered=False)

Supplying a CategoricalDtype will make the categories in each column consistent with the supplied dtype:

In [55]: from pandas.api.types import CategoricalDtype
In [56]: df = pd.DataFrame({'A': list('abca'), 'B': list('abcd')})
In [57]: cdt = CategoricalDtype(categories=list('abcd'), ordered=True)
In [58]: df = df.astype(cdt)
In [59]: df['A'].dtype
Out[59]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)
In [60]: df['B'].dtype
Out[60]: CategoricalDtype(categories=['a', 'b', 'c', 'd'], ordered=True)

1.1.1.12 Extending Pandas with Custom Types (Experimental)

Pandas now supports storing array-like objects that aren’t necessarily 1-D NumPy arrays as columns in a DataFrame or values in a Series. This allows third-party libraries to implement extensions to NumPy’s types, similar to how pandas implemented categoricals, datetimes with timezones, periods, and intervals.

As a demonstration, we’ll use cyberpandas, which provides an IPArray type for storing ip addresses.

IPArray isn’t a normal 1-D NumPy array, but because it’s a pandas ~pandas.api.extension.ExtensionArray, it can be stored properly inside pandas’ containers.

In [1]: from cyberpandas import IPArray
In [2]: values = IPArray([
...:     0,
...:     3232235777,
...:     4254076645264154071740215577757643572
...: ])

In [3]: ser = pd.Series(values)
In [4]: ser
Out[4]:
0     0.0.0.0
1  192.168.1.1
2  2001:db8:85a3::8a2e:370:7334
dtype: ip

Notice that the dtype is ip. The missing value semantics of the underlying array are respected:
In [5]: ser.isna()
Out[5]:
0   True
1  False
2  False
dtype: bool

For more, see the extension types documentation. If you build an extension array, publicize it on our ecosystem page.

1.1.1.13 Categorical Groupers has gained an observed keyword

In previous versions, grouping by 1 or more categorical columns would result in an index that was the cartesian product of all of the categories for each grouper, not just the observed values. `groupby` has gained the observed keyword to toggle this behavior. The default remains backward compatible (generate a cartesian product). (GH14942, GH8138, GH15217, GH17594, GH8669, GH20583)

In [61]: cat1 = pd.Categorical(["a", "a", "b", "b"],
    categories=["a", "b", "z"], ordered=True)

In [62]: cat2 = pd.Categorical(["c", "d", "c", "d"],
    categories=["c", "d", "y"], ordered=True)

In [63]: df = pd.DataFrame({"A": cat1, "B": cat2, "values": [1, 2, 3, 4]})

In [64]: df['C'] = ['foo', 'bar'] * 2

In [65]: df
Out[65]:
    A  B  values  C
0  a  c       1  foo
1  a  d       2  bar
2  b  c       3  foo
3  b  d       4  bar

To show all values, the previous behavior:

In [66]: df.groupby(['A', 'B', 'C'], observed=False).count()
Out[66]:
    values
    A  B  C
   a  c  bar  NaN
      foo  1.0
   d  b  bar  1.0
      foo  NaN
   y  d  bar  NaN
      foo  NaN
   b  c  bar  NaN
    ...  ...  ...
   y  foo  NaN
   z  c  bar  NaN
      foo  NaN
   d  b  bar  NaN
      foo  NaN
   y  bar  NaN

(continues on next page)
To show only observed values:

```python
In [67]: df.groupby(['A', 'B', 'C'], observed=True).count()
Out[67]:
   values
   A  B  C
   a  c  foo 1
   d  bar  1
   b  c  foo 1
   d  bar  1
```

For pivoting operations, this behavior is already controlled by the `dropna` keyword:

```python
In [68]: cat1 = pd.Categorical(['a', 'a', 'b', 'b'],
                       categories=['a', 'b', 'z'], ordered=True)
   ...
In [69]: cat2 = pd.Categorical(['c', 'd', 'c', 'd'],
                       categories=['c', 'd', 'y'], ordered=True)
   ...
In [70]: df = DataFrame({'A': cat1, 'B': cat2, 'values': [1, 2, 3, 4]})
   ...
In [71]: df
Out[71]:
       A  B  values
   0  a  c    1
   1  a  d    2
   2  b  c    3
   3  b  d    4
In [72]: pd.pivot_table(df, values='values', index=['A', 'B'],
                        dropna=True)
   ...
Out[72]:
   values
   A  B
   a  c    1
   d    2
   b  c    3
   d    4
In [73]: pd.pivot_table(df, values='values', index=['A', 'B'],
                        dropna=False)
   ...
Out[73]:
   values
   A  B
   a  c  1.0
   d  2.0
   y  NaN
```

(continues on next page)
### 1.1.1.14 Other Enhancements

- Unary + now permitted for `Series` and `DataFrame` as numeric operator (GH16073)
- Better support for `to_excel()` output with the `xlsxwriter` engine. (GH16149)
- `pandas.tseries.frequencies.to_offset()` now accepts leading ‘+’ signs e.g. ‘+1h’. (GH18171)
- `MultiIndex.unique()` now supports the `level=` argument, to get unique values from a specific index level (GH17896)
- `pandas.io.formats.style.Styler` now has method `hide_index()` to determine whether the index will be rendered in output (GH14194)
- `pandas.io.formats.style.Styler` now has method `hide_columns()` to determine whether columns will be hidden in output (GH14194)
- Improved wording of `ValueError` raised in `to_datetime()` when `unit=` is passed with a non-convertible value (GH14350)
- `Series.fillna()` now accepts a `Series` or a dict as a value for a categorical dtype (GH17033)
- `pandas.read_clipboard()` updated to use qtpy, falling back to PyQt5 and then PyQt4, adding compatibility with Python3 and multiple python-qt bindings (GH17722)
- Improved wording of `ValueError` raised in `read_csv()` when `usecols` argument cannot match all columns. (GH17301)
- `DataFrame.corrwith()` now silently drops non-numeric columns when passed a `Series`. Before, an exception was raised (GH18570).
- `IntervalIndex` now supports time zone aware `Interval` objects (GH18537, GH18538)
- `Series()` / `DataFrame()` tab completion also returns identifiers in the first level of a `MultiIndex()`. (GH16326)
- `read_excel()` has gained the `nrows` parameter (GH16645)
- `DataFrame.append()` can now in more cases preserve the type of the calling dataframe’s columns (e.g. if both are `CategoricalIndex`) (GH18359)
- `DataFrame.to_json()` and `Series.to_json()` now accept an `index` argument which allows the user to exclude the index from the JSON output (GH1794)
- `IntervalIndex.to_tuples()` has gained the `na_tuple` parameter to control whether NA is returned as a tuple of NA, or NA itself (GH18756)
- `Categorical.rename_categories`, `CategoricalIndex.rename_categories` and `Series.cat.rename_categories` can now take a callable as their argument (GH18862)
- `Interval` and `IntervalIndex` have gained a `length` attribute (GH18789)
- `Resampler` objects now have a functioning `pipe` method. Previously, calls to `pipe` were diverted to the `mean` method (GH17905).
- `is_scalar()` now returns True for `DateOffset` objects (GH18943).

- `DataFrame.pivot()` now accepts a list for the `values=` kwarg (GH17160).

- Added `pandas.api.extensions.register_dataframe_accessor()`, `pandas.api.extensions.register_series_accessor()`, and `pandas.api.extensions.register_index_accessor()`, accessor for libraries downstream of pandas to register custom accessors like `.cat` on pandas objects. See Registering Custom Accessors for more (GH14781).

- `IntervalIndex.astype` now supports conversions between subtypes when passed an `IntervalDtype` (GH19197)

- `IntervalIndex` and its associated constructor methods (`from_arrays`, `from_breaks`, `from_tuples`) have gained a `dtype` parameter (GH19262)

- Added `pandas.core.groupby.SeriesGroupBy.is_monotonic_increasing()` and `pandas.core.groupby.SeriesGroupBy.is_monotonic_decreasing()` (GH17015)

- For subclassed DataFrames, `DataFrame.apply()` will now preserve the Series subclass (if defined) when passing the data to the applied function (GH19822)

- `DataFrame.from_dict()` now accepts a `columns` argument that can be used to specify the column names when `orient='index'` is used (GH18529)

- Added option `display.html.use_mathjax` so MathJax can be disabled when rendering tables in Jupyter notebooks (GH19856, GH19824)

- `DataFrame.replace()` now supports the `method` parameter, which can be used to specify the replacement method when `to_replace` is a scalar, list or tuple and `value` is None (GH19632)

- `Timestamp.month_name()`, `DatetimeIndex.month_name()`, and `Series.dt.month_name()` are now available (GH12805)

- `Timestamp.day_name()` and `DatetimeIndex.day_name()` are now available to return day names with a specified locale (GH12806)

- `DataFrame.to_sql()` now performs a multivalue insert if the underlying connection supports itk rather than inserting row by row. SQLAlchemy dialects supporting multivalue inserts include: mysql, postgresql, sqlite and any dialect with `supports_multivalues_insert`. (GH14315, GH8953)

- `read_html()` now accepts a `displayed_only` keyword argument to controls whether or not hidden elements are parsed (True by default) (GH20027)

- `read_html()` now reads all `<tbody>` elements in a `<table>`, not just the first. (GH20690)

- `quantile()` and `quantile()` now accept the `interpolation` keyword, linear by default (GH20497)

- zip compression is supported via `compression=zip` in `DataFrame.to_pickle()`, `Series.to_pickle()`, `DataFrame.to_csv()`, `Series.to_csv()`, `DataFrame.to_json()`, `Series.to_json()` (GH17778)

- `pandas.tseries.api.offsets.WeekOfMonth` constructor now supports `n=0` (GH20517).

- `DataFrame` and `Series` now support matrix multiplication (`@`) operator (GH10259) for Python>=3.5

- Updated `DataFrame.to_gbq()` and `pandas.read_gbq()` signature and documentation to reflect changes from the Pandas-GBQ library version 0.4.0. Adds intersphinx mapping to Pandas-GBQ library. (GH20564)

- Added new writer for exporting Stata dta files in version 117, `StataWriter117`. This format supports exporting strings with lengths up to 2,000,000 characters (GH16450)
• to_hdf() and read_hdf() now accept an errors keyword argument to control encoding error handling (GH20835)

1.1.2 Backwards incompatible API changes

1.1.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15184). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
<th>Issue</th>
</tr>
</thead>
<tbody>
<tr>
<td>python-dateutil</td>
<td>2.5.0</td>
<td>X</td>
<td>GH15184</td>
</tr>
<tr>
<td>openpyxl</td>
<td>2.4.0</td>
<td></td>
<td>GH15184</td>
</tr>
<tr>
<td>beautifulsoup4</td>
<td>4.2.1</td>
<td></td>
<td>GH20082</td>
</tr>
<tr>
<td>setuptools</td>
<td>24.2.0</td>
<td></td>
<td>GH20698</td>
</tr>
</tbody>
</table>

1.1.2.2 Instantation from dicts preserves dict insertion order for python 3.6+

Until Python 3.6, dicts in Python had no formally defined ordering. For Python version 3.6 and later, dicts are ordered by insertion order, see PEP 468. Pandas will use the dict’s insertion order, when creating a Series or DataFrame from a dict and you’re using Python version 3.6 or higher. (GH19884)

Previous Behavior (and current behavior if on Python < 3.6):

```python
In [1]: pd.Series({'Income': 2000,
     ...:            'Expenses': -1500,
     ...:            'Taxes': -200,
     ...:            'Net result': 300})
```

```
Expenses     -1500
Income       2000
Taxes        -200
Net result   300
```
dtype: int64

Note the Series above is ordered alphabetically by the index values.

New Behavior (for Python >= 3.6):

```python
In [74]: pd.Series({'Income': 2000,
     ....:            'Expenses': -1500,
     ....:            'Taxes': -200,
     ....:            'Net result': 300})
```

```
Income       2000
Expenses     -1500
Taxes        -200
Net result   300
```
dtype: int64

Notice that the Series is now ordered by insertion order. This new behavior is used for all relevant pandas types (Series, DataFrame, SparseSeries and SparseDataFrame).

If you wish to retain the old behavior while using Python >= 3.6, you can use .sort_index():

```python
1.1. v0.23.0
```
In [75]: pd.Series({'Income': 2000,  
.....:     'Expenses': -1500,  
.....:     'Taxes': -200,  
.....:     'Net result': 300}).sort_index()  
.....:  
Out[75]:  
Expenses -1500  
Income  2000  
Net result  300  
Taxes -200  
dtype: int64  

1.1.2.3 Deprecate Panel  
Panel was deprecated in the 0.20.x release, showing as a DeprecationWarning. Using Panel will now show a  
FutureWarning. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the  
to_frame() or with the xarray package. Pandas provides a to_xarray() method to automate this conversion.  
For more details see Deprecate Panel documentation. (GH13563, GH18324).  

In [76]: p = tm.makePanel()  
In [77]: p  
Out[77]:  
<class 'pandas.core.panel.Panel'>

* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'

### 1.1.2.4 pandas.core.common removals

The following error & warning messages are removed from pandas.core.common (GH13634, GH19769):

- PerformanceWarning
- UnsupportedFunctionCall
- UnsortedIndexError
- AbstractMethodError

These are available from import from pandas.errors (since 0.19.0).

### 1.1.2.5 Changes to make output of DataFrame.apply consistent

`DataFrame.apply()` was inconsistent when applying an arbitrary user-defined-function that returned a list-like with `axis=1`. Several bugs and inconsistencies are resolved. If the applied function returns a Series, then pandas will return a DataFrame; otherwise a Series will be returned, this includes the case where a list-like (e.g. tuple or list is returned) (GH16353, GH17437, GH17970, GH17348, GH17892, GH18573, GH17602, GH18775, GH18901, GH18919).

```python
In [80]: df = pd.DataFrame(np.tile(np.arange(3), 6).reshape(6, -1) + 1, columns=['A', 'B', 'C'])

In [81]: df
Out[81]:
   A  B  C
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

Previous Behavior: if the returned shape happened to match the length of original columns, this would return a DataFrame. If the return shape did not match, a Series with lists was returned.

```python
In [3]: df.apply(lambda x: [1, 2, 3], axis=1)
Out[3]:
   A  B  C
0  1  2  3
```

(continues on next page)
New Behavior: When the applied function returns a list-like, this will now always return a Series.

To have expanded columns, you can use `result_type='expand'`

To broadcast the result across the original columns (the old behaviour for list-likes of the correct length), you can use `result_type='broadcast'`. The shape must match the original columns.
Returning a `Series` allows one to control the exact return structure and column names:

```python
In [86]: df.apply(lambda x: Series([1, 2, 3], index=['D', 'E', 'F']), axis=1)
```

```plaintext
Out[86]:
     D  E  F
0  1  2  3
1  1  2  3
2  1  2  3
3  1  2  3
4  1  2  3
5  1  2  3
```

### 1.1.2.6 Concatenation will no longer sort

In a future version of pandas, `pandas.concat()` will no longer sort the non-concatenation axis when it is not already aligned. The current behavior is the same as the previous (sorting), but now a warning is issued when `sort` is not specified and the non-concatenation axis is not aligned (GH4588).

```python
In [87]: df1 = pd.DataFrame({"a": [1, 2], "b": [1, 2]}, columns=['b', 'a'])
In [88]: df2 = pd.DataFrame({"a": [4, 5]})
In [89]: pd.concat([df1, df2])
```

```plaintext
Out[89]:
a  b
0 1 1.0
1 2 2.0
0 4 NaN
1 5 NaN
```

To keep the previous behavior (sorting) and silence the warning, pass `sort=True`

```python
In [90]: pd.concat([df1, df2], sort=True)
```

```plaintext
Out[90]:
a  b
0 1 1.0
1 2 2.0
0 4 NaN
1 5 NaN
```

To accept the future behavior (no sorting), pass `sort=False`

Note that this change also applies to `DataFrame.append()`, which has also received a `sort` keyword for controlling this behavior.
1.1.2.7 Build Changes

- Building pandas for development now requires `cython >= 0.24` (GH18613)
- Building from source now explicitly requires `setuptools` in `setup.py` (GH18113)
- Updated conda recipe to be in compliance with conda-build 3.0+ (GH18002)

1.1.2.8 Index Division By Zero Fills Correctly

Division operations on `Index` and subclasses will now fill division of positive numbers by zero with `np.inf`, division of negative numbers by zero with `-np.inf` and `0 / 0` with `np.nan`. This matches existing `Series` behavior. (GH19322, GH19347)

Previous Behavior:

```
In [6]: index = pd.Int64Index([-1, 0, 1])
In [7]: index / 0
Out[7]: Int64Index([0, 0, 0], dtype='int64')
# Previous behavior yielded different results depending on the type of zero in the divisor
In [8]: index / 0.0
Out[8]: Float64Index([-inf, nan, inf], dtype='float64')
In [9]: index = pd.UInt64Index([0, 1])
In [10]: index / np.array([0, 0], dtype=np.uint64)
Out[10]: UInt64Index([0, 0], dtype='uint64')
In [11]: pd.RangeIndex(1, 5) / 0
ZeroDivisionError: integer division or modulo by zero
```

Current Behavior:

```
In [91]: index = pd.Int64Index([-1, 0, 1])
# division by zero gives -infinity where negative, +infinity where positive, and NaN for 0 / 0
In [92]: index / 0
Out[92]: Float64Index([-inf, nan, inf], dtype='float64')
# The result of division by zero should not depend on whether the zero is int or float
In [93]: index / 0.0
Out[93]: Float64Index([-inf, nan, inf], dtype='float64')
In [94]: index = pd.UInt64Index([0, 1])
In [95]: index / np.array([0, 0], dtype=np.uint64)
Out[95]: Float64Index([nan, inf], dtype='float64')
In [96]: pd.RangeIndex(1, 5) / 0
Out[96]: Float64Index([inf, inf, inf, inf, inf], dtype='float64')
```
1.1.2.9 Extraction of matching patterns from strings

By default, extracting matching patterns from strings with `str.extract()` used to return a Series if a single group was being extracted (a DataFrame if more than one group was extracted). As of Pandas 0.23.0 `str.extract()` always returns a DataFrame, unless `expand` is set to `False`. Finally, `None` was an accepted value for the `expand` parameter (which was equivalent to `False`), but now raises a `ValueError`. (GH11386)

Previous Behavior:

```python
In [1]: s = pd.Series(['number 10', '12 eggs'])
In [2]: extracted = s.str.extract('.*(\d\d).*')
In [3]: extracted
Out [3]:
0  10
1  12
dtype: object
In [4]: type(extracted)
Out [4]:
pandas.core.series.Series
```

New Behavior:

```python
In [97]: s = pd.Series(['number 10', '12 eggs'])
In [98]: extracted = s.str.extract('.*(\d\d).*')
In [99]: extracted
Out[99]:
   0  10
  1  12
In [100]: type(extracted)
   Out[100]: pandas.core.frame.DataFrame
```

To restore previous behavior, simply set `expand` to `False`:

```python
In [101]: s = pd.Series(['number 10', '12 eggs'])
In [102]: extracted = s.str.extract('.*(\d\d).*', expand=False)
In [103]: extracted
Out[103]:
   0  10
  1  12
dtype: object
In [104]: type(extracted)
   Out[104]: pandas.core.series.Series
```

1.1.2.10 Default value for the `ordered` parameter of `CategoricalDtype`

The default value of the `ordered` parameter for `CategoricalDtype` has changed from `False` to `None` to allow updating of categories without impacting `ordered`. Behavior should remain consistent for downstream objects,
such as \texttt{Categorical} (GH18790)

In previous versions, the default value for the \texttt{ordered} parameter was \texttt{False}. This could potentially lead to the \texttt{ordered} parameter unintentionally being changed from \texttt{True} to \texttt{False} when users attempt to update categories if \texttt{ordered} is not explicitly specified, as it would silently default to \texttt{False}. The new behavior for \texttt{ordered=None} is to retain the existing value of \texttt{ordered}.

New Behavior:

```
In [105]: from pandas.api.types import CategoricalDtype
In [106]: cat = pd.Categorical(list('abcaba'), ordered=True, categories=list('cba'))
In [107]: cat
Out[107]: [a, b, c, a, b, a]
   Categories (3, object): [c < b < a]
In [108]: cdt = CategoricalDtype(categories=list('cbad'))
In [109]: cat.astype(cdt)
Out[109]: [a, b, c, a, b, a]
   Categories (4, object): [c < b < a < d]
```

Notice in the example above that the converted \texttt{Categorical} has retained \texttt{ordered=True}. Had the default value for \texttt{ordered} remained as \texttt{False}, the converted \texttt{Categorical} would have become unordered, despite \texttt{ordered=False} never being explicitly specified. To change the value of \texttt{ordered}, explicitly pass it to the new \texttt{dtype}, e.g. \texttt{CategoricalDtype(categories=list('cbad'), ordered=False)}.

Note that the unintentional conversion of \texttt{ordered} discussed above did not arise in previous versions due to separate bugs that prevented \texttt{astype} from doing any type of category to category conversion (GH10696, GH18593). These bugs have been fixed in this release, and motivated changing the default value of \texttt{ordered}.

1.1.2.11 Better pretty-printing of DataFrames in a terminal

Previously, the default value for the maximum number of columns was \texttt{pd.options.display.max_columns=20}. This meant that relatively wide data frames would not fit within the terminal width, and pandas would introduce line breaks to display these 20 columns. This resulted in an output that was relatively difficult to read:
If Python runs in a terminal, the maximum number of columns is now determined automatically so that the printed data frame fits within the current terminal width (`pd.options.display.max_columns=0`) (GH17023). If Python runs as a Jupyter kernel (such as the Jupyter QtConsole or a Jupyter notebook, as well as in many IDEs), this value cannot be inferred automatically and is thus set to 20 as in previous versions. In a terminal, this results in a much nicer output:
Note that if you don’t like the new default, you can always set this option yourself. To revert to the old setting, you can run this line:

```
pd.options.display.max_columns = 20
```  

### 1.1.2.12 Datetimelike API Changes

- The default `Timedelta` constructor now accepts an ISO 8601 Duration string as an argument (GH19040)

- Subtracting `NaT` from a `Series` with `dtype='datetime64[ns]'` returns a `Series` with `dtype='timedelta64[ns]'` instead of `dtype='datetime64[ns]'` (GH18808)

- Addition or subtraction of `NaT` from `TimedeltaIndex` will return `TimedeltaIndex` instead of `DatetimeIndex` (GH19124)

- `TimedeltaIndex.shift()` and `TimedeltaIndex.shift()` will now raise `NullFrequencyError` (which subclasses `ValueError`, which was raised in older versions) when the index object frequency is `None` (GH19147)

- Addition and subtraction of `NaN` from a `Series` with `dtype='timedelta64[ns]'` will raise a `TypeError` instead of treating the `NaN` as `NaT` (GH19274)

- `NaT` division with `datetime.timedelta` will now return `NaN` instead of raising (GH17876)
• Operations between a `Series` with `dtype='datetime64[ns]'` and a `PeriodIndex` will correctly raise `TypeError` (GH18850)

• Subtraction of `Series` with timezone-aware `dtype='datetime64[ns]'` with mis-matched timezones will raise `TypeError` instead of `ValueError` (GH18817)

• `Timestamp` will no longer silently ignore unused or invalid `tz` or `tzinfo` keyword arguments (GH17690)

• `Timestamp` will no longer silently ignore invalid `freq` arguments (GH17690)

• `CacheableOffset` and `WeekDay` are no longer available in the `pandas.tseries.offsets` module (GH17830)

• `pandas.tseries.frequencies.get_freq_group()` and `pandas.tseries.frequencies.DAYS` are removed from the public API (GH18034)

• `Series.truncate()` and `DataFrame.truncate()` will raise a `ValueError` if the index is not sorted instead of an unhelpful `KeyError` (GH17935)

• Restricted `DateOffset` keyword arguments. Previously, `DateOffset` subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176, GH18226).

• `pandas.merge()` provides a more informative error message when trying to merge on timezone-aware and timezone-naive columns (GH15800)

• For `DatetimeIndex` and `TimedeltaIndex` with `freq=None`, addition or subtraction of integer-dtyped array or `Index` will raise `NullFrequencyError` instead of `TypeError` (GH19895)

• `Timestamp` constructor now accepts a `nanosecond` keyword or positional argument (GH18898)

• `DatetimeIndex` will now raise an `AttributeError` when the `tz` attribute is set after instantiation (GH3746)

• `DatetimeIndex` with a `pytz` timezone will now return a consistent `pytz` timezone (GH18595)

1.1.2.13 Other API Changes

• `Series.astype()` and `Index.astype()` with an incompatible `dtype` will now raise a `TypeError` rather than a `ValueError` (GH18231)

• Series construction with an object `dtype` tz-aware datetime and `dtype=object` specified, will now return an `object` dtyped `Series`, previously this would infer the datetime `dtype` (GH18231)

• A `Series` of `dtype=category` constructed from an empty `dict` will now have categories of `dtype=object` rather than `dtype=float64`, consistently with the case in which an empty list is passed (GH18515)

• All-NaN levels in a `MultiIndex` are now assigned `float` rather than `object` `dtype`, promoting consistency with `Index` (GH17929).

• Levels names of a `MultiIndex` (when not None) are now required to be unique: trying to create a `MultiIndex` with repeated names will raise a `ValueError` (GH18872)

• Both construction and renaming of `Index/MultiIndex` with non-hashable name/names will now raise `TypeError` (GH20527)

• `Index.map()` can now accept `Series` and dictionary input objects (GH12756, GH18482, GH18509).

• `DataFrame.unstack()` will now default to filling with `np.nan` for object columns. (GH12815)

• `IntervalIndex` constructor will raise if the `closed` parameter conflicts with how the input data is inferred to be closed (GH18421)
• Inserting missing values into indexes will work for all types of indexes and automatically insert the correct type of missing value (NaN, NaT, etc.) regardless of the type passed in (GH18295)

• When created with duplicate labels, MultiIndex now raises a ValueError (GH17464)

• Series.fillna() now raises a TypeError instead of a ValueError when passed a list, tuple or DataFrame as a value (GH18293)

• pandas.DataFrame.merge() no longer casts a float column to object when merging on int and float columns (GH16572)

• pandas.merge() now raises a ValueError when trying to merge on incompatible data types (GH9780)

• The default NA value for UInt64Index has changed from 0 to NaN, which impacts methods that mask with NA, such as UInt64Index.where() (GH18398)

• Refactored setup.py to use find_packages instead of explicitly listing out all subpackages (GH18535)

• Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

• wide_to_long() previously kept numeric-like suffixes as object dtype. Now they are cast to numeric if possible (GH17627)

• In read_excel(), the comment argument is now exposed as a named parameter (GH18735)

• Rearranged the order of keyword arguments in read_excel() to align with read_csv() (GH16672)

• The options html.border and mode.use_inf_as_null were deprecated in prior versions, these will now show FutureWarning rather than a DeprecationWarning (GH19003)

• IntervalIndex and IntervalDtype no longer support categorical, object, and string subtypes (GH19016)

• IntervalDtype now returns True when compared against 'interval' regardless of subtype, and IntervalDtype.name now returns 'interval' regardless of subtype (GH18980)

• KeyError now raises instead of ValueError in drop(), drop(), drop(), drop() when dropping a non-existent element in an axis with duplicates (GH19186)

• Series.to_csv() now accepts a compression argument that works in the same way as the compression argument in DataFrame.to_csv() (GH18958)

• Set operations (union, difference...) on IntervalIndex with incompatible index types will now raise a TypeError rather than a ValueError (GH19329)

• DateOffset objects render more simply, e.g. <DateOffset:   days=1> instead of <DateOffset: kwds={'days': 1}> (GH19403)

• Categorical.fillna now validates its value and method keyword arguments. It now raises when both or none are specified, matching the behavior of Series.fillna() (GH19682)

• pd.to_datetime('today') now returns a datetime, consistent with pd.Timestamp('today'); previously pd.to_datetime('today') returned a .normalized() datetime (GH19935)

• Series.str.replace() now takes an optional regex keyword which, when set to False, uses literal string replacement rather than regex replacement (GH16808)

• DatetimeIndex.strftime() and PeriodIndex.strftime() now return an Index instead of a numpy array to be consistent with similar accessors (GH20127)

• Constructing a Series from a list of length 1 no longer broadcasts this list when a longer index is specified (GH19714, GH20391).

• DataFrame.to_dict() with orient='index' no longer casts int columns to float for a DataFrame with only int and float columns (GH18580)
• A user-defined-function that is passed to `Series.rolling().aggregate()`, `DataFrame.rolling().aggregate()`, or its expanding cousins, will now always be passed a Series, rather than a np.array; `.apply()` only has the raw keyword, see here. This is consistent with the signatures of `.aggregate()` across pandas (GH20584)

1.1.3 Deprecations

• `Series.from_array` and `SparseSeries.from_array` are deprecated. Use the normal constructor `Series(..)` and `SparseSeries(..)` instead (GH18213).

• `DataFrame.as_matrix` is deprecated. Use `DataFrame.values` instead (GH18458).

• `Series.asobject`, `DatetimeIndex.asobject`, `PeriodIndex.asobject` and `TimeDeltaIndex.asobject` have been deprecated. Use `.astype(object)` instead (GH18572)

• Grouping by a tuple of keys now emits a `FutureWarning` and is deprecated. In the future, a tuple passed to `by` will always refer to a single key that is the actual tuple, instead of treating the tuple as multiple keys. To retain the previous behavior, use a list instead of a tuple (GH18314)

• `Series.valid` is deprecated. Use `Series.dropna()` instead (GH18800).

• `read_excel()` has deprecated the `skip_footer` parameter. Use `skipfooter` instead (GH18836)

• The `is_copy` attribute is deprecated and will be removed in a future version (GH18801).

• `IntervalIndex.from_intervals` is deprecated in favor of the `IntervalIndex` constructor (GH19263)

• `DataFrame.from_items` is deprecated. Use `DataFrame.from_dict()` instead, or `DataFrame.from_dict(OrderedDict())` if you wish to preserve the key order (GH17320, GH17312)

• Indexing a `MultiIndex` or a `FloatIndex` with a list containing some missing keys will now show a `FutureWarning`, which is consistent with other types of indexes (GH17758).

• The broadcast parameter of `.apply()` is deprecated in favor of `result_type='broadcast'` (GH18577)

• The reduce parameter of `.apply()` is deprecated in favor of `result_type='reduce'` (GH18577)

• The order parameter of `factorize()` is deprecated and will be removed in a future release (GH19727)

• `Timestamp.weekday_name`, `DatetimeIndex.weekday_name`, and `Series.dt.weekday_name` are deprecated in favor of `Timestamp.day_name()`, `DatetimeIndex.day_name()`, and `Series.dt.day_name()` (GH12806)

• `pandas.tseries.plotting.tsplot` is deprecated. Use `Series.plot()` instead (GH18627)

• `Index.summary()` is deprecated and will be removed in a future version (GH18217)

• `NDFrame.get_ftype_counts()` is deprecated and will be removed in a future version (GH18243)

• The `convert_datetime64` parameter in `DataFrame.to_records()` has been deprecated and will be removed in a future version. The NumPy bug motivating this parameter has been resolved. The default value for this parameter has also changed from `True` to `None` (GH18160).

• `Series.rolling().apply()`, `DataFrame.rolling().apply()`, `Series.expanding().apply()`, and `DataFrame.expanding().apply()` have deprecated passing an np.array by default. One will need to pass the new raw parameter to be explicit about what is passed (GH20584)

• The `data`, `base`, `strides`, `flags` and `itemsize` properties of the `Series` and `Index` classes have been deprecated and will be removed in a future version (GH20419).

• `DatetimeIndex.offset` is deprecated. Use `DatetimeIndex.freq` instead (GH20716)
Setting `PeriodIndex.freq` (which was not guaranteed to work correctly) is deprecated. Use `PeriodIndex.asfreq()` instead (GH20678)

Index.get_duplicates() is deprecated and will be removed in a future version (GH20239)

The previous default behavior of negative indices in `Categorical.take` is deprecated. In a future version it will change from meaning missing values to meaning positional indices from the right. The future behavior is consistent with `Series.take()` (GH20664).

### 1.1.4 Removal of prior version deprecations/changes

- Warnings against the obsolete usage `Categorical(codes, categories)`, which were emitted for instance when the first two arguments to `Categorical()` had different dtypes, and recommended the use of `Categorical.from_codes`, have now been removed (GH8074)

- The `levels` and `labels` attributes of a MultiIndex can no longer be set directly (GH4039).

- `pd.tseries.util.pivot_annual` has been removed (deprecated since v0.19). Use `pivot_table` instead (GH18370)

- `pd.tseries.util.isleapyear` has been removed (deprecated since v0.19). Use `.is_leap_year` property in Datetime-likes instead (GH18370)

- `pd.ordered_merge` has been removed (deprecated since v0.19). Use `pd.merge_ordered` instead (GH18459)

- The `SparseList` class has been removed (GH14007)

- The `pandas.io.wb` and `pandas.io.data` stub modules have been removed (GH13735)

- `Categorical.from_array` has been removed (GH13854)

- The `freq` and `how` parameters have been removed from the `rolling/expanding/ewm` methods of `DataFrame` and `Series` (deprecated since v0.18). Instead, resample before calling the methods. (GH18601 & GH18668)

- `DatetimeIndex.to_datetime`, `Timestamp.to_datetime`, `PeriodIndex.to_datetime`, and `Index.to_datetime` have been removed (GH8254, GH14096, GH14113)

- `read_csv()` has dropped the `skip_footer` parameter (GH13386)

- `read_csv()` has dropped the `as_recarray` parameter (GH13373)

- `read_csv()` has dropped the `buffer_lines` parameter (GH13360)

- `read_csv()` has dropped the `compact_ints` and `use_unsigned` parameters (GH13323)

- The `Timestamp` class has dropped the `offset` attribute in favor of `freq` (GH13593)

- The `Series`, `Categorical`, and `Index` classes have dropped the `reshape` method (GH13012)

- `pandas.tseries.frequencies.get_standard_freq` has been removed in favor of `pandas.tseries.frequencies.to_offset(freq).rule_code` (GH13874)

- The `freqstr` keyword has been removed from `pandas.tseries.frequencies.to_offset` in favor of `freq` (GH13874)

- The `Panel4D` and `PanelND` classes have been removed (GH13776)

- The `Panel` class has dropped the `to_long` and `toLong` methods (GH19077)

- The options `display.line_with` and `display.height` are removed in favor of `display.width` and `display.max_rows` respectively (GH4391, GH19107)
• The labels attribute of the Categorical class has been removed in favor of Categorical.codes (GH7768)

• The flavor parameter have been removed from func:to_sql method (GH13611)

• The modules pandas.tools.hashing and pandas.util.hashing have been removed (GH16223)

• The top-level functions pd.rolling_*, pd.expanding_* and pd.ewm* have been removed (Deprecated since v0.18). Instead, use the DataFrame/Series methods rolling, expanding and ewm (GH18723)

• The modules pandas.tools.hashing and pandas.util.hashing have been removed (GH16223)

• The top-level functions pd.rolling_*, pd.expanding_* and pd.ewm* have been removed (Deprecated since v0.18). Instead, use the DataFrame/Series methods rolling, expanding and ewm (GH18723)

• Imports from pandas.core.common for functions such as is_datetime64_dtype are now removed. These are located in pandas.api.types. (GH13634, GH19769)

• The infer_dst keyword in Series.tz_localize(), DatetimeIndex.tz_localize() and DatetimeIndex have been removed. infer_dst=True is equivalent to ambiguous='infer', and infer_dst=False to ambiguous='raise' (GH7963).

• When .resample() was changed from an eager to a lazy operation, like .groupby() in v0.18.0, we put in place compatibility (with a FutureWarning), so operations would continue to work. This is now fully removed, so a Resampler will no longer forward compat operations (GH20554)

1.1.5 Performance Improvements

• Indexers on Series or DataFrame no longer create a reference cycle (GH17956)

• Added a keyword argument, cache, to to_datetime() that improved the performance of converting duplicate datetime arguments (GH11665)

• DateOffset arithmetic performance is improved (GH18218)

• Converting a Series of Timedelta objects to days, seconds, etc... sped up through vectorization of underlying methods (GH18092)

• Improved performance of .map() with a Series/dict input (GH15081)

• The overridden Timedelta properties of days, seconds and microseconds have been removed, leveraging their built-in Python versions instead (GH18242)

• Series construction will reduce the number of copies made of the input data in certain cases (GH17449)

• Improved performance of Series.dt.date() and DatetimeIndex.date() (GH18058)

• Improved performance of Series.dt.time() and DatetimeIndex.time() (GH18461)

• Improved performance of IntervalIndex.symmetric_difference() (GH18475)

• Improved performance of DatetimeIndex and Series arithmetic operations with Business-Month and Business-Quarter frequencies (GH18489)

• Series() / DataFrame() tab completion limits to 100 values, for better performance. (GH18587)

• Improved performance of DataFrame.median() with axis=1 when bottleneck is not installed (GH16468)

• Improved performance of MultiIndex.get_loc() for large indexes, at the cost of a reduction in performance for small ones (GH18519)

• Improved performance of MultiIndex.remove unused levels() when there are no unused levels, at the cost of a reduction in performance when there are (GH19289)

• Improved performance of pairwise .rolling() and .expanding() with .cov() and .corr() operations (GH17917)

• Improved performance of pandas.core.groupby.GroupBy.rank() (GH15779)

• Improved performance of variable .rolling() on .min() and .max() (GH19521)
• Improved performance of `pandas.core.groupby.GroupBy.ffill()` and `pandas.core.groupby.GroupBy.bfill()` (GH11296)
• Improved performance of `pandas.core.groupby.GroupBy.any()` and `pandas.core.groupby.GroupBy.all()` (GH15435)
• Improved performance of `pandas.core.groupby.GroupBy.pct_change()` (GH19165)
• Improved performance of `Series.isin()` in the case of categorical dtypes (GH20003)
• Improved performance of `getattr(Series, attr)` when the Series has certain index types. This manifested in slow printing of large Series with a `DatetimeIndex` (GH19764)
• Fixed a performance regression for `GroupBy.nth()` and `GroupBy.last()` with some object columns (GH19283)

1.1.6 Documentation Changes

Thanks to all of the contributors who participated in the Pandas Documentation Sprint, which took place on March 10th. We had about 500 participants from over 30 locations across the world. You should notice that many of the API docstrings have greatly improved.

There were too many simultaneous contributions to include a release note for each improvement, but this GitHub search should give you an idea of how many docstrings were improved.

Special thanks to Marc Garcia for organizing the sprint. For more information, read the NumFOCUS blogpost recapping the sprint.

• Changed spelling of “numpy” to “NumPy”, and “python” to “Python”. (GH19017)
• Consistency when introducing code samples, using either colon or period. Rewrote some sentences for greater clarity, added more dynamic references to functions, methods and classes. (GH18941, GH18948, GH18973, GH19017)
• Added a reference to `DataFrame.assign()` in the concatenate section of the merging documentation (GH18665)

1.1.7 Bug Fixes

1.1.7.1 Categorical

Warning: A class of bugs were introduced in pandas 0.21 with `CategoricalDtype` that affects the correctness of operations like `merge`, `concat`, and indexing when comparing multiple unordered `Categorical` arrays that have the same categories, but in a different order. We highly recommend upgrading or manually aligning your categories before doing these operations.

• Bug in `Categorical.equals` returning the wrong result when comparing two unordered `Categorical` arrays with the same categories, but in a different order (GH16603)
• Bug in `pandas.api.types.union_categoricals()` returning the wrong result when for unordered categoricals with the categories in a different order. This affected `pandas.concat()` with Categorical data (GH19096).
• Bug in `pandas.merge()` returning the wrong result when joining on an unordered `Categorical` that had the same categories but in a different order (GH19551)
- Bug in `CategoricalIndex.get_indexer()` returning the wrong result when target was an unordered Categorical that had the same categories as self but in a different order (GH19551)
- Bug in `Index.astype()` with a categorical dtype where the resultant index is not converted to a `CategoricalIndex` for all types of index (GH18630)
- Bug in `Series.astype()` and `Categorical.astype()` where an existing categorical data does not get updated (GH10696, GH18593)
- Bug in `Series.str.split()` with expand=True incorrectly raising an IndexError on empty strings (GH20002).
- Bug in `Index` constructor with dtype=CategoricalDtype(...) where categories and ordered are not maintained (GH19032)
- Bug in `Series` constructor with scalar and dtype=CategoricalDtype(...) where categories and ordered are not maintained (GH19565)
- Bug in Categorical.__iter__ not converting to Python types (GH19909)
- Bug in `pandas.factorize()` returning the unique codes for the uniques. This now returns a Categorical with the same dtype as the input (GH19721)
- Bug in `pandas.factorize()` including an item for missing values in the uniques return value (GH19721)
- Bug in `Series.take()` with categorical data interpreting -1 in indices as missing value markers, rather than the last element of the Series (GH20664)

### 1.1.7.2 Datetimelike

- Bug in `Series.__sub__()` subtracting a non-nanosecond np.datetime64 object from a Series gave incorrect results (GH7996)
- Bug in `DatetimeIndex, TimedeltaIndex` addition and subtraction of zero-dimensional integer arrays gave incorrect results (GH19012)
- Bug in `DatetimeIndex` and `TimedeltaIndex` where adding or subtracting an array-like of DateOffset objects either raised (np.array, pd.Index) or broadcast incorrectly (pd.Series) (GH18849)
- Bug in `Series.__add__()` adding Series with dtype timedelta64[ns] to a timezone-aware DatetimeIndex incorrectly dropped timezone information (GH13905)
- Adding a Period object to a datetime or Timestamp object will now correctly raise a TypeError (GH17983)
- Bug in `Timestamp` where comparison with an array of Timestamp objects would result in a RecursionError (GH15183)
- Bug in `Series` floor-division where operating on a scalar timedelta raises an exception (GH18846)
- Bug in `DatetimeIndex` where the repr was not showing high-precision time values at the end of a day (e.g., 23:59:59.999999999) (GH19030)
- Bug in `astype()` to non-ns timedelta units would hold the incorrect dtype (GH19176, GH19223, GH12425)
- Bug in subtracting `Series` from NaT incorrectly returning NaT (GH19158)
- Bug in `Series.truncate()` which raises TypeError with a monotonic PeriodIndex (GH17717)
- Bug in `pct_change()` using periods and freq returned different length outputs (GH7292)
• Bug in comparison of `DatetimeIndex` against `None` or `datetime.date` objects raising `TypeError` for `==` and `!=` comparisons instead of all-`False` and all-`True`, respectively (GH19301)

• Bug in `Timestamp` and `to_datetime()` where a string representing a barely out-of-bounds timestamp would be incorrectly rounded down instead of raising `OutOfBoundsDatetime` (GH19382)

• Bug in `Timestamp.floor()` `DatetimeIndex.floor()` where time stamps far in the future and past were not rounded correctly (GH19206)

• Bug in `to_datetime()` where passing an out-of-bounds datetime with `errors='coerce'` and `utc=True` would raise `OutOfBoundsDatetime` instead of parsing to `NaT` (GH19612)

• Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where name of the returned object was not always set consistently. (GH19744)

• Bug in `DatetimeIndex` and `TimedeltaIndex` addition and subtraction where operations with numpy arrays raised `TypeError` (GH19847)

• Bug in `DatetimeIndex` and `TimedeltaIndex` where setting the `freq` attribute was not fully supported (GH20678)

1.1.7.3 Timedelta

• Bug in `Timedelta.__mul__()` where multiplying by `NaT` returned `NaT` instead of raising a `TypeError` (GH19819)

• Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` had results cast to `dtype='int64'` (GH17250)

• Bug in `Series` with `dtype='timedelta64[ns]'` where addition or subtraction of `TimedeltaIndex` could return a `Series` with an incorrect name (GH19043)

• Bug in `Timedelta.__floordiv__()` and `Timedelta.__rfloordiv__()` dividing by many incompatible numpy objects was incorrectly allowed (GH18846)

• Bug where dividing a scalar timedelta-like object with `TimedeltaIndex` performed the reciprocal operation (GH19125)

• Bug in `TimedeltaIndex` where division by a Series would return a `TimedeltaIndex` instead of a `Series` (GH19042)

• Bug in `Timedelta.__add__()`, `Timedelta.__sub__()` where adding or subtracting a `np.timedelta64` object would return another `np.timedelta64` instead of a `Timedelta` (GH19738)

• Bug in `Timedelta.__floordiv__()`, `Timedelta.__rfloordiv__()` where operating with a `Tick` object would raise a `TypeError` instead of returning a numeric value (GH19738)

• Bug in `Period.asfreq()` where periods near `datetime(1, 1)` could be converted incorrectly (GH19643, GH19834)

• Bug in `Timedelta.total_seconds()` causing precision errors, for example `Timedelta('30S').total_seconds()==30.000000000000004` (GH19458)

• Bug in `Timedelta.__rmod__()` where operating with a `numpy.timedelta64` returned a `timedelta64` object instead of a `Timedelta` (GH19820)

• Multiplication of `TimedeltaIndex` by `TimedeltaIndex` will now raise `TypeError` instead of raising `ValueError` in cases of length mis-match (GH19333)

• Bug in indexing a `TimedeltaIndex` with a `np.timedelta64` object which was raising a `TypeError` (GH20393)
1.1.7.4 Timezones

- Bug in creating a `Series` from an array that contains both tz-naive and tz-aware values will result in a `Series` whose dtype is tz-aware instead of object (GH16406)
- Bug in comparison of timezone-aware `DatetimeIndex` against `NaN` incorrectly raising `TypeError` (GH19276)
- Bug in `DatetimeIndex.astype()` when converting between timezone aware dtypes, and converting from timezone aware to naive (GH18951)
- Bug in comparing `DatetimeIndex`, which failed to raise `TypeError` when attempting to compare timezone-aware and timezone-naive datetimelike objects (GH18162)
- Bug in localization of a naive, datetime string in a `Series` constructor with a `datetime64[ns, tz]` dtype (GH174151)
- `Timestamp.replace()` will now handle Daylight Savings transitions gracefully (GH18319)
- Bug in tz-aware `DatetimeIndex` where addition/subtraction with a `TimedeltaIndex` or array with `dtype='timedelta64[ns]'` was incorrect (GH17558)
- Bug in `DatetimeIndex.insert()` where inserting `NaN` into a timezone-aware index incorrectly raised (GH16357)
- Bug in `DataFrame` constructor, where tz-aware Datetimeindex and a given column name will result in an empty `DataFrame` (GH19157)
- Bug in `Timestamp.tz_localize()` where localizing a timestamp near the minimum or maximum valid values could overflow and return a timestamp with an incorrect nanosecond value (GH12677)
- Bug when iterating over `DatetimeIndex` that was localized with fixed timezone offset that rounded nanosecond precision to microseconds (GH19603)
- Bug in `DataFrame.diff()` that raised an `IndexError` with tz-aware values (GH18578)
- Bug in `melt()` that converted tz-aware dtypes to tz-naive (GH15785)
- Bug in `Dataframe.count()` that raised an `ValueError`, if `Dataframe.dropna()` was called for a single column with timezone-aware values. (GH13407)

1.1.7.5 Offsets

- Bug in `WeekOfMonth` and `Week` where addition and subtraction did not roll correctly (GH18510, GH18672, GH18864)
- Bug in `WeekOfMonth` and `LastWeekOfMonth` where default keyword arguments for constructor raised `ValueError` (GH19142)
- Bug in `FY5253Quarter`, `LastWeekOfMonth` where rollback and rollforward behavior was inconsistent with addition and subtraction behavior (GH18854)
- Bug in `FY5253` where datetime addition and subtraction incremented incorrectly for dates on the year-end but not normalized to midnight (GH18854)
- Bug in `FY5253` where date offsets could incorrectly raise an `AssertionError` in arithmetic operatons (GH14774)
1.1.7.6 Numeric

- Bug in `Series` constructor with an int or float list where specifying `dtype=str`, `dtype='str'` or `dtype='U'` failed to convert the data elements to strings (GH16605)
- Bug in `Index` multiplication and division methods where operating with a `Series` would return an `Index` object instead of a `Series` object (GH19042)
- Bug in the `DataFrame` constructor in which data containing very large positive or very large negative numbers was causing `OverflowError` (GH18584)
- Bug in `Index` constructor with `dtype='uint64'` where int-like floats were not coerced to `UInt64Index` (GH18400)
- Bug in `DataFrame` flex arithmetic (e.g. `df.add(other, fill_value=foo)`) with a `fill_value` other than `None` failed to raise `NotImplementedError` in corner cases where either the frame or `other` has length zero (GH19522)
- Multiplication and division of numeric-dtyped `Index` objects with timedelta-like scalars returns `TimedeltaIndex` instead of raising `TypeError` (GH19333)
- Bug where `NaN` was returned instead of 0 by `Series.pct_change()` and `DataFrame.pct_change()` when `fill_method` is not `None` (GH19873)

1.1.7.7 Strings

- Bug in `Series.str.get()` with a dictionary in the values and the index not in the keys, raising `KeyError` (GH20671)

1.1.7.8 Indexing

- Bug in `Index` construction from list of mixed type tuples (GH18505)
- Bug in `Index.drop()` when passing a list of both tuples and non-tuples (GH18304)
- Bug in `DataFrame.drop()`, `Panel.drop()`, `Series.drop()`, `Index.drop()` where no `KeyError` is raised when dropping a non-existent element from an axis that contains duplicates (GH19186)
- Bug in indexing a datetime-like `Index` that raised `ValueError` instead of `IndexError` (GH19386).
- `Index.to_series()` now accepts `index` and `name` kwargs (GH18699)
- `DatetimeIndex.to_series()` now accepts `index` and `name` kwargs (GH18699)
- Bug in indexing non-scalar value from `Series` having non-unique `Index` will return value flattened (GH17610)
- Bug in indexing with iterator containing only missing keys, which raised no error (GH20748)
- Fixed inconsistency in `.ix` between list and scalar keys when the index has integer dtype and does not include the desired keys (GH20753)
- Bug in `__setitem__` when indexing a `DataFrame` with a 2-d boolean `ndarray` (GH18582)
- Bug in `str.extractall` when there were no matches empty `Index` was returned instead of appropriate `MultiIndex` (GH19034)
- Bug in `IntervalIndex` where empty and purely NA data was constructed inconsistently depending on the construction method (GH18421)
• Bug in `IntervalIndex.symmetric_difference()` where the symmetric difference with a non-
IntervalIndex did not raise (GH18475)

• Bug in `IntervalIndex` where set operations that returned an empty `IntervalIndex` had the wrong dtype
(GH19101)

• Bug in `DataFrame.drop_duplicates()` where no `KeyError` is raised when passing in columns that
don’t exist on the `DataFrame` (GH19726)

• Bug in `Index` subclasses constructors that ignore unexpected keyword arguments (GH19348)

• Bug in `Index.difference()` when taking difference of an `Index` with itself (GH20040)

• Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` in presence
of entire rows of NaNs in the middle of values (GH20499).

• Bug in `IntervalIndex` where some indexing operations were not supported for overlapping or non-
monotonic uint64 data (GH20636)

• Bug in `Series.is_unique` where extraneous output in stderr is shown if `Series` contains objects with
`__ne__` defined (GH20661)

• Bug in `.loc` assignment with a single-element list-like incorrectly assigns as a list (GH19474)

• Bug in partial string indexing on a `Series/DataFrame` with a monotonic decreasing `DatetimeIndex`
(GH19362)

1.1.7.9 MultiIndex

• Bug in `MultiIndex.__contains__()` where non-tuple keys would return `True` even if they had been
dropped (GH19027)

• Bug in `MultiIndex.set_labels()` which would cause casting (and potentially clipping) of the new labels
if the `level` argument is not 0 or a list like `[0, 1, ...]` (GH19057)

• Bug in `MultiIndex.get_level_values()` which would return an invalid index on level of ints with
missing values (GH17924)

• Bug in `MultiIndex.unique()` when called on empty `MultiIndex` (GH20568)

• Bug in `MultiIndex.unique()` which would not preserve level names (GH20570)

• Bug in `MultiIndex.remove_unused_levels()` which would fill NaN values (GH18417)

• Bug in `MultiIndex.from_tuples()` which would fail to take zipped tuples in python3 (GH18434)

• Bug in `MultiIndex.get_loc()` which would fail to automatically cast values between float and int
(GH18818, GH15994)

• Bug in `MultiIndex.get_loc()` which would cast boolean to integer labels (GH19086)

• Bug in `MultiIndex.get_loc()` which would fail to locate keys containing NaN (GH18485)

• Bug in `MultiIndex.get_loc()` in large `MultiIndex`, would fail when levels had different dtypes
(GH18520)

• Bug in indexing where nested indexers having only numpy arrays are handled incorrectly (GH19686)

1.1.7.10 I/O

• `read_html()` now rewinds seekable IO objects after parse failure, before attempting to parse with a new
parser. If a parser errors and the object is non-seekable, an informative error is raised suggesting the use of a
different parser (GH17975)
• *DataFrame.to_html()* now has an option to add an id to the leading `<table>` tag (GH8496)
• Bug in *read_msgpack()* with a non-existent file is passed in Python 2 (GH15296)
• Bug in *read_csv()* where a MultiIndex with duplicate columns was not being mangled appropriately (GH18062)
• Bug in *read_csv()* where missing values were not being handled properly when `keep_default_na=False` with dictionary `na_values` (GH19227)
• Bug in *read_csv()* causing heap corruption on 32-bit, big-endian architectures (GH20785)
• Bug in *read_sas()* where a file with 0 variables gave an AttributeError incorrectly. Now it gives an EmptyDataError (GH18184)
• Bug in *DataFrame.to_latex()* where pairs of braces meant to serve as invisible placeholders were escaped (GH18667)
• Bug in *DataFrame.to_latex()* where a NaN in a MultiIndex would cause an IndexError or incorrect output (GH14249)
• Bug in *DataFrame.to_latex()* where a non-string index-level name would result in an AttributeError (GH19981)
• Bug in *DataFrame.to_latex()* where the combination of an index name and the `index_names=False` option would result in incorrect output (GH18326)
• Bug in *DataFrame.to_latex()* where a MultiIndex with an empty string as its name would result in incorrect output (GH18669)
• Bug in *DataFrame.to_latex()* where missing space characters caused wrong escaping and produced non-valid latex in some cases (GH20859)
• Bug in *read_json()* where large numeric values were causing an OverflowError (GH18842)
• Bug in *DataFrame.to_parquet()* where an exception was raised if the write destination is S3 (GH19134)
• *Interval* now supported in *DataFrame.to_excel()* for all Excel file types (GH19242)
• *Timedelta* now supported in *DataFrame.to_excel()* for all Excel file types (GH19242, GH9155, GH19900)
• Bug in *pandas.io.stata.StataReader.value_labels()* raising an AttributeError when called on very old files. Now returns an empty dict (GH19417)
• Bug in *read_pickle()* when unpickling objects with *TimedeltaIndex* or *Float64Index* created with pandas prior to version 0.20 (GH19939)
• Bug in *pandas.io.json.json_normalize()* where subrecords are not properly normalized if any sub-records values are NoneType (GH20030)
• Bug in *usecols* parameter in *read_csv()* where error is not raised correctly when passing a string (GH20529)
• Bug in *HDFStore.keys()* when reading a file with a softlink causes exception (GH20523)
• Bug in *HDFStore.select_column()* where a key which is not a valid store raised an AttributeError instead of a KeyError (GH17912)

### 1.1.7.11 Plotting

• Better error message when attempting to plot but matplotlib is not installed (GH19810).
• *DataFrame.plot()* now raises a `ValueError` when the `x` or `y` argument is improperly formed (GH18671)
• **Bug in \texttt{DataFrame.plot()}** when \texttt{x} and \texttt{y} arguments given as positions caused incorrect referenced columns for line, bar and area plots (GH20056).

• Bug in formatting tick labels with \texttt{datetime.time()} and fractional seconds (GH18478).

• **\texttt{Series.plot.kde()}** has exposed the args \texttt{ind} and \texttt{bw_method} in the docstring (GH18461). The argument \texttt{ind} may now also be an integer (number of sample points).

• **\texttt{DataFrame.plot()}** now supports multiple columns to the \texttt{y} argument (GH19699)

### 1.1.7.12 Groupby/Resample/Rolling

• Bug when grouping by a single column and aggregating with a class like \texttt{list} or \texttt{tuple} (GH18079)

• Fixed regression in \texttt{DataFrame.groupby()} which would not emit an error when called with a tuple key not in the index (GH18798)

• Bug in \texttt{DataFrame.resample()} which silently ignored unsupported (or mistyped) options for \texttt{label}, \texttt{closed} and \texttt{convention} (GH19303)

• Bug in \texttt{DataFrame.groupby()} where tuples were interpreted as lists of keys rather than as keys (GH17979, GH18249)

• Bug in \texttt{DataFrame.groupby()} where aggregation by \texttt{first/last/min/max} was causing timestamps to lose precision (GH19526)

• Bug in \texttt{DataFrame.transform()} where particular aggregation functions were being incorrectly cast to match the dtype(s) of the grouped data (GH19200)

• Bug in \texttt{DataFrame.groupby()} passing the \texttt{on} kwarg, and subsequently using \texttt{.apply()} (GH17813)

• Bug in \texttt{DataFrame.resample().aggregate} not raising a \texttt{KeyError} when aggregating a non-existent column (GH16766, GH19566)

• Bug in \texttt{DataFrameGroupBy.cumsum()} and \texttt{DataFrameGroupBy.cumprod()} when \texttt{skipna} was passed (GH19806)

• Bug in \texttt{DataFrame.resample()} that dropped timezone information (GH13238)

• Bug in \texttt{DataFrame.groupby()} where transformations using \texttt{np.all} and \texttt{np.any} were raising a \texttt{ValueError} (GH20653)

• Bug in \texttt{DataFrame.resample()} where \texttt{ffill, bfill, pad, backfill, fillna, interpolate, and asfreq} were ignoring \texttt{loffset}. (GH20744)

### 1.1.7.13 Sparse

• Bug in which creating a \texttt{SparseDataFrame} from a dense \texttt{Series} or an unsupported type raised an uncontrolled exception (GH19374)

• Bug in \texttt{SparseDataFrame.to_csv} causing exception (GH19384)

• Bug in \texttt{SparseSeries.memory_usage} which caused segfault by accessing non sparse elements (GH19368)

• Bug in constructing a \texttt{SparseArray}; if \texttt{data} is a scalar and \texttt{index} is defined it will coerce to \texttt{float64} regardless of scalar’s dtype. (GH19163)
1.1.7.14 Reshaping

- Bug in `DataFrame.stack()` which fails trying to sort mixed type levels under Python 3 (GH18310)
- Bug in `DataFrame.unstack()` which casts int to float if `columns` is a `MultiIndex` with unused levels (GH17845)
- Bug in `DataFrame.unstack()` which raises an error if `index` is a `MultiIndex` with unused labels on the unstacked level (GH18562)
- Fixed construction of a `Series` from a `dict` containing NaN as key (GH18480)
- Fixed construction of a `DataFrame` from a `dict` containing NaN as key (GH18455)
- Disabled construction of a `Series` where `len(index) > len(data) = 1`, which previously would broadcast the data item, and now raises a `ValueError` (GH18819)
- Suppressed error in the construction of a `DataFrame` from a `dict` containing scalar values when the corresponding keys are not included in the passed index (GH18600)
- Fixed (changed from `object` to `float64`) dtype of `DataFrame` initialized with axes, no data, and `dtype=int` (GH19646)
- Bug in `Series.rank()` where `Series` containing NaT modifies the `Series` inplace (GH18521)
- Bug in `cut()` which fails when using readonly arrays (GH18773)
- Bug in `DataFrame.pivot_table()` which fails when the `aggfunc` arg is of type string. The behavior is now consistent with other methods like `agg` and `apply` (GH18713)
- Bug in `DataFrame.merge()` in which merging using `Index` objects as vectors raised an Exception (GH19038)
- Bug in `DataFrame.stack()`, `DataFrame.unstack()`, `Series.unstack()` which were not returning subclasses (GH15563)
- Bug in timezone comparisons, manifesting as a conversion of the index to UTC in `.concat()` (GH18523)
- Bug in `concat()` when concattting sparse and dense series it returns only a `SparseDataFrame`. Should be a `DataFrame`. (GH18914, GH18686, and GH16874)
- Improved error message for `DataFrame.merge()` when there is no common merge key (GH19427)
- Bug in `DataFrame.join()` which does an outer instead of a left join when being called with multiple DataFrames and some have non-unique indices (GH19624)
- `Series.rename()` now accepts `axis` as a kwarg (GH18589)
- Comparisons between `Series` and `Index` would return a `Series` with an incorrect name, ignoring the `Index`’s name attribute (GH19582)
- Bug in `qcut()` where datetime and timedelta data with NaT present raised a `ValueError` (GH19768)
- Bug in `DataFrame.iterrows()`, which would infers strings not compliant to ISO8601 to datetimes (GH19671)
- Bug in `Series` constructor with `Categorical` where a `ValueError` is not raised when an index of different length is given (GH19342)
- Bug in `DataFrame.astype()` where column metadata is lost when converting to categorical or a dictionary of dtypes (GH19920)
- Bug in `cut()` and `qcut()` where timezone information was dropped (GH19872)
- Bug in `Series` constructor with a `dtype=str`, previously raised in some cases (GH19853)
1.1.7.15 Other

- Improved error message when attempting to use a Python keyword as an identifier in a numexpr backed query (GH18221)
- Bug in accessing a pandas.get_option(), which raised KeyError rather than OptionError when looking up a non-existant option key in some cases (GH19789)
- Bug in testing.assert_series_equal() and testing.assert_frame_equal() for Series or DataFrames with differing unicode data (GH20503)

1.2 v0.22.0 (December 29, 2017)

This is a major release from 0.21.1 and includes a single, API-breaking change. We recommend that all users upgrade to this version after carefully reading the release note (singular!).

1.2.1 Backwards incompatible API changes

Pandas 0.22.0 changes the handling of empty and all-NA sums and products. The summary is that

- The sum of an empty or all-NA Series is now 0
- The product of an empty or all-NA Series is now 1
- We’ve added a min_count parameter to .sum() and .prod() controlling the minimum number of valid values for the result to be valid. If fewer than min_count non-NA values are present, the result is NA. The default is 0. To return NaN, the 0.21 behavior, use min_count=1.

Some background: In pandas 0.21, we fixed a long-standing inconsistency in the return value of all-NA series depending on whether or not bottleneck was installed. See Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN. At the same time, we changed the sum and prod of an empty Series to also be NaN.

Based on feedback, we’ve partially reverted those changes.

1.2.1.1 Arithmetic Operations

The default sum for empty or all-NA Series is now 0.

-pandas 0.21.x-

```
In [1]: pd.Series([]).sum()
Out[1]: nan

In [2]: pd.Series([np.nan]).sum()
Out[2]: nan
```

-pandas 0.22.0-

```
In [1]: pd.Series([]).sum()
Out[1]: 0.0

In [2]: pd.Series([np.nan]).sum()
```

```
Out[2]: 0.0
```
The default behavior is the same as pandas 0.20.3 with bottleneck installed. It also matches the behavior of NumPy’s np.nansum on empty and all-NA arrays.

To have the sum of an empty series return NaN (the default behavior of pandas 0.20.3 without bottleneck, or pandas 0.21.x), use the min_count keyword.

```
In [3]: pd.Series([]).sum(min_count=1)
Out[3]: nan
```

Thanks to the skipna parameter, the .sum on an all-NA series is conceptually the same as the .sum of an empty one with skipna=True (the default).

```
In [4]: pd.Series([np.nan]).sum(min_count=1)  # skipna=True by default
Out[4]: nan
```

The min_count parameter refers to the minimum number of non-null values required for a non-NA sum or product. `Series.prod()` has been updated to behave the same as `Series.sum()`, returning 1 instead.

```
In [5]: pd.Series([]).prod()
Out[5]: 1.0

In [6]: pd.Series([np.nan]).prod()
Out[6]: 1.0

In [7]: pd.Series([]).prod(min_count=1)
Out[7]: nan
```

These changes affect `DataFrame.sum()` and `DataFrame.prod()` as well. Finally, a few less obvious places in pandas are affected by this change.

### 1.2.1.2 Grouping by a Categorical

Grouping by a Categorical and summing now returns 0 instead of NaN for categories with no observations. The product now returns 1 instead of NaN.

**pandas 0.21.x**

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a 3.0
   b NaN
dtype: float64
```

**pandas 0.22**

```
In [8]: grouper = pd.Categorical(['a', 'a'], categories=['a', 'b'])

In [9]: pd.Series([1, 2]).groupby(grouper).sum()
Out[9]:
   a 3
   b 0
dtype: int64
```

To restore the 0.21 behavior of returning NaN for unobserved groups, use min_count>=1.
1.2.1.3 Resample

The sum and product of all-NA bins has changed from NaN to 0 for sum and 1 for product.

pandas 0.21.x

In [11]: s = pd.Series([1, 1, np.nan, np.nan],
                    index=pd.date_range('2017', periods=4))
Out[11]:
2017-01-01  1.0
2017-01-02  1.0
2017-01-03  NaN
2017-01-04  NaN
Freq: D, dtype: float64

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01  2.0
2017-01-03  NaN
Freq: 2D, dtype: float64

pandas 0.22.0

In [11]: s = pd.Series([1, 1, np.nan, np.nan],
                    index=pd.date_range('2017', periods=4))

In [12]: s.resample('2d').sum()
Out[12]:
2017-01-01  2.0
2017-01-03  0.0
dtype: float64

To restore the 0.21 behavior of returning NaN, use min_count>=1.

In [13]: s.resample('2d').sum(min_count=1)
Out[13]:
2017-01-01  2.0
2017-01-03  NaN
dtype: float64

In particular, upsampling and taking the sum or product is affected, as upsampling introduces missing values even if the original series was entirely valid.

pandas 0.21.x

In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])
In [15]: pd.Series([1, 2], index=idx).resample('12H').sum()
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

```
Out[15]:
2017-01-01 00:00:00  1.0
2017-01-01 12:00:00   NaN
2017-01-02 00:00:00  2.0
Freq: 12H, dtype: float64
```

```
pandas 0.22.0
```

```
In [14]: idx = pd.DatetimeIndex(['2017-01-01', '2017-01-02'])

In [15]: pd.Series([1, 2], index=idx).resample("12H").sum()
```

```
Out[15]:
2017-01-01 00:00:00   1
2017-01-01 12:00:00   NaN
2017-01-02 00:00:00   2
Freq: 12H, dtype: int64
```

Once again, the `min_count` keyword is available to restore the 0.21 behavior.

```
In [16]: pd.Series([1, 2], index=idx).resample("12H").sum(min_count=1)
```

```
Out[16]:
2017-01-01 00:00:00   1.0
2017-01-01 12:00:00   NaN
2017-01-02 00:00:00   2.0
Freq: 12H, dtype: float64
```

### 1.2.1.4 Rolling and Expanding

Rolling and expanding already have a `min_periods` keyword that behaves similar to `min_count`. The only case that changes is when doing a rolling or expanding sum with `min_periods=0`. Previously this returned NaN, when fewer than `min_periods` non-NA values were in the window. Now it returns 0.

```
pandas 0.21.1
```

```
In [17]: s = pd.Series([np.nan, np.nan])

In [18]: s.rolling(2, min_periods=0).sum()
```

```
Out[18]:
0    NaN
1    NaN
dtype: float64
```

```
pandas 0.22.0
```

```
In [17]: s = pd.Series([np.nan, np.nan])

In [18]: s.rolling(2, min_periods=0).sum()
```

```
Out[18]:
0    0.0
1    0.0
dtype: float64
```

The default behavior of `min_periods=None`, implying that `min_periods` equals the window size, is unchanged.

---

Chapter 1. What's New
1.2.2 Compatibility

If you maintain a library that should work across pandas versions, it may be easiest to exclude pandas 0.21 from your requirements. Otherwise, all your `sum()` calls would need to check if the `Series` is empty before summing.

With setuptools, in your `setup.py` use:

```python
install_requires=['pandas!=0.21.0', ...]
```

With conda, use

```bash
requirements:
  run:
    - pandas !=0.21.0,!=0.21.1
```

Note that the inconsistency in the return value for all-NA series is still there for pandas 0.20.3 and earlier. Avoiding pandas 0.21 will only help with the empty case.

1.3 v0.21.1 (December 12, 2017)

This is a minor bug-fix release in the 0.21.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Temporarily restore matplotlib datetime plotting functionality. This should resolve issues for users who implicitly relied on pandas to plot datetimes with matplotlib. See here.
- Improvements to the Parquet IO functions introduced in 0.21.0. See here.

What's new in v0.21.1

- *Restore Matplotlib datetime Converter Registration*
- **New features**
  - Improvements to the Parquet IO functionality
  - Other Enhancements
- **Deprecations**
- **Performance Improvements**
- **Bug Fixes**
  - Conversion
  - Indexing
  - I/O
  - Plotting
  - Groupby/Resample/Rolling
  - Reshaping
  - Numeric
  - Categorical
1.3.1 Restore Matplotlib datetime Converter Registration

Pandas implements some matplotlib converters for nicely formatting the axis labels on plots with datetime or Period values. Prior to pandas 0.21.0, these were implicitly registered with matplotlib, as a side effect of import pandas.

In pandas 0.21.0, we required users to explicitly register the converter. This caused problems for some users who relied on those converters being present for regular matplotlib.pyplot plotting methods, so we’re temporarily reverting that change; pandas 0.21.1 again registers the converters on import, just like before 0.21.0.

We’ve added a new option to control the converters: `pd.options.plotting.matplotlib.register_converters`. By default, they are registered. Toggling this to `False` removes pandas’ formatters and restore any converters we overwrote when registering them (GH18301).

We’re working with the matplotlib developers to make this easier. We’re trying to balance user convenience (automatically registering the converters) with import performance and best practices (importing pandas shouldn’t have the side effect of overwriting any custom converters you’ve already set). In the future we hope to have most of the datetime formatting functionality in matplotlib, with just the pandas-specific converters in pandas. We’ll then gracefully deprecate the automatic registration of converters in favor of users explicitly registering them when they want them.

1.3.2 New features

1.3.2.1 Improvements to the Parquet IO functionality

- `DataFrame.to_parquet()` will now write non-default indexes when the underlying engine supports it. The indexes will be preserved when reading back in with `read_parquet()` (GH18581).
- `read_parquet()` now allows to specify the columns to read from a parquet file (GH18154)
- `read_parquet()` now allows to specify kwargs which are passed to the respective engine (GH18216)

1.3.2.2 Other Enhancements

- `Timestamp.timestamp()` is now available in Python 2.7. (GH17329)
- `Grouper` and `TimeGrouper` now have a friendly repr output (GH18203).

1.3.3 Deprecations

- `pandas.tseries.register` has been renamed to `pandas.plotting.register_matplotlib_converters` (GH18301)

1.3.4 Performance Improvements

- Improved performance of plotting large series/dataframes (GH18236).
1.3.5 Bug Fixes

1.3.5.1 Conversion

- Bug in TimedeltaIndex subtraction could incorrectly overflow when NaT is present (GH17791)
- Bug in DatetimeIndex subtracting datetimelike from DatetimeIndex could fail to overflow (GH18020)
- Bug in IntervalIndex.copy() when copying and IntervalIndex with non-default closed (GH18339)
- Bug in DataFrame.to_dict() where columns of datetime that are tz-aware were not converted to required arrays when used with orient='records', raising ‘TypeError’ (GH18372)
- Bug in DateTimeIndex and date_range() where mismatching tz-aware start and end timezones would not raise an err if end.tzinfo is None (GH18431)
- Bug in Series.fillna() which raised when passed a long integer on Python 2 (GH18159).

1.3.5.2 Indexing

- Bug in a boolean comparison of a datetime.datetime and a datetime64[ns] dtype Series (GH17965)
- Bug where a MultiIndex with more than a million records was not raising AttributeError when trying to access a missing attribute (GH18165)
- Bug in IntervalIndex constructor when a list of intervals is passed with non-default closed (GH18334)
- Bug in Index.putmask when an invalid mask passed (GH18368)
- Bug in masked assignment of a timedelta64[ns] dtype Series, incorrectly coerced to float (GH18493)

1.3.5.3 I/O

- Bug in class:~pandas.io.stata.StataReader not converting date/time columns with display formatting addressed (GH17990). Previously columns with display formatting were normally left as ordinal numbers and not converted to datetime objects.
- Bug in read_csv() when reading a compressed UTF-16 encoded file (GH18071)
- Bug in read_csv() for handling null values in index columns when specifying na_filter=False (GH5239)
- Bug in read_csv() when reading numeric category fields with high cardinality (GH18186)
- Bug in DataFrame.to_csv() when the table had MultiIndex columns, and a list of strings was passed in for header (GH5539)
- Bug in parsing integer datet ime-like columns with specified format in read_sql (GH17855).
- Bug in DataFrame.to_msgpack() when serializing data of the numpy.bool_ datatype (GH18390)
- Bug in read_json() not decoding when reading line delimited JSON from S3 (GH17200)
- Bug in pandas.io.json.json_normalize() to avoid modification of meta (GH18610)
- Bug in to_latex() where repeated multi-index values were not printed even though a higher level index differed from the previous row (GH14484)
- Bug when reading NaN-only categorical columns in HDFStore (GH18413)
• Bug in DataFrame.to_latex() with longtable=True where a latex multicolumn always spanned over three columns (GH17959)

1.3.5.4 Plotting

• Bug in DataFrame.plot() and Series.plot() with DatetimeIndex where a figure generated by them is not pickleable in Python 3 (GH18439)

1.3.5.5 Groupby/Resample/Rolling

• Bug in DataFrame.resample(...).apply(...) when there is a callable that returns different columns (GH15169)
• Bug in DataFrame.resample(...) when there is a time change (DST) and resampling frequency is 12h or higher (GH15549)
• Bug in pd.DataFrameGroupBy.count() when counting over a datetimelike column (GH13393)
• Bug in rolling.var where calculation is inaccurate with a zero-valued array (GH18430)

1.3.5.6 Reshaping

• Error message in pd.merge_asof() for key datatype mismatch now includes datatype of left and right key (GH18068)
• Bug in pd.concat when empty and non-empty DataFrames or Series are concatenated (GH18178 GH18187)
• Bug in DataFrame.filter(...) when unicode is passed as a condition in Python 2 (GH13101)
• Bug when merging empty DataFrames when np.seterr(divide='raise') is set (GH17776)

1.3.5.7 Numeric

• Bug in pd.Series.rolling.skew() and rolling.kurt() with all equal values has floating issue (GH18044)

1.3.5.8 Categorical

• Bug in DataFrame.astype() where casting to ‘category’ on an empty DataFrame causes a segmentation fault (GH18004)
• Error messages in the testing module have been improved when items have different CategoricalDtype (GH18069)
• CategoricalIndex can now correctly take a pd.api.types.CategoricalDtype as its dtype (GH18116)
• Bug in Categorical.unique() returning read-only codes array when all categories were NaN (GH18051)
• Bug in DataFrame.groupby(axis=1) with a CategoricalIndex (GH18432)
1.3.5.9 String

- `Series.str.split()` will now propagate NaN values across all expanded columns instead of None (GH18450)

1.4 v0.21.0 (October 27, 2017)

This is a major release from 0.20.3 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- Integration with Apache Parquet, including a new top-level `read_parquet()` function and `DataFrame.to_parquet()` method, see here.
- New user-facing `pandas.api.types.CategoricalDtype` for specifying categoricals independent of the data, see here.
- The behavior of `sum` and `prod` on all-NaN Series/DataFrames is now consistent and no longer depends on whether bottleneck is installed, and `sum` and `prod` on empty Series now return NaN instead of 0, see here.
- Compatibility fixes for pypy, see here.
- Additions to the `drop`, `reindex` and `rename` API to make them more consistent, see here.
- Addition of the new methods `DataFrame.infer_objects` (see here) and `GroupBy.pipe` (see here).
- Indexing with a list of labels, where one or more of the labels is missing, is deprecated and will raise a KeyError in a future version, see here.

Check the API Changes and deprecations before updating.

### What’s new in v0.21.0

- **New features**
  - Integration with Apache Parquet file format
  - `infer_objects` type conversion
  - Improved warnings when attempting to create columns
  - `drop` now also accepts index/columns keywords
  - `rename`, `reindex` now also accept axis keyword
  - `CategoricalDtype` for specifying categoricals
  - `GroupBy` objects now have a `pipe` method
  - `Categorical.rename_categories` accepts a dict-like
  - Other Enhancements

- **Backwards incompatible API changes**
  - Dependencies have increased minimum versions
  - Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN
  - Indexing with a list with missing labels is Deprecated
1.4.1 New features

1.4.1.1 Integration with Apache Parquet file format

Integration with Apache Parquet, including a new top-level `read_parquet()` and `DataFrame.to_parquet()` method, see here (GH15838, GH17438).
Apache Parquet provides a cross-language, binary file format for reading and writing data frames efficiently. Parquet is designed to faithfully serialize and de-serialize DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as date-time with timezones.

This functionality depends on either the pyarrow or fastparquet library. For more details, see the IO docs on Parquet.

1.4.1.2 infer_objects type conversion

The DataFrame.infer_objects() and Series.infer_objects() methods have been added to perform dtype inference on object columns, replacing some of the functionality of the deprecated convert_objects method. See the documentation here for more details. (GH11221)

This method only performs soft conversions on object columns, converting Python objects to native types, but not any coercive conversions. For example:

```python
In [1]: df = pd.DataFrame({'A': [1, 2, 3],
                        'B': np.array([1, 2, 3], dtype='object'),
                        'C': ['1', '2', '3']})

In [2]: df.dtypes
Out[2]:
A    int64
B    object
C    object
dtype: object

In [3]: df.infer_objects().dtypes

Out[3]:
A    int64
B    int64
C    object
dtype: object
```

Note that column 'C' was not converted - only scalar numeric types will be converted to a new type. Other types of conversion should be accomplished using the to_numeric() function (or to_datetime(), to_timedelta()).

```python
In [4]: df = df.infer_objects()

In [5]: df['C'] = pd.to_numeric(df['C'], errors='coerce')

In [6]: df.dtypes
Out[6]:
A    int64
B    int64
C    int64
dtype: object
```

1.4.1.3 Improved warnings when attempting to create columns

New users are often puzzled by the relationship between column operations and attribute access on DataFrame instances (GH7175). One specific instance of this confusion is attempting to create a new column by setting an attribute on the DataFrame:
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In[2]: df.two = [4, 5, 6]

This does not raise any obvious exceptions, but also does not create a new column:

In[3]: df
Out[3]:
    one
0  1.0
1  2.0
2  3.0

Setting a list-like data structure into a new attribute now raises a UserWarning about the potential for unexpected behavior. See Attribute Access.

1.4.1.4 drop now also accepts index/columns keywords

The drop() method has gained index/columns keywords as an alternative to specifying the axis. This is similar to the behavior of reindex (GH12392).

For example:

In [7]: df = pd.DataFrame(np.arange(8).reshape(2,4),
                    columns=['A', 'B', 'C', 'D'])
In [8]: df
Out[8]:
   A  B  C  D
0  0  1  2  3
1  4  5  6  7
In [9]: df.drop(['B', 'C'], axis=1)
Out[9]:
   A  D
0  0  3
1  4  7

# the following is now equivalent
In [10]: df.drop(columns=['B', 'C'])
Out[10]:
   A  D
0  0  3
1  4  7

1.4.1.5 rename, reindex now also accept axis keyword

The DataFrame.rename() and DataFrame.reindex() methods have gained the axis keyword to specify the axis to target with the operation (GH12392).

Here’s rename:

In [11]: df = pd.DataFrame({'A': [1, 2, 3], 'B': [4, 5, 6]})
```
In [12]: df.rename(str.lower, axis='columns')
Out[12]:
   a  b
0 1  4
1 2  5
2 3  6

In [13]: df.rename(id, axis='index')
Out[13]:
   A  B
4387648832 1  4
4387648864 2  5
4387648896 3  6

And reindex:
```
```
In [14]: df.reindex(['A', 'B', 'C'], axis='columns')
Out[14]:
   A  B  C
0 1.0 4.0 NaN
1 2.0 5.0 NaN
2 NaN NaN NaN
```
```
In [15]: df.reindex([0, 1, 3], axis='index')
Out[15]:
   A  B
0 1.0 4.0
1 2.0 5.0
3 NaN NaN
```
```
The “index, columns” style continues to work as before.
```
```
In [16]: df.rename(index=id, columns=str.lower)
Out[16]:
   a  b
4387648832 1  4
4387648864 2  5
4387648896 3  6

In [17]: df.reindex(index=[0, 1, 3], columns=['A', 'B', 'C'])
```
```
We highly encourage using named arguments to avoid confusion when using either style.

### 1.4.1.6 CategoricalDtype for specifying categoricals

*pandas.api.types.CategoricalDtype* has been added to the public API and expanded to include the categories and ordered attributes. A CategoricalDtype can be used to specify the set of categories and orderedness of an array, independent of the data. This can be useful for example, when converting string data to a Categorical (GH14711, GH15078, GH16015, GH17643):
One place that deserves special mention is in `read_csv()`. Previously, with `dtype={'col': 'category'}`, the returned values and categories would always be strings.

Notice the “object” dtype.

With a `CategoricalDtype` of all numerics, datetimes, or timedeltas, we can automatically convert to the correct type

The values have been correctly interpreted as integers.

The `.dtype` property of a `Categorical`, `CategoricalIndex` or a `Series` with categorical type will now return an instance of `CategoricalDtype`. While the repr has changed, `str(CategoricalDtype())` is still the string 'category'. We’ll take this moment to remind users that the preferred way to detect categorical data is to use `pandas.api.types.is_categorical_dtype()`, and not `str(dtype) == 'category'`. See the `CategoricalDtype docs` for more.

### 1.4.1.7 GroupBy objects now have a pipe method

GroupBy objects now have a `pipe` method, similar to the one on DataFrame and Series, that allow for functions that take a GroupBy to be composed in a clean, readable syntax. (GH17871)

For a concrete example on combining `.groupby` and `.pipe`, imagine having a DataFrame with columns for stores, products, revenue and sold quantity. We’d like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable.

First we set the data:
In [28]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
                     'Product': np.random.choice(['Product_1', 'Product_2', 'Product_3'], n),
                     'Revenue': (np.random.random(n)*50+10).round(2),
                     'Quantity': np.random.randint(1, 10, size=n)})

In [29]: df.head(2)
Out[29]:
   Store   Product  Revenue  Quantity
0  Store_1  Product_3    54.28      3
1  Store_2  Product_2    30.91      1

Now, to find prices per store/product, we can simply do:

In [30]: (df.groupby(['Store', 'Product'])
       .pipe(lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
       .unstack().round(2))

Out[30]:
       Product    Product_1    Product_2    Product_3
    Store
  Store_1    6.37         6.98         7.49
  Store_2    7.60         7.01         7.13

See the documentation for more.

1.4.1.8 Categorical.rename_categories accepts a dict-like

rename_categories() now accepts a dict-like argument for new_categories. The previous categories are looked up in the dictionary’s keys and replaced if found. The behavior of missing and extra keys is the same as in DataFrame.rename().

In [31]: c = pd.Categorical(['a', 'a', 'b'])
In [32]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))

Out[32]:
[0, 0, 1]
Categories (2, int64): [0, 1]

Warning: To assist with upgrading pandas, rename_categories treats Series as list-like. Typically, Series are considered to be dict-like (e.g. in rename, map). In a future version of pandas rename_categories will change to treat them as dict-like. Follow the warning message’s recommendations for writing future-proof code.

In [33]: c.rename_categories(pd.Series([0, 1], index=['a', 'c']))

FutureWarning: Treating Series 'new_categories' as a list-like and using the values. In a future version, 'rename_categories' will treat Series like a dictionary.
For dict-like, use 'new_categories.to_dict()' For list-like, use 'new_categories.values'.

Out[33]:
[0, 0, 1]
Categories (2, int64): [0, 1]
1.4.1.9 Other Enhancements

New functions or methods

- `nearest()` is added to support nearest-neighbor upsampling (GH17496).
- `Index` has added support for a `to_frame` method (GH15230).

New keywords

- Added a `skipna` parameter to `infer_dtype()` to support type inference in the presence of missing values (GH17059).
- `Series.to_dict()` and `DataFrame.to_dict()` now support an `into` keyword which allows you to specify the `collections.Mapping` subclass that you would like returned. The default is `dict`, which is backwards compatible. (GH16122)
- `Series.set_axis()` and `DataFrame.set_axis()` now support the `inplace` parameter. (GH14636)
- `Series.to_pickle()` and `DataFrame.to_pickle()` have gained a `protocol` parameter (GH16252). By default, this parameter is set to `HIGHEST_PROTOCOL`.
- `read_feather()` has gained the `nthreads` parameter for multi-threaded operations (GH16359)
- `DataFrame.clip()` and `Series.clip()` have gained an `inplace` argument. (GH15388)
- `crosstab()` has gained a `margins_name` parameter to define the name of the row / column that will contain the totals when `margins=True`. (GH15972)
- `read_json()` now accepts a `chunksize` parameter that can be used when `lines=True`. If `chunksize` is passed, `read_json` now returns an iterator which reads in `chunksize` lines with each iteration. (GH17048)
- `read_json()` and `to_json()` now accept a `compression` argument which allows them to transparently handle compressed files. (GH17798)

Various enhancements

- Improved the import time of pandas by about 2.25x. (GH16764)
- Support for PEP 519 – Adding a file system path protocol on most readers (e.g. `read_csv()`) and writers (e.g. `DataFrame.to_csv()`)) (GH13823).
- Added a `__fspath__` method to `pd.HDFStore`, `pd.ExcelFile`, and `pd.ExcelWriter` to work properly with the file system path protocol (GH13823).
- The `validate` argument for `merge()` now checks whether a merge is one-to-one, one-to-many, many-to-one, or many-to-many. If a merge is found to not be an example of specified merge type, an exception of type `MergeError` will be raised. For more, see here (GH16270)
- Added support for PEP 518 (`pyproject.toml`) to the build system (GH16745)
- `RangeIndex.append()` now returns a `RangeIndex` object when possible (GH16212)
- `Series.rename_axis()` and `DataFrame.rename_axis()` with `inplace=True` now return `None` while renaming the axis inplace. (GH15704)
- `api.types.infer_dtype()` now infers decimals. (GH15690)
- `DataFrame.select_dtypes()` now accepts scalar values for include/exclude as well as list-like. (GH16855)
- `date_range()` now accepts ‘YS’ in addition to ‘AS’ as an alias for start of year. (GH9313)
- `date_range()` now accepts ‘Y’ in addition to ‘A’ as an alias for end of year. (GH9313)
- `DataFrame.add_prefix()` and `DataFrame.add_suffix()` now accept strings containing the ‘%’ character. (GH17151)
- `read_sas()` now recognizes much more of the most frequently used date (datetime) formats in SAS7BDAT files. (GH15871)
- `DataFrame.items()` and `Series.items()` are now present in both Python 2 and 3 and is lazy in all cases. (GH13918, GH17213)
- `pandas.io.formats.style.Styler.where()` has been implemented as a convenience for `pandas.io.formats.style.Styler.applymap()`. (GH17474)
- `MultiIndex.is_monotonic_decreasing()` has been implemented. Previously returned `False` in all cases. (GH16554)
- `read_excel()` raises `ImportError` with a better message if `xlrd` is not installed. (GH17613)
- `DataFrame.assign()` will preserve the original order of `**kwargs` for Python 3.6+ users instead of sorting the column names. (GH14207)
- `Series.reindex()`, `DataFrame.reindex()`, `Index.get_indexer()` now support list-like argument for tolerance. (GH17367)

### 1.4.2 Backwards incompatible API changes

#### 1.4.2.1 Dependencies have increased minimum versions

We have updated our minimum supported versions of dependencies (GH15206, GH15543, GH15214). If installed, we now require:

<table>
<thead>
<tr>
<th>Package</th>
<th>Minimum Version</th>
<th>Required</th>
</tr>
</thead>
<tbody>
<tr>
<td>Numpy</td>
<td>1.9.0</td>
<td>X</td>
</tr>
<tr>
<td>Matplotlib</td>
<td>1.4.3</td>
<td></td>
</tr>
<tr>
<td>Scipy</td>
<td>0.14.0</td>
<td></td>
</tr>
<tr>
<td>Bottleneck</td>
<td>1.0.0</td>
<td></td>
</tr>
</tbody>
</table>

Additionally, support has been dropped for Python 3.4 (GH15251).

#### 1.4.2.2 Sum/Prod of all-NaN or empty Series/DataFrames is now consistently NaN

**Note:** The changes described here have been partially reverted. See the v0.22.0 Whatsnew for more.

The behavior of `sum` and `prod` on all-NaN Series/DataFrames no longer depends on whether `bottleneck` is installed, and return value of `sum` and `prod` on an empty Series has changed (GH9422, GH15507).

Calling `sum` or `prod` on an empty or all-NaN Series, or columns of a DataFrame, will result in NaN. See the docs.
Previously WITHOUT bottleneck installed:

```python
In [2]: s.sum()
Out[2]: np.nan
```

Previously WITH bottleneck:

```python
In [2]: s.sum()
Out[2]: 0.0
```

New Behavior, without regard to the bottleneck installation:

```python
In [34]: s.sum()
Out[34]: 0.0
```

Note that this also changes the sum of an empty Series. Previously this always returned 0 regardless of a bottleneck installation:

```python
In [1]: pd.Series([]).sum()
Out[1]: 0
```

but for consistency with the all-NaN case, this was changed to return NaN as well:

```python
In [35]: pd.Series([]).sum()
Out[35]: 0.0
```

### 1.4.2.3 Indexing with a list with missing labels is Deprecated

Previously, selecting with a list of labels, where one or more labels were missing would always succeed, returning NaN for missing labels. This will now show a FutureWarning. In the future this will raise a `KeyError` (GH15747). This warning will trigger on a DataFrame or a Series for using `.loc[]` or `[]` when passing a list-of-labels with at least 1 missing label. See the [deprecation docs](https://pandas.pydata.org/pandas-docs/stable/user_guide/changes.html#1-4-2-2)

```python
In [36]: s = pd.Series([1, 2, 3])

In [37]: s
Out[37]:
   0  1
   1  2
   2  3
dtype: int64
```

Previous Behavior

```python
In [4]: s.loc[[1, 2, 3]]
Out[4]:
   1  2.0
   2  3.0
   NaN
```

Current Behavior

```python
In [4]: s.loc[[1, 2, 3]]
```
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc or [] with any missing label will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
˓→listlike

Out[4]:
1  2.0
2  3.0
3  NaN
dtype: float64

The idiomatic way to achieve selecting potentially not-found elements is via .reindex()

In [38]: s.reindex([1, 2, 3])
Out[38]:
1  2.0
2  3.0
3  NaN
dtype: float64

Selection with all keys found is unchanged.

In [39]: s.loc[[1, 2]]
Out[39]:
1  2
2  3
dtype: int64

1.4.2.4 NA naming Changes

In order to promote more consistency among the pandas API, we have added additional top-level functions isna() and notna() that are aliases for isnull() and notnull(). The naming scheme is now more consistent with methods like .dropna() and .fillna(). Furthermore in all cases where .isnull() and .notnull() methods are defined, these have additional methods named .isna() and .notna(), these are included for classes Categorical, Index, Series, and DataFrame. (GH15001).

The configuration option pd.options.mode.use_inf_as_null is deprecated, and pd.options.mode. use_inf_as_na is added as a replacement.

1.4.2.5 Iteration of Series/Index will now return Python scalars

Previously, when using certain iteration methods for a Series with dtype int or float, you would receive a numpy scalar, e.g. np.int64, rather than a Python int. Issue (GH10904) corrected this for Series.tolist() and list(Series). This change makes all iteration methods consistent, in particular, for __iter__() and .map(); note that this only affects int/float dtypes. (GH13236, GH13258, GH14216).

In [40]: s = pd.Series([1, 2, 3])
In [41]: s
Out[41]:
0   1
(continues on next page)
1  2
2  3
dtype: int64

Previously:

In [2]: type(list(s)[0])
Out[2]: numpy.int64

New Behaviour:

In [42]: type(list(s)[0])
Out[42]: int

Furthermore this will now correctly box the results of iteration for `DataFrame.to_dict()` as well.

In [43]: d = {'a':[1], 'b':['b']}
In [44]: df = pd.DataFrame(d)

Previously:

In [8]: type(df.to_dict()['a'][0])
Out[8]: numpy.int64

New Behaviour:

In [45]: type(df.to_dict()['a'][0])
Out[45]: int

### 1.4.2.6 Indexing with a Boolean Index

Previously when passing a boolean `Index` to `.loc`, if the index of the `Series/DataFrame` had boolean labels, you would get a label based selection, potentially duplicating result labels, rather than a boolean indexing selection (where `True` selects elements), this was inconsistent how a boolean numpy array indexed. The new behavior is to act like a boolean numpy array indexer. (GH17738)

Previous Behavior:

In [46]: s = pd.Series([1, 2, 3], index=[False, True, False])

    In [47]: s
    Out[47]:
        False  1
        True   2
        False  3
dtype: int64

    In [59]: s.loc[pd.Index([True, False, True])]
    Out[59]:
        True  2
        False 1
        False 3
        True  2
dtype: int64
Current Behavior

```
In [48]: s.loc[pd.Index([True, False, True])]
Out[48]:
False  1
False  3
dtype: int64
```

Furthermore, previously if you had an index that was non-numeric (e.g. strings), then a boolean Index would raise a `KeyError`. This will now be treated as a boolean indexer.

Previously Behavior:

```
In [49]: s = pd.Series([1,2,3], index=['a', 'b', 'c'])
In [50]: s
Out[50]:
a  1
b  2
c  3
dtype: int64
In [39]: s.loc[pd.Index([True, False, True])]
KeyError: "None of [Index([True, False, True], dtype='object')] are in the [index]"
```

Current Behavior

```
In [51]: s.loc[pd.Index([True, False, True])]
Out[51]:
a  1
c  3
dtype: int64
```

### 1.4.2.7 PeriodIndex resampling

In previous versions of pandas, resampling a `Series/DataFrame` indexed by a `PeriodIndex` returned a `DatetimeIndex` in some cases (GH12884). Resampling to a multiplied frequency now returns a `PeriodIndex` (GH15944). As a minor enhancement, resampling a `PeriodIndex` can now handle `NaT` values (GH13224)

Previous Behavior:

```
In [1]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [2]: s = pd.Series(np.arange(12), index=pi)
In [3]: resampled = s.resample('2Q').mean()
In [4]: resampled
Out[4]:
2017-03-31  1.0
2017-09-30  5.5
2018-03-31 10.0
Freq: 2Q-DEC, dtype: float64
In [5]: resampled.index
Out[5]: DatetimeIndex(['2017-03-31', '2017-09-30', '2018-03-31'], dtype='datetime64[ns]', freq='2Q-DEC')
```
New Behavior:

```python
In [52]: pi = pd.period_range('2017-01', periods=12, freq='M')
In [53]: s = pd.Series(np.arange(12), index=pi)
In [54]: resampled = s.resample('2Q').mean()
In [55]: resampled
Out[55]:
2017Q1  2.5
2017Q3  8.5
Freq: 2Q-DEC, dtype: float64
```

Upsampling and calling `.ohlc()` previously returned a `Series`, basically identical to calling `.asfreq()`. OHLC upsampling now returns a DataFrame with columns `open`, `high`, `low` and `close` (GH13083). This is consistent with downsampling and `DatetimeIndex` behavior.

Previous Behavior:

```python
In [1]: pi = pd.PeriodIndex(start='2000-01-01', freq='D', periods=10)
In [2]: s = pd.Series(np.arange(10), index=pi)
In [3]: s.resample('H').ohlc()
Out[3]:
2000-01-01 00:00 0.0
... ...
2000-01-10 23:00 NaN
Freq: H, Length: 240, dtype: float64
```

New Behavior:

```python
In [57]: pi = pd.PeriodIndex(start='2000-01-01', freq='D', periods=10)
In [58]: s = pd.Series(np.arange(10), index=pi)
In [59]: s.resample('H').ohlc()
Out[59]:
          open  high  low  close
2000-01-01 00:00  0.0   0.0   0.0   0.0
2000-01-01 01:00  NaN   NaN   NaN   NaN
2000-01-01 02:00  NaN   NaN   NaN   NaN
2000-01-01 03:00  NaN   NaN   NaN   NaN
2000-01-01 04:00  NaN   NaN   NaN   NaN
2000-01-01 05:00  NaN   NaN   NaN   NaN
2000-01-01 06:00  NaN   NaN   NaN   NaN
... ... ... ... ...
2000-01-10 17:00  NaN   NaN   NaN   NaN
```

(continues on next page)
In [60]: s.resample('M').ohlc()

\[ \begin{array}{cccc}
\text{open} & \text{high} & \text{low} & \text{close} \\
2000-01 & 0 & 9 & 0 & 9 \\
\end{array} \] [240 rows x 4 columns]

1.4.2.8 Improved error handling during item assignment in pd.eval

eval() will now raise a ValueError when item assignment malfunctions, or inplace operations are specified, but there is no item assignment in the expression (GH16732)

In [61]: arr = np.array([1, 2, 3])

Previously, if you attempted the following expression, you would get a not very helpful error message:

In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
IndexError: only integers, slices (`:`), ellipsis (`...`), numpy.newaxis (`None`) and integer or boolean arrays are valid indices

This is a very long way of saying numpy arrays don’t support string-item indexing. With this change, the error message is now this:

In [3]: pd.eval("a = 1 + 2", target=arr, inplace=True)
...
ValueError: Cannot assign expression output to target

It also used to be possible to evaluate expressions inplace, even if there was no item assignment:

In [4]: pd.eval("1 + 2", target=arr, inplace=True)
Out[4]: 3

However, this input does not make much sense because the output is not being assigned to the target. Now, a ValueError will be raised when such an input is passed in:

In [4]: pd.eval("1 + 2", target=arr, inplace=True)
...
ValueError: Cannot operate inplace if there is no assignment

1.4.2.9 Dtype Conversions

Previously assignments, .where() and .fillna() with a bool assignment, would coerce to same the type (e.g. int / float), or raise for datetimelikes. These will now preserve the bools with object dtypes. (GH16821).
In [62]: s = Series([1, 2, 3])

In [5]: s[1] = True

In [6]: s
Out[6]:
   0  1
   1 1
   2 3
dtype: int64

New Behavior

In [63]: s[1] = True

In [64]: s
Out[64]:
   0  1
   1 True
   2 3
dtype: object

Previously, as assignment to a datetimelike with a non-datetimelike would coerce the non-datetime-like item being assigned (GH14145).

In [65]: s = pd.Series([pd.Timestamp('2011-01-01'), pd.Timestamp('2012-01-01')])

In [1]: s[1] = 1

In [2]: s
Out[2]:
   0  2011-01-01 00:00:00.000000000
   1 1970-01-01 00:00:00.000000001
dtype: datetime64[ns]

These now coerce to object dtype.

In [66]: s[1] = 1

In [67]: s
Out[67]:
   0  2011-01-01 00:00:00
   1 1
dtype: object

• Inconsistent behavior in .where() with datetimelikes which would raise rather than coerce to object (GH16402)
• Bug in assignment against int64 data with np.ndarray with float64 dtype may keep int64 dtype (GH14001)

1.4.2.10 MultiIndex Constructor with a Single Level

The MultiIndex constructors no longer squeezes a MultiIndex with all length-one levels down to a regular Index. This affects all the MultiIndex constructors. (GH17178)

Previous behavior:
Length 1 levels are no longer special-cased. They behave exactly as if you had length 2+ levels, so a `MultiIndex` is always returned from all of the `MultiIndex` constructors:

```python
In [68]: pd.MultiIndex.from_tuples([('a',), ('b',)])
Out[68]:
MultiIndex(levels=[['a', 'b']],
          labels=[[0, 1]])
```

### 1.4.2.11 UTC Localization with Series

Previously, `to_datetime()` did not localize datetime `Series` data when `utc=True` was passed. Now, `to_datetime()` will correctly localize `Series` with a `datetime64[ns, UTC]` dtype to be consistent with how list-like and `Index` data are handled. (GH6415).

**Previous Behavior**

```python
In [69]: s = Series(['20130101 00:00:00'] * 3)
In [12]: pd.to_datetime(s, utc=True)
Out[12]:
0  2013-01-01
1  2013-01-01
2  2013-01-01
dtype: datetime64[ns]
```

**New Behavior**

```python
In [70]: pd.to_datetime(s, utc=True)
Out[70]:
0  2013-01-01 00:00:00+00:00
1  2013-01-01 00:00:00+00:00
2  2013-01-01 00:00:00+00:00
dtype: datetime64[ns, UTC]
```

Additionally, DataFrames with datetime columns that were parsed by `read_sql_table()` and `read_sql_query()` will also be localized to UTC only if the original SQL columns were timezone aware datetime columns.

### 1.4.2.12 Consistency of Range Functions

In previous versions, there were some inconsistencies between the various range functions: `date_range()`, `bdate_range()`, `period_range()`, `timedelta_range()`, and `interval_range()` (GH17471).

One of the inconsistent behaviors occurred when the `start`, `end` and `period` parameters were all specified, potentially leading to ambiguous ranges. When all three parameters were passed, `interval_range` ignored the `period` parameter, `period_range` ignored the `end` parameter, and the other range functions raised. To promote consistency among the range functions, and avoid potentially ambiguous ranges, `interval_range` and `period_range` will now raise when all three parameters are passed.

**Previous Behavior:**
In [2]: pd.interval_range(start=0, end=4, periods=6)
Out[2]:
IntervalIndex([(0, 1], (1, 2], (2, 3])
   closed='right',
   dtype='interval[int64]'

In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
Out[3]: PeriodIndex(['2017Q1', '2017Q2', '2017Q3', '2017Q4', '2018Q1', '2018Q2'],
   dtype='period[Q-DEC]', freq='Q-DEC')

New Behavior:

In [2]: pd.interval_range(start=0, end=4, periods=6)
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be specified
In [3]: pd.period_range(start='2017Q1', end='2017Q4', periods=6, freq='Q')
---------------------------------------------------------------------------
ValueError: Of the three parameters: start, end, and periods, exactly two must be specified

Additionally, the endpoint parameter `end` was not included in the intervals produced by `interval_range`. However, all other range functions include `end` in their output. To promote consistency among the range functions, `interval_range` will now include `end` as the right endpoint of the final interval, except if `freq` is specified in a way which skips `end`.

Previous Behavior:

In [4]: pd.interval_range(start=0, end=4)
Out[4]:
IntervalIndex([(0, 1], (1, 2], (2, 3])
   closed='right',
   dtype='interval[int64]'

New Behavior:

In [71]: pd.interval_range(start=0, end=4)
Out[71]:
IntervalIndex([(0, 1], (1, 2], (2, 3], (3, 4])
   closed='right',
   dtype='interval[int64]'

1.4.2.13 No Automatic Matplotlib Converters

Pandas no longer registers our `date`, `time`, `datetime`, `datetime64`, and `Period` converters with matplotlib when pandas is imported. Matplotlib plot methods (`plt.plot`, `ax.plot`, ...), will not nicely format the x-axis for `DatetimeIndex` or `PeriodIndex` values. You must explicitly register these methods:

Pandas built-in `Series.plot` and `DataFrame.plot` will register these converters on first-use (:issue:17710).

Note: This change has been temporarily reverted in pandas 0.21.1, for more details see here.
1.4.2.14 Other API Changes

- The Categorical constructor no longer accepts a scalar for the categories keyword. (GH16022)
- Accessing a non-existent attribute on a closed HDFStore will now raise an AttributeError rather than a ClosedFileError (GH16301)
- `read_csv()` now issues a UserWarning if the names parameter contains duplicates (GH17095)
- `read_csv()` now treats 'null' and 'n/a' strings as missing values by default (GH16471, GH16078)
- pandas.HDFStore's string representation is now faster and less detailed. For the previous behavior, use `pandas.HDFStore.info()` (GH16503).
- Compression defaults in HDF stores now follow pytables standards. Default is no compression and if complib is missing and complevel > 0 zlib is used (GH15943)
- Index.get_indexer_non_unique() now returns a ndarray indexer rather than an Index; this is consistent with Index.get_indexer() (GH16819)
- Removed the @slow decorator from pandas.util.testing, which caused issues for some downstream packages' test suites. Use @pytest.mark.slow instead, which achieves the same thing (GH16850)
- Moved definition of MergeError to the pandas.errors module.
- The signature of Series.set_axis() and DataFrame.set_axis() has been changed from `set_axis(axis, labels)` to `set_axis(labels, axis=0)`, for consistency with the rest of the API. The old signature is deprecated and will show a FutureWarning (GH14636)
- Series.argmin() and Series.argmax() will now raise a TypeError when used with object dtypes, instead of a ValueError (GH13595)
- Period is now immutable, and will now raise an AttributeError when a user tries to assign a new value to the ordinal or freq attributes (GH17116).
- `to_datetime()` when passed a tz-aware origin= kwarg will now raise a more informative ValueError rather than a TypeError (GH16842)
- `to_datetime()` now raises a ValueError when format includes %W or %U without also including day of the week and calendar year (GH16774)
- Renamed non-functional index to index_col in read_stata() to improve API consistency (GH16342)
- Bug in DataFrame.drop() caused boolean labels False and True to be treated as labels 0 and 1 respectively when dropping indices from a numeric index. This will now raise a ValueError (GH16877)
- Restricted DateOffset keyword arguments. Previously, DateOffset subclasses allowed arbitrary keyword arguments which could lead to unexpected behavior. Now, only valid arguments will be accepted. (GH17176).

1.4.3 Deprecations

- DataFrame.from_csv() and Series.from_csv() have been deprecated in favor of read_csv() (GH4191)
- read_excel() has deprecated sheetname in favor of sheet_name for consistency with .to_excel() (GH10559).
- read_excel() has deprecated parse_cols in favor of usecols for consistency with read_csv() (GH4988)
- read_csv() has deprecated the tupleize_cols argument. Column tuples will always be converted to a MultiIndex (GH17060)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- `DataFrame.to_csv()` has deprecated the `tupleize_cols` argument. Multi-index columns will be always written as rows in the CSV file (GH17060).
- The `convert` parameter has been deprecated in the `.take()` method, as it was not being respected (GH16948).
- `pd.options.html.border` has been deprecated in favor of `pd.options.display.html.border` (GH15793).
- `SeriesGroupBy.nth()` has deprecated `True` in favor of `all` for its kwarg `dropna` (GH11038).
- `DataFrame.as_blocks()` is deprecated, as this is exposing the internal implementation (GH17302).
- `pd.TimeGrouper` is deprecated in favor of `pandas.Grouper` (GH16747).
- `cdate_range` has been deprecated in favor of `bdate_range()`, which has gained `weekmask` and `holidays` parameters for building custom frequency date ranges. See the documentation for more details (GH17596).
- Passing categories or ordered kwargs to `Series.astype()` is deprecated, in favor of passing a `CategoricalDtype` (GH17636).
- `.get_value` and `.set_value` on Series, DataFrame, Panel, SparseSeries, and SparseDataFrame are deprecated in favor of using `.iat[]` or `.at[]` accessors (GH15269).
- Passing a non-existent column in `.to_excel(..., columns=)` is deprecated and will raise a `KeyError` in the future (GH17295).
- `raise_on_error` parameter to `Series.where()`, `Series.mask()`, `DataFrame.where()`, `DataFrame.mask()` is deprecated, in favor of `errors=` (GH14968).
- Using `DataFrame.rename_axis()` and `Series.rename_axis()` to alter index or column labels is now deprecated in favor of using `.rename.rename_axis` may still be used to alter the name of the index or columns (GH17833).
- `reindex_axis()` has been deprecated in favor of `reindex()`. See here for more (GH17833).

### 1.4.3.1 Series.select and DataFrame.select

The `Series.select()` and `DataFrame.select()` methods are deprecated in favor of using `df.loc[labels.map(crit)]` (GH12401)

```
In [72]: df = DataFrame({'A': [1, 2, 3]}, index=['foo', 'bar', 'baz'])

In [3]: df.select(lambda x: x in ['bar', 'baz'])
FutureWarning: select is deprecated and will be removed in a future release. You can use .loc[crit] as a replacement
Out[3]:
   A  
bar 2
baz 3

In [73]: df.loc[df.index.map(lambda x: x in ['bar', 'baz'])]
Out[73]:
   A  
bar 2
baz 3
```
1.4.3.2 Series.argmax and Series.argmin

The behavior of Series.argmax() and Series.argmin() have been deprecated in favor of Series.idxmax() and Series.idxmin(), respectively (GH16830).

For compatibility with NumPy arrays, pd.Series implements argmax and argmin. Since pandas 0.13.0, argmax has been an alias for pandas.Series.idxmax(), and argmin has been an alias for pandas.Series.idxmin(). They return the label of the maximum or minimum, rather than the position.

We've deprecated the current behavior of Series.argmax and Series.argmin. Using either of these will emit a FutureWarning. Use Series.idxmax() if you want the label of the maximum. Use Series.values.argmax() if you want the position of the maximum. Likewise for the minimum. In a future release Series.argmax and Series.argmin will return the position of the maximum or minimum.

1.4.4 Removal of prior version deprecations/changes

- read_excel() has dropped the has_index_names parameter (GH10967)
- The pd.options.display.height configuration has been dropped (GH3663)
- The pd.options.display.line_width configuration has been dropped (GH2881)
- The pd.options.display.mpl_style configuration has been dropped (GH12190)
- Index has dropped the .sym_diff() method in favor of .symmetric_difference() (GH12591)
- Categorical has dropped the .order() and .sort() methods in favor of .sort_values() (GH12882)
- eval() and DataFrame.eval() have changed the default of inplace from None to False (GH11149)
- The function get_offset_name has been dropped in favor of the .freqstr attribute for an offset (GH11834)
- pandas no longer tests for compatibility with hdf5-files created with pandas < 0.11 (GH17404).

1.4.5 Performance Improvements

- Improved performance of instantiating SparseDataFrame (GH16773)
- Series.dt no longer performs frequency inference, yielding a large speedup when accessing the attribute (GH17210)
- Improved performance of set_categories() by not materializing the values (GH17508)
- Timestamp.microsecond no longer re-computes on attribute access (GH17331)
- Improved performance of the CategoricalIndex for data that is already categorical dtype (GH17513)
- Improved performance of RangeIndex.min() and RangeIndex.max() by using RangeIndex properties to perform the computations (GH17607)

1.4.6 Documentation Changes

- Several NaT method docstrings (e.g. NaT.ctime()) were incorrect (GH17327)
- The documentation has had references to versions < v0.17 removed and cleaned up (GH17442, GH17442, GH17404 & GH17504)
1.4.7 Bug Fixes

1.4.7.1 Conversion

- Bug in assignment against datetime-like data with `int` may incorrectly convert to datetime-like (GH14145)
- Bug in assignment against `int64` data with `np.ndarray` with `float64` dtype may keep `int64` dtype (GH14001)
- Fixed the return type of IntervalIndex.is_non_overlapping_monotonic to be a Python bool for consistency with similar attributes/methods. Previously returned a numpy.bool_. (GH17237)
- Bug in IntervalIndex.is_non_overlapping_monotonic when intervals are closed on both sides and overlap at a point (GH16560)
- Bug in Series.fillna() returns frame when inplace=True and value is dict (GH16156)
- Bug in Timestamp.weekday_name returning a UTC-based weekday name when localized to a timezone (GH17354)
- Bug in Timestamp.replace when replacing tzinfo around DST changes (GH15683)
- Bug in Timedelta construction and arithmetic that would not propagate the Overflow exception (GH17367)
- Bug in astype() converting to object dtype when passed extension type classes (DatetimeTZDtype, CategoricalDtype) rather than instances. Now a TypeError is raised when a class is passed (GH17780).
- Bug in to_numeric() in which elements were not always being coerced to numeric when errors='coerce' (GH17007, GH17125)
- Bug in DataFrame and Series constructors where range objects are converted to int32 dtype on Windows instead of int64 (GH16804)

1.4.7.2 Indexing

- When called with a null slice (e.g. df.iloc[:]), the .iloc and .loc indexers return a shallow copy of the original object. Previously they returned the original object. (GH13873).
- When called on an unsorted MultiIndex, the loc indexer now will raise UnsortedIndexError only if proper slicing is used on non-sorted levels (GH16734).
- Fixes regression in 0.20.3 when indexing with a string on a TimedeltaIndex (GH16896).
- Fixed TimedeltaIndex.get_loc() handling of np.timedelta64 inputs (GH16909).
- Fix MultiIndex.sort_index() ordering when ascending argument is a list, but not all levels are specified, or are in a different order (GH16934).
- Fixes bug where indexing with np.inf caused an OverflowError to be raised (GH16957)
- Bug in reindexing on an empty CategoricalIndex (GH16770)
- Fixes DataFrame.loc for setting with alignment and tz-aware DatetimeIndex (GH16889)
- Avoids IndexError when passing an Index or Series to .iloc with older numpy (GH17193)
- Allow unicode empty strings as placeholders in multilevel columns in Python 2 (GH17099)
- Bug in .iloc when used with inplace addition or assignment and an int indexer on a MultiIndex causing the wrong indexes to be read from and written to (GH17148)
- Bug in .isin() in which checking membership in empty Series objects raised an error (GH16991)
• Bug in `CategoricalIndex` reindexing in which specified indices containing duplicates were not being respected (GH17323)
• Bug in intersection of `RangeIndex` with negative step (GH17296)
• Bug in `IntervalIndex` where performing a scalar lookup fails for included right endpoints of non-overlapping monotonic decreasing indexes (GH16417, GH17271)
• Bug in `DataFrame.first_valid_index()` and `DataFrame.last_valid_index()` when no valid entry (GH17400)
• Bug in `Series.rename()` when called with a callable, incorrectly alters the name of the `Series`, rather than the name of the `Index`. (GH17407)
• Bug in `String.str_get()` raises `IndexError` instead of inserting NaNs when using a negative index. (GH17704)

1.4.7.3 I/O

• Bug in `read_hdf()` when reading a timezone aware index from fixed format HDFStore (GH17618)
• Bug in `read_csv()` in which columns were not being thoroughly de-duplicated (GH17060)
• Bug in `read_csv()` in which specified column names were not being thoroughly de-duplicated (GH17095)
• Bug in `read_csv()` in which non integer values for the header argument generated an unhelpful / unrelated error message (GH16338)
• Bug in `read_csv()` in which memory management issues in exception handling, under certain conditions, would cause the interpreter to segfault (GH14696, GH16798).
• Bug in `read_csv()` when called with `low_memory=False` in which a CSV with at least one column > 2GB in size would incorrectly raise a `MemoryError` (GH16798).
• Bug in `read_csv()` when called with a single-element list `header` would return a `DataFrame` of all NaN values (GH7757)
• Bug in `DataFrame.to_csv()` defaulting to ‘ascii’ encoding in Python 3, instead of ‘utf-8’ (GH17097)
• Bug in `read_stata()` where value labels could not be read when using an iterator (GH16923)
• Bug in `read_stata()` where the index was not set (GH16342)
• Bug in `read_html()` where import check fails when run in multiple threads (GH16928)
• Bug in `read_csv()` where automatic delimiter detection caused a `TypeError` to be thrown when a bad line was encountered rather than the correct error message (GH13374)
• Bug in `DataFrame.to_html()` with `notebook=True` where DataFrames with named indices or non-MultiIndex indices had undesired horizontal or vertical alignment for column or row labels, respectively (GH16792)
• Bug in `DataFrame.to_html()` in which there was no validation of the `justify` parameter (GH17527)
• Bug in `HDFStore.select()` when reading a contiguous mixed-data table featuring VLArray (GH17021)
• Bug in `to_json()` where several conditions (including objects with unprintable symbols, objects with deep recursion, overlong labels) caused segfaults instead of raising the appropriate exception (GH14256)
1.4.7.4 Plotting

- Bug in plotting methods using `secondary_y` and `fontsize` not setting secondary axis font size (GH12565)
- Bug when plotting `timedelta` and `datetime` dtypes on y-axis (GH16953)
- Line plots no longer assume monotonic x data when calculating xlimits, they show the entire lines now even for unsorted x data. (GH11310, GH11471)
- With matplotlib 2.0.0 and above, calculation of x limits for line plots is left to matplotlib, so that its new default settings are applied. (GH15495)
- Bug in `Series.plot.bar` or `DataFrame.plot.bar` with `y` not respecting user-passed color (GH16822)
- Bug causing `plotting.parallel_coordinates` to reset the random seed when using random colors (GH17525)

1.4.7.5 Groupby/Resample/Rolling

- Bug in `DataFrame.resample(...)`.size() where an empty DataFrame did not return a `Series` (GH14962)
- Bug in `infer_freq()` causing indices with 2-day gaps during the working week to be wrongly inferred as business daily (GH16624)
- Bug in `.rolling(...)`.quantile() which incorrectly used different defaults than `Series.quantile()` and `DataFrame.quantile()` (GH9413, GH16211)
- Bug in `groupby.transform()` that would coerce boolean dtypes back to float (GH16875)
- Bug in `Series.resample(...).apply()` where an empty Series modified the source index and did not return the name of a `Series` (GH14313)
- Bug in `.rolling(...).apply(...)` with a DataFrame with a `DatetimeIndex`, a window of a timedelta-convertible and `min_periods` >= 1 (GH15305)
- Bug in `DataFrame.groupby` where index and column keys were not recognized correctly when the number of keys equaled the number of elements on the groupby axis (GH16859)
- Bug in `groupby.nunique()` with `TimeGrouper` which cannot handle NaT correctly (GH17575)
- Bug in `DataFrame.groupby` where a single level selection from a `MultiIndex` unexpectedly sorts (GH17537)
- Bug in `DataFrame.groupby` where spurious warning is raised when `Grouper` object is used to override ambiguous column name (GH17383)
- Bug in `TimeGrouper` differs when passes as a list and as a scalar (GH17530)

1.4.7.6 Sparse

- Bug in `SparseSeries` raises `AttributeError` when a dictionary is passed in as data (GH16905)
- Bug in `SparseDataFrame.fillna()` not filling all NaNs when frame was instantiated from SciPy sparse matrix (GH16112)
- Bug in `SparseSeries.unstack()` and `SparseDataFrame.stack()` (GH16614, GH15045)
- Bug in `make_sparse()` treating two numeric/boolean data, which have same bits, as same when array `dtype` is `object` (GH17574)
• SparseArray.all() and SparseArray.any() are now implemented to handle SparseArray, these were used but not implemented (GH17570)

1.4.7.7 Reshaping

• Joining/Merging with a non unique PeriodIndex raised a TypeError (GH16871)
• Bug in crosstab() where non-aligned series of integers were casted to float (GH17005)
• Bug in merging with categorical dtypes with datetimelikes incorrectly raised a TypeError (GH16900)
• Bug when using isin() on a large object series and large comparison array (GH16012)
• Fixes regression from 0.20, Series.aggregate() and DataFrame.aggregate() allow dictionaries as return values again (GH16741)
• Fixes dtype of result with integer dtype input, from pivot_table() when called with margins=True (GH17013)
• Bug in crosstab() where passing two Series with the same name raised a KeyError (GH13279)
• Series.argmin(), Series.argmax(), and their counterparts on DataFrame and groupby objects work correctly with floating point data that contains infinite values (GH13959).
• Bug in unique() where checking a tuple of strings raised a TypeError (GH17108)
• Bug in concat() where order of result index was unpredictable if it contained non-comparable elements (GH17344)
• Fixes regression when sorting by multiple columns on a datetime64 dtype Series with NaT values (GH16836)
• Bug in pivot_table() where the result’s columns did not preserve the categorical dtype of columns when dropna was False (GH17842)
• Bug in DataFrame.drop_duplicates where dropping with non-unique column names raised a ValueError (GH17836)
• Bug in unstack() which, when called on a list of levels, would discard the fillna argument (GH13971)
• Bug in the alignment of range objects and other list-likes with DataFrame leading to operations being performed row-wise instead of column-wise (GH17901)

1.4.7.8 Numeric

• Bug in .clip() with axis=1 and a list-like for threshold is passed; previously this raised ValueError (GH15390)
• Series.clip() and DataFrame.clip() now treat NA values for upper and lower arguments as None instead of raising ValueError (GH17276).

1.4.7.9 Categorical

• Bug in Series.isin() when called with a categorical (GH16639)
• Bug in the categorical constructor with empty values and categories causing the .categories to be an empty Float64Index rather than an empty Index with object dtype (GH17248)
• Bug in categorical operations with Series.cat not preserving the original Series’ name (GH17509)
• Bug in DataFrame.merge() failing for categorical columns with boolean/int data types (GH17187)
• Bug in constructing a Categorical/CategoricalDtype when the specified categories are of categorical type (GH17884).

1.4.7.10 PyPy

• Compatibility with PyPy in read_csv() with usecols=[<unsorted ints>] and read_json() (GH17351)
• Split tests into cases for CPython and PyPy where needed, which highlights the fragility of index matching with float('nan'), np.nan and NAT (GH17351)
• Fix DataFrame.memory_usage() to support PyPy. Objects on PyPy do not have a fixed size, so an approximation is used instead (GH17228)

1.4.7.11 Other

• Bug where some inplace operators were not being wrapped and produced a copy when invoked (GH12962)
• Bug in eval() where the inplace parameter was being incorrectly handled (GH16732)

1.5 v0.20.3 (July 7, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes and bug fixes. We recommend that all users upgrade to this version.

What’s new in v0.20.3

• Bug Fixes
  – Conversion
  – Indexing
  – I/O
  – Plotting
  – Reshaping
  – Categorical

1.5.1 Bug Fixes

• Fixed a bug in failing to compute rolling computations of a column-MultiIndexed DataFrame (GH16789, GH16825)
• Fixed a pytest marker failing downstream packages’ tests suites (GH16680)

1.5.1.1 Conversion

• Bug in pickle compat prior to the v0.20.x series, when UTC is a timezone in a Series/DataFrame/Index (GH16608)
• Bug in Series construction when passing a Series with dtype='category' (GH16524).
• Bug in DataFrame.astype() when passing a Series as the dtype kwarg. (GH16717).

1.5.1.2 Indexing

• Bug in Float64Index causing an empty array instead of None to be returned from .get(np.nan) on a Series whose index did not contain any NaNs (GH8569)
• Bug in MultiIndex.isin causing an error when passing an empty iterable (GH16777)
• Fixed a bug in a slicing DataFrame/Series that have a TimedeltaIndex (GH16637)

1.5.1.3 I/O

• Bug in read_csv() in which files weren’t opened as binary files by the C engine on Windows, causing EOF characters mid-field, which would fail (GH16039, GH16559, GH16675)
• Bug in read_hdf() in which reading a Series saved to an HDF file in ‘fixed’ format fails when an explicit mode='r' argument is supplied (GH16583)
• Bug in DataFrame.to_latex() where bold_rows was wrongly specified to be True by default, whereas in reality row labels remained non-bold whatever parameter provided. (GH16707)
• Fixed an issue with DataFrame.style() where generated element ids were not unique (GH16780)
• Fixed loading a DataFrame with a PeriodIndex, from a format='fixed' HDFStore, in Python 3, that was written in Python 2 (GH16781)

1.5.1.4 Plotting

• Fixed regression that prevented RGB and RGBA tuples from being used as color arguments (GH16233)
• Fixed an issue with DataFrame.plot.scatter() that incorrectly raised a KeyError when categorical data is used for plotting (GH16199)

1.5.1.5 Reshaping

• PeriodIndex/TimedeltaIndex.join was missing the sort= kwarg (GH16541)
• Bug in joining on a MultiIndex with a category dtype for a level (GH16627).
• Bug in merge() when merging/joining with multiple categorical columns (GH16767)

1.5.1.6 Categorical

• Bug in DataFrame.sort_values not respecting the kind parameter with categorical data (GH16793)

1.6 v0.20.2 (June 4, 2017)

This is a minor bug-fix release in the 0.20.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.
What’s new in v0.20.2

- **Enhancements**
- **Performance Improvements**
- **Bug Fixes**
  - Conversion
  - Indexing
  - I/O
  - Plotting
  - Groupby/Resample/Rolling
  - Sparse
  - Reshaping
  - Numeric
  - Categorical
  - Other

1.6.1 Enhancements

- Series provides a to_latex method (GH16180)
- A new groupby method ngroup(), parallel to the existing cumcount(), has been added to return the group order (GH11642); see here.

1.6.2 Performance Improvements

- Performance regression fix when indexing with a list-like (GH16285)
- Performance regression fix for MultiIndexes (GH16319, GH16346)
- Improved performance of .clip() with scalar arguments (GH15400)
- Improved performance of groupby with categorical groupers (GH16413)
- Improved performance of MultiIndex.remove_unused_levels() (GH16556)

1.6.3 Bug Fixes

- Silenced a warning on some Windows environments about “tput: terminal attributes: No such device or address” when detecting the terminal size. This fix only applies to python 3 (GH16496)
- Bug in using pathlib.Path or py.path.local objects with io functions (GH16291)
- Bug in Index.symmetric_difference() on two equal MultiIndex’s, results in a TypeError (issue 13490)
• Bug in `DataFrame.update()` with overwrite=False and NaN values (GH15593)
• Passing an invalid engine to `read_csv()` now raises an informative ValueError rather than UnboundLocalError. (GH16511)
• Bug in `unique()` on an array of tuples (GH16519)
• Bug in `cut()` when labels are set, resulting in incorrect label ordering (GH16459)
• Fixed a compatibility issue with IPython 6.0’s tab completion showing deprecation warnings on Categoricals (GH16409)

1.6.3.1 Conversion
• Bug in `to_numeric()` in which empty data inputs were causing a segfault of the interpreter (GH16302)
• Silence numpy warnings when broadcasting DataFrame to Series with comparison ops (GH16378, GH16306)

1.6.3.2 Indexing
• Bug in `DataFrame.reset_index(level=)` with single level index (GH16263)
• Bug in partial string indexing with a monotonic, but not strictly-monotonic, index incorrectly reversing the slice bounds (GH16515)
• Bug in `MultiIndex.remove_unused_levels()` that would not return a MultiIndex equal to the original. (GH16556)

1.6.3.3 I/O
• Bug in `read_csv()` when comment is passed in a space delimited text file (GH16472)
• Bug in `read_csv()` not raising an exception with nonexistent columns in usecols when it had the correct length (GH14671)
• Bug that would force importing of the clipboard routines unnecessarily, potentially causing an import error on startup (GH16288)
• Bug that raised IndexError when HTML-rendering an empty DataFrame (GH15953)
• Bug in `read_csv()` in which tarfile object inputs were raising an error in Python 2.x for the C engine (GH16530)
• Bug where `DataFrame.to_html()` ignored the index_names parameter (GH16493)
• Bug where `pd.read_hdf()` returns numpy strings for index names (GH13492)
• Bug in `HDFStore.select_as_multiple()` where start/stop arguments were not respected (GH16209)

1.6.3.4 Plotting
• Bug in `DataFrame.plot` with a single column and a list-like color (GH3486)
• Bug in `plot` where NaT in DatetimeIndex results in Timestamp.min (:issue: 12405)
• Bug in `DataFrame.boxplot` where figsize keyword was not respected for non-grouped boxplots (GH11959)
1.6.3.5 Groupby/Resample/Rolling

- Bug in creating a time-based rolling window on an empty DataFrame (GH15819)
- Bug in rolling.cov() with offset window (GH16058)
- Bug in .resample() and .groupby() when aggregating on integers (GH16361)

1.6.3.6 Sparse

- Bug in construction of SparseDataFrame from scipy.sparse.dok_matrix (GH16179)

1.6.3.7 Reshaping

- Bug in DataFrame.stack with unsorted levels in MultiIndex columns (GH16323)
- Bug in pd.wide_to_long() where no error was raised when i was not a unique identifier (GH16382)
- Bug in Series.isin(..) with a list of tuples (GH16394)
- Bug in construction of a DataFrame with mixed dtypes including an all-NaT column. (GH16395)
- Bug in DataFrame.agg() and Series.agg() with aggregating on non-callable attributes (GH16405)

1.6.3.8 Numeric

- Bug in .interpolate(), where limit_direction was not respected when limit=None (default) was passed (GH16282)

1.6.3.9 Categorical

- Fixed comparison operations considering the order of the categories when both categoricals are unordered (GH16014)

1.6.3.10 Other

- Bug in DataFrame.drop() with an empty-list with non-unique indices (GH16270)

1.7 v0.20.1 (May 5, 2017)

This is a major release from 0.19.2 and includes a number of API changes, deprecations, new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

- New .agg() API for Series/DataFrame similar to the groupby-rolling-resample API’s, see here
- Integration with the feather-format, including a new top-level pd.read_feather() and DataFrame.to_feather() method, see here.
- The .ix indexer has been deprecated, see here
- Panel has been deprecated, see here
• Addition of an IntervalIndex and Interval scalar type, see here
• Improved user API when grouping by index levels in .groupby(), see here
• Improved support for UInt64 dtypes, see here
• A new orient for JSON serialization, orient='table', that uses the Table Schema spec and that gives the possibility for a more interactive repr in the Jupyter Notebook, see here
• Experimental support for exporting styled DataFrames (DataFrame.style) to Excel, see here
• Window binary corr/cov operations now return a MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see here
• Support for S3 handling now uses s3fs, see here
• Google BigQuery handling now uses the pandas-gbq library, see here

**Warning:** Pandas has changed the internal structure and layout of the codebase. This can affect imports that are not from the top-level pandas.* namespace, please see the changes here.

Check the API Changes and deprecations before updating.

**Note:** This is a combined release for 0.20.0 and 0.20.1. Version 0.20.1 contains one additional change for backwards-compatibility with downstream projects using pandas’ utils routines. (GH16250)

### What’s new in v0.20.0

**New features**

- `agg` API for DataFrame/Series
- `dtype` keyword for data IO
- `.to_datetime()` has gained an origin parameter
- Groupby Enhancements
- Better support for compressed URLs in `read_csv`
- Pickle file I/O now supports compression
- UInt64 Support Improved
- GroupBy on Categoricals
- Table Schema Output
- SciPy sparse matrix from/to SparseDataFrame
- Excel output for styled DataFrames
- `Int64Index`
- Other Enhancements

**Backwards incompatible API changes**

- Possible incompatibility for HDF5 formats created with pandas < 0.13.0
- Map on Index types now return other Index types
- Accessing datetime fields of Index now return Index
- `pd.unique` will now be consistent with extension types
- S3 File Handling
- Partial String Indexing Changes
- Concat of different float dtypes will not automatically upcast
- Pandas Google BigQuery support has moved
- Memory Usage for Index is more Accurate
- DataFrame.sort_index changes
- Groupby Describe Formatting
- Window Binary Corr/Cov operations return a MultiIndex DataFrame
- HDFStore where string comparison
- Index.intersection and inner join now preserve the order of the left Index
- Pivot Table always returns a DataFrame
- Other API Changes

• Reorganization of the library: Privacy Changes
  - Modules Privacy Has Changed
  - `pandas.errors`
  - `pandas.testing`
  - `pandas.plotting`
  - Other Development Changes

• Deprecations
  - Deprecate `.ix`
  - Deprecate Panel
  - Deprecate groupby.agg() with a dictionary when renaming
  - Deprecate .plotting
  - Other Deprecations

• Removal of prior version deprecations/changes

• Performance Improvements

• Bug Fixes
  - Conversion
  - Indexing
  - I/O
  - Plotting
  - Groupby/Resample/Rolling
  - Sparse
1.7.1 New features

1.7.1.1 agg API for DataFrame/Series

Series & DataFrame have been enhanced to support the aggregation API. This is a familiar API from groupby, window operations, and resampling. This allows aggregation operations in a concise way by using `agg()` and `transform()`. The full documentation is here (GH1623).

Here is a sample

```python
In [1]: df = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                      index=pd.date_range('1/1/2000', periods=10))

In [2]: df.iloc[3:7] = np.nan

In [3]: df
Out[3]:
     A       B       C
2000-01-01 1.682600 0.413582 1.689516
2000-01-02 -2.099110 -1.180182 1.595661
2000-01-03 -0.419048 0.522165 -1.208946
2000-01-04 NaN  NaN  NaN
2000-01-05 NaN  NaN  NaN
2000-01-06 NaN  NaN  NaN
2000-01-07 NaN  NaN  NaN
2000-01-08 0.955435 -0.133009 2.011466
2000-01-09 0.578780 0.897126 -0.980013
2000-01-10 0.955435 -0.133009 2.011466
```

One can operate using string function names, callables, lists, or dictionaries of these.

Using a single function is equivalent to `.apply`.

```python
In [4]: df.agg('sum')
Out[4]:
     A       B       C
0  0.652908  0.881282  2.899645
```

Multiple aggregations with a list of functions.

```python
In [5]: df.agg(['sum', 'min'])
Out[5]:
     A       B       C
   sum  0.652908  0.881282  2.899645
  min -2.099110 -1.180182 -1.208946
```

Using a dict provides the ability to apply specific aggregations per column. You will get a matrix-like output of all of the aggregators. The output has one column per unique function. Those functions applied to a particular column will
be NaN:

```python
In [6]: df.agg({'A': ['sum', 'min'], 'B': ['min', 'max']})
Out[6]:
          A   B
    max     NaN  0.897126
    min -2.099110 -1.180182
    sum  0.652908       NaN
```

The API also supports a `.transform()` function for broadcasting results.

```python
In [7]: df.transform(['abs', lambda x: x - x.min()])
Out[7]:
          A      B     C
    2000-01-01    1.682600  3.781710  0.413582  1.593764  1.689516  2.898461
    2000-01-02    2.099110  0.000000  1.180182  0.000000  1.595661  2.804606
    2000-01-03    0.419048  1.680062  0.522185  1.702346  1.208946  0.000000
    2000-01-04    NaN    NaN    NaN    NaN    NaN    NaN
    2000-01-05    NaN    NaN    NaN    NaN    NaN    NaN
    2000-01-06    NaN    NaN    NaN    NaN    NaN    NaN
    2000-01-07    NaN    NaN    NaN    NaN    NaN    NaN
    2000-01-08    0.955435  3.054545  0.133009  1.047173  2.011466  3.220412
    2000-01-09    0.578780  2.677890  0.897126  2.077307  0.980013  0.228932
    2000-01-10    0.045748  2.053362  0.361601  1.541782  0.208039  1.000907
```

When presented with mixed dtypes that cannot be aggregated, `.agg()` will only take the valid aggregations. This is similar to how groupby `.agg()` works. (GH15015)

```python
In [8]: df = pd.DataFrame({'A': [1, 2, 3],
                        'B': [1.0, 2.0, 3.0],
                        'C': ['foo', 'bar', 'baz'],
                        'D': pd.date_range('20130101', periods=3)})

In [9]: df.dtypes
Out[9]:
        A    B     C                             D
dtype: int64  float64 object  dtype: datetime64[ns]
```

```python
In [10]: df.agg(['min', 'sum'])
Out[10]:
          A   B     C   D
    min  1.0 NaN   bar 2013-01-01
    sum  6.0 foobar baz  NaN
```

### 1.7.1.2 dtype keyword for data IO

The 'python' engine for `read_csv()`, as well as the `read_fwf()` function for parsing fixed-width text files and `read_excel()` for parsing Excel files, now accept the `dtype` keyword argument for specifying the types of specific columns (GH14295). See the `io docs` for more information.
1.7.1.3 \texttt{to_datetime()} has gained an origin parameter

\texttt{to_datetime()} has gained a new parameter, \texttt{origin}, to define a reference date from where to compute the resulting timestamps when parsing numerical values with a specific \texttt{unit} specified. (GH11276, GH11745)

For example, with 1960-01-01 as the starting date:

\begin{verbatim}
In [14]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[14]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'],
                     dtype='datetime64[ns]', freq=None)
\end{verbatim}

The default is set at \texttt{origin='unix'}, which defaults to 1970-01-01 00:00:00, which is commonly called 'unix epoch' or POSIX time. This was the previous default, so this is a backward compatible change.

\begin{verbatim}
In [15]: pd.to_datetime([1, 2, 3], unit='D')
                     dtype='datetime64[ns]', freq=None)
\end{verbatim}

1.7.1.4 Groupby Enhancements

Strings passed to \texttt{DataFrame.groupby()} as the \texttt{by} parameter may now reference either column names or index level names. Previously, only column names could be referenced. This allows to easily group by a column and index level at the same time. (GH5677)

\begin{verbatim}
in [16]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
               ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
   ....:     ...
   ....:     ...
in [17]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
in [18]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3],
                   ....:     'B': np.arange(8)},
                   ....:     index=index)
in [19]: df
Out[19]:
   A  B
first second
bar  one  1  0
\end{verbatim}
1.7.1.5 Better support for compressed URLs in `read_csv`

The compression code was refactored (GH12688). As a result, reading dataframes from URLs in `read_csv()` or `read_table()` now supports additional compression methods: xz, bz2, and zip (GH14570). Previously, only gzip compression was supported. By default, compression of URLs and paths are now inferred using their file extensions. Additionally, support for bz2 compression in the python 2 C-engine improved (GH14874).

```
In [21]: url = 'https://github.com/{repo}/raw/{branch}/{path}'.format(
    ...:     repo = 'pandas-dev/pandas',
    ...:     branch = 'master',
    ...:     path = 'pandas/tests/io/parser/data/salaries.csv.bz2',
    ...: )

In [22]: df = pd.read_table(url, compression='infer')  # default, infer compression

In [23]: df = pd.read_table(url, compression='bz2')    # explicitly specify compression

In [24]: df.head(2)
Out[24]:
   S  X  E  M
0  0  1  1  1
1  1  1  3  0
```

1.7.1.6 Pickle file I/O now supports compression

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can now read from and write to compressed pickle files. Compression methods can be an explicit parameter or be inferred from the file extension. See the docs here.

```
In [25]: df = pd.DataFrame({
    ...:     'A': np.random.randn(1000),
    ...:     'B': 'foo',
```

(continues on next page)
Using an explicit compression type

```python
In [26]: df.to_pickle("data.pkl.compress", compression="gzip")
In [27]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")
In [28]: rt.head()
Out[28]:
   A    B    C
0  1.578227  foo  2013-01-01 00:00:00
1 -0.230575  foo  2013-01-01 00:00:01
2  0.695530  foo  2013-01-01 00:00:02
3 -0.466001  foo  2013-01-01 00:00:03
4 -0.154972  foo  2013-01-01 00:00:04
```

The default is to infer the compression type from the extension (`compression='infer'`):

```python
In [29]: df.to_pickle("data.pkl.gz")
In [30]: rt = pd.read_pickle("data.pkl.gz")
In [31]: rt.head()
Out[31]:
   A    B    C
0  1.578227  foo  2013-01-01 00:00:00
1 -0.230575  foo  2013-01-01 00:00:01
2  0.695530  foo  2013-01-01 00:00:02
3 -0.466001  foo  2013-01-01 00:00:03
4 -0.154972  foo  2013-01-01 00:00:04
In [32]: df["A"].to_pickle("s1.pkl.bz2")
In [33]: rt = pd.read_pickle("s1.pkl.bz2")
In [34]: rt.head()
Out[34]:
   A
0  1.578227
1 -0.230575
2  0.695530
3 -0.466001
4 -0.154972
Name: A, dtype: float64
```

### 1.7.1.7 UInt64 Support Improved

Pandas has significantly improved support for operations involving unsigned, or purely non-negative, integers. Previously, handling these integers would result in improper rounding or data-type casting, leading to incorrect results. Notably, a new numerical index, `UInt64Index`, has been created (GH14937)

```python
In [35]: idx = pd.UInt64Index([1, 2, 3])
In [36]: df = pd.DataFrame({"A": ["a", "b", "c"], index=idx})
```
• Bug in converting object elements of array-like objects to unsigned 64-bit integers (GH4471, GH14982)
• Bug in Series.unique() in which unsigned 64-bit integers were causing overflow (GH14721)
• Bug in DataFrame construction in which unsigned 64-bit integer elements were being converted to objects (GH14881)
• Bug in pd.read_csv() in which unsigned 64-bit integer elements were being improperly converted to the wrong data types (GH14983)
• Bug in pd.unique() in which unsigned 64-bit integers were causing overflow (GH14915)
• Bug in pd.value_counts() in which unsigned 64-bit integers were being erroneously truncated in the output (GH14934)

1.7.1.8 GroupBy on Categoricals

In previous versions, .groupby(..., sort=False) would fail with a ValueError when grouping on a categorical series with some categories not appearing in the data. (GH13179)

In [38]: chromosomes = np.r_[np.arange(1, 23).astype(str), ['X', 'Y']]

In [39]: df = pd.DataFrame({
......: 'A': np.random.randint(100),
......: 'B': np.random.randint(100),
......: 'C': np.random.randint(100),
......: 'chromosomes': pd.Categorical(np.random.choice(chromosomes, 100),
......: categories=chromosomes,
......: ordered=True))

In [40]: df
Out[40]:
     A  B  C    chromosomes
0   80 36 94    12
1   80 36 94    X
2   80 36 94    19
3   80 36 94    22
4   80 36 94    17
5   80 36 94     6
6   80 36 94    13
..   ..   ..    ...
93  80 36 94    21
94  80 36 94    20
95  80 36 94    11
96  80 36 94    16
97  80 36 94    21
98  80 36 94    18
99  80 36 94     8

[100 rows x 4 columns]

Previous Behavior:
In [3]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
ValueError: items in new_categories are not the same as in old categories

New Behavior:

In [41]: df[df.chromosomes != '1'].groupby('chromosomes', sort=False).sum()
Out[41]:

<table>
<thead>
<tr>
<th>chromosomes</th>
<th>A</th>
<th>B</th>
<th>C</th>

[24 rows x 3 columns]

1.7.1.9 Table Schema Output

The new orient 'table' for DataFrame.to_json() will generate a Table Schema compatible string representation of the data.

In [42]: df = pd.DataFrame(
    ....:     {"A": [1, 2, 3],
    ....:      "B": ["a", "b", "c"],
    ....:      "C": pd.date_range(\'2016-01-01\', freq='d', periods=3),
    ....:     }, index=pd.Index(range(3), name='idx'))

In [43]: df
to_json(orient='table')

<table>
<thead>
<tr>
<th>idx</th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
<td>a</td>
<td>2016-01-01</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
<td>b</td>
<td>2016-01-02</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>c</td>
<td>2016-01-03</td>
</tr>
</tbody>
</table>

In [44]: df.to_json(orient='table')

"schema": {
"fields": [{"name":"idx","type":"integer"},
            {"name":"A","type":"integer"},
            {"name":"B","type":"string"},
            {"name":"C","type":"datetime"}],
"primaryKey": "idx",
"pandas_version": "0.20.0"},
"data": [{"idx":0,"A":1,"B":"a","C":"2016-01-01T00:00:00.000Z"},{"idx":1,"A":2,"B":"b","C":"2016-01-02T00:00:00.000Z"},{"idx":2,"A":3,"B":"c","C":"2016-01-03T00:00:00.000Z"}]

See IO: Table Schema for more information.

1.7. v0.20.1 (May 5, 2017)
Additionally, the repr for DataFrame and Series can now publish this JSON Table schema representation of the Series or DataFrame if you are using IPython (or another frontend like nteract using the Jupyter messaging protocol). This gives frontends like the Jupyter notebook and nteract more flexibility in how they display pandas objects, since they have more information about the data. You must enable this by setting the `display.html.table_schema` option to `True`.

### 1.7.1.10 SciPy sparse matrix from/to SparseDataFrame

Pandas now supports creating sparse dataframes directly from `scipy.sparse.spmatrix` instances. See the [documentation](#) for more information. (GH4343)

All sparse formats are supported, but matrices that are not in **COOrdinate** format will be converted, copying data as needed.

```python
In [45]: from scipy.sparse import csr_matrix
In [46]: arr = np.random.random(size=(1000, 5))
In [47]: arr[arr < .9] = 0
In [48]: sp_arr = csr_matrix(arr)
In [49]: sp_arr
Out[49]: <1000x5 sparse matrix of type '<class 'numpy.float64'>'>
          with 521 stored elements in Compressed Sparse Row format>
In [50]: sdf = pd.SparseDataFrame(sp_arr)
In [51]: sdf
Out[51]:
          0     1     2     3     4
   0   NaN   NaN   NaN   NaN   NaN
   1   NaN   NaN 0.955103   NaN   NaN
   2   NaN   NaN 0.900469   NaN   NaN
   3   NaN   NaN   NaN   NaN   NaN
   4  0.924771   NaN   NaN   NaN   NaN
   5   NaN   NaN   NaN   NaN   NaN
   6   NaN   NaN   NaN   NaN   NaN
...   ...   ...   ...   ...   ...
 993   NaN   NaN   NaN   NaN   NaN
 994   NaN   NaN   NaN 0.972191   NaN
 995   NaN 0.979898 0.97901   NaN   NaN
 996   NaN   NaN   NaN   NaN   NaN
 997   NaN   NaN   NaN   NaN   NaN
 998   NaN   NaN   NaN   NaN   NaN
 999   NaN   NaN   NaN   NaN   NaN

[1000 rows x 5 columns]
```

To convert a `SparseDataFrame` back to sparse SciPy matrix in COO format, you can use:

```python
In [52]: sdf.to_coo()
Out[52]:
<1000x5 sparse matrix of type '<class 'numpy.float64'>'>
          with 521 stored elements in COOrdinate format>
```

88 Chapter 1. What's New
1.7.1.11 Excel output for styled DataFrames

Experimental support has been added to export DataFrame.style formats to Excel using the openpyxl engine. (GH15530)

For example, after running the following, styled.xlsx renders as below:

```python
In [53]: np.random.seed(24)
In [54]: df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
In [55]: df = pd.concat([df, pd.DataFrame(np.random.RandomState(24).randn(10, 4),
                     columns=list('BCDE'))],
                      axis=1)
In [56]: df.iloc[0, 2] = np.nan
In [57]: df
Out[57]:
    A      B       C        D       E

   .....:
In [59]: styled.to_excel('styled.xlsx', engine='openpyxl')
```
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

1.7.1.12 IntervalIndex

pandas has gained an `IntervalIndex` with its own dtype, `interval` as well as the `Interval` scalar type. These allow first-class support for interval notation, specifically as a return type for the categories in `cut()` and `qcut()`. The `IntervalIndex` allows some unique indexing, see the docs. (GH7640, GH8625)

**Warning:** These indexing behaviors of the `IntervalIndex` are provisional and may change in a future version of pandas. Feedback on usage is welcome.

Previous behavior:

The returned categories were strings, representing Intervals

```
In [1]: c = pd.cut(range(4), bins=2)
In [2]: c
Out[2]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3], (1.5, 3]
Categories (2, object): [(-0.003, 1.5] < (1.5, 3]
```

New behavior:

```
In [60]: c = pd.cut(range(4), bins=2)
In [61]: c
Out[61]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]
```

(continues on next page)
Furthermore, this allows one to bin other data with these same bins, with NaN representing a missing value similar to other dtypes.

```python
In [63]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[63]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]
Categories (2, interval[float64]): [(-0.003, 1.5] < (1.5, 3.0]
```

An `IntervalIndex` can also be used in `Series` and `DataFrame` as the index.

```python
In [64]: df = pd.DataFrame({'A': range(4),
....:                      'B': pd.cut([0, 3, 1, 1], bins=c.categories)}
....:               ).set_index('B')
In [65]: df
Out[65]:
   A  B
0 (-0.003, 1.5] 0
1 (1.5, 3.0] 1
2 (-0.003, 1.5] 2
3 (-0.003, 1.5] 3
```

Selecting via a specific interval:

```python
In [66]: df.loc[pd.Interval(1.5, 3.0)]
Out[66]:
       A
Name: (1.5, 3.0], dtype: int64
```

Selecting via a scalar value that is contained in the intervals.

```python
In [67]: df.loc[0]
Out[67]:
   A  B
0 (-0.003, 1.5] 0
1 (-0.003, 1.5] 2
2 (-0.003, 1.5] 3
```

### 1.7.1.13 Other Enhancements

- `DataFrame.rolling()` now accepts the parameter `closed='right'|'left'|'both'|'neither'` to choose the rolling window-endpoint closedness. See the documentation (GH13965)
• Integration with the feather-format, including a new top-level `pd.read_feather()` and `DataFrame.to_feather()` method, see here.
• `Series.str.replace()` now accepts a callable, as replacement, which is passed to `re.sub` (GH15055)
• `Series.str.replace()` now accepts a compiled regular expression as a pattern (GH15446)
• `Series.sort_index` accepts parameters `kind` and `na_position` (GH13589, GH14444)
• `DataFrame` and `DataFrame.groupby()` have gained a `nunique()` method to count the distinct values over an axis (GH14336, GH15197).
• `DataFrame` has gained a `melt()` method, equivalent to `pd.melt()`, for unpivoting from a wide to long format (GH12640).
• `pd.read_excel()` now preserves sheet order when using `sheetname=None` (GH9930)
• Multiple offset aliases with decimal points are now supported (e.g. `0.5min` is parsed as `30s`) (GH8419)
• `.isnull()` and `.notnull()` have been added to `Index` object to make them more consistent with the `Series` API (GH15300)
• New `UnsortedIndexError` (subclass of `KeyError`) raised when indexing/slicing into an unsorted `MultiIndex` (GH11897). This allows differentiation between errors due to lack of sorting or an incorrect key. See here
• `MultiIndex` has gained a `.to_frame()` method to convert to a `DataFrame` (GH12397)
• `pd.cut` and `pd.qcut` now support `datetime64` and `timedelta64` dtypes (GH14714, GH14798)
• `pd.qcut` has gained the `duplicates='raise'`|`'drop'` option to control whether to raise on duplicated edges (GH7751)
• `Series` provides a `to_excel` method to output Excel files (GH8825)
• The `usecols` argument in `pd.read_csv()` now accepts a callable function as a value (GH14154)
• The `skiprows` argument in `pd.read_csv()` now accepts a callable function as a value (GH10882)
• The `nrows` and `chunksize` arguments in `pd.read_csv()` are supported if both are passed (GH6774, GH15755)
• `DataFrame.plot` now prints a title above each subplot if `subplots=True` and `title` is a list of strings (GH14753)
• `DataFrame.plot` can pass the matplotlib 2.0 default color cycle as a single string as color parameter, see here. (GH15516)
• `Series.interpolate()` now supports `timedelta` as an index type with `method='time'` (GH6424)
• Addition of a `level` keyword to `DataFrame/Series.rename` to rename labels in the specified level of a `MultiIndex` (GH4160).
• `DataFrame.reset_index()` will now interpret a tuple `index.name` as a key spanning across levels of columns, if this is a `MultiIndex` (GH16164)
• `Timedelta.isoformat` method added for formatting `Timedeltas` as an ISO 8601 duration. See the `Timedelta docs` (GH15136)
• `.select_dtypes()` now allows the string `datetimetz` to generically select datetimes with `tz` (GH14910)
• The `.to_latex()` method will now accept `multicolumn` and `multirow` arguments to use the accompanying LaTeX enhancements
• `pd.merge_asof()` gained the option `direction='backward'`|`'forward'`|`'nearest'` (GH14887)
• Series/DataFrame.asfreq() have gained a fill_value parameter, to fill missing values (GH3715).
• Series/DataFrame.resample.asfreq() have gained a fill_value parameter, to fill missing values during resampling (GH3715).
• pandas.util.hash_pandas_object() has gained the ability to hash a MultiIndex (GH15224).
• Series/DataFrame.squeeze() have gained the axis parameter. (GH15339)
• DataFrame.to_excel() has a new freeze_panes parameter to turn on Freeze Panes when exporting to Excel (GH15160).
• pd.read_html() will parse multiple header rows, creating a MultiIndex header. (GH13434).
• HTML table output skips colspan or rowspan attribute if equal to 1. (GH15403)
• pandas.io.formats.style.Styler template now has blocks for easier extension, see the example notebook (GH15649).
• Styler.render() now accepts **kwargs to allow user-defined variables in the template (GH15649).
• Compatibility with Jupyter notebook 5.0; MultiIndex column labels are left-aligned and MultiIndex row-labels are top-aligned (GH15379).
• TimedeltaIndex now has a custom date-tick formatter specifically designed for nanosecond level precision (GH8711).
• pd.api.types.union_categoricals gained the ignore_ordered argument to allow ignoring the ordered attribute of unioned categoricals (GH13410). See the categorical union docs for more information.
• DataFrame.to_latex() and DataFrame.to_string() now allow optional header aliases. (GH15536)
• Re-enable the parse_dates keyword of pd.read_excel() to parse string columns as dates (GH14326).
• Added .empty property to subclasses of Index. (GH15270)
• Enabled floor division for Timedelta and TimedeltaIndex (GH15828).
• pandas.io.json.json_normalize() gained the option errors='ignore' | 'raise'; the default is errors='raise' which is backward compatible. (GH14583). 
• pandas.io.json.json_normalize() with an empty list will return an empty DataFrame (GH15534).
• pandas.io.json.json_normalize() has gained a sep option that accepts str to separate joined fields; the default is "." which is backward compatible. (GH14883).
• MultiIndex.remove_unused_levels() has been added to facilitate removing unused levels. (GH15694)
• pd.read_csv() will now raise a ParserError error whenever any parsing error occurs (GH15913, GH15925).
• pd.read_csv() now supports the error_bad_lines and warn_bad_lines arguments for the Python parser (GH15925).
• The display.show_dimensions option can now also be used to specify whether the length of a Series should be shown in its repr (GH7117).
• parallel_coordinates() has gained a sort_labels keyword argument that sorts class labels and the colors assigned to them (GH15908).
• Options added to allow one to turn on/off using bottleneck and numexpr, see here (GH16157).
- DataFrame.style.bar() now accepts two more options to further customize the bar chart. Bar alignment is set with align='left'|'mid'|'zero', the default is “left”, which is backward compatible; You can now pass a list of color=[color_negative, color_positive]. (GH14757)

1.7.2 Backwards incompatible API changes

1.7.2.1 Possible incompatibility for HDF5 formats created with pandas < 0.13.0

pd.TimeSeries was deprecated officially in 0.17.0, though has already been an alias since 0.13.0. It has been dropped in favor of pd.Series. (GH15098).

This may cause HDF5 files that were created in prior versions to become unreadable if pd.TimeSeries was used. This is most likely to be for pandas < 0.13.0. If you find yourself in this situation. You can use a recent prior version of pandas to read in your HDF5 files, then write them out again after applying the procedure below.

```python
In [2]: s = pd.TimeSeries([1,2,3], index=pd.date_range('20130101', periods=3))
In [3]: s
Out[3]:
Freq: D, dtype: int64
2013-01-01  1
2013-01-02  2
2013-01-03  3
In [4]: type(s)
Out[4]: pandas.core.series.TimeSeries
In [5]: s = pd.Series(s)
In [6]: s
Out[6]:
Freq: D, dtype: int64
2013-01-01  1
2013-01-02  2
2013-01-03  3
In [7]: type(s)
Out[7]: pandas.core.series.Series
```

1.7.2.2 Map on Index types now return other Index types

map on an Index now returns an Index, not a numpy array (GH12766)

```python
In [68]: idx = Index([1, 2])
In [69]: idx
Out[69]: Int64Index([1, 2], dtype='int64')
In [70]: mi = MultiIndex.from_tuples([(1, 2), (2, 4)])
In [71]: mi
Out[71]: MultiIndex(levels=[(1, 2), (2, 4)],
labels=[[0, 1], [0, 1]])
```

Previous Behavior:
In [5]: idx.map(lambda x: x * 2)
Out[5]: array([2, 4])

In [6]: idx.map(lambda x: (x, x * 2))
Out[6]: array([(1, 2), (2, 4)], dtype=object)

In [7]: mi.map(lambda x: x)
Out[7]: array([(1, 2), (2, 4)], dtype=object)

In [8]: mi.map(lambda x: x[0])
Out[8]: array([1, 2])

New Behavior:

In [72]: idx.map(lambda x: x * 2)
Out[72]: Int64Index([2, 4], dtype='int64')

In [73]: idx.map(lambda x: (x, x * 2))
Out[73]: MultiIndex(levels=[1, 2], labels=[0, 1], [0, 1])

In [74]: mi.map(lambda x: x)
Out[74]: MultiIndex(levels=[1, 2], labels=[0, 1], [0, 1])

In [75]: mi.map(lambda x: x[0])
Out[75]: Int64Index([1, 2], dtype='int64')

map on a Series with datetime64 values may return int64 dtypes rather than int32

In [76]: s = Series(date_range('2011-01-02T00:00', '2011-01-02T02:00', freq='H').tz_localize('Asia/Tokyo'))

In [77]: s
Out[77]:
0 2011-01-02 00:00:00+09:00
1 2011-01-02 01:00:00+09:00
2 2011-01-02 02:00:00+09:00
dtype: datetime64[ns, Asia/Tokyo]

Previous Behavior:

In [9]: s.map(lambda x: x.hour)
Out[9]:
0 0
1 1
2 2
dtype: int32

New Behavior:

In [78]: s.map(lambda x: x.hour)
Out[78]: (continues on next page)
1.7.2.3 Accessing datetime fields of Index now return Index

The datetime-related attributes (see here for an overview) of DatetimeIndex, PeriodIndex and TimedeltaIndex previously returned numpy arrays. They will now return a new Index object, except in the case of a boolean field, where the result will still be a boolean ndarray. (GH15022)

Previous behaviour:

```
In [1]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [2]: idx.hour
Out[2]: array([ 0, 10, 20, 6, 16], dtype=int32)
```

New Behavior:

```
In [79]: idx = pd.date_range("2015-01-01", periods=5, freq='10H')
In [80]: idx.hour
Out[80]: Int64Index([0, 10, 20, 6, 16], dtype='int64')
```

This has the advantage that specific Index methods are still available on the result. On the other hand, this might have backward incompatibilities: e.g. compared to numpy arrays, Index objects are not mutable. To get the original ndarray, you can always convert explicitly using np.asarray(idx.hour).

1.7.2.4 pd.unique will now be consistent with extension types

In prior versions, using Series.unique() and pandas.unique() on Categorical and tz-aware data-types would yield different return types. These are now made consistent. (GH15903)

- Datetime tz-aware

  Previous behaviour:

  ```
  # Series
  In [5]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                     pd.Timestamp('20160101', tz='US/Eastern')]).unique()
  Out[5]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')
  
  In [6]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                            pd.Timestamp('20160101', tz='US/Eastern')]))
  Out[6]: array([2016-01-01 00:00:00.000000000], dtype='datetime64[ns]')
  ```

  ```
  # Index
  In [7]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                  pd.Timestamp('20160101', tz='US/Eastern')]).unique()
  Out[7]: DatetimeIndex(['2016-01-01 00:00:00-05:00'], dtype='datetime64[ns, US/Eastern]', freq=None)
  ```

(continues on next page)
In [8]: pd.unique([pd.Timestamp('20160101', tz='US/Eastern'),
                     pd.Timestamp('20160101', tz='US/Eastern')])
Out[8]: array(['2016-01-01T05:00:00.000000000'], dtype='datetime64[ns]')

New Behavior:

# Series, returns an array of Timestamp tz-aware
In [81]: pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                 pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[81]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
              dtype=object)

In [82]: pd.unique(pd.Series([pd.Timestamp('20160101', tz='US/Eastern'),
                          pd.Timestamp('20160101', tz='US/Eastern')]))
Out[82]: array([Timestamp('2016-01-01 00:00:00-0500', tz='US/Eastern')],
              dtype=object)

# Index, returns a DatetimeIndex
In [83]: pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
               pd.Timestamp('20160101', tz='US/Eastern')]).unique()
Out[83]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                         dtype='datetime64[ns, US/Eastern]',
                         freq=None)

In [84]: pd.unique(pd.Index([pd.Timestamp('20160101', tz='US/Eastern'),
                          pd.Timestamp('20160101', tz='US/Eastern')]))
Out[84]: DatetimeIndex(['2016-01-01 00:00:00-05:00'],
                         dtype='datetime64[ns, US/Eastern]',
                         freq=None)

• Categoricals

Previous behaviour:

In [1]: pd.Series(list('baabc'), dtype='category').unique()
Out[1]:
[b, a, c]
Categories (3, object): [b, a, c]

In [2]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[2]: array(['b', 'a', 'c'], dtype=object)

New Behavior:

# returns a Categorical
In [85]: pd.Series(list('baabc'), dtype='category').unique()
Out[85]:
[b, a, c]
Categories (3, object): [b, a, c]

In [86]: pd.unique(pd.Series(list('baabc'), dtype='category'))
Out[86]:
[b, a, c]
1.7.2.5 S3 File Handling

pandas now uses s3fs for handling S3 connections. This shouldn’t break any code. However, since s3fs is not a required dependency, you will need to install it separately, like boto in prior versions of pandas. (GH11915).

1.7.2.6 Partial String Indexing Changes

DatetimeIndex Partial String Indexing now works as an exact match, provided that string resolution coincides with index resolution, including a case when both are seconds (GH14826). See Slice vs. Exact Match for details.

In [87]: df = DataFrame({'a': [1, 2, 3]}, DatetimeIndex(['2011-12-31 23:59:59', '2012-01-01 00:00:00', '2012-01-01 00:00:01']))

Previous Behavior:

In [4]: df['2011-12-31 23:59:59']
Out[4]:
   a
2011-12-31 23:59:59    1

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]:
2011-12-31 23:59:59    1
Name: a, dtype: int64

New Behavior:

In [4]: df['2011-12-31 23:59:59']
KeyError: '2011-12-31 23:59:59'

In [5]: df['a']['2011-12-31 23:59:59']
Out[5]: 1

1.7.2.7 Concat of different float dtypes will not automatically upcast

Previously, concat of multiple objects with different float dtypes would automatically upcast results to a dtype of float64. Now the smallest acceptable dtype will be used (GH13247)

In [88]: df1 = pd.DataFrame(np.array([1.0], dtype=np.float32, ndmin=2))
In [89]: df1.dtypes
Out[89]:
0  float32
dtype: object

In [90]: df2 = pd.DataFrame(np.array([np.nan], dtype=np.float32, ndmin=2))
In [91]: df2.dtypes
(continues on next page)
Out[91]:
0    float32
dtype: object

Previous Behavior:

In [7]: pd.concat([df1, df2]).dtypes
Out[7]:
0    float64
dtype: object

New Behavior:

In [92]: pd.concat([df1, df2]).dtypes
Out[92]:
0    float32
dtype: object

1.7.2.8 Pandas Google BigQuery support has moved

pandas has split off Google BigQuery support into a separate package pandas-gbq. You can conda install pandas-gbq -c conda-forge or pip install pandas-gbq to get it. The functionality of read_gbq() and DataFrame.to_gbq() remain the same with the currently released version of pandas-gbq=0.1.4. Documentation is now hosted here (GH15347)

1.7.2.9 Memory Usage for Index is more Accurate

In previous versions, showing .memory_usage() on a pandas structure that has an index, would only include actual index values and not include structures that facilitated fast indexing. This will generally be different for Index and MultiIndex and less-so for other index types. (GH15237)
1.7.2.10 DataFrame.sort_index changes

In certain cases, calling `sort_index()` on a MultiIndexed DataFrame would return the same DataFrame without seeming to sort. This would happen with a lexsorted, but non-monotonic levels. (GH15622, GH15687, GH14015, GH13431, GH15797)

This is unchanged from prior versions, but shown for illustration purposes:

```python
In [95]: df.index.is_lexsorted()
Out[95]: False
```

Sorting works as expected

```python
In [97]: df.sort_index()
Out[97]:
   value
  A 0 3
   1 4
   2 5
  B 0 0
   1 1
   2 2
```

However, this example, which has a non-monotonic 2nd level, doesn’t behave as desired.

```python
In [100]: df = pd.DataFrame(
.....:     {'value': [1, 2, 3, 4]},
.....:     index=pd.MultiIndex(levels=[['a', 'b'], ['bb', 'aa']],
.....:                        labels=[[0, 0, 1, 1], [0, 1, 0, 1]]))
```
In [101]: df
Out[101]:
   value
   a  bb  1
   aa  2
   b  bb  3
   aa  4

Previous Behavior:

In [11]: df.sort_index()
Out[11]:
   value
   a  bb  1
   aa  2
   b  bb  3
   aa  4
In [14]: df.sort_index().index.is_lexsorted()
Out[14]: True
In [15]: df.sort_index().index.is_monotonic
Out[15]: False

New Behavior:

In [102]: df.sort_index()
Out[102]:
   value
   a  aa  2
   bb  1
   b  aa  4
   bb  3
In [103]: df.sort_index().index.is_lexsorted()
Out[103]: True
In [104]: df.sort_index().index.is_monotonic
Out[104]: True

1.7.2.11 Groupby Describe Formatting

The output formatting of `groupby.describe()` now labels the `describe()` metrics in the columns instead of the index. This format is consistent with `groupby.agg()` when applying multiple functions at once. (GH4792)

Previous Behavior:

In [1]: df = pd.DataFrame({'A': [1, 1, 2, 2], 'B': [1, 2, 3, 4]})
In [2]: df.groupby('A').describe()
Out[2]:

In [107]: df.groupby('A').agg([np.mean, np.std, np.min, np.max])

1.7.2.12 Window Binary Corr/Cov operations return a MultiIndex DataFrame

A binary window operation, like .corr() or .cov(), when operating on a .rolling(..),.expanding(..), or .ewm(..) object, will now return a 2-level MultiIndexed DataFrame rather than a Panel, as Panel is now deprecated, see here. These are equivalent in function, but a MultiIndexed DataFrame enjoys more support in pandas. See the section on Windowed Binary Operations for more information. (GH15677)
In [108]: np.random.seed(1234)

In [109]: df = pd.DataFrame(np.random.rand(100, 2),
                      columns=pd.Index(['A', 'B'], name='bar'),
                      index=pd.date_range('20160101',
                                          periods=100, freq='D', name='foo'))

In [110]: df.tail()
Out[110]:
      bar    A    B

      B -0.13209  1.0000

1.7.2.13 HDFStore where string comparison

In previous versions most types could be compared to string column in a HDFStore usually resulting in an invalid comparison, returning an empty result frame. These comparisons will now raise a TypeError (GH15492)
In [114]: df = pd.DataFrame({'unparsed_date': ['2014-01-01', '2014-01-01']})

In [115]: df.to_hdf('store.h5', 'key', format='table', data_columns=True)

In [116]: df.dtypes
Out[116]:
unparsed_date    object
dtype: object

Previous Behavior:

In [4]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
File "<string>", line 1
  (unparsed_date > 1970-01-01 00:00:00)
^  
SyntaxError: invalid token

New Behavior:

In [18]: ts = pd.Timestamp('2014-01-01')

In [19]: pd.read_hdf('store.h5', 'key', where='unparsed_date > ts')
TypeError: Cannot compare 2014-01-01 00:00:00 of type <class 'pandas.tslib.Timestamp'> to string column

1.7.2.14 Index.intersection and inner join now preserve the order of the left Index

`Index.intersection()` now preserves the order of the calling Index (left) instead of the other Index (right) (GH15582). This affects inner joins, `DataFrame.join()` and `merge()`, and the `.align` method.

- Index.intersection

In [117]: left = pd.Index([2, 1, 0])

In [118]: left
Out[118]: Int64Index([2, 1, 0], dtype='int64')

In [119]: right = pd.Index([1, 2, 3])

In [120]: right
Out[120]: Int64Index([1, 2, 3], dtype='int64')

Previous Behavior:

In [4]: left.intersection(right)
Out[4]: Int64Index([1, 2], dtype='int64')

New Behavior:

In [121]: left.intersection(right)
Out[121]: Int64Index([2, 1], dtype='int64')

- DataFrame.join and pd.merge

In [122]: left = pd.DataFrame({'a': [20, 10, 0]}, index=[2, 1, 0])
In [123]: left
Out[123]:
   a
0  0
1  10
2  20

In [124]: right = pd.DataFrame({'b': [100, 200, 300]}, index=[1, 2, 3])

In [125]: right
Out[125]:
   b
1  100
2  200
3  300

Previous Behavior:

In [4]: left.join(right, how='inner')
Out[4]:
   a   b
0  0   0
1  10  100
2  20  200

New Behavior:

In [126]: left.join(right, how='inner')
Out[126]:
   a   b
0  0   0
1  10  100
2  20  200

1.7.2.15 Pivot Table always returns a DataFrame

The documentation for `pivot_table()` states that a DataFrame is always returned. Here a bug is fixed that allowed this to return a Series under certain circumstance. (GH4386)

In [127]: df = DataFrame({'col1': [3, 4, 5],
                    'col2': ['C', 'D', 'E'],
                    'col3': [1, 3, 9]})

In [128]: df
Out[128]:
   col1 col2 col3
0   3    C   1
1   4    D   3
2   5    E   9

Previous Behavior:

In [2]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[2]:
   col3  col2
0     C    1
1     C    3
New Behavior:

```plaintext
In [129]: df.pivot_table('col1', index=['col3', 'col2'], aggfunc=np.sum)
Out[129]:
   col1
col3 col2
1  C  3
3  D  4
9  E  5
```

1.7.2.16 Other API Changes

- `numexpr` version is now required to be >= 2.4.6 and it will not be used at all if this requisite is not fulfilled (GH15213).
- `CParserError` has been renamed to `ParserError` in `pd.read_csv()` and will be removed in the future (GH12665)
- `SparseArray.cumsum()` and `SparseSeries.cumsum()` will now always return `SparseArray` and `SparseSeries` respectively (GH12855)
- `DataFrame.applymap()` with an empty `DataFrame` will return a copy of the empty `DataFrame` instead of a `Series` (GH8222)
- `Series.map()` now respects default values of dictionary subclasses with a `__missing__` method, such as `collections.Counter` (GH15999)
- `.loc` has compat with `.ix` for accepting iterators, and NamedTuples (GH15120)
- `interpolate()` and `fillna()` will raise a `ValueError` if the `limit` keyword argument is not greater than 0. (GH9217)
- `pd.read_csv()` will now issue a `ParserWarning` whenever there are conflicting values provided by the `dialect` parameter and the user (GH14898)
- `pd.read_csv()` will now raise a `ValueError` for the C engine if the quote character is larger than than one byte (GH11592)
- `inplace` arguments now require a boolean value, else a `ValueError` is thrown (GH14189)
- `pandas.api.types.is_datetime64_ns_dtype` will now report `True` on a tz-aware dtype, similar to `pandas.api.types.is_datetime64_any_dtype`
- `DataFrame.asof()` will return a null filled `Series` instead the scalar `NaN` if a match is not found (GH15118)
- Specific support for `copy.copy()` and `copy.deepcopy()` functions on `NDFrame` objects (GH15444)
- `Series.sort_values()` accepts a one element list of bool for consistency with the behavior of `DataFrame.sort_values()` (GH15604)
- `.merge()` and `.join()` on category dtype columns will now preserve the category dtype when possible (GH10409)
- `SparseDataFrame.default_fill_value` will be 0, previously was `nan` in the return from `pd.get_dummies(..., sparse=True)` (GH15594)
• The default behaviour of `Series.str.match` has changed from extracting groups to matching the pattern. The extracting behaviour was deprecated since pandas version 0.13.0 and can be done with the `Series.str.extract` method (GH5224). As a consequence, the `as_indexer` keyword is ignored (no longer needed to specify the new behaviour) and is deprecated.

• `NaT` will now correctly report `False` for datetimelike boolean operations such as `is_month_start` (GH15781)

• `NaT` will now correctly return `np.nan` for `Timedelta` and `Period` accessors such as `days` and `quarter` (GH15782)

• `NaT` will now return `NaT` for `tz_localize` and `tz_convert` methods (GH15830)

• `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `PandasError`, if called with scalar inputs and not axes (GH15541)

• `DataFrame` and `Panel` constructors with invalid input will now raise `ValueError` rather than `pandas.core.common.PandasError`, if called with scalar inputs and not axes; The exception `PandasError` is removed as well. (GH15541)

• The exception `pandas.core.common.AmbiguousIndexError` is removed as it is not referenced (GH15541)

1.7.3 Reorganization of the library: Privacy Changes

1.7.3.1 Modules Privacy Has Changed

Some formerly public python/c/c++/cython extension modules have been moved and/or renamed. These are all removed from the public API. Furthermore, the `pandas.core`, `pandas.compat`, and `pandas.util` top-level modules are now considered to be PRIVATE. If indicated, a deprecation warning will be issued if you reference theses modules. (GH12588)

</table>
Some new subpackages are created with public functionality that is not directly exposed in the top-level namespace: `pandas.errors`, `pandas.plotting` and `pandas.testing` (more details below). Together with `pandas.api.types` and certain functions in the `pandas.io` and `pandas.tseries` submodules, these are now the public subpackages.

Further changes:

- The function `union_categoricals()` is now importable from `pandas.api.types`, formerly from `pandas.types.concat` (GH15998)
- The type import `pandas.tslib.NaTType` is deprecated and can be replaced by using `type(pandas.NaT)` (GH16146)
- The public functions in `pandas.tools.hashing` deprecated from that locations, but are now importable from `pandas.util` (GH16223)
- The modules in `pandas.util`: decorators, print_versions, doctools, validators, depr_module are now private. Only the functions exposed in `pandas.util` itself are public (GH16223)

### 1.7.3.2 pandas.errors

We are adding a standard public module for all pandas exceptions & warnings `pandas.errors`. (GH14800). Previously these exceptions & warnings could be imported from `pandas.core.common` or `pandas.io.common`. These exceptions and warnings will be removed from the `*.common` locations in a future release. (GH15541)

The following are now part of this API:

```python
['DtypeWarning',
 'EmptyDataError',
 'OutOfBoundsDatetime',
 'ParserError',
 'ParserWarning',
 'PerformanceWarning',
 'UnsortedIndexError',
 'UnsupportedFunctionCall']
```

### 1.7.3.3 pandas.testing

We are adding a standard module that exposes the public testing functions in `pandas.testing` (GH9895). Those functions can be used when writing tests for functionality using pandas objects.

The following testing functions are now part of this API:

- `testing.assert_frame_equal()`
- `testing.assert_series_equal()`
- `testing.assert_index_equal()`

### 1.7.3.4 pandas.plotting

A new public `pandas.plotting` module has been added that holds plotting functionality that was previously in either `pandas.tools.plotting` or in the top-level namespace. See the deprecations sections for more details.
1.7.3.5 Other Development Changes

- Building pandas for development now requires cython >= 0.23 (GH14831)
- Require at least 0.23 version of cython to avoid problems with character encodings (GH14699)
- Switched the test framework to use pytest (GH13097)
- Reorganization of tests directory layout (GH14854, GH15707).

1.7.4 Deprecations

1.7.4.1 Deprecate .ix

The .ix indexer is deprecated, in favor of the more strict .iloc and .loc indexers. .ix offers a lot of magic on the inference of what the user wants to do. To wit, .ix can decide to index *positionally OR via labels*, depending on the data type of the index. This has caused quite a bit of user confusion over the years. The full indexing documentation is [here](#).(GH14218)

The recommended methods of indexing are:

- .loc if you want to *label* index
- .iloc if you want to *positionally* index.

Using .ix will now show a DeprecationWarning with a link to some examples of how to convert code [here](#).

```python
In [130]: df = pd.DataFrame({'A': [1, 2, 3],
                        ....: 'B': [4, 5, 6]},
                        ....: index=list('abc'))

In [131]: df
Out[131]:
   A  B
  a 1 4
  b 2 5
  c 3 6

Previous Behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```python
In [3]: df.ix[[0, 2], 'A']
Out[3]:
   a 1 4
   c 3
Name: A, dtype: int64
```

Using .loc. Here we will select the appropriate indexes from the index, then use *label* indexing.

```python
In [132]: df.loc[df.index[[0, 2]], 'A']
Out[132]:
   a 1
   c 3
Name: A, dtype: int64
```

Using .iloc. Here we will get the location of the ‘A’ column, then use *positional* indexing to select things.
In [133]: df.iloc[[0, 2], df.columns.get_loc('A')]
Out[133]:
   a  
0  1  
1  c  3
Name: A, dtype: int64

1.7.4.2 Deprecate Panel

Panel is deprecated and will be removed in a future version. The recommended way to represent 3-D data are with a MultiIndex on a DataFrame via the `to_frame()` or with the xarray package. Pandas provides a `to_xarray()` method to automate this conversion. For more details see Deprecate Panel documentation. (GH13563).

In [134]: p = tm.makePanel()

In [135]: p
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame

In [136]: p.to_frame()
Out[136]:
      ItemA  ItemB  ItemC
major minor
2000-01-03  A   0.628776 -1.409432  0.209395
          B   0.988138 -1.347533 -0.896581
          C  -0.938153  1.272395 -0.161137

        [ 0.988138, -1.347533, -0.896581, -0.591863],
        [ 0.628776,  0.988138, -0.938153, -0.223019]],
       [ 0.988138, -1.347533, -0.896581, -0.591863],
       [ 0.628776,  0.988138, -0.938153, -0.223019]]),
(continues on next page)
1.7.4.3 Deprecate groupby.agg() with a dictionary when renaming

The `.groupby(..).agg(..), .rolling(..).agg(..), and .resample(..).agg(..)` syntax can accept a variable of inputs, including scalars, list, and a dict of column names to scalars or lists. This provides a useful syntax for constructing multiple (potentially different) aggregations.

However, `.agg(..)` can also accept a dict that allows ‘renaming’ of the result columns. This is a complicated and confusing syntax, as well as not consistent between `Series` and `DataFrame`. We are deprecating this ‘renaming’ functionality.

* We are deprecating passing a dict to a grouped/rolled/resampled `Series`. This allowed one to rename the resulting aggregation, but this had a completely different meaning than passing a dictionary to a grouped `DataFrame`, which accepts column-to-aggregations.

* We are deprecating passing a dict-of-dicts to a grouped/rolled/resampled `DataFrame` in a similar manner.

This is an illustrative example:

```python
In [138]: df = pd.DataFrame({'A': [1, 1, 1, 2, 2], 'B': range(5), 'C': range(5)})

In [139]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
```

Here is a typical useful syntax for computing different aggregations for different columns. This is a natural, and useful syntax. We aggregate from the dict-to-list by taking the specified columns and applying the list of functions. This returns a MultiIndex for the columns (this is not deprecated).

```python
In [140]: df.groupby('A').agg({'B': 'sum', 'C': 'min'})
```

Here’s an example of the first deprecation, passing a dict to a grouped `Series`. This is a combination aggregation & renaming:

```python
In [6]: df.groupby('A').B.agg({'foo': 'count'})
```

(continues on next page)
You can accomplish the same operation, more idiomatically by:

```
In [141]: df.groupby('A').B.agg({'count': 'foo'}).rename(columns={'count': 'foo'})
```

```
Out[141]:
     foo
   A
1  3
2  2
```

Here’s an example of the second deprecation, passing a dict-of-dict to a grouped DataFrame:

```
In [23]: (df.groupby('A')
    .agg({'B': {'foo': 'sum'}, 'C': {'bar': 'min'}})
```

```
FutureWarning: using a dict with renaming is deprecated and will be removed in a future version
```

```
Out[23]:
      B   C
     foo bar
   A
1  3  0
2  7  3
```

You can accomplish nearly the same by:

```
In [142]: (df.groupby('A')
    .......
    .agg({'B': 'sum', 'C': 'min'})
    .......
    .rename(columns={'B': 'foo', 'C': 'bar'})
    .......
```

```
Out[142]:
     foo  bar
   A
1  3  0
2  7  3
```

### 1.7.4.4 Deprecate .plotting

The `pandas.tools.plotting` module has been deprecated, in favor of the top level `pandas.plotting` module. All the public plotting functions are now available from `pandas.plotting` (GH12548).

Furthermore, the top-level `pandas.scatter_matrix` and `pandas.plot_params` are deprecated. Users can import these from `pandas.plotting` as well.

Previous script:
pd.tools.plotting.scatter_matrix(df)
pd.scatter_matrix(df)

Should be changed to:

pd.plotting.scatter_matrix(df)

1.7.4.5 Other Deprecations

- `SparseArray.to_dense()` has deprecated the `fill` parameter, as that parameter was not being respected (GH14647)
- `SparseSeries.to_dense()` has deprecated the `sparse_only` parameter (GH14647)
- `Series.repeat()` has deprecated the `reps` parameter in favor of `repeats` (GH12662)
- The `Series` constructor and `.astype` method have deprecated accepting timestamp dtypes without a frequency (e.g. `np.datetime64`) for the `dtype` parameter (GH15524)
- `Index.repeat()` and `MultiIndex.repeat()` have deprecated the `n` parameter in favor of `repeats` (GH12662)
- `Categorical.searchsorted()` and `Series.searchsorted()` have deprecated the `v` parameter in favor of `value` (GH12662)
- `TimedeltaIndex.searchsorted()`, `DatetimeIndex.searchsorted()`, and `PeriodIndex.searchsorted()` have deprecated the `key` parameter in favor of `value` (GH12662)
- `DataFrame.astype()` has deprecated the `raise_on_error` parameter in favor of `errors` (GH14878)
- `Series.sortlevel` and `DataFrame.sortlevel` have been deprecated in favor of `Series.sort_index` and `DataFrame.sort_index` (GH15099)
- importing `concat` from `pandas.tools.merge` has been deprecated in favor of imports from the `pandas` namespace. This should only affect explicit imports (GH15358)
- `Series/DataFrame/Panel.consolidate()` been deprecated as a public method. (GH15483)
- The `as_indexer` keyword of `Series.str.match()` has been deprecated (ignored keyword) (GH15257).
- The following top-level pandas functions have been deprecated and will be removed in a future version (GH13790, GH15940)
  - `pd.pnow()`, replaced by `Period.now()`
  - `pd.Term`, is removed, as it is not applicable to user code. Instead use in-line string expressions in the where clause when searching in HDFStore
  - `pd.Expr`, is removed, as it is not applicable to user code.
  - `pd.match()`, is removed.
  - `pd.groupby()`, replaced by using the `.groupby()` method directly on a Series/DataFrame
  - `pd.get_store()`, replaced by a direct call to `pd.HDFStore(...)`
- `is_any_int_dtype`, `is_floating_dtype`, and `is_sequence` are deprecated from `pandas.api.types` (GH16042)
1.7.5 Removal of prior version deprecations/changes

- The pandas.rpy module is removed. Similar functionality can be accessed through the rpy2 project. See the *R interfacing docs* for more details.

- The pandas.io.ga module with a google-analytics interface is removed (GH11308). Similar functionality can be found in the Google2Pandas package.

- pd.to_datetime and pd.to_timedelta have dropped the coerce parameter in favor of errors (GH13602)

- pandas.stats.fama_macbeth, pandas.stats.ols, pandas.stats.plm and pandas.stats.var, as well as the top-level pandas.fama_macbeth and pandas.ols routines are removed. Similar functionality can be found in the statsmodels package. (GH11898)

- The TimeSeries and SparseTimeSeries classes, aliases of Series and SparseSeries, are removed (GH10890, GH15098).

- Series.is_time_series is dropped in favor of Series.index.is_all_dates (GH15098)

- The deprecated irow, icol, iget and iget_value methods are removed in favor of iloc and iat as explained here (GH10711).

- The deprecated DataFrame.iterkv() has been removed in favor of DataFrame.iteritems() (GH10711)

- The Categorical constructor has dropped the name parameter (GH10632)

- Categorical has dropped support for NaN categories (GH10748)

- The take_last parameter has been dropped from duplicated(), drop_duplicates(), nlargest(), and nsmallest() methods (GH10236, GH10792, GH10920)

- Series, Index, and DataFrame have dropped the sort and order methods (GH10726)

- Where clauses in pytables are only accepted as strings and expressions types and not other data-types (GH12027)

- DataFrame has dropped the combineAdd and combineMult methods in favor of add and mul respectively (GH10735)

1.7.6 Performance Improvements

- Improved performance of pd.wide_to_long() (GH14779)

- Improved performance of pd.factorize() by releasing the GIL with object dtype when inferred as strings (GH14859, GH16057)

- Improved performance of timeseries plotting with an irregular DatetimeIndex (or with compat_x=True) (GH15073).

- Improved performance of groupby().cummin() and groupby().cummax() (GH15048, GH15109, GH15561, GH15635)

- Improved performance and reduced memory when indexing with a MultiIndex (GH15245)

- When reading buffer object in read_sas() method without specified format, filepath string is inferred rather than buffer object. (GH14947)

- Improved performance of .rank() for categorical data (GH15498)

- Improved performance when using .unstack() (GH15503)
• Improved performance of merge/join on category columns (GH10409)
• Improved performance of drop_duplicates() on bool columns (GH12963)
• Improve performance of pd.core.groupby.GroupBy.apply when the applied function used the .name attribute of the group DataFrame (GH15062).
• Improved performance of iloc indexing with a list or array (GH15504).
• Improved performance of Series.sort_index() with a monotonic index (GH15694)
• Improved performance in pd.read_csv() on some platforms with buffered reads (GH16039)

1.7.7 Bug Fixes

1.7.7.1 Conversion

• Bug in Timestamp.replace now raises TypeError when incorrect argument names are given; previously this raised ValueError (GH15240)
• Bug in Timestamp.replace with compat for passing long integers (GH15030)
• Bug in Timestamp returning UTC based time/date attributes when a timezone was provided (GH13303, GH6538)
• Bug in Timestamp incorrectly localizing timezones during construction (GH11481, GH15777)
• Bug in TimedeltaIndex addition where overflow was being allowed without error (GH14816)
• Bug in TimedeltaIndex raising a ValueError when boolean indexing with loc (GH14946)
• Bug in catching an overflow in Timestamp + Timedelta/Offset operations (GH15126)
• Bug in DatetimeIndex.round() and Timestamp.round() floating point accuracy when rounding by milliseconds or less (GH14440, GH15578)
• Bug in astype() where inf values were incorrectly converted to integers. Now raises error now with astype() for Series and DataFrames (GH14265)
• Bug in DataFrame(...).apply(to_numeric) when values are of type decimal.Decimal. (GH14827)
• Bug in describe() when passing a numpy array which does not contain the median to the percentiles keyword argument (GH14908)
• Cleaned up PeriodIndex constructor, including raising on floats more consistently (GH13277)
• Bug in using __deepcopy__ on empty NDFrame objects (GH15370)
• Bug in .replace() may result in incorrect dtypes. (GH12747, GH15765)
• Bug in Series.replace and DataFrame.replace which failed on empty replacement dicts (GH15289)
• Bug in Series.replace which replaced a numeric by string (GH15743)
• Bug in Index construction with NaN elements and integer dtype specified (GH15187)
• Bug in Series construction with a datetimetz (GH14928)
• Bug in Series.dt.round() inconsistent behaviour on NaT `s with different arguments (GH14940)
• Bug in Series constructor when both copy=True and dtype arguments are provided (GH15125)
• Incorrect dtyped Series was returned by comparison methods (e.g., lt, gt, ...) against a constant for an empty DataFrame (GH15077)
• Bug in Series.ffill() with mixed dtypes containing tz-aware datetimes. (GH14956)
• Bug in DataFrame.fillna() where the argument downcast was ignored when fillna value was of type dict (GH15277)
• Bug in .asfreq(), where frequency was not set for empty Series (GH14320)
• Bug in DataFrame construction with nulls and datetimes in a list-like (GH15869)
• Bug in DataFrame.fillna() with tz-aware datetimes (GH15855)
• Bug in is_string_dtype, is_timedelta64_ns_dtype, and is_string_like_dtype in which an error was raised when None was passed in (GH15941)
• Bug in the return type of pd.unique on a Categorical, which was returning an ndarray and not a Categorical (GH15903)
• Bug in Index.to_series() where the index was not copied (and so mutating later would change the original), (GH15949)
• Bug in indexing with partial string indexing with a len-1 DataFrame (GH16071)
• Bug in Series construction where passing invalid dtype didn’t raise an error. (GH15520)

1.7.7.2 Indexing

• Bug in Index power operations with reversed operands (GH14973)
• Bug in DataFrame.sort_values() when sorting by multiple columns where one column is of type int64 and contains NaT (GH14922)
• Bug in DataFrame.reindex() in which method was ignored when passing columns (GH14992)
• Bug in DataFrame.loc with indexing a MultiIndex with a Series indexer (GH14730, GH15424)
• Bug in DataFrame.loc with indexing a MultiIndex with a numpy array (GH15434)
• Bug in Series.asof which raised if the series contained all np.nan (GH15713)
• Bug in .at when selecting from a tz-aware column (GH15822)
• Bug in Series.where() and DataFrame.where() where array-like conditionals were being rejected (GH15414)
• Bug in Series.where() where TZ-aware data was converted to float representation (GH15701)
• Bug in .loc that would not return the correct dtype for scalar access for a DataFrame (GH11617)
• Bug in output formatting of a MultiIndex when names are integers (GH12223, GH15262)
• Bug in Categorical.searchsorted() where alphabetical instead of the provided categorical order was used (GH14522)
• Bug in Series.iloc where a Categorical object for list-like indexes input was returned, where a Series was expected. (GH14580)
• Bug in DataFrame.isin comparing datetimelike to empty frame (GH15473)
• Bug in .reset_index() when an all NaN level of a MultiIndex would fail (GH6322)
• Bug in .reset_index() when raising error for index name already present in MultiIndex columns (GH16120)
• Bug in creating a MultiIndex with tuples and not passing a list of names; this will now raise ValueError (GH15110)
• Bug in the HTML display with with a MultiIndex and truncation (GH14882)
• Bug in the display of `.info()` where a qualifier (+) would always be displayed with a MultiIndex that contains only non-strings (GH15245)
• Bug in `pd.concat()` where the names of MultiIndex of resulting DataFrame are not handled correctly when None is presented in the names of MultiIndex of input DataFrame (GH15787)
• Bug in `DataFrame.sort_index()` and `Series.sort_index()` where na_position doesn’t work with a MultiIndex (GH14784, GH16604)
• Bug in `pd.concat()` when combining objects with a CategoricalIndex (GH16111)
• Bug in indexing with a scalar and a CategoricalIndex (GH16123)

1.7.7.3 I/O

• Bug in `pd.to_numeric()` in which float and unsigned integer elements were being improperly casted (GH14941, GH15005)
• Bug in `pd.read_fwf()` where the skiprows parameter was not being respected during column width inference (GH11256)
• Bug in `pd.read_csv()` in which the dialect parameter was not being verified before processing (GH14898)
• Bug in `pd.read_csv()` in which missing data was being improperly handled with usecols (GH6710)
• Bug in `pd.read_csv()` in which a file containing a row with many columns followed by rows with fewer columns would cause a crash (GH14125)
• Bug in `pd.read_csv()` for the C engine where usecols were being indexed incorrectly with parse_dates (GH14792)
• Bug in `pd.read_csv()` with parse_dates when multiline headers are specified (GH15376)
• Bug in `pd.read_csv()` with float_precision='round_trip' which caused a segfault when a text entry is parsed (GH15140)
• Bug in `pd.read_csv()` when an index was specified and no values were specified as null values (GH15835)
• Bug in `pd.read_csv()` in which certain invalid file objects caused the Python interpreter to crash (GH15337)
• Bug in `pd.read_csv()` in which invalid values for nrows and chunksize were allowed (GH15767)
• Bug in `pd.read_csv()` for the Python engine in which unhelpful error messages were being raised when parsing errors occurred (GH15910)
• Bug in `pd.read_csv()` in which the skipfooter parameter was not being properly validated (GH15925)
• Bug in `pd.to_csv()` in which there was numeric overflow when a timestamp index was being written (GH15982)
• Bug in `pd.util.hashing.hash_pandas_object()` in which hashing of categoricals depended on the ordering of categories, instead of just their values. (GH15143)
• Bug in `.to_json()` where lines=True and contents (keys or values) contain escaped characters (GH15096)
• Bug in `.to_json()` causing single byte ascii characters to be expanded to four byte unicode (GH15344)
• Bug in `.to_json()` for the C engine where rollover was not correctly handled for case where frac is odd and diff is exactly 0.5 (GH15716, GH15864)
• Bug in `pd.read_json()` for Python 2 where lines=True and contents contain non-ascii unicode characters (GH15132)
• Bug in `pd.read_msgpack()` in which `Series` categoricals were being improperly processed (GH14901)
• Bug in `pd.read_msgpack()` which did not allow loading of a dataframe with an index of type `CategoricalIndex` (GH15487)
• Bug in `pd.read_msgpack()` when deserializing a `CategoricalIndex` (GH15487)
• Bug in `DataFrame.to_records()` with converting a `DatetimeIndex` with a timezone (GH13937)
• Bug in `DataFrame.to_records()` which failed with unicode characters in column names (GH11879)
• Bug in `.to_sql()` when writing a `DataFrame` with numeric index names (GH15404).
• Bug in `DataFrame.to_html()` with `index=False` and `max_rows` raising in `IndexError` (GH14998)
• Bug in `pd.read_hdf()` passing a `Timestamp` to the `where` parameter with a non date column (GH15492)
• Bug in `DataFrame.to_stata()` and `StataWriter` which produces incorrectly formatted files to be produced for some locales (GH13856)
• Bug in `StataReader` and `StataWriter` which allows invalid encodings (GH15723)
• Bug in the `Series` repr not showing the length when the output was truncated (GH15962).

1.7.7.4 Plotting

• Bug in `DataFrame.hist` where `plt.tight_layout` caused an `AttributeError` (use `matplotlib >= 2.0.1`) (GH9351)
• Bug in `DataFrame.boxplot` where `fontsize` was not applied to the tick labels on both axes (GH15108)
• Bug in the date and time converters pandas registers with `matplotlib` not handling multiple dimensions (GH16026)
• Bug in `pd.scatter_matrix()` could accept either `color` or `c`, but not both (GH14855)

1.7.7.5 Groupby/Resample/Rolling

• Bug in `.groupby(..).resample()` when passed the `on= kwarg` (GH15021)
• Properly set `__name__` and `__qualname__` for `Groupby.*` functions (GH14620)
• Bug in `GroupBy.get_group()` failing with a categorical grouper (GH15155)
• Bug in `.groupby(...).rolling(...)` when `on` is specified and using a `DatetimeIndex` (GH15130, GH13966)
• Bug in groupby operations with `timedelta64` when passing `numeric_only=False` (GH5724)
• Bug in `groupby.apply()` coercing `object` dtypes to numeric types, when not all values were numeric (GH14423, GH15421, GH15670)
• Bug in `resample`, where a non-string `loffset` argument would not be applied when resampling a timeseries (GH13218)
• Bug in `DataFrame.groupby().describe()` when grouping on `Index` containing tuples (GH14848)
• Bug in `groupby().nunique()` with a datetimelike-grouper where bins counts were incorrect (GH13453)
• Bug in `groupby.transform()` that would coerce the resultant dtypes back to the original (GH10972, GH11444)
• Bug in `groupby.agg()` incorrectly localizing timezone on `datetime` (GH15426, GH10668, GH13046)
• Bug in `.rolling/expanding()` functions where count() was not counting np.inf, nor handling object dtypes (GH12541)
• Bug in `.rolling()` where pd.Timedelta or datetime.timedelta was not accepted as a window argument (GH15440)
• Bug in `Rolling.quantile` function that caused a segmentation fault when called with a quantile value outside of the range [0, 1] (GH15463)
• Bug in `DataFrame.resample().median()` if duplicate column names are present (GH14233)

### 1.7.7.6 Sparse

• Bug in `SparseSeries.reindex` on single level with list of length 1 (GH15447)
• Bug in repr-formatting a `SparseDataFrame` after a value was set on (a copy of) one of its series (GH15488)
• Bug in `SparseDataFrame` construction with lists not coercing to dtype (GH15682)
• Bug in sparse array indexing in which indices were not being validated (GH15863)

### 1.7.7.7 Reshaping

• Bug in `pd.merge_asof()` where `left_index` or `right_index` caused a failure when `multiple by` was specified (GH15676)
• Bug in `pd.merge_asof()` where `left_index/right_index` together caused a failure when `tolerance` was specified (GH15135)
• Bug in `DataFrame.pivot_table()` where `dropna=True` would not drop all-NaN columns when the columns was a category dtype (GH15193)
• Bug in `pd.melt()` where passing a tuple value for `value_vars` caused a TypeError (GH15348)
• Bug in `pd.pivot_table()` where no error was raised when values argument was not in the columns (GH14938)
• Bug in `pd.concat()` in which concatenating with an empty dataframe with `join='inner'` was being improperly handled (GH15328)
• Bug with `sort=True` in `DataFrame.join` and `pd.merge` when joining on indexes (GH15582)
• Bug in `DataFrame.nsmallest` and `DataFrame.nlargest` where identical values resulted in duplicated rows (GH15297)
• Bug in `pandas.pivot_table()` incorrectly raising UnicodeError when passing unicode input for `margins` keyword (GH13292)

### 1.7.7.8 Numeric

• Bug in `.rank()` which incorrectly ranks ordered categories (GH15420)
• Bug in `.corr()` and `.cov()` where the column and index were the same object (GH14617)
• Bug in `.mode()` where `mode` was not returned if was only a single value (GH15714)
• Bug in `pd.cut()` with a single bin on an all 0s array (GH15428)
• Bug in `pd.qcut()` with a single quantile and an array with identical values (GH15431)
• Bug in `pandas.tools.utils.cartesian_product()` with large input can cause overflow on windows (GH15265)
• Bug in `.eval()` which caused multiline evals to fail with local variables not on the first line (GH15342)

1.7.7.9 Other
• Compat with SciPy 0.19.0 for testing on `.interpolate()` (GH15662)
• Compat for 32-bit platforms for `.qcut/cut`; bins will now be int64 dtype (GH14866)
• Bug in interactions with Qt when a QtApplication already exists (GH14372)
• Avoid use of `np.finfo()` during import pandas removed to mitigate deadlock on Python GIL misuse (GH14641)

1.8 v0.19.2 (December 24, 2016)
This is a minor bug-fix release in the 0.19.x series and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

Highlights include:
• Compatibility with Python 3.6
• Added a Pandas Cheat Sheet. (GH13202).

What’s new in v0.19.2
• Enhancements
• Performance Improvements
• Bug Fixes

1.8.1 Enhancements
The `pd.merge_asof()`, added in 0.19.0, gained some improvements:
• `pd.merge_asof()` gained `left_index/right_index` and `left_by/right_by` arguments (GH14253)
• `pd.merge_asof()` can take multiple columns in `by` parameter and has specialized dtypes for better performance (GH13936)

1.8.2 Performance Improvements
• Performance regression with `PeriodIndex` (GH14822)
• Performance regression in indexing with `getitem` (GH14930)
• Improved performance of `.replace()` (GH12745)
• Improved performance `Series` creation with a datetime index and dictionary data (GH14894)
1.8.3 Bug Fixes

- Compat with python 3.6 for pickling of some offsets (GH14685)
- Compat with python 3.6 for some indexing exception types (GH14684, GH14689)
- Compat with python 3.6 for deprecation warnings in the test suite (GH14681)
- Compat with python 3.6 for Timestamp pickles (GH14689)
- Compat with dateutil==2.6.0; segfault reported in the testing suite (GH14621)
- Allow nanoseconds in Timestamp.replace as a kwarg (GH14621)
- Bug in pd.read_csv in which aliasing was being done for na_values when passed in as a dictionary (GH14203)
- Bug in pd.read_csv in which column indices for a dict-like na_values were not being respected (GH14203)
- Bug in pd.read_csv where reading files fails, if the number of headers is equal to the number of lines in the file (GH14515)
- Bug in pd.read_csv for the Python engine in which an unhelpful error message was being raised when multi-char delimiters were not being respected with quotes (GH14582)
- Fix bugs (GH14734, GH13654) in pd.read_sas and pandas.io.sas.SAS7BDATReader that caused problems when reading a SAS file incrementally.
- Bug in pd.read_csv for the Python engine in which an unhelpful error message was being raised when skipfooter was not being respected by Python’s CSV library (GH13879)
- Bug in .fillna() in which timezone aware datetime64 values were incorrectly rounded (GH14872)
- Bug in .groupby(..., sort=True) of a non-lexsorted MultiIndex when grouping with multiple levels (GH14776)
- Bug in pd.cut with negative values and a single bin (GH14652)
- Bug in pd.to_numeric where a 0 was not unsigned on a downcast='unsigned' argument (GH14401)
- Bug in plotting regular and irregular timeseries using shared axes (sharex=True or ax.twinx()) (GH13341, GH14322).
- Bug in not propagating exceptions in parsing invalid datetimes, noted in python 3.6 (GH14561)
- Bug in resampling a DatetimeIndex in local TZ, covering a DST change, which would raise AmbiguousTimeError (GH14682)
- Bug in indexing that transformed RecursionError into KeyError or IndexError (GH14554)
- Bug in HDFStore when writing a MultiIndex when using data_columns=True (GH14435)
- Bug in HDFStore.append() when writing a Series and passing a min_itemsize argument containing a value for the index (GH11412)
- Bug when writing to a HDFStore in table format with a min_itemsize value for the index and without asking to append (GH10381)
- Bug in Series.groupby.nunique() raising an IndexError for an empty Series (GH12553)
- Bug in DataFrame.nlargest and DataFrame.nsmallest when the index had duplicate values (GH13412)
- Bug in clipboard functions on linux with python2 with unicode and separators (GH13747)
- Bug in clipboard functions on Windows 10 and python 3 (GH14362, GH12807)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

• Bug in `.to_clipboard()` and Excel compat (GH12529)
• Bug in DataFrame.combine_first() for integer columns (GH14687).
• Bug in pd.read_csv() in which the dtype parameter was not being respected for empty data (GH14712)
• Bug in pd.read_csv() in which the nrows parameter was not being respected for large input when using the C engine for parsing (GH7626)
• Bug in pd.merge_asof() could not handle timezone-aware DatetimeIndex when a tolerance was specified (GH14844)
• Explicit check in to_stata and StataWriter for out-of-range values when writing doubles (GH14618)
• Bug in .plot(kind='kde') which did not drop missing values to generate the KDE Plot, instead generating an empty plot. (GH14821)
• Bug in unstack() if called with a list of column(s) as an argument, regardless of the dtypes of all columns, they get coerced to object (GH11847)

1.9 v0.19.1 (November 3, 2016)

This is a minor bug-fix release from 0.19.0 and includes some small regression fixes, bug fixes and performance improvements. We recommend that all users upgrade to this version.

What’s new in v0.19.1

• Performance Improvements
• Bug Fixes

1.9.1 Performance Improvements

• Fixed performance regression in factorization of Period data (GH14338)
• Fixed performance regression in Series.asof(when) when where is a scalar (GH14461)
• Improved performance in DataFrame.asof(when) when where is a scalar (GH14461)
• Improved performance in .to_json() when lines=True (GH14408)
• Improved performance in certain types of loc indexing with a MultiIndex (GH14551).

1.9.2 Bug Fixes

• Source installs from PyPI will now again work without cython installed, as in previous versions (GH14204)
• Compat with Cython 0.25 for building (GH14496)
• Fixed regression where user-provided file handles were closed in read_csv (c engine) (GH14418).
• Fixed regression in DataFrame.quantile when missing values were present in some columns (GH14357).
• Fixed regression in Index.difference where the freq of a DatetimeIndex was incorrectly set (GH14323)
• Added back pandas.core.common.array_equivalent with a deprecation warning (GH14555).
• Bug in pd.read_csv for the C engine in which quotation marks were improperly parsed in skipped rows (GH14459)
• Bug in pd.read_csv for Python 2.x in which Unicode quote characters were no longer being respected (GH14477)
• Fixed regression in Index.append when categorical indices were appended (GH14545).
• Fixed regression in pd.DataFrame where constructor fails when given dict with None value (GH14381)
• Fixed regression in DatetimeIndex._maybe_cast_slice_bound when index is empty (GH14354).
• Bug in localizing an ambiguous timezone when a boolean is passed (GH14402)
• Bug in TimedeltaIndex addition with a Datetime-like object where addition overflow in the negative direction was not being caught (GH14068, GH14453)
• Bug in string indexing against data with object Index may raise AttributeError (GH14424)
• Correctly raise ValueError on empty input to pd.eval() and df.query() (GH13139)
• Bug in RangeIndex.intersection when result is a empty set (GH14364).
• Bug in groupby-transform broadcasting that could cause incorrect dtype coercion (GH14457)
• Bug in Series.__setitem__ which allowed mutating read-only arrays (GH14359).
• Bug in DataFrame.insert where multiple calls with duplicate columns can fail (GH14291)
• pd.merge() will raise ValueError with non-boolean parameters in passed boolean type arguments (GH14434)
• Bug in Timestamp where dates very near the minimum (1677-09) could underflow on creation (GH14415)
• Bug in pd.concat where names of the keys were not propagated to the resulting MultiIndex (GH14252)
• Bug in pd.concat where axis cannot take string parameters 'rows' or 'columns' (GH14369)
• Bug in pd.concat with dataframes heterogeneous in length and tuple keys (GH14438)
• Bug in MultiIndex.set_levels where illegal level values were still set after raising an error (GH13754)
• Bug in DataFrame.to_json where illegal level values were still set after raising an error (GH13754)
• Bug in df.groupby causing an AttributeError when grouping a single index frame by a column and the index level (:issue'14327')
• Bug in df.groupby where TypeError raised when pd.Grouper(key=...) is passed in a list (GH14334)
• Bug in pd.pivot_table may raise TypeError or ValueError when index or columns is not scalar and values is not specified (GH14380)

1.10 v0.19.0 (October 2, 2016)

This is a major release from 0.18.1 and includes number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• merge_asof() for asof-style time-series joining, see here
• .rolling() is now time-series aware, see here
• **read_csv()** now supports parsing **Categorical** data, see [here](#)
• A function **union_categorical()** has been added for combining categoricals, see [here](#)
• **PeriodIndex** now has its own **period** dtype, and changed to be more consistent with other **Index** classes. See [here](#)
• Sparse data structures gained enhanced support of **int** and **bool** dtypes, see [here](#)
• Comparison operations with **Series** no longer ignores the index, see [here](#) for an overview of the API changes.
• Introduction of a pandas development API for utility functions, see [here](#).
• Deprecation of **Panel4D** and **PanelND**. We recommend to represent these types of n-dimensional data with the **xarray** package.
• Removal of the previously deprecated modules **pandas.io.data**, **pandas.io.wb**, **pandas.tools.rplot**.

**Warning:** pandas >= 0.19.0 will no longer silence numpy ufunc warnings upon import, see [here](#).

### What’s new in v0.19.0

- **New features**
  - **merge_asof** for asof-style time-series joining
  - **.rolling()** is now time-series aware
  - **read_csv** has improved support for duplicate column names
  - **read_csv** supports parsing **Categorical** directly
  - **Categorical Concatenation**
  - **Semi-Month Offsets**
  - **New Index methods**
  - **Google BigQuery Enhancements**
  - **Fine-grained numpy errstate**
  - **get_dummies** now returns integer dtypes
  - **Downcast values to smallest possible dtype in to_numeric**
  - **pandas development API**
  - **Other enhancements**

- **API changes**
  - **Series.tolist()** will now return Python types
  - **Series operators for different indexes**
    * **Arithmetic operators**
    * **Comparison operators**
    * **Logical operators**
    * **Flexible comparison methods**
Series type promotion on assignment
.to_datetime() changes
Merging changes
.describe() changes
Period changes
* PeriodIndex now has period dtype
* Period('NaT') now returns pd.NaT
* PeriodIndex.values now returns array of Period object
Index + / − no longer used for set operations
Index.difference and .symmetric_difference changes
Index.unique consistently returns Index
MultiIndex constructors, groupby and set_index preserve categorical dtypes
read_csv will progressively enumerate chunks
Sparse Changes
* int64 and bool support enhancements
* Operators now preserve dtypes
* Other sparse fixes
Indexer dtype changes
Other API Changes

Deprecations
Removal of prior version deprecations/changes
Performance Improvements
Bug Fixes

1.10.1 New features

1.10.1.1 merge_asof for asof-style time-series joining

A long-time requested feature has been added through the merge_asof() function, to support asof style joining of time-series (GH1870, GH13695, GH13709, GH13902). Full documentation is here.

The merge_asof() performs an asof merge, which is similar to a left-join except that we match on nearest key rather than equal keys.

| In [1]: left = pd.DataFrame({'a': [1, 5, 10],
...:                         'left_val': ['a', 'b', 'c']})
| ...:
| In [2]: right = pd.DataFrame({'a': [1, 2, 3, 6, 7],
...:                           'right_val': [1, 2, 3, 6, 7]})

(continues on next page)
In [3]: left
Out[3]:
     left_val
0 1
1 5
2 10

In [4]: right
Out[4]:
    right_val
0 1
1 2
2 3
3 6
4 7

We typically want to match exactly when possible, and use the most recent value otherwise.

In [5]: pd.merge_asof(left, right, on='a')
Out[5]:
     left_val  right_val
0 1      a        1
1 5      b        3
2 10     c        7

We can also match rows ONLY with prior data, and not an exact match.

In [6]: pd.merge_asof(left, right, on='a', allow_exact_matches=False)
Out[6]:
     left_val  right_val
0 1      a         NaN
1 5      b        3.0
2 10     c        7.0

In a typical time-series example, we have trades and quotes and we want to asof-join them. This also illustrates using the by parameter to group data before merging.

In [7]: trades = pd.DataFrame({
    ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
    ...:                               '20160525 13:30:00.038',
    ...:                               '20160525 13:30:00.048',
    ...:                               '20160525 13:30:00.048',
    ...:                               '20160525 13:30:00.048'],
    ...:     'ticker': ['MSFT', 'MSFT',
    ...:                  'GOOG', 'GOOG', 'AAPL'],
    ...:     'price': [51.95, 51.95,
    ...:                  720.77, 720.92, 98.00],
    ...:     'quantity': [75, 155,
    ...:                     100, 100, 100]})

In [8]: quotes = pd.DataFrame({
    ...:     'time': pd.to_datetime(['20160525 13:30:00.023',
    ...:                                '20160525 13:30:00.023'],
    ...:     'ticker': ['MSFT', 'MSFT'],
    ...:     'quote': [51.95, 51.95],
    ...:     'quantity': [75, 155],
    ...:     'mid': [720.77, 720.92],
    ...:     'high': [98.00, 98.00]})
An asof merge joins on the `on`, typically a datetimelike field, which is ordered, and in this case we are using a grouper in the `by` field. This is like a left-outer join, except that forward filling happens automatically taking the most recent non-NaN value.

```
In [11]: pd.merge_asof(trades, quotes,
                   on='time',
                   by='ticker')
```

This returns a merged DataFrame with the entries in the same order as the original left passed DataFrame (trades in this case), with the fields of the quotes merged.
1.10.1.2 Rolling() is now time-series aware

Rolling() objects are now time-series aware and can accept a time-series offset (or convertible) for the window argument (GH13327, GH12995). See the full documentation here.

```
In [12]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                      index=pd.date_range('20130101 09:00:00', periods=5, freq='s'))
   ....:
   ....:
In [13]: dft
Out[13]:
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03  NaN
2013-01-01 09:00:04  4.0

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.
```

```
In [14]: dft.rolling(2).sum()
Out[14]:
         B
2013-01-01 09:00:00 NaN
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04 NaN

In [15]: dft.rolling(2, min_periods=1).sum()
   
   →
         B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

Specifying an offset allows a more intuitive specification of the rolling frequency.
```

```
In [16]: dft.rolling('2s').sum()
Out[16]:
         B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  3.0
2013-01-01 09:00:03  2.0
2013-01-01 09:00:04  4.0

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.
```

```
In [17]: dft = DataFrame({'B': [0, 1, 2, np.nan, 4]},
                      index = pd.Index([pd.Timestamp('20130101 09:00:00'),
                                          pd.Timestamp('20130101 09:00:01'),
                                          pd.Timestamp('20130101 09:00:02'),
                                          pd.Timestamp('20130101 09:00:03'),
                                          pd.Timestamp('20130101 09:00:04')])
   ....:
   ....:
   ....:
   ....:
   ....:
```

(continues on next page)
....:
....:
....:

In [18]: dft
Out[18]:

B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0

In [19]: dft.rolling(2).sum()
Out[19]:

B
foo
2013-01-01 09:00:00 NaN
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 NaN

Using the time-specification generates variable windows for this sparse data.

In [20]: dft.rolling('2s').sum()
Out[20]:

B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 NaN

Furthermore, we now allow an optional on parameter to specify a column (rather than the default of the index) in a DataFrame.

In [21]: dft = dft.reset_index()

In [22]: dft
Out[22]:

foo B
0 2013-01-01 09:00:00 0.0
1 2013-01-01 09:00:02 1.0
2 2013-01-01 09:00:03 2.0
3 2013-01-01 09:00:05 NaN
4 2013-01-01 09:00:06 4.0

In [23]: dft.rolling('2s', on='foo').sum()
Out[23]:

foo B
0 2013-01-01 09:00:00 0.0
1.10.1.3 read_csv has improved support for duplicate column names

Duplicate column names are now supported in read_csv() whether they are in the file or passed in as the names parameter (GH7160, GH9424)

In [24]: data = '0,1,2
n3,4,5'

In [25]: names = ['a', 'b', 'a']

Previous behavior:

In [2]: pd.read_csv(StringIO(data), names=names)
Out[2]:
   a  b  a
0  2  1  2
1  5  4  5

The first a column contained the same data as the second a column, when it should have contained the values [0, 3].

New behavior:

In [26]: pd.read_csv(StringIO(data), names=names)
Out[26]:
   a  b  a.1
0  0  1  2
1  3  4  5

1.10.1.4 read_csv supports parsing Categorical directly

The read_csv() function now supports parsing a Categorical column when specified as a dtype (GH10153). Depending on the structure of the data, this can result in a faster parse time and lower memory usage compared to converting to Categorical after parsing. See the io docs here.

In [27]: data = 'col1,col2,col3
nna,b,1
nc,d,3'

In [28]: pd.read_csv(StringIO(data))
Out[28]:
   col1  col2  col3
0   a    b    1
1   a    b    2
2   c    d    3

In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
   col1    object
   col2    object
Individual columns can be parsed as a Categorical using a dict specification

```python
In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
\Out[31]:
col1    category
col2    object
col3    int64
dtype: object
```

Note: The resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

```python
In [32]: df = pd.read_csv(StringIO(data), dtype='category')
In [33]: df.dtypes
\Out[33]:
col1    category
col2    category
col3    category
dtype: object
```

```python
In [34]: df['col3']
\Out[34]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]
```

```python
In [35]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)
In [36]: df['col3']
\Out[36]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]

1.10.1.5 Categorical Concatenation

- A function `union_categoricals()` has been added for combining categoricals, see [Unioning Categoricals](GH13361, GH:13763, issue:13846, GH14173)
In [37]: from pandas.api.types import union_categoricals

In [38]: a = pd.Categorical(['b', 'c'])

In [39]: b = pd.Categorical(['a', 'b'])

In [40]: union_categoricals([a, b])
Out[40]:
[b, c, a, b]
Categories (3, object): [b, c, a]

• *concat* and *append* now can *concat* *category* dtypes with different *categories* as *object* dtype (GH13524)

In [41]: s1 = pd.Series(['a', 'b'], dtype='category')

In [42]: s2 = pd.Series(['b', 'c'], dtype='category')

Previous behavior:

In [1]: pd.concat([s1, s2])
ValueError: incompatible categories in categorical concat

New behavior:

In [43]: pd.concat([s1, s2])
Out[43]:
   0   a
   1   b
   0   b
   1   c
dtype: object

1.10.1.6 Semi-Month Offsets

Pandas has gained new frequency offsets, *SemiMonthEnd ('SM')* and *SemiMonthBegin ('SMS')*. These provide date offsets anchored (by default) to the 15th and end of month, and 15th and 1st of month respectively. (GH1543)

In [44]: from pandas.tseries.offsets import SemiMonthEnd, SemiMonthBegin

SemiMonthEnd:

In [45]: Timestamp('2016-01-01') + SemiMonthEnd()
Out[45]: Timestamp('2016-01-15 00:00:00')

In [46]: pd.date_range('2015-01-01', freq='SM', periods=4)

SemiMonthBegin:

In [47]: Timestamp('2016-01-01') + SemiMonthBegin()
Out[47]: Timestamp('2016-01-15 00:00:00')

In [48]: pd.date_range('2015-01-01', freq='SMS', periods=4)
Out[48]: DatetimeIndex(['2015-01-01', '2015-01-15', '2015-02-01', '2015-02-15'], dtype='datetime64[ns]', freq='SMS') (continues on next page)
Using the anchoring suffix, you can also specify the day of month to use instead of the 15th.

```python
In [49]: pd.date_range('2015-01-01', freq='SMS-16', periods=4)
Out[49]: DatetimeIndex(['2015-01-01', '2015-01-16', '2015-02-01', '2015-02-16'],
                   dtype='datetime64[ns]', freq='SMS-16')
```

```python
In [50]: pd.date_range('2015-01-01', freq='SM-14', periods=4)
```

1.10.1.7 New Index methods

The following methods and options are added to Index, to be more consistent with the Series and DataFrame API.

Index now supports the .where() function for same shape indexing (GH13170)

```python
In [51]: idx = pd.Index(['a', 'b', 'c'])
In [52]: idx.where([True, False, True])
Out[52]: Index(['a', nan, 'c'], dtype='object')
```

Index now supports .dropna() to exclude missing values (GH6194)

```python
In [53]: idx = pd.Index([1, 2, np.nan, 4])
In [54]: idx.dropna()
Out[54]: Float64Index([1.0, 2.0, 4.0], dtype='float64')
```

For MultiIndex, values are dropped if any level is missing by default. Specifying how='all' only drops values where all levels are missing.

```python
In [55]: midx = pd.MultiIndex.from_arrays([[1, 2, np.nan, 4],
                                           [1, 2, np.nan, np.nan]])
    ....:
    ....:
In [56]: midx
Out[56]: MultiIndex(levels=[[1, 2, 4], [1, 2]],
                   labels=[[0, 1, -1, 2], [0, 1, -1, -1]])
In [57]: midx.dropna()
    ...
    MultiIndex(levels=[[1, 2, 4], [1, 2]],
               labels=[[0, 1], [0, 1]])
In [58]: midx.dropna(how='all')
    ...
    MultiIndex(levels=[[1, 2, 4], [1, 2]],
               labels=[[0, 1, 2], [0, 1, -1]])
```
Index now supports .str.extractall() which returns a DataFrame, see the docs here (GH10008, GH13156)

```python
In [59]: idx = pd.Index(["ala2", "bi", "cl"])  
In [60]: idx.str.extractall("[ab]?(\d+)")
```

<table>
<thead>
<tr>
<th>digit</th>
<th>match</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

Index.astype() now accepts an optional boolean argument copy, which allows optional copying if the requirements on dtype are satisfied (GH13209)

### 1.10.1.8 Google BigQuery Enhancements

- The `read_gbq()` method has gained the dialect argument to allow users to specify whether to use BigQuery’s legacy SQL or BigQuery’s standard SQL. See the docs for more details (GH13615).
- The `to_gbq()` method now allows the DataFrame column order to differ from the destination table schema (GH11359).

### 1.10.1.9 Fine-grained numpy errstate

Previous versions of pandas would permanently silence numpy’s ufunc error handling when pandas was imported. Pandas did this in order to silence the warnings that would arise from using numpy ufuncs on missing data, which are usually represented as NaNs. Unfortunately, this silenced legitimate warnings arising in non-pandas code in the application. Starting with 0.19.0, pandas will use the `numpy.errstate` context manager to silence these warnings in a more fine-grained manner, only around where these operations are actually used in the pandas codebase. (GH13109, GH13145)

After upgrading pandas, you may see new `RuntimeWarning`s being issued from your code. These are likely legitimate, and the underlying cause likely existed in the code when using previous versions of pandas that simply silenced the warning. Use `numpy.errstate` around the source of the `RuntimeWarning` to control how these conditions are handled.

### 1.10.1.10 get_dummies now returns integer dtypes

The `pd.get_dummies` function now returns dummy-encoded columns as small integers, rather than floats (GH8725). This should provide an improved memory footprint.

Previous behavior:

```python
In [1]: pd.get_dummies(['a', 'b', 'a', 'c']).dtypes
```

```
Out[1]:
    a  float64
dtype: object
```

New behavior:
1.10.1.11 Downcast values to smallest possible dtype in to_numeric

df.to_numeric() now accepts a downcast parameter, which will downcast the data if possible to smallest specified numerical dtype (GH13352)

```python
In [62]: s = [1', 2, 3]
In [63]: df.to_numeric(s, downcast='unsigned')
Out[63]: array([1, 2, 3], dtype=uint8)
In [64]: df.to_numeric(s, downcast='integer')
```

1.10.1.12 pandas development API

As part of making pandas API more uniform and accessible in the future, we have created a standard sub-package of pandas, pandas.api to hold public API's. We are starting by exposing type introspection functions in pandas.api.types. More sub-packages and officially sanctioned API's will be published in future versions of pandas (GH13147, GH13634)

The following are now part of this API:

```python
In [65]: import pprint
In [66]: from pandas.api import types
In [67]: funcs = [ f for f in dir(types) if not f.startswith('_') ]
In [68]: pprint.pprint(funcs)
```

(continues on next page)
'is_dict_like',
'is_dtype_equal',
'is_extension_type',
'is_file_like',
'is_float',
'is_float_dtype',
'is_floating_dtype',
'is_hashable',
'is_int64_dtype',
'is_integer',
'is_integer_dtype',

'is_timedelta64_dtype',
'is_timedelta64_ns_dtype',
'is_unsigned_integer_dtype',
'pandas_dtype',
'union_categoricals']

Note: Calling these functions from the internal module `pandas.core.common` will now show a DeprecationWarning (GH13990)

1.10.1.13 Other enhancements

• Timestamp can now accept positional and keyword parameters similar to `datetime.datetime()` (GH10758, GH11630)

```python
In [69]: pd.Timestamp(2012, 1, 1)
Out[69]: Timestamp('2012-01-01 00:00:00')
```

```python
In [70]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
    \-------------------------
Out[70]: Timestamp('2012-01-01 08:30:00')
```

• The `.resample()` function now accepts a `on=` or `level=` parameter for resampling on a datetimelike column or `MultiIndex` level (GH13500)

```python
In [71]: pd.Timestamp(2012, 1, 1)
Out[71]: Timestamp('2012-01-01 00:00:00')
```

```python
In [72]: pd.Timestamp(year=2012, month=1, day=1, hour=8, minute=30)
    \-------------------------
Out[72]: Timestamp('2012-01-01 08:30:00')
```
In [71]: df = pd.DataFrame({
    ...:     'date': pd.date_range('2015-01-01', freq='W', periods=5),
    ...:     'a': np.arange(5),
    ...:     'v': np.arange(5)
    ...: },
    ...:      index=pd.MultiIndex.from_arrays([
    ...:        [1, 2, 3, 4, 5],
    ...:        pd.date_range('2015-01-01', freq='W', periods=5)
    ...: ],
    ...:      names=['v', 'd'])).

In [72]: df
Out[72]:

    date      a     v  d
0  2015-01-04  2015-01-04  0
1  2015-01-11  2015-01-11  1
2  2015-01-18  2015-01-18  2
3  2015-01-25  2015-01-25  3
4  2015-02-01  2015-02-01  4

In [73]: df.resample('M', on='date').sum()

    a
date
2015-01-31  6
2015-02-28  4

In [74]: df.resample('M', level='d').sum()

    a
    d
2015-01-31  6
2015-02-28  4

- The `.get_credentials()` method of GbqConnector can now first try to fetch the application default credentials. See the docs for more details (GH13577).
- The `.tz_localize()` method of DatetimeIndex and Timestamp has gained the `errors` keyword, so you can potentially coerce nonexistent timestamps to NaT. The default behavior remains to raising a NonExistentTimeError (GH13057)
- `.to_hdf/read_hdf()` now accept path objects (e.g. pathlib.Path, py.path.local) for the file path (GH11773)
- The `pd.read_csv()` with engine='python' has gained support for the decimal (GH12933), `na_filter` (GH13321) and the memory_map option (GH13381).
- Consistent with the Python API, `pd.read_csv()` will now interpret +inf as positive infinity (GH13274)
- The `pd.read_html()` has gained support for the `na_values`, `converters`, `keep_default_na` options (GH13461)
- `Categorical.astype()` now accepts an optional boolean argument `copy`, effective when dtype is categorical (GH13209)
- `DataFrame` has gained the `.asof()` method to return the last non-NaN values according to the selected subset (GH13358)
• The DataFrame constructor will now respect key ordering if a list of OrderedDict objects are passed in (GH13304)

• pd.read_html() has gained support for the decimal option (GH12907)

• Series has gained the properties .is_monotonic, .is_monotonic_increasing, .is_monotonic_decreasing, similar to Index (GH13336)

• DataFrame.to_sql() now allows a single value as the SQL type for all columns (GH11886).

• Series.append now supports the ignore_index option (GH13677)

• .to_stata() and StataWriter can now write variable labels to Stata dta files using a dictionary to make column names to labels (GH13535, GH13536)

• .to_stata() and StataWriter will automatically convert datetime64[ns] columns to Stata format %tc, rather than raising a ValueError (GH12259)

• read_stata() and StataReader raise with a more explicit error message when reading Stata files with repeated value labels when convert_categoricals=True (GH13923)

• DataFrame.style will now render sparsified MultiIndexes (GH11655)

• DataFrame.style will now show column level names (e.g. DataFrame.columns.names) (GH13775)

• DataFrame has gained support to re-order the columns based on the values in a row using df.sort_values(by='...', axis=1) (GH10806)

```python
In [75]: df = pd.DataFrame({'A': [2, 7], 'B': [3, 5], 'C': [4, 8]},
                      index=['row1', 'row2'])

In [76]: df.sort_values(by='row2', axis=1)

Out[76]:
         B  A  C
row1  3  2  4
row2  5  7  8
```

• Added documentation to I/O regarding the perils of reading in columns with mixed dtypes and how to handle it (GH13746)

• to_html() now has a border argument to control the value in the opening <table> tag. The default is the value of the html.border option, which defaults to 1. This also affects the notebook HTML repr, but since Jupyter’s CSS includes a border-width attribute, the visual effect is the same. (GH11563).

• Raise ImportError in the sql functions when sqlalchemy is not installed and a connection string is used (GH11920).

• Compatibility with matplotlib 2.0. Older versions of pandas should also work with matplotlib 2.0 (GH13333)

• Timestamp, Period, DatetimeIndex, PeriodIndex and .dt accessor have gained a .is_leap_year property to check whether the date belongs to a leap year. (GH13727)

• astype() will now accept a dict of column name to data types mapping as the dtype argument. (GH12086)

• The pd.read_json and DataFrame.to_json has gained support for reading and writing json lines with lines option see Line delimited json (GH9180)
- `read_excel()` now supports the `true_values` and `false_values` keyword arguments (GH13347)
- `groupby()` will now accept a scalar and a single-element list for specifying `level` on a non-MultiIndex grouper. (GH13907)
- Non-convertible dates in an excel date column will be returned without conversion and the column will be `object` dtype, rather than raising an exception (GH10001).
- `pd.Timedelta(None)` is now accepted and will return `NaT`, mirroring `pd.Timestamp` (GH13687)
- `pd.read_stata()` can now handle some format 111 files, which are produced by SAS when generating Stata dta files (GH11526)
- `Series` and `Index` now support `divmod` which will return a tuple of series or indices. This behaves like a standard binary operator with regards to broadcasting rules (GH14208).

### 1.10.2 API changes

#### 1.10.2.1 Series.toリスト() will now return Python types

`Series.toリスト()` will now return Python types in the output, mimicking NumPy `.toリスト()` behavior (GH10904)

```python
In [78]: s = pd.Series([1,2,3])
```

**Previous behavior:**

```python
In [7]: type(s.toリスト()[0])
Out[7]: <class 'numpy.int64'>
```

**New behavior:**

```python
In [79]: type(s.toリスト()[0])
Out[79]: int
```

#### 1.10.2.2 Series operators for different indexes

Following `Series` operators have been changed to make all operators consistent, including `DataFrame` (GH1134, GH4581, GH13538)

- `Series` comparison operators now raise `ValueError` when `index` are different.
- `Series` logical operators align both `index` of left and right hand side.

**Warning:** Until 0.18.1, comparing `Series` with the same length, would succeed even if the `.index` are different (the result ignores `.index`). As of 0.19.0, this will raise `ValueError` to be more strict. This section also describes how to keep previous behavior or align different indexes, using the flexible comparison methods like `.eq`.

As a result, `Series` and `DataFrame` operators behave as below:
Arithmetic operators

Arithmetic operators align both index (no changes).

```python
In [80]: s1 = pd.Series([1, 2, 3], index=list('ABC'))
In [81]: s2 = pd.Series([2, 2, 2], index=list('ABD'))
In [82]: s1 + s2
Out[82]:
A   3.0
B   4.0
C  NaN
D  NaN
dtype: float64
```

```python
In [83]: df1 = pd.DataFrame([1, 2, 3], index=list('ABC'))
In [84]: df2 = pd.DataFrame([2, 2, 2], index=list('ABD'))
In [85]: df1 + df2
Out[85]:
0  3.0
A  3.0
B  4.0
C  NaN
D  NaN
```

Comparison operators

Comparison operators raise `ValueError` when `.index` are different.

**Previous Behavior** (Series):
Series compared values ignoring the `.index` as long as both had the same length:

```python
In [1]: s1 == s2
Out[1]:
A   False
B    True
C   False
dtype: bool
```

**New behavior** (Series):

```python
In [2]: s1 == s2
Out[2]:
ValueError: Can only compare identically-labeled Series objects
```

**Note:** To achieve the same result as previous versions (compare values based on locations ignoring `.index`), compare both `.values`.

```python
In [86]: s1.values == s2.values
Out[86]: array([False, True, False], dtype=bool)
```

If you want to compare `Series` aligning its `.index`, see flexible comparison methods section below:
In [87]: s1.eq(s2)
Out[87]:
A  False
B  True
C  False
D   False
dtype: bool

Current Behavior (DataFrame, no change):

In [3]: df1 == df2
Out[3]:
ValueError: Can only compare identically-labeled DataFrame objects

Logical operators

Logical operators align both .index of left and right hand side.

Previous behavior (Series), only left hand side index was kept:

In [4]: s1 = pd.Series([True, False, True], index=list('ABC'))
In [5]: s2 = pd.Series([True, True, True], index=list('ABD'))
In [6]: s1 & s2
Out[6]:
A   True
B   False
C   False
dtype: bool

New behavior (Series):

In [88]: s1 = pd.Series([True, False, True], index=list('ABC'))

In [89]: s2 = pd.Series([True, True, True], index=list('ABD'))

In [90]: s1 & s2
Out[90]:
A   True
B   False
C   False
D   False
dtype: bool

Note: Series logical operators fill a NaN result with False.

Note: To achieve the same result as previous versions (compare values based on only left hand side index), you can use reindex_like:

In [91]: s1 & s2.reindex_like(s1)
Out[91]:
A   True
B   False

(continues on next page)
C False
dtype: bool

**Current Behavior** *(DataFrame, no change)*:

```python
In [92]: df1 = pd.DataFrame([True, False, True], index=list('ABC'))
In [93]: df2 = pd.DataFrame([True, True, True], index=list('ABD'))
```

```
In [94]: df1 & df2
Out[94]:
0   A  True
     B  False
     C  NaN
     D  NaN
```

**Flexible comparison methods**

Series flexible comparison methods like `eq`, `ne`, `le`, `lt`, `ge` and `gt` now align both index. Use these operators if you want to compare two `Series` which has the different index.

```python
In [95]: s1 = pd.Series([1, 2, 3], index=['a', 'b', 'c'])
In [96]: s2 = pd.Series([2, 2, 2], index=['b', 'c', 'd'])
```

```
In [97]: s1.eq(s2)
Out[97]:
a  False
   b  True
   c  False
d  False
dtype: bool
```

```
In [98]: s1.ge(s2)

Out[98]:
a  False
   b  True
   c  True
d  False
dtype: bool
```

Previously, this worked the same as comparison operators (see above).

**1.10.2.3 Series type promotion on assignment**

A `Series` will now correctly promote its dtype for assignment with incompat values to the current dtype *(GH13234)*

```python
In [99]: s = pd.Series()
```

**Previous behavior:**
In [2]: s["a"] = pd.Timestamp("2016-01-01")
In [3]: s["b"] = 3.0
TypeError: invalid type promotion

New behavior:
In [100]: s["a"] = pd.Timestamp("2016-01-01")
In [101]: s["b"] = 3.0
In [102]: s
Out[102]:
   a  2016-01-01 00:00:00
   b    3
   dtype: object

1.10.2.4 .to_datetime() changes

Previously if .to_datetime() encountered mixed integers/floats and strings, but no datetimes with errors='coerce' it would convert all to NaT.

Previous behavior:
In [2]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[2]: DatetimeIndex(['NaT', 'NaT'], dtype='datetime64[ns]', freq=None)

Current behavior:
This will now convert integers/floats with the default unit of ns.
In [104]: pd.to_datetime([1, 'foo'], errors='coerce')
Out[104]: DatetimeIndex(['1970-01-01 00:00:00.000000001', 'NaT'], dtype='datetime64[ns]', freq=None)

Bug fixes related to .to_datetime():
- Bug in pd.to_datetime() when passing integers or floats, and no unit and errors='coerce' (GH13180).
- Bug in pd.to_datetime() when passing invalid datatypes (e.g. bool); will now respect the errors keyword (GH13176)
- Bug in pd.to_datetime() which overflowed on int8, and int16 dtypes (GH13451)
- Bug in pd.to_datetime() raise AttributeError with NaN and the other string is not valid when errors='ignore' (GH12424)
- Bug in pd.to_datetime() did not cast floats correctly when unit was specified, resulting in truncated datetime (GH13834)

1.10.2.5 Merging changes

Merging will now preserve the dtype of the join keys (GH8596)
In [105]: df1 = pd.DataFrame({'key': [1], 'v1': [10]})

In [106]: df1
Out[106]:
   key v1
0  1  10

In [107]: df2 = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [108]: df2
   key v1
0  1  20
1  2  30

Previous behavior:

In [5]: pd.merge(df1, df2, how='outer')
Out[5]:
   key  v1
0   1.0 10.0
1   1.0 20.0
2   2.0 30.0

In [6]: pd.merge(df1, df2, how='outer').dtypes
Out[6]:
key    float64
v1     float64
dtype: object

New behavior:

We are able to preserve the join keys

In [109]: pd.merge(df1, df2, how='outer')
Out[109]:
   key  v1
0   1  10
1   1  20
2   2  30

In [110]: pd.merge(df1, df2, how='outer').dtypes
Out[110]:
key     int64
v1      int64
dtype: object

Of course if you have missing values that are introduced, then the resulting dtype will be upcast, which is unchanged from previous.

In [111]: pd.merge(df1, df2, how='outer', on='key')
Out[111]:
   key  v1_x  v1_y
0   1    10.0  20
1   2       NaN  30

In [112]: pd.merge(df1, df2, how='outer', on='key').dtypes
(continues on next page)
1.10.2.6 .describe() changes

Percentile identifiers in the index of a .describe() output will now be rounded to the least precision that keeps them distinct (GH13104)

```
In [113]: s = pd.Series([0, 1, 2, 3, 4])
In [114]: df = pd.DataFrame([0, 1, 2, 3, 4])
```

**Previous behavior:**

The percentiles were rounded to at most one decimal place, which could raise `ValueError` for a data frame if the percentiles were duplicated.

```
In [3]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[3]:
   count     5.000000
   mean      2.000000
   std       1.581139
   min       0.000000
   0.0%      0.000000
   0.1%      0.002000
   0.1%      0.004000
   50%       2.000000
   99.9%     3.996000
   100.0%    3.999000
   100.0%    3.999600
   max       4.000000
   dtype: float64
```

```
In [4]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
```

```
ValueError: cannot reindex from a duplicate axis
```

**New behavior:**

```
In [115]: s.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
Out[115]:
   count     5.000000
   mean      2.000000
   std       1.581139
   min       0.000000
   0.01%     0.000000
   0.1%      0.002000
   0.1%      0.004000
   50%       2.000000
   99.9%     3.996000
   99.95%    3.998000
   99.99%    3.999600
```

(continues on next page)
max 4.000000
dtype: float64

In [116]: df.describe(percentiles=[0.0001, 0.0005, 0.001, 0.999, 0.9995, 0.9999])
   →
 count 5.000000
mean 2.000000
std 1.581139
min 0.000000
 0.01% 0.000400
 0.05% 0.002000
 0.1% 0.004000
 50% 2.000000
99.9% 3.996000
99.95% 3.998000
99.99% 3.999600
max 4.000000

Furthermore:

- Passing duplicated percentiles will now raise a ValueError.
- Bug in .describe() on a DataFrame with a mixed-dtype column index, which would previously raise a TypeError (GH13288)

1.10.2.7 Period changes

**PeriodIndex now has period dtype**

PeriodIndex now has its own period dtype. The period dtype is a pandas extension dtype like category or the timezone aware dtype (datetime64[ns, tz])(GH13941). As a consequence of this change, PeriodIndex no longer has an integer dtype:

**Previous behavior:**

```python
In [1]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [2]: pi
Out[2]: PeriodIndex(['2016-08-01'], dtype='int64', freq='D')
In [3]: pd.api.types.is_integer_dtype(pi)
Out[3]: True
In [4]: pi.dtype
Out[4]: dtype('int64')
```

**New behavior:**

```python
In [117]: pi = pd.PeriodIndex(['2016-08-01'], freq='D')
In [118]: pi
Out[118]: PeriodIndex(['2016-08-01'], dtype='period[D]', freq='D')
In [119]: pd.api.types.is_integer_dtype(pi)
```
Period('NaT') now returns pd.NaT

Previously, Period has its own Period('NaT') representation different from pd.NaT. Now Period('NaT') has been changed to return pd.NaT. (GH12759, GH13582)

**Previous behavior:**

```
In [5]: pd.Period('NaT', freq='D')
Out[5]: Period('NaT', 'D')
```

**New behavior:**

These result in pd.NaT without providing freq option.

```
In [123]: pd.Period('NaT')
Out[123]: NaT

In [124]: pd.Period(None)
Out[124]: NaT
```

To be compatible with Period addition and subtraction, pd.NaT now supports addition and subtraction with int. Previously it raised ValueError.

**Previous behavior:**

```
In [5]: pd.NaT + 1
...: ValueError: Cannot add integral value to Timestamp without freq.
```

**New behavior:**

```
In [125]: pd.NaT + 1
Out[125]: NaT

In [126]: pd.NaT - 1
Out[126]: NaT
```

PeriodIndex.values now returns array of Period object

.values is changed to return an array of Period objects, rather than an array of integers (GH13988).
Previous behavior:

```
In [6]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [7]: pi.values
array([492, 493])
```

New behavior:

```
In [127]: pi = pd.PeriodIndex(['2011-01', '2011-02'], freq='M')
In [128]: pi.values
Out[128]: array([Period('2011-01', 'M'), Period('2011-02', 'M')], dtype=object)
```

### 1.10.2.8 Index + / – no longer used for set operations

Addition and subtraction of the base Index type and of DatetimeIndex (not the numeric index types) previously performed set operations (set union and difference). This behavior was already deprecated since 0.15.0 (in favor using the specific `.union()` and `.difference()` methods), and is now disabled. When possible, + and – are now used for element-wise operations, for example for concatenating strings or subtracting datetimes (GH8227, GH14127).

**Previous behavior:**

```
In [1]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
FutureWarning: using '+' to provide set union with Indexes is deprecated, use '|' or .union()
Out[1]: Index(['a', 'b', 'c'], dtype='object')
```

**New behavior:** the same operation will now perform element-wise addition:

```
In [129]: pd.Index(['a', 'b']) + pd.Index(['a', 'c'])
Out[129]: Index(['aa', 'bc'], dtype='object')
```

Note that numeric Index objects already performed element-wise operations. For example, the behavior of adding two integer Indexes is unchanged. The base Index is now made consistent with this behavior.

```
In [130]: pd.Index([1, 2, 3]) + pd.Index([2, 3, 4])
Out[130]: Int64Index([3, 5, 7], dtype='int64')
```

Further, because of this change, it is now possible to subtract two DatetimeIndex objects resulting in a TimedeltaIndex:

**Previous behavior:**

```
In [1]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
FutureWarning: using '-' to provide set differences with datetimelike Indexes is deprecated, use .difference()
Out[1]: DatetimeIndex(['2016-01-01'], dtype='datetime64[ns]', freq=None)
```

**New behavior:**

```
In [131]: pd.DatetimeIndex(['2016-01-01', '2016-01-02']) - pd.DatetimeIndex(['2016-01-02', '2016-01-03'])
Out[131]: TimedeltaIndex(['-1 days', '-1 days'], dtype='timedelta64[ns]', freq=None)
```
1.10.2.9 Index.difference and .symmetric_difference changes

Index.difference and Index.symmetric_difference will now, more consistently, treat NaN values as any other values. (GH13514)

In [132]: idx1 = pd.Index([1, 2, 3, np.nan])
In [133]: idx2 = pd.Index([0, 1, np.nan])

Previous behavior:

In [3]: idx1.difference(idx2)
Out[3]: Float64Index([nan, 2.0, 3.0], dtype='float64')

In [4]: idx1.symmetric_difference(idx2)
Out[4]: Float64Index([0.0, nan, 2.0, 3.0], dtype='float64')

New behavior:

In [134]: idx1.difference(idx2)
Out[134]: Float64Index([2.0, 3.0], dtype='float64')

In [135]: idx1.symmetric_difference(idx2)
Out[135]: Float64Index([0.0, 2.0, 3.0], dtype='float64')

1.10.2.10 Index.unique consistently returns Index

Index.unique() now returns unique values as an Index of the appropriate dtype. (GH13395). Previously, most Index classes returned np.ndarray, and DatetimeIndex, TimedeltaIndex and PeriodIndex returned Index to keep metadata like timezone.

Previous behavior:

In [1]: pd.Index([1, 2, 3]).unique()
Out[1]: array([1, 2, 3])

In [2]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo').unique()
Out[2]: DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
                      '2011-01-03 00:00:00+09:00'],
                      dtype='datetime64[ns, Asia/Tokyo]', freq=None)

New behavior:

In [136]: pd.Index([1, 2, 3]).unique()
Out[136]: Int64Index([1, 2, 3], dtype='int64')

In [137]: pd.DatetimeIndex(['2011-01-01', '2011-01-02', '2011-01-03'], tz='Asia/Tokyo').unique()
Out[137]: DatetimeIndex(['2011-01-01 00:00:00+09:00', '2011-01-02 00:00:00+09:00',
                      '2011-01-03 00:00:00+09:00'],
                      dtype='datetime64[ns, Asia/Tokyo]', freq=None)
1.10.2.11 MultiIndex constructors, groupby and set_index preserve categorical dtypes

MultiIndex.from_arrays and MultiIndex.from_product will now preserve categorical dtype in MultiIndex levels (GH13743, GH13854).

In [138]: cat = pd.Categorical(['a', 'b'], categories=list("bac"))
In [139]: lvl1 = ['foo', 'bar']
In [140]: midx = pd.MultiIndex.from_arrays([cat, lvl1])
In [141]: midx
Out[141]: MultiIndex(levels=[['b', 'a', 'c'], ['bar', 'foo']],
                   labels=[[1, 0], [1, 0]])

Previous behavior:

In [4]: midx.levels[0]
Out[4]: Index(['b', 'a', 'c'], dtype='object')
In [5]: midx.get_level_values[0]
Out[5]: Index(['a', 'b'], dtype='object')

New behavior: the single level is now a CategoricalIndex:

In [142]: midx.levels[0]
Out[142]: CategoricalIndex(['b', 'a', 'c'], categories=['b', 'a', 'c'], ordered=False,
-> dtype='category')
In [143]: midx.get_level_values(0)
Out[143]: CategoricalIndex(['a', 'b'], categories=['b', 'a', 'c'], ordered=False, dtype=
-> 'category')

An analogous change has been made to MultiIndex.from_product. As a consequence, groupby and set_index also preserve categorical dtypes in indexes

In [144]: df = pd.DataFrame({'A': [0, 1], 'B': [10, 11], 'C': cat})
In [145]: df_grouped = df.groupby(by=['A', 'C']).first()
In [146]: df_set_idx = df.set_index(['A', 'C'])

Previous behavior:

In [11]: df_grouped.index.levels[1]
Out[11]: Index(['b', 'a', 'c'], dtype='object', name='C')
In [12]: df_grouped.reset_index().dtypes
Out[12]:
A    int64
C     object
B    float64
dtype: object
In [13]: df_set_idx.index.levels[1]
Out[13]: Index(['b', 'a', 'c'], dtype='object', name='C')

(continues on next page)
1.10.2.12 `read_csv` will progressively enumerate chunks

When `read_csv()` is called with `chunksize=n` and without specifying an index, each chunk used to have an independently generated index from 0 to n-1. They are now given instead a progressive index, starting from 0 for the first chunk, from n for the second, and so on, so that, when concatenated, they are identical to the result of calling `read_csv()` without the `chunksize=` argument (GH12185).

**Previous behavior:**

```
In [2]: pd.concat(pd.read_csv(StringIO(data), chunksize=2))
Out[2]:
   A  B
0  0  1
1  2  3
2  4  5
3  6  7
```
1.10.2.13 Sparse Changes

These changes allow pandas to handle sparse data with more dtypes, and for work to make a smoother experience with data handling.

**int64 and bool support enhancements**

Sparse data structures now gained enhanced support of int64 and bool dtype (GH667, GH13849).

Previously, sparse data were float64 dtype by default, even if all inputs were of int or bool dtype. You had to specify dtype explicitly to create sparse data with int64 dtype. Also, fill_value had to be specified explicitly because the default was np.nan which doesn’t appear in int64 or bool data.

As of v0.19.0, sparse data keeps the input dtype, and uses more appropriate fill_value defaults (0 for int64 dtype, False for bool dtype).
In [154]: pd.SparseArray([True, False, False, False])
\[\text{Out}[154]:\]

[True, False, False, False]
Fill: False
IntIndex
Indices: array([0], dtype=int32)

See the docs for more details.

Operators now preserve dtypes

- Sparse data structure now can preserve dtype after arithmetic ops (GH13848)

In [155]: s = pd.SparseSeries([0, 2, 0, 1], fill_value=0, dtype=np.int64)
In [156]: s.dtype
Out[156]: dtype('int64')
In [157]: s + 1
\[\text{Out}[157]:\]

0 1
1 3
2 1
3 2
dtype: int64
BlockIndex
Block locations: array([1, 3], dtype=int32)
Block lengths: array([1, 1], dtype=int32)

- Sparse data structure now support astype to convert internal dtype (GH13900)

In [158]: s = pd.SparseSeries([1., 0., 2., 0.], fill_value=0)
In [159]: s
Out[159]:
0 1.0
1 0.0
2 2.0
3 0.0
dtype: float64
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 2], dtype=int32)
In [160]: s.astype(np.int64)
\[\text{Out}[160]:\]

0 1
1 0
2 2
3 0
dtype: int64
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 1], dtype=int32)
**astype** fails if data contains values which cannot be converted to specified **dtype**. Note that the limitation is applied to **fill_value** which default is **np.nan**.

```python
In [7]: pd.SparseSeries([1., np.nan, 2., np.nan], fill_value=np.nan).astype(np.int64)
Out[7]:
ValueError: unable to coerce current fill_value nan to int64 dtype
```

### Other sparse fixes

- Subclassed **SparseDataFrame** and **SparseSeries** now preserve class types when slicing or transposing. (GH13787)
- **SparseArray** with bool **dtype** now supports logical (bool) operators (GH14000)
- **Bug in SparseSeries** with MultiIndex [] indexing may raise IndexError (GH13144)
- **Bug in SparseSeries** with MultiIndex [] indexing result may have normal Index (GH13144)
- **Bug in SparseDataFrame** in which axis=None did not default to axis=0 (GH13048)
- **Bug in SparseSeries and SparseDataFrame** creation with object **dtype** may raise TypeError (GH11633)
- **Bug in SparseDataFrame** doesn’t respect passed SparseArray or SparseSeries ‘s **dtype** and **fill_value** (GH13866)
- **Bug in SparseArray and SparseSeries** don’t apply ufunc to **fill_value** (GH13853)
- **Bug in SparseSeries.abs** incorrectly keeps negative **fill_value** (GH13853)
- **Bug in single row slicing on multi-type SparseDataFrame** s, types were previously forced to float (GH13917)
- **Bug in SparseSeries slicing changes integer **dtype** to float** (GH8292)
- **Bug in SparseDataFrame comparison ops may raise TypeError** (GH13001)
- **Bug in SparseDataFrame.isnull raises ValueError** (GH8276)
- **Bug in SparseSeries representation with bool **dtype** may raise IndexError** (GH13110)
- **Bug in SparseSeries and SparseDataFrame of bool or int64 **dtype** may display its values like float64 **dtype** (GH13110)
- **Bug in sparse indexing using SparseArray with bool **dtype** may return incorrect result** (GH13985)
- **Bug in SparseArray created from SparseSeries may lose **dtype** (GH13999)
- **Bug in SparseSeries comparison with dense returns normal Series rather than SparseSeries** (GH13999)

### 1.10.2.14 Indexer **dtype** changes

**Note:** This change only affects 64 bit python running on Windows, and only affects relatively advanced indexing operations

Methods such as **Index.get_indexer** that return an indexer array, coerce that array to a “platform int”, so that it can be directly used in 3rd party library operations like **numpy.take**. Previously, a platform int was defined as
np.int_ which corresponds to a C integer, but the correct type, and what is being used now, is np.intp, which corresponds to the C integer size that can hold a pointer (GH3033, GH13972).

These types are the same on many platform, but for 64 bit python on Windows, np.int_ is 32 bits, and np.intp is 64 bits. Changing this behavior improves performance for many operations on that platform.

**Previous behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int32')
```

**New behavior:**

```
In [1]: i = pd.Index(['a', 'b', 'c'])
In [2]: i.get_indexer(['b', 'b', 'c']).dtype
Out[2]: dtype('int64')
```

### 1.10.2.15 Other API Changes

- `Timestamp.to_pydatetime` will issue a `UserWarning` when `warn=True`, and the instance has a non-zero number of nanoseconds, previously this would print a message to stdout (GH14101).
- `Series.unique()` with datetime and timezone now returns return array of `Timestamp` with timezone (GH13565).
- `Panel.to_sparse()` will raise a `NotImplementedError` exception when called (GH13778).
- `Index.reshape()` will raise a `NotImplementedError` exception when called (GH12882).
- `.filter()` enforces mutual exclusion of the keyword arguments (GH12399).
- `eval`'s upcasting rules for `float32` types have been updated to be more consistent with NumPy's rules. New behavior will not upcast to `float64` if you multiply a pandas `float32` object by a scalar `float64` (GH12388).
- An `UnsupportedFunctionCall` error is now raised if NumPy ufuncs like `np.mean` are called on groupby or resample objects (GH12811).
- `__setitem__` will no longer apply a callable rhs as a function instead of storing it. Call `where` directly to get the previous behavior (GH13299).
- Calls to `.sample()` will respect the random seed set via `numpy.random.seed(n)` (GH13161)
- `Styler.apply` is now more strict about the outputs your function must return. For `axis=0` or `axis=1`, the output shape must be identical. For `axis=None`, the output must be a `DataFrame` with identical columns and index labels (GH13222).
- `Float64Index.astype(int)` will now raise `ValueError` if `Float64Index` contains NaN values (GH13149)
- `TimedeltaIndex.astype(int)` and `DatetimeIndex.astype(int)` will now return `Int64Index` instead of `np.array` (GH13209)
- Passing `Period` with multiple frequencies to normal `Index` now returns `Index` with object dtype (GH13664)
- `PeriodIndexfillna` with `Period` has different freq now coerces to object dtype (GH13664)
Faceted boxplots from `DataFrame.boxplot(by=col)` now return a `Series` when `return_type` is not None. Previously these returned an `OrderedDict`. Note that when `return_type=None`, the default, these still return a 2-D NumPy array (GH12216, GH7096).

`pd.read_hdf` will now raise a `ValueError` instead of `KeyError`, if a mode other than `r`, `r+` and `a` is supplied. (GH13623)

`pd.read_csv()`, `pd.read_table()`, and `pd.read_hdf()` raise the builtin `FileNotFoundError` exception for Python 3.x when called on a nonexistent file; this is back-ported as `IOError` in Python 2.x (GH14086)

More informative exceptions are passed through the csv parser. The exception type would now be the original exception type instead of `CParserError` (GH13652).

`pd.read_csv()` in the C engine will now issue a `ParserWarning` or raise a `ValueError` when `sep` encoded is more than one character long (GH14065)

`DataFrame.values` will now return `float64` with a `DataFrame` of mixed `int64` and `uint64` dtypes, conforming to `np.find_common_type` (GH10364, GH13917)

`.groupby.groups` will now return a dictionary of `Index` objects, rather than a dictionary of `np.ndarray` or lists (GH14293)

### 1.10.3 Deprecations

- `Series.reshape` and `Categorical.reshape` have been deprecated and will be removed in a subsequent release (GH12882, GH12882)
- `PeriodIndex.to_datetime` has been deprecated in favor of `PeriodIndex.to_timestamp` (GH8254)
- `Timestamp.to_datetime` has been deprecated in favor of `Timestamp.to_pydatetime` (GH8254)
- `Index.to_datetime` and `DatetimeIndex.to_datetime` have been deprecated in favor of `pd.to_datetime` (GH8254)
- `pandas.core.datetools` module has been deprecated and will be removed in a subsequent release (GH14094)
- `SparseList` has been deprecated and will be removed in a future version (GH13784)
- `DataFrame.to_html()` and `DataFrame.to_latex()` have dropped the `colSpace` parameter in favor of `col_space` (GH13857)
- `DataFrame.to_sql()` has deprecated the `flavor` parameter, as it is superfluous when SQLAlchemy is not installed (GH13611)
- Deprecated `read_csv` keywords:
  - `compact_ints` and `use_unsigned` have been deprecated and will be removed in a future version (GH13320)
  - `buffer_lines` has been deprecated and will be removed in a future version (GH13360)
  - `as_recarray` has been deprecated and will be removed in a future version (GH13373)
  - `skip_footer` has been deprecated in favor of `skipfooter` and will be removed in a future version (GH13349)
- `pd.ordered_merge()` has been renamed to `pd.merge_ordered()` and the original name will be removed in a future version (GH13358)
• Timestamp.offset property (and named arg in the constructor), has been deprecated in favor of freq (GH12160)

• pd.tseries.util.pivot_annual is deprecated. Use pivot_table as alternative, an example is here (GH736)

• pd.tseries.util.isleapyear has been deprecated and will be removed in a subsequent release. Datetime-likes now have a .is_leap_year property (GH13727)

• Panel4D and PanelND constructors are deprecated and will be removed in a future version. The recommended way to represent these types of n-dimensional data are with the xarray package. Pandas provides a to_xarray() method to automate this conversion (GH13564).

• pandas.tseries.frequencies.get_standard_freq is deprecated. Use pandas.tseries.frequencies.to_offset(freq).rule_code instead (GH13874)

• pandas.tseries.frequencies.to_offset's freqstr keyword is deprecated in favor of freq (GH13874)

• Categorical.from_array has been deprecated and will be removed in a future version (GH13854)

1.10.4 Removal of prior version deprecations/changes

• The SparsePanel class has been removed (GH13778)

• The pd.sandbox module has been removed in favor of the external library pandas-qt (GH13670)

• The pandas.io.data and pandas.io.wb modules are removed in favor of the pandas-datareader package (GH13724).

• The pandas.tools.rplot module has been removed in favor of the seaborn package (GH13855)

• DataFrame.to_csv() has dropped the engine parameter, as was deprecated in 0.17.1 (GH11274, GH13419)

• DataFrame.to_dict() has dropped the outtype parameter in favor of orient (GH13627, GH8486)

• pd.Categorical has dropped setting of the ordered attribute directly in favor of the set_ordered method (GH13671)

• pd.Categorical has dropped the levels attribute in favor of categories (GH8376)

• DataFrame.to_sql() has dropped the mysql option for the flavor parameter (GH13611)

• Panel.shift() has dropped the lags parameter in favor of periods (GH14041)

• pd.Index has dropped the diff method in favor of difference (GH13669)

• pd.DataFrame has dropped the to_wide method in favor of to_panel (GH14039)

• Series.to_csv has dropped the to_wide method in favor of to_panel (GH14039)

• Series.xs, DataFrame.xs, Panel.xs, Panel.major_xs, and Panel.minor_xs have dropped the copy parameter (GH13781)

• str.split has dropped the return_type parameter in favor of expand (GH13701)

• Removal of the legacy time rules (offset aliases), deprecated since 0.17.0 (this has been alias since 0.8.0) (GH13590, GH13868). Now legacy time rules raises ValueError. For the list of currently supported offsets, see here.

• The default value for the return_type parameter for DataFrame.plot.box and DataFrame.boxplot changed from None to "axes". These methods will now return a matplotlib axes by default instead of a dictionary of artists. See here (GH6581).
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- The `tquery` and `uquery` functions in the `pandas.io.sql` module are removed (GH5950).

### 1.10.5 Performance Improvements

- Improved performance of sparse `IntIndex.intersect` (GH13082)
- Improved performance of sparse arithmetic with `BlockIndex` when the number of blocks are large, though recommended to use `IntIndex` in such cases (GH13082)
- Improved performance of `DataFrame.quantile()` as it now operates per-block (GH11623)
- Improved performance of float64 hash table operations, fixing some very slow indexing and groupby operations in python 3 (GH13166, GH13334)
- Improved performance of `DataFrameGroupBy.transform` (GH12737)
- Improved performance of `Index` and `Series.duplicated` (GH10235)
- Improved performance of `Index.difference` (GH12044)
- Improved performance of `RangeIndex.is_monotonic_increasing` and `is_monotonic_decreasing` (GH13749)
- Improved performance of datetime string parsing in `DatetimeIndex` (GH13692)
- Improved performance of hashing `Period` (GH12817)
- Improved performance of `factorize` of datetime with timezone (GH13750)
- Improved performance of by lazily creating indexing hashtables on larger Indexes (GH14266)
- Unnecessary materializing of a MultiIndex when introspecting for memory usage (GH14308)

### 1.10.6 Bug Fixes

- Bug in `groupby().shift()`, which could cause a segfault or corruption in rare circumstances when grouping by columns with missing values (GH13813)
- Bug in `groupby().cumsum()` calculating `cumprod` when `axis=1` (GH13994)
- Bug in `pd.to_timedelta()` in which the `errors` parameter was not being respected (GH13613)
- Bug in `io.json.json_normalize()` where non-ascii keys raised an exception (GH13213)
- Bug when passing a not-default-indexed `Series` as `xerr` or `yerr` in `.plot()` (GH11858)
- Bug in area plot draws legend incorrectly if subplot is enabled or legend is moved after plot (matplotlib 1.5.0 is required to draw area plot legend properly) (GH9161, GH13544)
- Bug in `DataFrame` assignment with an object-dtyped `Index` where the resultant column is mutable to the original object. (GH13522)
- Bug in `matplotlib.AutomaFormatter`; this restores the second scaled formatting and re-adds micro-second scaled formatting (GH13131)
- Bug in selection from a `HDFStore` with a fixed format and `start` and/or `stop` specified will now return the selected range (GH8287)
- Bug in `Categorical.from_codes()` where an unhelpful error was raised when an invalid `ordered` parameter was passed in (GH14058)
- Bug in `Series` construction from a tuple of integers on windows not returning default dtype (int64) (GH13646)
• Bug in `TimedeltaIndex` addition with a Datetime-like object where addition overflow was not being caught (GH14068)
• Bug in `.groupby(..).resample(..)` when the same object is called multiple times (GH13174)
• Bug in `.to_records()` when index name is a unicode string (GH13172)
• Bug in calling `.memory_usage()` on object which doesn’t implement (GH12924)
• Regression in `Series.quantile` with nans (also shows up in `.median()` and `.describe()`); furthermore now names the `Series` with the quantile (GH13098, GH13146)
• Bug in `SeriesGroupBy.transform` with datetime values and missing groups (GH13191)
• Bug where empty `Series` were incorrectly coerced in datetime-like numeric operations (GH13844)
• Bug in `Categorical` constructor when passed a `Categorical` containing datetimes with timezones (GH14190)
• Bug in `Series.str.extractall()` with `str` index raises `ValueError` (GH13156)
• Bug in `Series.str.extractall()` with single group and quantifier (GH13382)
• Bug in `DatetimeIndex` and `Period` subtraction raises `ValueError` or `AttributeError` rather than `TypeError` (GH13078)
• Bug in `Index` and `Series` created with `NaN` and `NaT` mixed data may not have `datetime64` dtype (GH13324)
• Bug in `Index` and `Series` may ignore `np.datetime64('nat')` and `np.timedelta64('nat')` to infer `dtype` (GH13324)
• Bug in `PeriodIndex` and `Period` subtraction raises `AttributeError` (GH13071)
• Bug in `PeriodIndex` construction returning a `float64` index in some circumstances (GH13067)
• Bug in `.resample(..)` with a `PeriodIndex` not changing its `freq` appropriately when empty (GH13067)
• Bug in `.resample(..)` with a `PeriodIndex` not retaining its type or name with an empty DataFrame appropriately when empty (GH13212)
• Bug in `groupby(..).apply(..)` when the passed function returns scalar values per group (GH13468).
• Bug in `groupby(..).resample(..)` where passing some keywords would raise an exception (GH13235)
• Bug in `.tz_convert` on a tz-aware `DateTimeIndex` that relied on index being sorted for correct results (GH13306)
• Bug in `.tz_localize` with `dateutil.tz.tzlocal` may return incorrect result (GH13583)
• Bug in `DateTimeTZDtype` `dtype` with `dateutil.tz.tzlocal` cannot be regarded as valid `dtype` (GH13583)
• Bug in `pd.read_hdf()` where attempting to load an HDF file with a single dataset, that had one or more categorical columns, failed unless the key argument was set to the name of the dataset. (GH13583)
• Bug in `.rolling()` that allowed a negative integer window in construction of the `Rolling()` object, but would later fail on aggregation (GH13383)
• Bug in `Series` indexing with tuple-valued data and a numeric index (GH13509)
• Bug in printing `pd.DataFrame` where unusual elements with the `object` `dtype` were causing segfaults (GH13717)
• Bug in ranking `Series` which could result in segfaults (GH13445)
• Bug in various index types, which did not propagate the name of passed index (GH12309)
• **Bug in DatetimeIndex**, which did not honour the `copy=True` (GH13205)

• **Bug in DatetimeIndex.is_normalized** returns incorrectly for normalized date_range in case of local timezones (GH13459)

• **Bug in pd.concat and .append** may coerce `datetime64` and `timedelta` to object dtype containing python built-in `datetime` or `timedelta` rather than `Timestamp` or `Timedelta` (GH13626)

• **Bug in PeriodIndex.append** may raises `AttributeError` when the result is object dtype (GH13221)

• **Bug in CategoricalIndex.append** may accept normal list (GH13626)

• **Bug in pd.concat and .append** with the same timezone get reset to UTC (GH7795)

• **Bug in Series and DataFrame .append** raises `AmbiguousTimeError` if data contains datetime near DST boundary (GH13626)

• **Bug in DataFrame.to_csv()** in which float values were being quoted even though quotations were specified for non-numeric values only (GH12922, GH13259)

• **Bug in DataFrame.describe()** raising `ValueError` with only boolean columns (GH13898)

• **Bug in MultiIndex slicing** where extra elements were returned when level is non-unique (GH12896)

• **Bug in .str.replace** slicing does not raise `TypeError` for invalid replacement (GH13438)

• **Bug in MultiIndex.from_arrays** which didn’t check for input array lengths matching (GH13599)

• **Bug in cartesian_product and MultiIndex.from_product** which may raise with empty input arrays (GH12258)

• **Bug in pd.read_csv()** which may cause a segfault or corruption when iterating in large chunks over a stream/file under rare circumstances (GH13703)

• **Bug in pd.read_csv()** which caused errors to be raised when a dictionary containing scalars is passed in for `na_values` (GH12224)

• **Bug in pd.read_csv()** which caused BOM files to be incorrectly parsed by not ignoring the BOM (GH4793)

• **Bug in pd.read_csv()** with `engine='python'` which raised errors when a numpy array was passed in for `usecols` (GH12546)

• **Bug in pd.read_csv()** where the index columns were being incorrectly parsed when parsed as dates with a `thousands` parameter (GH14066)

• **Bug in pd.read_csv()** with `engine='python'` in which NaN values weren’t being detected after data was converted to numeric values (GH13314)

• **Bug in pd.read_csv()** in which the `nrows` argument was not properly validated for both engines (GH10476)

• **Bug in pd.read_csv()** with `engine='python'` in which infinities of mixed-case forms were not being interpreted properly (GH13274)

• **Bug in pd.read_csv()** with `engine='python'` in which trailing NaN values were not being parsed (GH13320)

• **Bug in pd.read_csv()** with `engine='python'` when reading from a `tempfile.TemporaryFile` on Windows with Python 3 (GH13398)

• **Bug in pd.read_csv()** that prevents `usecols` kwarg from accepting single-byte unicode strings (GH13219)

• **Bug in pd.read_csv()** that prevents `usecols` from being an empty set (GH13402)
• Bug in `pd.read_csv()` in the C engine where the NULL character was not being parsed as NULL (GH14012)

• Bug in `pd.read_csv()` with `engine='c'` in which NULL quotechar was not accepted even though quoting was specified as None (GH13411)

• Bug in `pd.read_csv()` with `engine='c'` in which fields were not properly cast to float when quoting was specified as non-numeric (GH13411)

• Bug in `pd.read_csv()` in Python 2.x with non-UTF8 encoded, multi-character separated data (GH3404)

• Bug in `pd.read_csv()`, where aliases for utf-xx (e.g. UTF-xx, UTF_xx, utf_xx) raised UnicodeDecodeError (GH13549)

• Bug in `pd.read_csv(), pd.read_table, pd.read_fwf, pd.read_stata and pd.read_sas` where files were opened by parsers but not closed if both chunksize and iterator were none. (GH13940)

• Bug in `StataReader, StataWriter, XportReader and SAS7BDATReader` where a file was not properly closed when an error was raised. (GH13940)

• Bug in `pd.pivot_table()` where `margins_name` is ignored when `aggfunc` is a list (GH13354)

• Bug in `pd.Series.str.zfill, center, ljust, rjust, and pad` when passing non-integers, did not raise TypeError (GH13598)

• Bug in checking for any null objects in a `TimedeltaIndex`, which always returned True (GH13603)

• Bug in `Series arithmetic raises TypeError` if it contains datetime-like as object dtype (GH13043)

• Bug in `Series.isnull()` and `Series.notnull()` ignore `Period('NaT')` (GH13737)

• Bug in `Series.fillna()` and `Series.dropna()` don’t affect to `Period('NaT')` (GH13737)

• Bug in `.fillna(value=np.nan) incorrectly raises KeyError on a category dtyped Series (GH14021)

• Bug in extension dtype creation where the created types were not is/identical (GH13285)

• Bug in `.resample(..)` where incorrect warnings were triggered by IPython introspection (GH13618)

• Bug in `NaT - Period raises AttributeError` (GH13071)

• Bug in `Series comparison may output incorrect result if rhs contains NaT` (GH9005)

• Bug in `Series and Index comparison may output incorrect result if it contains NaT with object dtype` (GH13592)

• Bug in `Period addition raises TypeError if Period is on right hand side` (GH13069)

• Bug in `Period and Series or Index comparison raises TypeError` (GH13200)

• Bug in `.set_eng_float_format()` that would prevent NaN and Inf from formatting (GH11981)

• Bug in `.unstack with Categorical dtype resets .ordered to True` (GH13249)

• Clean some compile time warnings in datetime parsing (GH13607)

• Bug in `factorize raises AmbiguousTimeError` if data contains datetime near DST boundary (GH13750)

• Bug in `.set_index raises AmbiguousTimeError` if new index contains DST boundary and multi levels (GH12920)

• Bug in `.shift raises AmbiguousTimeError` if data contains datetime near DST boundary (GH13926)

• Bug in `pd.read_hdf()` returns incorrect result when a DataFrame with a categorical column and a query which doesn’t match any values (GH13792)

• Bug in `.iloc when indexing with a non lex-sorted MultiIndex` (GH13797)
• Bug in .loc when indexing with date strings in a reverse sorted DatetimeIndex (GH14316)
• Bug in Series comparison operators when dealing with zero dim NumPy arrays (GH13006)
• Bug in .combine_first may return incorrect dtype (GH7630, GH10567)
• Bug in groupby where apply returns different result depending on whether first result is None or not (GH12824)
• Bug in groupby(...).nth() where the group key is included inconsistently if called after .head()/.tail() (GH12839)
• Bug in .to_html,.to_latex and .to_string silently ignore custom datetime formatter passed through the formatters key word (GH10690)
• Bug in DataFrame.iterrows(), not yielding a Series subclass if defined (GH13977)
• Bug in pd.to_numeric when errors='coerce' and input contains non-hashable objects (GH13324)
• Bug in invalid Timedelta arithmetic and comparison may raise ValueError rather than TypeError (GH13624)
• Bug in invalid datetime parsing in to_datetime and DatetimeIndex may raise TypeError rather than ValueError (GH11169, GH11287)
• Bug in Index created with tz-aware Timestamp and mismatched tz option incorrectly coerces timezone (GH13692)
• Bug in DatetimeIndex with nanosecond frequency does not include timestamp specified with end (GH13672)
• Bug in `Series` when setting a slice with a `np.timedelta64` (GH14155)
• Bug in Index raises OutOfBoundsDatet ime if datetime exceeds datetime64[ns] bounds, rather than coercing to object dtype (GH13663)
• Bug in Index may ignore specified datetime64 or timedelta64 passed as dtype (GH13981)
• Bug in RangeIndex can be created without no arguments rather than raises TypeError (GH13793)
• Bug in .value_counts() raises OutOfBoundsDatet ime if data exceeds datetime64[ns] bounds (GH13663)
• Bug in DatetimeIndex may raise OutOfBoundsDatetime if input np.datetime64 has other unit than ns (GH9114)
• Bug in Series creation with np.datetime64 which has other unit than ns as object dtype results in incorrect values (GH13876)
• Bug in resample with timedelta data where data was casted to float (GH13119).
• Bug in pd.isnull() pd.notnull() raise TypeError if input datetime-like has other unit than ns (GH13389)
• Bug in pd.merge() may raise TypeError if input datetime-like has other unit than ns (GH13389)
• Bug in HDFStore/read_hdf() discarded DatetimeIndex.name if tz was set (GH13884)
• Bug in Categorical.remove_unused_categories() changes .codes dtype to platform int (GH13261)
• Bug in groupby with as_index=False returns all NaN’s when groupin on multiple columns including a categorical one (GH13204)
• Bug in df.groupby(...)[...] where getitem with Int64Index raised an error (GH13731)
• Bug in the CSS classes assigned to `DataFrame.style` for index names. Previously they were assigned "col_heading level<n> col<c>" where n was the number of levels + 1. Now they are assigned "index_name level<n>", where n is the correct level for that MultiIndex.

• Bug where `pd.read_gbq()` could throw `ImportError`: No module named discovery as a result of a naming conflict with another python package called apiclient (GH13454)

• Bug in `Index.union` returns an incorrect result with a named empty index (GH13432)

• Bugs in `Index.difference` and `DataFrame.join` raise in Python3 when using mixed-integer indexes (GH13432, GH12814)

• Bug in `subtract` tz-aware `datetime.datetime` from tz-aware `datetime64` series (GH14088)

• Bug in `.to_excel()` when `DataFrame` contains a MultiIndex which contains a label with a NaN value (GH13511)

• Bug in invalid frequency offset string like “D1”, “-2-3H” may not raise `ValueError` (GH13930)

• Bug in `concat` and `groupby` for hierarchical frames with `RangeIndex` levels (GH13542).

• Bug in `Series.str.contains()` for Series containing only NaN values of object dtype (GH14171)

• Bug in `agg()` function on groupby dataframe changes dtype of `datetime64[ns]` column to float64 (GH12821)

• Bug in using NumPy ufunc with `PeriodIndex` to add or subtract integer raise `IncompatibleFrequency`. Note that using standard operator like + or - is recommended, because standard operators use more efficient path (GH13980)

• Bug in operations on NaN returning float instead of `datetime64[ns]` (GH12941)

• Bug in `Series` flexible arithmetic methods (like `.add()`) raises `ValueError` when `axis=None` (GH13894)

• Bug in `DataFrame.to_csv()` with MultiIndex columns in which a stray empty line was added (GH6618)

• Bug in `DatetimeIndex`, `TimedeltaIndex` and `PeriodIndex.equals()` may return True when input isn’t Index but contains the same values (GH13107)

• Bug in assignment against datetime with timezone may not work if it contains datetime near DST boundary (GH14146)

• Bug in `pd.eval()` and `HDFStore` query truncating long float literals with python 2 (GH14241)

• Bug in `Index` raises `KeyError` displaying incorrect column when column is not in the df and columns contains duplicate values (GH13822)

• Bug in `Period` and `PeriodIndex` creating wrong dates when frequency has combined offset aliases (GH13874)

• Bug in `.to_string()` when called with an integer `line_width` and `index=False` raises an Unbound-LocalError exception because `idx` referenced before assignment.

• Bug in `eval()` where the `resolvers` argument would not accept a list (GH14095)

• Bugs in `stack`, `get_dummies`, `make_axis_dummies` which don’t preserve categorical dtypes in (multi)indexes (GH13854)

• `PeriodIndex` can now accept list and array which contains `pd.NaT` (GH13430)

• Bug in `df.groupby` where `.median()` returns arbitrary values if grouped dataframe contains empty bins (GH13629)

• Bug in `Index.copy()` where name parameter was ignored (GH14302)
1.11 v0.18.1 (May 3, 2016)

This is a minor bug-fix release from 0.18.0 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- `.groupby(...)` has been enhanced to provide convenient syntax when working with `.rolling(..)`, `.expanding(..)` and `.resample(..)` per group, see here
- `pd.to_datetime()` has gained the ability to assemble dates from a DataFrame, see here
- Method chaining improvements, see here.
- Custom business hour offset, see here.
- Many bug fixes in the handling of sparse, see here
- Expanded the Tutorials section with a feature on modern pandas, courtesy of @TomAugsburger. (GH13045).

What’s new in v0.18.1

- **New features**
  - Custom Business Hour
  - `.groupby(..)` syntax with window and resample operations
  - Method chaining improvements
    - `.where()` and `.mask()`
    - `.loc[]`, `.iloc[]`, `.ix[]`
    - [] indexing
  - Partial string indexing on DateTimeIndex when part of a MultiIndex
  - Assembling Datetimes
  - Other Enhancements
- **Sparse changes**
- **API changes**
  - `.groupby(..).nth()` changes
  - numpy function compatibility
  - Using `.apply on groupby resampling`
  - Changes in read_csv exceptions
  - `to_datetime` error changes
  - Other API changes
  - Deprecations
- **Performance Improvements**
- **Bug Fixes**
1.11.1 New features

1.11.1.1 Custom Business Hour

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. For details, see Custom Business Hour (GH11514)

```python
In [1]: from pandas.tseries.offsets import CustomBusinessHour
In [2]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [3]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())
```

Friday before MLK Day

```python
In [4]: dt = datetime(2014, 1, 17, 15)
In [5]: dt + bhour_us
Out[5]: Timestamp('2014-01-17 16:00:00')
```

Tuesday after MLK Day (Monday is skipped because it’s a holiday)

```python
In [6]: dt + bhour_us * 2
Out[6]: Timestamp('2014-01-20 09:00:00')
```

1.11.1.2 .groupby(..) syntax with window and resample operations

.groupby(...) has been enhanced to provide convenient syntax when working with .rolling(..), .expanding(..) and .resample(..) per group, see (GH12486, GH12738).

You can now use .rolling(..) and .expanding(..) as methods on groupbys. These return another deferred object (similar to what .rolling() and .expanding() do on ungrouped pandas objects). You can then operate on these RollingGroupby objects in a similar manner.

Previously you would have to do this to get a rolling window mean per-group:

```python
                      ...:                      'B': np.arange(40))
In [8]: df
Out[8]:
     A   B
    0  1   0
    1  1   1
    2  1   2
    3  1   3
    4  1   4
    5  1   5
    6  1   6
    .. .. ..
   33 3  33
   34 3  34
   35 3  35
   36 3  36
   37 3  37
```

(continues on next page)
In [9]: df.groupby('A').apply(lambda x: x.rolling(4).B.mean())
Out [9]:
A
  1     0  NaN
  1     1  NaN
  2     2  NaN
  3     3    1.5
  4     4    2.5
  5     5    3.5
  6     6    4.5
  ...  ...  ...
  3     33   NaN
  34    NaN
  35    33.5
  36    34.5
  37    35.5
  38    36.5
  39    37.5
Name: B, Length: 40, dtype: float64

Now you can do:

In [10]: df.groupby('A').rolling(4).B.mean()
Out [10]:
A
  1     0  NaN
  1     1  NaN
  2     2  NaN
  3     3    1.5
  4     4    2.5
  5     5    3.5
  6     6    4.5
  ...  ...  ...
  3     33   NaN
  34    NaN
  35    33.5
  36    34.5
  37    35.5
  38    36.5
  39    37.5
Name: B, Length: 40, dtype: float64

For .resample(…) type of operations, previously you would have to:

In [11]: df = pd.DataFrame({'date': pd.date_range(start='2016-01-01',
                      ....:              periods=4,
                      ....:              freq='W'),
                      ....:              'group': [1, 1, 2, 2],
                      ....:              'val': [5, 6, 7, 8]}).set_index('date')
(continues on next page)
In [12]: df
Out[12]:
    group  val
date
2016-01-03  1  5
2016-01-10  1  6
2016-01-17  2  7
2016-01-24  2  8

In [13]: df.groupby('group').apply(lambda x: x.resample('1D').ffill())
Out[13]:
    group  val
group date
1  2016-01-03  1  5
   2016-01-04  1  5
   2016-01-05  1  5
   2016-01-06  1  5
   2016-01-07  1  5
   2016-01-08  1  5
   2016-01-09  1  5
   ...          ... ...
2  2016-01-18  2  7
   2016-01-19  2  7
   2016-01-20  2  7
   2016-01-21  2  7
   2016-01-22  2  7
   2016-01-23  2  7
   2016-01-24  2  8
[16 rows x 2 columns]

Now you can do:

In [14]: df.groupby('group').resample('1D').ffill()
Out[14]:
    group  val
group date
1  2016-01-03  1  5
   2016-01-04  1  5
   2016-01-05  1  5
   2016-01-06  1  5
   2016-01-07  1  5
   2016-01-08  1  5
   2016-01-09  1  5
   ...          ... ...
2  2016-01-18  2  7
   2016-01-19  2  7
   2016-01-20  2  7
   2016-01-21  2  7
   2016-01-22  2  7
   2016-01-23  2  7
   2016-01-24  2  8
[16 rows x 2 columns]
1.11.1.3 Method chaining improvements

The following methods / indexers now accept a callable. It is intended to make these more useful in method chains, see the documentation. (GH11485, GH12533)

- `.where()` and `.mask()`
- `.loc[]`, `.iloc[]` and `.ix[]`
- `[]` indexing

`.where()` and `.mask()`

These can accept a callable for the condition and other arguments.

```
In [15]: df = pd.DataFrame({'A': [1, 2, 3],
                           'B': [4, 5, 6],
                           'C': [7, 8, 9]})
...

In [16]: df.where(lambda x: x > 4, lambda x: x + 10)
Out[16]:
   A  B  C
0 11 14 7
1 12 5 8
2 13 6 9
```

`.loc[]`, `.iloc[]`, `.ix[]`

These can accept a callable, and a tuple of callable as a slicer. The callable can return a valid boolean indexer or anything which is valid for these indexer's input.

```
# callable returns bool indexer
In [17]: df.loc[lambda x: x.A >= 2, lambda x: x.sum() > 10]
Out[17]:
   B  C
0 5 8
1 6 9
```

```
# callable returns list of labels
In [18]: df.loc[lambda x: [1, 2], lambda x: ['A', 'B']]
Out[18]:
   A  B
0 2 5
1 3 6
```

`[]` indexing

Finally, you can use a callable in `[]` indexing of Series, DataFrame and Panel. The callable must return a valid input for `[]` indexing depending on its class and index type.

```
In [19]: df[lambda x: 'A']
Out[19]:
```

(continues on next page)
Using these methods / indexers, you can chain data selection operations without using temporary variable.

```
In [20]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [21]: (bb.groupby(['year', 'team'])
    ....:   .sum()
    ....:   .loc[lmbd df: df.r > 100]
    ....:   )

Out[21]:
        stint  g    ab   r    h  X2b  X3b  hr  rbi  sb  cs  bb  so  
    year team                  
  2007  CIN       6  379  745  101  203  35  2 36 125.0  10.0  1.0  105  127.0  14.
       0    1.0  15.0  18.0
       0  10.0  4.0  8.0  28.0
       0  9.0  16.0  6.0  17.0

       0  12.0  4.0  16.0  38.0
```

### 1.11.1.4 Partial string indexing on `DateTimeIndex` when part of a `MultiIndex`

Partial string indexing now matches on `DateTimeIndex` when part of a `MultiIndex` (GH10331)

```
In [22]: dft2 = pd.DataFrame(np.random.randn(20, 1),
    ....:   columns=['A'],
    ....:   index=pd.MultiIndex.from_product([pd.date_range('20130101',
    ....:                                             periods=10,
    ....:                                             freq='12H'),
    ....:                                             ['a', 'b']]))

In [23]: dft2

Out[23]:
     A
2013-01-01 00:00:00 0.156998
```

(continues on next page)
### On other levels

In [25]: idx = pd.IndexSlice

In [26]: dft2 = dft2.swaplevel(0, 1).sort_index()

In [27]: dft2

Out[27]:

...
1.11.1.5 Assembling Datetimes

pd.to_datetime() has gained the ability to assemble datetimes from a passed in DataFrame or a dict. (GH8158).

```python
In [29]: df = pd.DataFrame({'year': [2015, 2016],
                          'month': [2, 3],
                          'day': [4, 5],
                          'hour': [2, 3]})

In [30]: df
Out[30]:
       year  month  day  hour
0  2015   2     4     2
1  2016   3     5     3
```

Assembling using the passed frame.

```python
In [31]: pd.to_datetime(df)
Out[31]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```python
In [32]: pd.to_datetime(df[['year', 'month', 'day']])
Out[32]:
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

1.11.1.6 Other Enhancements

- pd.read_csv() now supports delim_whitespace=True for the Python engine (GH12958).
- pd.read_csv() now supports opening ZIP files that contains a single CSV, via extension inference or explicit compression='zip' (GH12175).
- pd.read_csv() now supports opening files using xz compression, via extension inference or explicit compression='xz' is specified; xz compressions is also supported by DataFrame.to_csv in the same way (GH11852).
- pd.read_msgpack() now always gives writeable ndarrays even when compression is used (GH12359).
- pd.read_msgpack() now supports serializing and de-serializing categoricals with msgpack (GH12573).
- .to_json() now supports NDFrames that contain categorical and sparse data (GH10778).
- interpolate() now supports method='akima' (GH7588).
• **pd.read_excel()** now accepts path objects (e.g. pathlib.Path, py.path.local) for the file path, in line with other read_* functions (GH12655)
• Added .weekday_name property as a component to DatetimeIndex and the .dt accessor. (GH11128)
• **Index.take** now handles allow_fill and fill_value consistently (GH12631)

```python
In [33]: idx = pd.Index([1., 2., 3., 4.], dtype='float')
   # default, allow_fill=True, fill_value=None
In [34]: idx.take([2, -1])
Out[34]: Float64Index([3.0, 4.0], dtype='float64')
In [35]: idx.take([2, -1], fill_value=True)
Out[35]: Float64Index([3.0, nan], dtype='float64')
```

• **Index** now supports .str.get_dummies() which returns MultiIndex, see Creating Indicator Variables (GH10008, GH10103)

```python
In [36]: idx = pd.Index(['a|b', 'a|c', 'b|c'])
In [37]: idx.str.get_dummies('|')
Out[37]: MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
   labels=[[1, 1, 0], [1, 0, 1], [0, 1, 1]],
   names=['a', 'b', 'c'])
```

• **pd.crosstab()** has gained a normalize argument for normalizing frequency tables (GH12569). Examples in the updated docs here.
• .resample(..).interpolate() is now supported (GH12925)
• .isin() now accepts passed sets (GH12988)

### 1.11.2 Sparse changes

These changes conform sparse handling to return the correct types and work to make a smoother experience with indexing.

SparseArray.take now returns a scalar for scalar input, SparseArray for others. Furthermore, it handles a negative indexer with the same rule as Index (GH10560, GH12796)

```python
In [38]: s = pd.SparseArray([np.nan, np.nan, 1, 2, 3, np.nan, 4, 5, np.nan, 6])
In [39]: s.take(0)
Out[39]: nan
In [40]: s.take([1, 2, 3])
Out[40]: [nan, 1.0, 2.0]
Fill: nan
IntIndex
Indices: array([1, 2], dtype=int32)
```

• Bug in SparseSeries[] indexing with Ellipsis raises KeyError (GH9467)
• Bug in SparseArray[] indexing with tuples are not handled properly (GH12966)
- Bug in `SparseSeries.loc[]` with list-like input raises `TypeError` (GH10560)
- Bug in `SparseSeries.iloc[]` with scalar input may raise `IndexError` (GH10560)
- Bug in `SparseSeries.loc[], .iloc[]` with slice returns `SparseArray`, rather than `SparseSeries` (GH10560)
- Bug in `SparseDataFrame.loc[], .iloc[]` may result in dense Series, rather than `SparseSeries` (GH12787)
- Bug in `SparseArray` addition ignores `fill_value` of right hand side (GH12910)
- Bug in `SparseArray` mod raises `AttributeError` (GH12910)
- Bug in `SparseArray` pow calculates $1 \times \text{np.nan} = \text{np.nan}$ which must be 1 (GH12910)
- Bug in `SparseArray` comparison output may incorrect result or raise `ValueError` (GH12971)
- Bug in `SparseSeries.__repr__` raises `TypeError` when it is longer than `max_rows` (GH10560)
- Bug in `SparseSeries.shape` ignores `fill_value` (GH10452)
- Bug in `SparseSeries` and `SparseArray` may have different `dtype` from its dense values (GH12908)
- Bug in `SparseSeries.reindex` incorrectly handle `fill_value` (GH12797)
- Bug in `SparseArray.to_frame()` results in `DataFrame`, rather than `SparseDataFrame` (GH9850)
- Bug in `SparseSeries.value_counts()` does not count `fill_value` (GH6749)
- Bug in `SparseArray.to_dense()` does not preserve `dtype` (GH10648)
- Bug in `SparseArray.to_dense()` incorrectly handle `fill_value` (GH12797)
- Bug in `pd.concat()` of `SparseSeries` results in dense (GH10536)
- Bug in `pd.concat()` of `SparseDataFrame` incorrectly handle `fill_value` (GH9765)
- Bug in `pd.concat()` of `SparseDataFrame` may raise `AttributeError` (GH12174)
- Bug in `SparseArray.shift()` may raise `NameError` or `TypeError` (GH12908)

### 1.11.3 API changes

#### 1.11.3.1 `.groupby(..).nth()` changes

The index in `.groupby(..).nth()` output is now more consistent when the `as_index` argument is passed (GH11039):

```python
In [41]: df = DataFrame({'A' : ['a', 'b', 'a'],
                      'B' : [1, 2, 3]})

In [42]: df
Out[42]:
   A  B
0  a  1
1  b  2
2  a  3
```

Previous Behavior:
```
In [3]: df.groupby('A', as_index=True)['B'].nth(0)
Out[3]:
   0  1
0  1  2
Name: B, dtype: int64

In [4]: df.groupby('A', as_index=False)['B'].nth(0)
Out[4]:
   0  1
0  1  2
Name: B, dtype: int64
```

**New Behavior:**

```
In [43]: df.groupby('A', as_index=True)['B'].nth(0)
Out[43]:
   A
a  1  2
b  1  2
Name: B, dtype: int64

In [44]: df.groupby('A', as_index=False)['B'].nth(0)
Out[44]:
   0  1
0  1  2
Name: B, dtype: int64
```

Furthermore, previously, a `.groupby` would always sort, regardless if `sort=False` was passed with `.nth()`.

```
In [45]: np.random.seed(1234)
In [46]: df = pd.DataFrame(np.random.randn(100, 2), columns=['a', 'b'])
In [47]: df['c'] = np.random.randint(0, 4, 100)
```

**Previous Behavior:**

```
In [4]: df.groupby('c', sort=True).nth(1)
Out[4]:
          a         b
     c         
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524

In [5]: df.groupby('c', sort=False).nth(1)
Out[5]:
          a         b
     c         
0 -0.334077  0.002118
1  0.036142 -2.074978
2 -0.720589  0.887163
3  0.859588 -0.636524
```

**New Behavior:**
In [48]: df.groupby('c', sort=True).nth(1)
Out[48]:
   a    b
   c
  0 -0.334077  0.002118
  1  0.036142 -2.074978
  2 -0.720589  0.887163
  3  0.859588 -0.636524

In [49]: df.groupby('c', sort=False).nth(1)
   a    b
   c
  0 -0.334077  0.002118
  1  0.036142 -2.074978
  2 -0.720589  0.887163
  3  0.859588 -0.636524

1.11.3.2 numpy function compatibility

Compatibility between pandas array-like methods (e.g. `sum` and `take`) and their numpy counterparts has been greatly increased by augmenting the signatures of the pandas methods so as to accept arguments that can be passed in from numpy, even if they are not necessarily used in the pandas implementation (GH12644, GH12638, GH12687)

- `.searchsorted()` for `Index` and `TimedeltaIndex` now accept a `sorter` argument to maintain compatibility with numpy's `searchsorted` function (GH12238)
- Bug in numpy compatibility of `np.round()` on a `Series` (GH12600)

An example of this signature augmentation is illustrated below:

In [50]: sp = pd.SparseDataFrame([[1, 2, 3]])
In [51]: sp
Out[51]:
   0
  0 1
  1 2
  2 3

Previous behaviour:

In [2]: np.cumsum(sp, axis=0)
...:
TypeError: cumsum() takes at most 2 arguments (4 given)

New behaviour:

In [52]: np.cumsum(sp, axis=0)
Out[52]:
   0
  0 1
  1 3
  2 6
1.11.3.3 Using `.apply` on groupby resampling

Using apply on resampling groupby operations (using a pd.TimeGrouper) now has the same output types as similar apply calls on other groupby operations. (GH11742).

```python
In [53]: df = pd.DataFrame({'date': pd.to_datetime(['10/10/2000', '11/10/2000']),
                       'value': [10, 13])

In [54]: df
Out[54]:
          date  value
0 2000-10-10     10
1 2000-11-10     13
```

Previous behavior:

```python
In [1]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
-->       .sum())
Out[1]:
TypeError: cannot concatenate a non-NDFrame object

# Output is a Series
In [2]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value']].
-->       .sum())
Out[2]:
    date     value
2000-10-31    10
2000-11-30    13
dtype: int64
```

New Behavior:

```python
# Output is a Series
In [55]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x.value.
-->       .sum())
Out[55]:
    date     value
2000-10-31    10
2000-11-30    13
Freq: M, dtype: int64

# Output is a DataFrame
In [56]: df.groupby(pd.TimeGrouper(key='date', freq='M')).apply(lambda x: x[['value']]
-->       .sum())
Out[56]:
          date  value
2000-10-31      10
2000-11-30      13
```

1.11.3.4 Changes in `read_csv` exceptions

In order to standardize the `read_csv` API for both the c and python engines, both will now raise an EmptyDataError, a subclass of ValueError, in response to empty columns or header (GH12493, GH12506)
Previous behaviour:

```
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...:
ValueError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...:
StopIteration
```

New behaviour:

```
In [1]: df = pd.read_csv(StringIO(''), engine='c')
...:
pandas.io.common.EmptyDataError: No columns to parse from file

In [2]: df = pd.read_csv(StringIO(''), engine='python')
...:
pandas.io.common.EmptyDataError: No columns to parse from file
```

In addition to this error change, several others have been made as well:

- `CParserError` now sub-classes `ValueError` instead of just a `Exception` (GH12551)
- A `CParserError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine cannot parse a column (GH12506)
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when the `c` engine encounters a NaN value in an integer column (GH12506)
- A `ValueError` is now raised instead of a generic `Exception` in `read_csv` when `true_values` is specified, and the `c` engine encounters an element in a column containing unencodable bytes (GH12506)
- `pandas.parser.OverflowError` exception has been removed and has been replaced with Python’s built-in `OverflowError` exception (GH12506)
- `pd.read_csv()` no longer allows a combination of strings and integers for the `usecols` parameter (GH12678)

### 1.11.3.5 to_datetime error changes

Bugs in `pd.to_datetime()` when passing a unit with convertible entries and `errors='coerce'` or non-convertible with `errors='ignore'`. Furthermore, an `OutOfBoundsDatetime` exception will be raised when an out-of-range value is encountered for that unit when `errors='raise'`. (GH11758, GH13052, GH13059)

Previous behaviour:

```
In [27]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[27]: NaT

In [28]: pd.to_datetime(11111111, unit='D', errors='ignore')
OverflowError: Python int too large to convert to C long

In [29]: pd.to_datetime(11111111, unit='D', errors='raise')
OverflowError: Python int too large to convert to C long
```

New behaviour:
In [2]: pd.to_datetime(1420043460, unit='s', errors='coerce')
Out[2]: Timestamp('2014-12-31 16:31:00')

In [3]: pd.to_datetime(11111111, unit='D', errors='ignore')
Out[3]: 11111111

In [4]: pd.to_datetime(11111111, unit='D', errors='raise')
OutOfBoundsDatetime: cannot convert input with unit 'D'

1.11.3.6 Other API changes

• `.swaplevel()` for Series, DataFrame, Panel, and MultiIndex now features defaults for its first two parameters i and j that swap the two innermost levels of the index. (GH12934)
• `.searchsorted()` for Index and TimedeltaIndex now accept a sorter argument to maintain compatibility with numpy's `searchsorted` function (GH12238)
• Period and PeriodIndex now raises IncompatibleFrequency error which inherits ValueError rather than raw ValueError (GH12615)
• Series.apply for category dtype now applies the passed function to each of the .categories (and not the .codes), and returns a category dtype if possible (GH12473)
• read_csv will now raise a TypeError if parse_dates is neither a boolean, list, or dictionary (matches the doc-string) (GH5636)
• The default for `.query()/.eval()` is now engine=None, which will use numexpr if it's installed; otherwise it will fallback to the python engine. This mimics the pre-0.18.1 behavior if numexpr is installed (and which, previously, if numexpr was not installed, .query()/.eval() would raise). (GH12749)
• pd.show_versions() now includes pandas_datareader version (GH12740)
• Provide a proper __name__ and __qualname__ attributes for generic functions (GH12021)
• pd.concat(ignore_index=True) now uses RangeIndex as default (GH12695)
• pd.merge() and DataFrame.join() will show a UserWarning when merging/joining a single- with a multi-leveled dataframe (GH9455, GH12219)
• Compat with scipy > 0.17 for deprecated piecewise_polynomial interpolation method; support for the replacement from_derivatives method (GH12887)

1.11.3.7 Deprecations

• The method name Index.sym_diff() is deprecated and can be replaced by Index.symmetric_difference() (GH12591)
• The method name Categorical.sort() is deprecated in favor of Categorical.sort_values() (GH12882)

1.11.4 Performance Improvements

• Improved speed of SAS reader (GH12656, GH12961)
• Performance improvements in .groupby(...).cumcount() (GH11039)
• Improved memory usage in pd.read_csv() when using skiprows=an_integer (GH13005)
• Improved performance of DataFrame.to_sql when checking case sensitivity for tables. Now only checks if table has been created correctly when table name is not lower case. (GH12876)
• Improved performance of Period construction and time series plotting (GH12903, GH11831).
• Improved performance of .str.encode() and .str.decode() methods (GH13008)
• Improved performance of to_numeric if input is numeric dtype (GH12777)
• Improved performance of sparse arithmetic with IntIndex (GH13036)

1.11.5 Bug Fixes

• usecols parameter in pd.read_csv is now respected even when the lines of a CSV file are not even (GH12203)
• Bug in groupby.transform(..) when axis=1 is specified with a non-monotonic ordered index (GH12713)
• Bug in Period and PeriodIndex creation raises KeyError if freq="Minute" is specified. Note that "Minute" freq is deprecated in v0.17.0, and recommended to use freq="T" instead (GH11854)
• Bug in .resample(...).count() with a PeriodIndex always raising a TypeError (GH12774)
• Bug in .resample(...) with a PeriodIndex casting to a DatetimeIndex when empty (GH12868)
• Bug in .resample(...) with a PeriodIndex when resampling to an existing frequency (GH12770)
• Bug in printing data which contains Period with different freq raises ValueError (GH12615)
• Bug in Series construction with Categorical and dtype='category' is specified (GH12574)
• Bugs in concatenation with a coercable dtype was too aggressive, resulting in different dtypes in output-formatting when an object was longer than display.max_rows (GH12411, GH12045, GH11594, GH10571, GH12211)
• Bug in float_format option with option not being validated as a callable. (GH12706)
• Bug in GroupBy.filter when dropna=False and no groups fulfilled the criteria (GH12768)
• Bug in __name__ of .cum* functions (GH12021)
• Bug in .astype() of a Float64Index/Int64Index to an Int64Index (GH12881)
• Bug in roundtripping an integer based index in .to_json()/.read_json() when orient='index' (the default) (GH12866)
• Bug in plotting Categorical dtypes cause error when attempting stacked bar plot (GH13019)
• Compat with >= numpy 1.11 for NaT comparisons (GH12969)
• Bug in .drop() with a non-unique MultiIndex. (GH12701)
• Bug in .concat of datetime tz-aware and naive DataFrames (GH12467)
• Bug in correctly raising a ValueError in .resample(...)fillna(..) when passing a non-string (GH12952)
• Bug fixes in various encoding and header processing issues in pd.read_sas() (GH12659, GH12654, GH12647, GH12809)
• Bug in pd.crosstab() where would silently ignore aggfunc if values=None (GH12569).
• Potential segfault in DataFrame.to_json when serialising datetime.time (GH11473).
• Potential segfault in DataFrame.to_json when attempting to serialise 0d array (GH11299).
- Segfault in to_json when attempting to serialize a DataFrame or Series with non-ndarray values; now supports serialization of category, sparse, and datetime64[ns, tz] dtypes (GH10778).
- Bug in DataFrame.to_json with unsupported dtype not passed to default handler (GH12554).
- Bug in .align not returning the sub-class (GH12983)
- Bug in aligning a Series with a DataFrame (GH13037)
- Bug in ABCPanel in which Panel4D was not being considered as a valid instance of this generic type (GH12810)
- Bug in consistency of .name on .groupby(..).apply(..) cases (GH12363)
- Bug in Timestamp.__repr__ that caused pprint to fail in nested structures (GH12622)
- Bug in Timedelta.min and Timedelta.max, the properties now report the true minimum/maximum timedeltas as recognized by pandas. See the documentation. (GH12727)
- Bug in .quantile() with interpolation may coerce to float unexpectedly (GH12772)
- Bug in .quantile() with empty Series may return scalar rather than empty Series (GH12772)
- Bug in .loc with out-of-bounds in a large indexer would raise IndexError rather than KeyError (GH12527)
- Bug in resampling when using a TimedeltaIndex and .asfreq(), would previously not include the final fencepost (GH12926)
- Bug in equality testing with a Categorical in a DataFrame (GH12564)
- Bug in GroupBy.first(), .last() returns incorrect row when TimeGrouper is used (GH7453)
- Bug in pd.read_csv() with the c engine when specifying skiprows with newlines in quoted items (GH10911, GH12775)
- Bug in DataFrame timezone lost when assigning tz-aware datetime Series with alignment (GH12981)
- Bug in .value_counts() when normalize=True and dropna=True where nulls still contributed to the normalized count (GH12558)
- Bug in Series.value_counts() loses name if its dtype is category (GH12835)
- Bug in Series.value_counts() loses timezone info (GH12835)
- Bug in Series.value_counts(normalize=True) with Categorical raises UnboundLocalError (GH12835)
- Bug in Panel.fillna() ignoring inplace=True (GH12633)
- Bug in pd.read_csv() when specifying names, usecols, and parse_dates simultaneously with the c engine (GH9755)
- Bug in pd.read_csv() when specifying delim_whitespace=True and lineterminator simultaneously with the c engine (GH12912)
- Bug in Series.rename, DataFrame.rename and DataFrame.rename_axis not treating Series as mappings to relabel (GH12623).
- Clean in .rolling.min and .rolling.max to enhance dtype handling (GH12373)
- Bug in groupby where complex types are coerced to float (GH12902)
- Bug in Series.map raises TypeError if its dtype is category or tz-aware datetime (GH12473)
- Bugs on 32bit platforms for some test comparisons (GH12972)
- Bug in index coercion when falling back from RangeIndex construction (GH12893)
• Better error message in window functions when invalid argument (e.g. a float window) is passed (GH12669)
• Bug in slicing subclassed DataFrame defined to return subclassed Series may return normal Series (GH11559)
• Bug in .str accessor methods may raise ValueError if input has name and the result is DataFrame or MultiIndex (GH12617)
• Bug in DataFrame.last_valid_index() and DataFrame.first_valid_index() on empty frames (GH12800)
• Bug in CategoricalIndex.get_loc returns different result from regular Index (GH12531)
• Bug in PeriodIndex.resample where name not propagated (GH12769)
• Bug in date_range closed keyword and timezones (GH12684).
• Bug in pd.concat raises AttributeError when input data contains tz-aware datetime and timedelta (GH12620)
• Bug in pd.concat did not handle empty Series properly (GH11082)
• Bug in .plot.bar alignment when width is specified with int (GH12979)
• Bug in fill_value is ignored if the argument to a binary operator is a constant (GH12723)
• Bug in pd.read_html() when using bs4 flavor and parsing table with a header and only one column (GH1978)
• Bug in .pivot_table when margins=True and dropna=True where nulls still contributed to margin count (GH12577)
• Bug in .pivot_table when dropna=False where table index/column names disappear (GH12133)
• Bug in pd.crosstab() when margins=True and dropna=False which raised (GH12642)
• Bug in Series.name when name attribute can be a hashable type (GH12610)
• Bug in .describe() resets categorical columns information (GH11558)
• Bug where loffset argument was not applied when calling resample().count() on a timeseries (GH12725)
• pd.read_excel() now accepts column names associated with keyword argument names (GH12870)
• Bug in pd.to_numeric() with Index returns np.ndarray, rather than Index (GH12777)
• Bug in pd.to_numeric() with datetime-like may raise TypeError (GH12777)
• Bug in pd.to_numeric() with scalar raises ValueError (GH12777)

1.12 v0.18.0 (March 13, 2016)

This is a major release from 0.17.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas >= 0.18.0 no longer supports compatibility with Python version 2.6 and 3.3 (GH7718, GH11273)
Warning: numexpr version 2.4.4 will now show a warning and not be used as a computation back-end for pandas because of some buggy behavior. This does not affect other versions (>= 2.1 and >= 2.4.6). (GH12489)

Highlights include:

- Moving and expanding window functions are now methods on Series and DataFrame, similar to `.groupby`, see here.
- Adding support for a `RangeIndex` as a specialized form of the `Int64Index` for memory savings, see here.
- API breaking change to the `.resample` method to make it more `.groupby` like, see here.
- Removal of support for positional indexing with floats, which was deprecated since 0.14.0. This will now raise a `TypeError`, see here.
- The `.to_xarray()` function has been added for compatibility with the `xarray` package, see here.
- The `read_sas` function has been enhanced to read `sas7bdat` files, see here.
- Addition of the `.str.extractall()` method, and API changes to the `.str.extract()` method and `.str.cat()` method.
- `pd.test()` top-level nose test runner is available (GH4327).

Check the API Changes and deprecations before updating.

What’s new in v0.18.0

- New features
  - Window functions are now methods
  - Changes to rename
  - Range Index
  - Changes to `str.extract`
  - Addition of `str.extractall`
  - Changes to `str.cat`
  - Datetimelike rounding
  - Formatting of Integers in `FloatIndex`
  - Changes to dtype assignment behaviors
  - `to_xarray`
  - Latex Representation
  - `pd.read_sas()` changes
  - Other enhancements
- Backwards incompatible API changes
  - `NaT` and Timedelta operations
  - Changes to msgpack
  - Signature change for `.rank`
  - Bug in QuarterBegin with `n=0`
1.12.1 New features

1.12.1.1 Window functions are now methods

Window functions have been refactored to be methods on Series/DataFrame objects, rather than top-level functions, which are now deprecated. This allows these window-type functions, to have a similar API to that of .groupby. See the full documentation here (GH11603, GH12373)

```python
In [1]: np.random.seed(1234)
In [2]: df = pd.DataFrame({'A' : range(10), 'B' : np.random.randn(10)})
In [3]: df
Out[3]:
   A    B
0   0  0.471435
1   1 -1.190976
2   2  1.432707
3   3 -0.312652
4   4 -0.720589
5   5  0.887163
6   6  0.859588
7   7 -0.636524
8   8  0.015696
9   9 -2.242685
```

Previous Behavior:

```python
In [8]: pd.rolling_mean(df,window=3)
FutureWarning: pd.rolling_mean is deprecated for DataFrame and will be
→ removed in a future version, replace with
DataFrame.rolling(window=3,center=False).mean()
Out[8]:
   A    B
0  NaN  NaN
1  NaN  NaN
2   1  0.237722
```

(continues on next page)
New Behavior:

```
In [4]: r = df.rolling(window=3)
```

These show a descriptive repr

```
In [5]: r
Out[5]: Rolling [window=3, center=False, axis=0]
```

with tab-completion of available methods and properties.

```
In [9]: r.
   : r.A r.agg r.apply r.count r.exclusions r.max r.
   : ──median r.name r.skew r.sum
   : r.B r.aggregate r.corr r.cov r.kurt r.mean r.
   : ──min r.quantile r.std r.var
```

The methods operate on the `Rolling` object itself

```
In [6]: r.mean()
Out[6]:
   :       A     B
   : 0   NaN     NaN
   : 1   NaN     NaN
   : 2  1.0  0.237722
   : 3  2.0 -0.023640
   : 4  3.0  0.133155
   : 5  4.0 -0.048693
   : 6  5.0  0.342054
   : 7  6.0  0.370076
   : 8  7.0  0.079587
   : 9  8.0 -0.954504
```

They provide getitem accessors

```
In [7]: r['A'].mean()
Out[7]:
   :       A
   : 0   NaN
   : 1   NaN
   : 2  1.0
   : 3  2.0
   : 4  3.0
   : 5  4.0
   : 6  5.0
   : 7  6.0
   : 8  7.0
   : 9  8.0
Name: A, dtype: float64
And multiple aggregations

```python
In [8]: r.agg({'A' : ['mean', 'std'],
     ...:          'B' : ['mean', 'std']})
```

```
Out[8]:
      A          B
     mean  std    mean  std
0    NaN    NaN    NaN    NaN
1    NaN    NaN    NaN    NaN
2     1.0  1.0  0.237722  1.327364
3     2.0  1.0 -0.023640  1.335505
4     3.0  1.0  0.133155  1.143778
5     4.0  1.0 -0.048693  0.835747
6     5.0  1.0  0.342054  0.920379
7     6.0  1.0  0.370076  0.750099
8     7.0  1.0 -0.954504  1.162285
```

### 1.12.1.2 Changes to rename

`Series.rename` and `NDFrame.rename_axis` can now take a scalar or list-like argument for altering the Series or axis name, in addition to their old behaviors of altering labels. (GH9494, GH11965)

```python
In [9]: s = pd.Series(np.random.randn(5))
In [10]: s.rename('newname')
```

```
Out[10]:
0    1.150036
1    0.991946
2    0.953324
3   -2.021255
4   -0.334077
Name: newname, dtype: float64
```

```python
In [11]: df = pd.DataFrame(np.random.randn(5, 2))
In [12]: (df.rename_axis("indexname")
     ....:     .rename_axis("columns_name", axis="columns"))
```

```
Out[12]:
      columns_name  0  1
     indexname
0           0.002118  0.405453
1           0.991946  1.321158
2           0.953324  1.321158
3           0.953324  1.321158
4           0.953324  1.321158
```

The new functionality works well in method chains. Previously these methods only accepted functions or dicts mapping a label to a new label. This continues to work as before for function or dict-like values.

### 1.12.1.3 Range Index

A `RangeIndex` has been added to the `Int64Index` sub-classes to support a memory saving alternative for common use cases. This has a similar implementation to the python `range` object (`xrange` in python 2), in that it only
stores the start, stop, and step values for the index. It will transparently interact with the user API, converting to Int64Index if needed.

This will now be the default constructed index for NDFrame objects, rather than previous an Int64Index. (GH939, GH12070, GH12071, GH12109, GH12888)

Previous Behavior:

```
In [3]: s = pd.Series(range(1000))
In [4]: s.index
Out[4]: Int64Index([ 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
               ..., 990, 991, 992, 993, 994, 995, 996, 997, 998, 999], dtype='int64',
               length=1000)
In [6]: s.index.nbytes
Out[6]: 8000
```

New Behavior:

```
In [13]: s = pd.Series(range(1000))
In [14]: s.index
Out[14]: RangeIndex(start=0, stop=1000, step=1)
In [15]: s.index.nbytes
```

1.12.1.4 Changes to str.extract

The .str.extract method takes a regular expression with capture groups, finds the first match in each subject string, and returns the contents of the capture groups (GH11386).

In v0.18.0, the expand argument was added to extract.

- expand=False: it returns a Series, Index, or DataFrame, depending on the subject and regular expression pattern (same behavior as pre-0.18.0).
- expand=True: it always returns a DataFrame, which is more consistent and less confusing from the perspective of a user.

Currently the default is expand=None which gives a FutureWarning and uses expand=False. To avoid this warning, please explicitly specify expand.

```
In [1]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=None)
FutureWarning: currently extract(expand=None) means expand=False (return Index/Series/Frame) but in a future version of pandas this will be changed to expand=True (return DataFrame)
Out[1]:
0  1
1  2
2  NaN
dtype: object
```

Extracting a regular expression with one group returns a Series if expand=False.
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

In [16]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=False)
Out[16]:
0
1
1
2
2
NaN
dtype: object

It returns a DataFrame with one column if expand=True.
In [17]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=True)
Out[17]:
0
0
1
1
2
2 NaN

Calling on an Index with a regex with exactly one capture group returns an Index if expand=False.
In [18]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])
In [19]: s.index
Out[19]: Index(['A11', 'B22', 'C33'], dtype='object')
In [20]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[20]: Index(['A', 'B', 'C'],
˓→dtype='object', name='letter')

It returns a DataFrame with one column if expand=True.
In [21]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
Out[21]:
letter
0
A
1
B
2
C

Calling on an Index with a regex with more than one capture group raises ValueError if expand=False.
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

It returns a DataFrame if expand=True.
In [22]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[22]:
letter
1
0
A 11
1
B 22
2
C 33

In summary, extract(expand=True) always returns a DataFrame with a row for every subject string, and a
column for every capture group.
1.12.1.5 Addition of str.extractall
The .str.extractall method was added (GH11386). Unlike extract, which returns only the first match.

1.12. v0.18.0 (March 13, 2016)

187


```python
In [23]: s = pd.Series([{"ala2", "bl", "cl"}, [{"A", "B", "C"}])

In [24]: s
Out[24]:
A  ala2
B  bl
C  cl
dtype: object

In [25]: s.str.extract("(?P<letter>[ab])(?P<digit>\d)", expand=False)
```

The extractall method returns all matches.

```python
In [26]: s.str.extractall("(?P<letter>[ab])(?P<digit>\d)")
```

1.12.1.6 Changes to str.cat

The method .str.cat() concatenates the members of a Series. Before, if NaN values were present in the Series, calling .str.cat() on it would return NaN, unlike the rest of the Series.str.* API. This behavior has been amended to ignore NaN values by default. (GH11435).

A new, friendlier ValueError is added to protect against the mistake of supplying the sep as an arg, rather than as a kwarg. (GH11334).

```python
In [27]: pd.Series(["a","b",np.nan,"c"]).str.cat(sep=' ')  
Out[27]: 'a b c'

In [28]: pd.Series(["a","b",np.nan,"c"]).str.cat(sep=' ', na_rep='?')
```

1.12.1.7 Datetimelike rounding

DatetimeIndex, Timestamp, TimedeltaIndex, Timedelta have gained the .round(), .floor() and .ceil() method for datetimelike rounding, flooring and ceiling. (GH4314, GH11963)

Naive datetimes

```python
In [29]: dr = pd.date_range("20130101 09:12:56.1234", periods=3)
In [30]: dr
```
Out[30]:
DatetimeIndex(['2013-01-01 09:12:56.123400', '2013-01-02 09:12:56.123400',
              '2013-01-03 09:12:56.123400'],
             dtype='datetime64[ns]', freq='D')

In [31]: dr.round('s')
→
DatetimeIndex(['2013-01-01 09:12:56', '2013-01-02 09:12:56',
                '2013-01-03 09:12:56'],
               dtype='datetime64[ns]', freq=None)

# Timestamp scalar
In [32]: dr[0]
→
Timestamp('2013-01-01 09:12:56.123400', freq='D')

In [33]: dr[0].round('10s')
→
Timestamp('2013-01-01 09:13:00')

Tz-aware are rounded, floored and ceiled in local times

In [34]: dr = dr.tz_localize('US/Eastern')

In [35]: dr
Out[35]:
DatetimeIndex(['2013-01-01 09:12:56.123400-05:00',
               '2013-01-02 09:12:56.123400-05:00',
               '2013-01-03 09:12:56.123400-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='D')

In [36]: dr.round('s')
→
DatetimeIndex(['2013-01-01 09:12:56-05:00', '2013-01-02 09:12:56-05:00',
                '2013-01-03 09:12:56-05:00'],
               dtype='datetime64[ns, US/Eastern]', freq=None)

Timedeltas

In [37]: t = timedelta_range('1 days 2 hr 13 min 45 us',periods=3,freq='d')

In [38]: t
Out[38]:
TimedeltaIndex(['1 days 02:13:00.000045', '2 days 02:13:00.000045',
                '3 days 02:13:00.000045'],
                dtype='timedelta64[ns]', freq='D')

In [39]: t.round('10min')
→
TimedeltaIndex(['1 days 02:10:00', '2 days 02:10:00', '3 days 02:10:00'],
                dtype='timedelta64[ns]', freq=None)

# Timedelta scalar
In [40]: t[0]
→
Timedelta('1 days 02:13:00.000045')
In addition, `.round()`, `.floor()` and `.ceil()` will be available thru the `.dt` accessor of `Series`.

```
In [42]: s = pd.Series(dr)

In [43]: s
Out[43]:
     0  2013-01-01 09:12:56.123400-05:00
     1  2013-01-02 09:12:56.123400-05:00
     2  2013-01-03 09:12:56.123400-05:00
 dtype: datetime64[ns, US/Eastern]
```

```
In [44]: s.dt.round('D')
     0  2013-01-01 00:00:00-05:00
     1  2013-01-02 00:00:00-05:00
     2  2013-01-03 00:00:00-05:00
 dtype: datetime64[ns, US/Eastern]
```

### 1.12.1.8 Formatting of Integers in `FloatIndex`

Integers in `FloatIndex`, e.g. 1., are now formatted with a decimal point and a 0 digit, e.g. 1.0 (GH11713) This change not only affects the display to the console, but also the output of IO methods like `.to_csv` or `.to_html`.

**Previous Behavior:**

```
In [2]: s = pd.Series([1,2,3], index=np.arange(3.))

In [3]: s
Out[3]:
     0  1
     1  2
     2  3
 dtype: int64
```
```
In [4]: s.index
Out[4]: Float64Index([0.0, 1.0, 2.0], dtype='float64')
```
```
In [5]: print(s.to_csv(path=None))
0,1
1,2
2,3
```

**New Behavior:**

```
In [45]: s = pd.Series([1,2,3], index=np.arange(3.))

In [46]: s
Out[46]:
     0.0  1
```
```
(continues on next page)```
1.12.1.9 Changes to dtype assignment behaviors

When a DataFrame’s slice is updated with a new slice of the same dtype, the dtype of the DataFrame will now remain the same. (GH10503)

Previous Behavior:

```plaintext
In [5]: df = pd.DataFrame({'a': [0, 1, 1],
                        'b': pd.Series([100, 200, 300], dtype='uint32')})

In [7]: df.dtypes
Out[7]:
          a    b
dtype: int64  uint32

In [8]: ix = df['a'] == 1
In [9]: df.loc[ix, 'b'] = df.loc[ix, 'b']

In [11]: df.dtypes
Out[11]:
          a    b
dtype: int64  int64
```

New Behavior:

```plaintext
In [49]: df = pd.DataFrame({'a': [0, 1, 1],
                        'b': pd.Series([100, 200, 300], dtype='uint32')})

In [50]: df.dtypes
Out[50]:
          a    b
dtype: int64  uint32

In [51]: ix = df['a'] == 1
In [52]: df.loc[ix, 'b'] = df.loc[ix, 'b']
```

(continues on next page)
When a DataFrame’s integer slice is partially updated with a new slice of floats that could potentially be downcasted to integer without losing precision, the dtype of the slice will be set to float instead of integer.

**Previous Behavior:**

```
In [4]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                      columns=list('abc'),
                      index=[[4,4,8], [8,10,12]])

In [5]: df
Out[5]:
   a  b  c
4  4  1  2  3
10 4  5  6
8  12 7  8  9

In [7]: df.ix[4, 'c'] = np.array([0., 1.])

In [8]: df
Out[8]:
   a  b  c
4  4  1  2  0
10 4  5  1
8  12 7  8  9
```

**New Behavior:**

```
In [54]: df = pd.DataFrame(np.array(range(1,10)).reshape(3,3),
                      columns=list('abc'),
                      index=[[4,4,8], [8,10,12]])

In [55]: df
Out[55]:
   a  b  c
4  4  1  2  3
10 4  5  6
8  12 7  8  9

In [56]: df.loc[4, 'c'] = np.array([0., 1.])

In [57]: df
Out[57]:
   a  b  c
4  4  1  2  0.0
10 4  5  1.0
8  12 7  8  9.0
```
1.12.1.10 to_xarray

In a future version of pandas, we will be deprecating Panel and other > 2 ndim objects. In order to provide for continuity, all NDFrame objects have gained the .to_xarray() method in order to convert to xarray objects, which has a pandas-like interface for > 2 ndim. (GH11972)

See the xarray full-documentation here.

```python
In [1]: p = Panel(np.arange(2*3*4).reshape(2,3,4))
In [2]: p.to_xarray()
Out[2]:
<xarray.DataArray (items: 2, major_axis: 3, minor_axis: 4)>
array(
[[0, 1, 2, 3],
 [4, 5, 6, 7],
 [8, 9, 10, 11]],
[[12, 13, 14, 15],

```

1.12.1.11 Latex Representation

DataFrame has gained a ._repr_latex_() method in order to allow for conversion to latex in a ipython/jupyter notebook using nbconvert. (GH11778)

Note that this must be activated by setting the option pd.display.latex.repr=True (GH12182)

For example, if you have a jupyter notebook you plan to convert to latex using nbconvert, place the statement pd.display.latex.repr=True in the first cell to have the contained DataFrame output also stored as latex.

The options display.latex.escape and display.latex.longtable have also been added to the configuration and are used automatically by the to_latex method. See the available options docs for more info.

1.12.1.12 pd.read_sas() changes

read_sas has gained the ability to read SAS7BDAT files, including compressed files. The files can be read in entirety, or incrementally. For full details see here. (GH4052)

1.12.1.13 Other enhancements

- Handle truncated floats in SAS xport files (GH11713)
- Added option to hide index in Series.to_string (GH11729)
- read_excel now supports s3 urls of the format s3://bucketname/filename (GH11447)
- add support for AWS_S3_HOST env variable when reading from s3 (GH12198)
- A simple version of Panel.round() is now implemented (GH11763)
- For Python 3.x, round(DataFrame), round(Series), round(Panel) will work (GH11763)
• `sys.getsizeof(obj)` returns the memory usage of a pandas object, including the values it contains (GH11597)
• Series gained an `is_unique` attribute (GH11946)
• DataFrame.quantile and Series.quantile now accept interpolation keyword (GH10174).
• Added `DataFrame.style.format` for more flexible formatting of cell values (GH11692)
• DataFrame.select_dtypes now allows the `np.float16` typecode (GH11990)
• `pivot_table()` now accepts most iterables for the values parameter (GH12017)
• Added Google BigQuery service account authentication support, which enables authentication on remote servers. (GH11881, GH12572). For further details see here
• `HDFStore` is now iterable: for `k` in `store` is equivalent to for `k` in `store.keys()` (GH12221).
• Add missing methods/fields to `.dt` for `Period` (GH8848)
• The entire codebase has been PEP-ified (GH12096)

1.12.2 Backwards incompatible API changes

• the leading whitespaces have been removed from the output of `.to_string(index=False)` method (GH11833)
• the `out` parameter has been removed from the Series.round() method. (GH11763)
• DataFrame.round() leaves non-numeric columns unchanged in its return, rather than raises. (GH11885)
• DataFrame.head(0) and DataFrame.tail(0) return empty frames, rather than self. (GH11937)
• Series.head(0) and Series.tail(0) return empty series, rather than self. (GH11937)
• `to_msgpack` and `read_msgpack` encoding now defaults to 'utf-8'. (GH12170)
• the order of keyword arguments to text file parsing functions (.read_csv(), .read_table(), .read_fwf()) changed to group related arguments. (GH11555)
• NaTType.isoformat now returns the string 'NaT to allow the result to be passed to the constructor of Timestamp. (GH12300)

1.12.2.1 NaT and Timedelta operations

NaT and Timedelta have expanded arithmetic operations, which are extended to Series arithmetic where applicable. Operations defined for datetime64[ns] or timedelta64[ns] are now also defined for NaT (GH11564).

NaT now supports arithmetic operations with integers and floats.

```
In [58]: pd.NaT * 1
Out[58]: NaT

In [59]: pd.NaT * 1.5
Out[59]: NaT

In [60]: pd.NaT / 2
Out[60]: NaT

In [61]: pd.NaT * np.nan
Out[61]: NaT
```
NaT defines more arithmetic operations with `datetime64[ns]` and `timedelta64[ns]`.

```python
In [62]: pd.NaT / pd.NaT
Out[62]: nan

In [63]: pd.Timedelta('1s') / pd.NaT
Out[63]: nan
```

NaT may represent either a `datetime64[ns]` null or a `timedelta64[ns]` null. Given the ambiguity, it is treated as a `timedelta64[ns]`, which allows more operations to succeed.

```python
In [64]: pd.NaT + pd.NaT
Out[64]: NaT

# same as
In [65]: pd.Timedelta('1s') + pd.Timedelta('1s')
Out[65]: Timedelta('0 days 00:00:02')
```

as opposed to

```python
In [3]: pd.Timestamp('19900315') + pd.Timestamp('19900315')
TypeError: unsupported operand type(s) for +: 'Timestamp' and 'Timestamp'
```

However, when wrapped in a `Series` whose `dtype` is `datetime64[ns]` or `timedelta64[ns]`, the `dtype` information is respected.

```python
In [1]: pd.Series([pd.NaT], dtype='<M8[ns]') + pd.Series([pd.NaT], dtype='<M8[ns]')
TypeError: can only operate on a datetimes for subtraction, but the operator [__add__] was passed

In [66]: pd.Series([pd.NaT], dtype='<m8[ns]') + pd.Series([pd.NaT], dtype='<m8[ns]')
Out[66]:
0   NaT
dtype: timedelta64[ns]
```

Timedelta division by floats now works.

```python
In [67]: pd.Timedelta('1s') / 2.0
Out[67]: Timedelta('0 days 00:00:00.500000')
```

Subtraction by Timedelta in a Series by a Timestamp works (GH11925)

```python
In [68]: ser = pd.Series(pd.timedelta_range('1 day', periods=3))

In [69]: ser
Out[69]:
0   1 days
1   2 days
2   3 days
dtype: timedelta64[ns]

In [70]: pd.Timestamp('2012-01-01') - ser
Out[70]:
0   2011-12-31
1   2011-12-30
2   2011-12-29
dtype: datetime64[ns]
```
NaT.isoformat() now returns 'NaT'. This change allows pd.Timestamp to rehydrate any timestamp like object from its isoformat (GH12300).

### 1.12.2.2 Changes to msgpack

Forward incompatible changes in msgpack writing format were made over 0.17.0 and 0.18.0; older versions of pandas cannot read files packed by newer versions (GH12129, GH10527)

Bugs in to_msgpack and read_msgpack introduced in 0.17.0 and fixed in 0.18.0, caused files packed in Python 2 unreadable by Python 3 (GH12142). The following table describes the backward and forward compat of msgpacks.

<table>
<thead>
<tr>
<th>Packed with</th>
<th>Can be unpacked with</th>
</tr>
</thead>
<tbody>
<tr>
<td>pre-0.17 / Python 2</td>
<td>any</td>
</tr>
<tr>
<td>pre-0.17 / Python 3</td>
<td>any</td>
</tr>
<tr>
<td>0.17 / Python 2</td>
<td>• ==0.17 / Python 2</td>
</tr>
<tr>
<td></td>
<td>• &gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.17 / Python 3</td>
<td>&gt;=0.18 / any Python</td>
</tr>
<tr>
<td>0.18</td>
<td>&gt;= 0.18</td>
</tr>
</tbody>
</table>

0.18.0 is backward-compatible for reading files packed by older versions, except for files packed with 0.17 in Python 2, in which case only they can only be unpacked in Python 2.

### 1.12.2.3 Signature change for .rank

Series.rank and DataFrame.rank now have the same signature (GH11759)

Previous signature

```python
In [3]: pd.Series([0,1]).rank(method='average', na_option='keep',
                     ascending=True, pct=False)
Out[3]:
0   1
1   2
dtype: float64
```

```python
In [4]: pd.DataFrame([0,1]).rank(axis=0, numeric_only=None,
                                  method='average', na_option='keep',
                                  ascending=True, pct=False)
Out[4]:
     0  1  2
0   1
1   2
```

New signature

```python
In [71]: pd.Series([0,1]).rank(axis=0, method='average', numeric_only=None,
                                 ....:       na_option='keep', ascending=True, pct=False)
 ....:      
Out[71]:
```

(continues on next page)
1.12.2.4 Bug in QuarterBegin with n=0

In previous versions, the behavior of the QuarterBegin offset was inconsistent depending on the date when the \( n \) parameter was 0. (GH11406)

The general semantics of anchored offsets for \( n=0 \) is to not move the date when it is an anchor point (e.g., a quarter start date), and otherwise roll forward to the next anchor point.

For the QuarterBegin offset in previous versions, the date would be rolled *backwards* if date was in the same month as the quarter start date.

1.12.2.5 Resample API

Like the change in the window functions API *above*, \( .resample(...) \) is changing to have a more groupby-like API. (GH11732, GH12702, GH12202, GH12332, GH12334, GH12348, GH12448).

1.12. v0.18.0 (March 13, 2016)
In [79]: np.random.seed(1234)

In [80]: df = pd.DataFrame(np.random.rand(10,4),
   ....:     columns=list('ABCD'),
   ....:     index=pd.date_range('2010-01-01 09:00:00', periods=10,  
   ....:     freq='s'))
   ....:

In [81]: df
Out[81]:
   A    B    C    D
2010-01-01 09:00:00 0.191519 0.622109 0.437728 0.785359
2010-01-01 09:00:01 0.779976 0.272593 0.276464 0.801872
2010-01-01 09:00:02 0.958139 0.875933 0.357817 0.500995
2010-01-01 09:00:03 0.683463 0.712702 0.370251 0.561196
2010-01-01 09:00:04 0.503083 0.013768 0.772827 0.882641
2010-01-01 09:00:05 0.364886 0.615396 0.075381 0.368824
2010-01-01 09:00:06 0.933140 0.651378 0.397203 0.788730
2010-01-01 09:00:07 0.316836 0.568099 0.869127 0.436173
2010-01-01 09:00:08 0.802148 0.143767 0.704261 0.704581
2010-01-01 09:00:09 0.218792 0.924868 0.442141 0.909316

Previous API:
You would write a resampling operation that immediately evaluates. If a how parameter was not provided, it would default to how='mean'.

In [6]: df.resample('2s')
Out[6]:
   A    B    C    D
2010-01-01 09:00:00 0.485748 0.447351 0.357096 0.793615
2010-01-01 09:00:02 0.820801 0.794317 0.364034 0.531096
2010-01-01 09:00:04 0.433985 0.314582 0.424104 0.625733
2010-01-01 09:00:06 0.933140 0.651378 0.397203 0.788730
2010-01-01 09:00:08 0.510470 0.534317 0.573201 0.806949

You could also specify a how directly

In [7]: df.resample('2s', how='sum')
Out[7]:
   A    B    C    D
2010-01-01 09:00:00 0.971495 0.894701 0.714192 1.587231
2010-01-01 09:00:02 1.641602 1.588635 0.728068 1.062191
2010-01-01 09:00:04 0.867969 0.629165 0.848208 1.251465
2010-01-01 09:00:06 1.249976 1.219477 1.266330 1.224904
2010-01-01 09:00:08 1.020940 1.068634 1.146402 1.613897

New API:
Now, you can write .resample(...) as a 2-stage operation like .groupby(...), which yields a Resampler.

In [82]: r = df.resample('2s')

In [83]: r
Out[83]: DatetimeIndexResampler [freq=<2 * Seconds>, axis=0, closed=left, label=left,  
   ....:   convention=start, base=0]
Downsampling

You can then use this object to perform operations. These are downsampling operations (going from a higher frequency to a lower one).

```python
In [84]: r.mean()
Out[84]:
          A    B    C    D
2010-01-01  09:00:00   0.485748  0.447351  0.357096  0.793615
2010-01-01  09:00:02   0.820801  0.794317  0.364034  0.531096
2010-01-01  09:00:04   0.433985  0.314582  0.424104  0.625733
2010-01-01  09:00:06   0.624988  0.609738  0.633165  0.612452
2010-01-01  09:00:08   0.510470  0.534317  0.573201  0.806949
```

Furthermore, resample now supports `getitem` operations to perform the resample on specific columns.

```python
In [85]: r[['A','C']].mean()
Out[85]:
          A    C
2010-01-01  09:00:00   0.485748  0.357096
2010-01-01  09:00:02   0.820801  0.364034
2010-01-01  09:00:04   0.433985  0.424104
2010-01-01  09:00:06   0.624988  0.633165
2010-01-01  09:00:08   0.510470  0.573201
```

and `.aggregate` type operations.

```python
In [86]: r.agg({'A' : 'mean', 'B' : 'sum'})
Out[86]:
          A    B
2010-01-01  09:00:00   0.485748  0.894701
2010-01-01  09:00:02   0.820801  1.588635
2010-01-01  09:00:04   0.433985  1.219477
2010-01-01  09:00:06   0.624988  1.266330
2010-01-01  09:00:08   0.510470  1.068634
```

These accessors can of course, be combined

```python
In [88]: r[['A','B']].agg({'mean': 'sum', 'sum': 'mean'})
Out[88]:
          A    B
mean  sum  mean  sum
2010-01-01  09:00:00   0.894701  0.971495   0.894701  0.971495
2010-01-01  09:00:02   1.588635  1.641602   1.588635  1.641602
2010-01-01  09:00:04   1.219477  1.249976   1.219477  1.249976
2010-01-01  09:00:06   1.266330  1.249976   1.266330  1.249976
2010-01-01  09:00:08   1.068634  1.020940   1.068634  1.020940
```
Upsampling

Upsampling operations take you from a lower frequency to a higher frequency. These are now performed with the `Resampler` objects with `backfill()`, `ffill()`, `fillna()` and `asfreq()` methods.

```python
In [89]: s = pd.Series(np.arange(5,dtype='int64'),
          index=date_range('2010-01-01', periods=5, freq='Q'))
....:
....:

In [90]: s
Out[90]:
2010-03-31  0
2010-06-30  1
2010-09-30  2
2010-12-31  3
2011-03-31  4
Freq: Q-DEC, dtype: int64
```

Previously

```python
In [6]: s.resample('M', fill_method='ffill')
Out[6]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, dtype: int64
```

New API

```python
In [91]: s.resample('M').ffill()
Out[91]:
2010-03-31  0
2010-04-30  0
2010-05-31  0
2010-06-30  1
2010-07-31  1
2010-08-31  1
2010-09-30  2
2010-10-31  2
2010-11-30  2
2010-12-31  3
2011-01-31  3
2011-02-28  3
2011-03-31  4
Freq: M, dtype: int64
```

Note: In the new API, you can either downsample OR upsample. The prior implementation would allow you to pass
an aggregator function (like `mean`) even though you were upsampling, providing a bit of confusion.

**Previous API will work but with deprecations**

**Warning:** This new API for resample includes some internal changes for the prior-to-0.18.0 API, to work with a deprecation warning in most cases, as the resample operation returns a deferred object. We can intercept operations and just do what the (pre 0.18.0) API did (with a warning). Here is a typical use case:

```python
In [4]: r = df.resample('2s')
In [6]: r*10
  1 pandas/tseries/resample.py:80: FutureWarning: .resample() is now a deferred operation
     use .resample(...).mean() instead of .resample(...)
Out[6]:
          A         B         C         D
2010-01-01 09:00:00  4.857476  4.473507  3.570960  7.936154
2010-01-01 09:00:02  8.208011  7.943173  3.640340  5.310957
2010-01-01 09:00:04  4.339846  3.145823  4.241039  6.257326
2010-01-01 09:00:06  6.249881  6.097384  6.331650  6.124518
2010-01-01 09:00:08  5.104699  5.343172  5.732009  8.069486
```

However, getting and assignment operations directly on a `Resampler` will raise a `ValueError`:

```python
In [7]: r.iloc[0] = 5
  2 ValueError: .resample() is now a deferred operation
     use .resample(...).mean() instead of .resample(...)
```

There is a situation where the new API can not perform all the operations when using original code. This code is intending to resample every 2s, take the `mean` AND then take the `min` of those results.

```python
In [4]: df.resample('2s').min()
Out [4]:
     A   B   C   D
2010-01-01 09:00:00  0.191519  0.272593  0.276464  0.785359
2010-01-01 09:00:02  0.683463  0.712702  0.357817  0.500995
2010-01-01 09:00:04  0.364886  0.013768  0.075381  0.368824
2010-01-01 09:00:06  0.316836  0.568099  0.397203  0.436173
2010-01-01 09:00:08  0.218792  0.143767  0.442141  0.704581
```

The new API will:

```python
In [92]: df.resample('2s').min()
Out [92]:
     A   B   C   D
2010-01-01 09:00:00  0.433985  0.314582  0.357096  0.531096
2010-01-01 09:00:02  0.364886  0.013768  0.075381  0.368824
2010-01-01 09:00:04  0.316836  0.568099  0.397203  0.436173
2010-01-01 09:00:06  0.316836  0.568099  0.397203  0.436173
2010-01-01 09:00:08  0.218792  0.143767  0.442141  0.704581
```

The good news is the return dimensions will differ between the new API and the old API, so this should loudly raise an exception.

To replicate the original operation...
In [93]: df.resample('2s').mean().min()
Out[93]:
   A  0.433985
   B  0.314582
   C  0.357096
   D  0.531096
dtype: float64

1.12.2.6 Changes to eval

In prior versions, new columns assignments in an eval expression resulted in an inplace change to the DataFrame.
(GH9297, GH8664, GH10486)

In [94]: df = pd.DataFrame({'a': np.linspace(0, 10, 5), 'b': range(5)})
In [95]: df
Out[95]:
   a  b
  0  0.0  0
  1  2.5  1
  2  5.0  2
  3  7.5  3
  4 10.0  4

In [12]: df.eval('c = a + b')
FutureWarning: eval expressions containing an assignment currently default to operating inplace. This will change in a future version of pandas, use inplace=True to avoid this warning.
In [13]: df
Out[13]:
   a  b  c
  0  0.0  0  0.0
  1  2.5  1  3.5
  2  5.0  2  7.0
  3  7.5  3 10.5
  4 10.0  4 14.0

In version 0.18.0, a new inplace keyword was added to choose whether the assignment should be done inplace or return a copy.

In [96]: df
Out[96]:
   a  b  c
  0  0.0  0  0.0
  1  2.5  1  3.5
  2  5.0  2  7.0
  3  7.5  3 10.5
  4 10.0  4 14.0

In [97]: df.eval('d = c - b', inplace=False)

(continues on next page)
In [98]: df

\[\begin{array}{cccc}
0 & 0.0 & 0.0 & 0.0 \\
1 & 2.5 & 1.0 & 3.5 \\
2 & 5.0 & 2.0 & 7.0 \\
3 & 7.5 & 3.0 & 10.5 \\
4 & 10.0 & 4.0 & 14.0 \\
\end{array}\]

In [99]: df.eval('d = c - b', inplace=True)

In [100]: df

\[\begin{array}{cccc}
0 & 0.0 & 0.0 & 0.0 \\
1 & 2.5 & 1.0 & 3.5 \\
2 & 5.0 & 2.0 & 7.0 \\
3 & 7.5 & 3.0 & 10.5 \\
4 & 10.0 & 4.0 & 14.0 \\
\end{array}\]

\[\begin{array}{cccc}
\text{Warning: } \text{For backwards compatibility, } inplace \text{ defaults to True if not specified. This will change in a future version of pandas. If your code depends on an inplace assignment you should update to explicitly set } inplace=True.
\end{array}\]

The `inplace` keyword parameter was also added the `query` method.

In [101]: df.query('a > 5')

Out[101]:
\[\begin{array}{cccc}
3 & 7.5 & 3.0 & 10.5 \\
4 & 10.0 & 4.0 & 14.0 \\
\end{array}\]

In [102]: df.query('a > 5', inplace=True)

In [103]: df

\[\begin{array}{cccc}
3 & 7.5 & 3.0 & 10.5 \\
4 & 10.0 & 4.0 & 14.0 \\
\end{array}\]

\[\begin{array}{cccc}
\text{Warning: } \text{Note that the default value for } inplace \text{ in a } query \text{ is False, which is consistent with prior versions.}
\end{array}\]

eval has also been updated to allow multi-line expressions for multiple assignments. These expressions will be evaluated one at a time in order. Only assignments are valid for multi-line expressions.
In [104]: df
Out[104]:
    a  b  c  d  e  f  g
3  7.5 3 10.5  7.5 15.0 -7.0 -3.5
4 10.0 4 14.0 10.0 20.0 -2.0 -1.0

In [105]: df.eval(""
       ....: e = d + a
       ....: f = e - 22
       ....: g = f / 2.0", inplace=True)

In [106]: df
Out[106]:
    a  b  c  d  e  f  g
3  7.5 3 10.5  7.5 15.0 -7.0 -3.5
4 10.0 4 14.0 10.0 20.0 -2.0 -1.0

1.12.2.7 Other API Changes

- DataFrame.between_time and Series.between_time now only parse a fixed set of time strings. Parsing of date strings is no longer supported and raises a `ValueError` (GH11818)

```python
In [107]: s = pd.Series(range(10), pd.date_range('2015-01-01', freq='H', periods=10))
In [108]: s.between_time("7:00am", "9:00am")
Out[108]:
2015-01-01 07:00:00    7
2015-01-01 08:00:00    8
2015-01-01 09:00:00    9
Freq: H, dtype: int64
```

This will now raise.

```python
In [2]: s.between_time('20150101 07:00:00','20150101 09:00:00')
ValueError: Cannot convert arg ['20150101 07:00:00'] to a time.
```

- `.memory_usage()` now includes values in the index, as does memory_usage in `.info()` (GH11597)
- DataFrame.to_latex() now supports non-ascii encodings (eg utf-8) in Python 2 with the parameter encoding (GH7061)
- pandas.merge() and DataFrame.merge() will show a specific error message when trying to merge with an object that is not of type DataFrame or a subclass (GH12081)
- DataFrame.unstack and Series.unstack now take fill_value keyword to allow direct replacement of missing values when an unstack results in missing values in the resulting DataFrame. As an added benefit, specifying fill_value will preserve the data type of the original stacked data. (GH9746)
- As part of the new API for window functions and resampling, aggregation functions have been clarified, raising more informative error messages on invalid aggregations. (GH9052). A full set of examples are presented in `groupby`.
- Statistical functions for NDFrame objects (like `sum()`, `mean()`, `min()`) will now raise if non-numpy-compatible arguments are passed in for `**kwargs` (GH12301)
- `.to_latex` and `.to_html` gain a decimal parameter like `.to_csv`; the default is "." (GH12031)
• More helpful error message when constructing a DataFrame with empty data but with indices (GH8020)
• .describe() will now properly handle bool dtype as a categorical (GH6625)
• More helpful error message with an invalid .transform with user defined input (GH10165)
• Exponentially weighted functions now allow specifying alpha directly (GH10789) and raise ValueError if parameters violate $0 < \alpha \leq 1$ (GH12492)

1.12.2.8 Deprecations

• The functions pd.rolling_* , pd.expanding_* , and pd.ewm* are deprecated and replaced by the corresponding method call. Note that the new suggested syntax includes all of the arguments (even if default) (GH11603)

```python
In [1]: s = pd.Series(range(3))
In [2]: pd.rolling_mean(s, window=2, min_periods=1)
   FutureWarning: pd.rolling_mean is deprecated for Series and will be removed in a future version, replace with Series.rolling(min_periods=1, window=2, center=False).mean()
Out[2]:
      0  0.0
     1  0.5
     2  1.5
    dtype: float64
In [3]: pd.rolling_cov(s, s, window=2)
   FutureWarning: pd.rolling_cov is deprecated for Series and will be removed in a future version, replace with Series.rolling(window=2).cov(other=<Series>)
Out[3]:
       0  NaN
      1  0.5
      2  0.5
    dtype: float64
```

• The freq and how arguments to the .rolling , .expanding, and .ewm (new) functions are deprecated, and will be removed in a future version. You can simply resample the input prior to creating a window function. (GH11603).

For example, instead of s.rolling(window=5, freq='D').max() to get the max value on a rolling 5 Day window, one could use s.resample('D').mean().rolling(window=5).max(), which first resamples the data to daily data, then provides a rolling 5 day window.

• pd.tseries.frequencies.get_offset_name function is deprecated. Use offset's .freqstr property as alternative (GH11192)
• pandas.stats.fama_macbeth routines are deprecated and will be removed in a future version (GH6077)
• pandas.stats.ols, pandas.stats.plm and pandas.stats.var routines are deprecated and will be removed in a future version (GH6077)
• show a FutureWarning rather than a DeprecationWarning on using long-time deprecated syntax in HDFStore.select, where the where clause is not a string-like (GH12027)
• The pandas.options.display.mpl_style configuration has been deprecated and will be removed in a future version of pandas. This functionality is better handled by matplotlib's style sheets (GH11783).

1.12. v0.18.0 (March 13, 2016)
1.12.2.9 Removal of deprecated float indexers

In GH4892 indexing with floating point numbers on a non-Float64Index was deprecated (in version 0.14.0). In 0.18.0, this deprecation warning is removed and these will now raise a TypeError. (GH12165, GH12333)

```python
In [109]: s = pd.Series([1, 2, 3], index=[4, 5, 6])

In [110]: s
Out[110]:
4 1  
5 2  
6 3  
dtype: int64

In [111]: s2 = pd.Series([1, 2, 3], index=list('abc'))

In [112]: s2
Out[112]:
a 1  
b 2  
c 3  
dtype: int64
```

Previous Behavior:

```python
# this is label indexing
In [2]: s[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[2]:

# this is positional indexing
In [3]: s.iloc[1.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[3]:

# this is label indexing
In [4]: s.loc[5.0]
FutureWarning: scalar indexers for index type Int64Index should be integers and not floating point
Out[4]:

# .ix would coerce 1.0 to the positional 1, and index
In [5]: s2.ix[1.0] = 10
FutureWarning: scalar indexers for index type Index should be integers and not floating point

In [6]: s2
Out[6]:
a 1  
b 10 
c 3  
dtype: int64
```

New Behavior:

For iloc, getting & setting via a float scalar will always raise.
Other indexers will coerce to a like integer for both getting and setting. The `FutureWarning` has been dropped for `.loc`, `.ix` and `[]`.

Positional setting with `.ix` and a float indexer will ADD this value to the index, rather than previously setting the value by position.

Slicing will also coerce integer-like floats to integers for a non-`Float64Index`.

Note that for floats that are NOT coercible to ints, the label based bounds will be excluded.
Float indexing on a Float64Index is unchanged.

```
In [123]: s = pd.Series([1, 2, 3], index=np.arange(3.))
In [124]: s[1.0]
Out[124]: 2
In [125]: s[1.0:2.5]
Out[125]:
1.0 2
2.0 3
dtype: int64
```

### 1.12.2.10 Removal of prior version deprecations/changes

- Removal of `rolling_corr_pairwise` in favor of `.rolling().corr(pairwise=True)` (GH4950)
- Removal of `expanding_corr_pairwise` in favor of `.expanding().corr(pairwise=True)` (GH4950)
- Removal of `DataMatrix` module. This was not imported into the pandas namespace in any event (GH12111)
- Removal of `cols` keyword in favor of `subset` in `DataFrame.duplicated()` and `DataFrame.drop_duplicates()` (GH6680)
- Removal of the `read_frame` and `frame_query` (both aliases for `pd.read_sql`) and `write_frame` (alias of `to_sql`) functions in the `pd.io.sql` namespace, deprecated since 0.14.0 (GH6292).
- Removal of the `order` keyword from `.factorize()` (GH6930)

### 1.12.3 Performance Improvements

- Improved performance of `andrews_curves` (GH11534)
- Improved huge `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex`’s ops performance including `NaT`(GH10277)
- Improved performance of `pandas.concat` (GH11958)
- Improved performance of `StataReader` (GH11591)
- Improved performance in construction of `Categoricals` with `Series` of datetimes containing `NaT` (GH12077)
- Improved performance of ISO 8601 date parsing for dates without separators (GH11899), leading zeros (GH11871) and with whitespace preceding the time zone (GH9714)

### 1.12.4 Bug Fixes

- Bug in `GroupBy.size` when data-frame is empty. (GH11699)
- Bug in `Period.end_time` when a multiple of time period is requested (GH11738)
• Regression in `.clip` with tz-aware datetimes (GH11838)
• Bug in `date_range` when the boundaries fell on the frequency (GH11804, GH12409)
• Bug in consistency of passing nested dicts to `.groupby(...).agg(...)` (GH9052)
• Accept unicode in `Timedelta` constructor (GH11995)
• Bug in value label reading for `StataReader` when reading incrementally (GH12014)
• Bug in vectorized `DateOffset` when \( n \) parameter is 0 (GH11370)
• Compat for numpy 1.11 w.r.t. `NaT` comparison changes (GH12049)
• Bug in `read_csv` when reading from a `StringIO` in threads (GH11790)
• Bug in not treating `NaT` as a missing value in datetimelikes when factorizing & with `Categoricals` (GH12077)
• Bug in `getitem` when the values of a `Series` were tz-aware (GH12089)
• Bug in `Series.str.get_dummies` when one of the variables was ‘name’ (GH12180)
• Bug in `pd.concat` while concatenating tz-aware NaT series. (GH11693, GH11755, GH12217)
• Bug in `pd.read_stata` with version <= 108 files (GH12232)
• Bug in `Series.resample` using a frequency of `Nano` when the index is a `DatetimeIndex` and contains non-zero nanosecond parts (GH12037)
• Bug in resampling with `.nunique` and a sparse index (GH12352)
• Removed some compiler warnings (GH12471)
• Work around compat issues with `boto` in python 3.5 (GH11915)
• Bug in `NaT` subtraction from `Timestamp` or `DatetimeIndex` with timezones (GH11718)
• Bug in subtraction of `Series` of a single tz-aware `Timestamp` (GH12290)
• Use compat iterators in PY2 to support `.next()` (GH12299)
• Bug in `Timedelta.round` with negative values (GH11690)
• Bug in `.loc` against `CategoricalIndex` may result in normal `Index` (GH11586)
• Bug in `DataFrame.info` when duplicated column names exist (GH11761)
• Bug in `.copy` of datetime tz-aware objects (GH11794)
• Bug in `Series.apply` and `Series.map` where `timedelta64` was not boxed (GH11349)
• Bug in `DataFrame.set_index()` with tz-aware `Series` (GH12358)
• Bug in subclasses of `DataFrame` where `AttributeError` did not propagate (GH11808)
• Bug groupby on tz-aware data where selection not returning `Timestamp` (GH11616)
• Bug in `pd.read_clipboard` and `pd.to_clipboard` functions not supporting Unicode; upgrade included `pyperclip` to v1.5.15 (GH9263)
• Bug in `DataFrame.query` containing an assignment (GH8664)
• Bug in `from_msgpack` where `__contains__()` fails for columns of the unpacked `DataFrame`, if the `DataFrame` has object columns. (GH11880)
• Bug in `.resample` on categorical data with `TimedeltaIndex` (GH12169)
• Bug in time zone info lost when broadcasting scalar datetime to `DataFrame` (GH11682)
• Bug in Index creation from Timestamp with mixed tz coerces to UTC (GH11488)
• Bug in to_numeric where it does not raise if input is more than one dimension (GH11776)
• Bug in parsing timezone offset strings with non-zero minutes (GH11708)
• Bug in df.plot using incorrect colors for bar plots under matplotlib 1.5+ (GH11614)
• Bug in the groupby plot method when using keyword arguments (GH11805).
• Bug in DataFrame.duplicated and drop_duplicates causing spurious matches when setting keep=False (GH11864)
• Bug in .loc result with duplicated key may have Index with incorrect dtype (GH1197)
• Bug in pd.rolling_median where memory allocation failed even with sufficient memory (GH11696)
• Bug in DataFrame.style with spurious zeros (GH12134)
• Bug in DataFrame.style with integer columns not starting at 0 (GH12125)
• Bug in .style.bar may not rendered properly using specific browser (GH11678)
• Bug in rich comparison of Timedelta with a numpy.array of Timedelta that caused an infinite recursion (GH1835)
• Bug in DataFrame.round dropping column index name (GH11986)
• Bug in df.replace while replacing value in mixed dtype DataFrame (GH11698)
• Bug in Index prevents copying name of passed Index, when a new name is not provided (GH1193)
• Bug in read_excel failing to read any non-empty sheets when empty sheets exist and sheetname=None (GH11711)
• Bug in read_excel failing to raise NotImplemented error when keywords parse_dates and date_parser are provided (GH11544)
• Bug in read_sql with pymysql connections failing to return chunked data (GH11522)
• Bug in .to_csv ignoring formatting parameters decimal, na_rep, float_format for float indexes (GH1153)
• Bug in Int64Index and Float64Index preventing the use of the modulo operator (GH9244)
• Bug in MultiIndex.drop for not lexsorted multi-indexes (GH12078)
• Bug in DataFrame when masking an empty DataFrame (GH11859)
• Bug in .plot potentially modifying the colors input when the number of columns didn’t match the number of series provided (GH12039).
• Bug in Series.plot failing when index has a CustomBusinessDay frequency (GH7222).
• Bug in .to_sql for datetime.time values with sqlite fallback (GH8341)
• Bug in read_excel failing to read data with one column when squeeze=True (GH12157)
• Bug in read_excel failing to read one empty column (GH12292, GH9002)
• Bug in .groupby where a KeyError was not raised for a wrong column if there was only one row in the dataframe (GH11741)
• Bug in .read_csv with dtype specified on empty data producing an error (GH12048)
• Bug in .read_csv where strings like '2E' are treated as valid floats (GH12237)
• Bug in building pandas with debugging symbols (GH12123)
- **Removed** millisecond property of `DatetimeIndex`. This would always raise a `ValueError` (GH12019).
- **Bug in** `Series` constructor with read-only data (GH11502)
- **Removed** `pandas.util.testing.choice()`. Should use `np.random.choice()`, instead. (GH12386)
- **Bug in** `.loc` setitem indexer preventing the use of a TZ-aware `DatetimeIndex` (GH12050)
- **Bug in** `.style` indexes and multi-indexes not appearing (GH11655)
- **Bug in** `to_msgpack` and `from_msgpack` which did not correctly serialize or deserialize `NaT` (GH12307).
- **Bug in** `.skew` and `.kurt` due to roundoff error for highly similar values (GH11974)
- **Bug in** `Timestamp` constructor where microsecond resolution was lost if HHMMSS were not separated with `:` (GH10041)
- **Bug in** `buffer_rd_bytes` src->buffer could be freed more than once if reading failed, causing a segfault (GH12098)
- **Bug in** `crosstab` where arguments with non-overlapping indexes would return a `KeyError` (GH10291)
- **Bug in** `DataFrame.apply` in which reduction was not being prevented for cases in which `dtype` was not a numpy `dtype` (GH12244)
- **Bug when** initializing categorical series with a scalar value. (GH12336)
- **Bug when** specifying a UTC `DatetimeIndex` by setting `utc=True` in `.to_datetime` (GH11934)
- **Bug when increasing the buffer size of CSV reader in** `read_csv` (GH12494)
- **Bug when setting columns of a** `DataFrame` with duplicate column names (GH12344)

### 1.13 v0.17.1 (November 21, 2015)

**Note:** We are proud to announce that `pandas` has become a sponsored project of the (NumFOCUS organization). This will help ensure the success of development of `pandas` as a world-class open-source project.

This is a minor bug-fix release from 0.17.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

- Support for Conditional HTML Formatting, see [here](#)
- Releasing the GIL on the csv reader & other ops, see [here](#)
- Fixed regression in `DataFrame.drop_duplicates` from 0.16.2, causing incorrect results on integer values (GH11376)

**What’s new in v0.17.1**

- **New features**
  - Conditional HTML Formatting
- **Enhancements**
1.13.1 New features

1.13.1.1 Conditional HTML Formatting

Warning: This is a new feature and is under active development. We’ll be adding features an possibly making breaking changes in future releases. Feedback is welcome.

We’ve added experimental support for conditional HTML formatting: the visual styling of a DataFrame based on the data. The styling is accomplished with HTML and CSS. Acesses the styler class with the pandas.DataFrame.style.attribute, an instance of Styler with your data attached.

Here’s a quick example:

```
In [1]: np.random.seed(123)
In [2]: df = DataFrame(np.random.randn(10, 5), columns=list('abcde'))
In [3]: html = df.style.background_gradient(cmap='viridis', low=.5)
```

We can render the HTML to get the following table.

Styler interacts nicely with the Jupyter Notebook. See the documentation for more.

1.13.2 Enhancements

- DatetimeIndex now supports conversion to strings with astype(str) (GH10442)
- Support for compression (gzip/bz2) in pandas.DataFrame.to_csv() (GH7615)
- pd.read_* functions can now also accept pathlib.Path, or py._path.local.LocalPath objects for the filepath_or_buffer argument. (GH11033) - The DataFrame and Series functions .to_csv(), .to_html() and .to_latex() can now handle paths beginning with tildes (e.g. ~/Documents/) (GH11438)
- DataFrame now uses the fields of a namedtuple as columns, if columns are not supplied (GH11181)
- DataFrame.itertuples() now returns namedtuple objects, when possible. (GH11269, GH11625)
- Added axvlines_kwds to parallel coordinates plot (GH10709)
- Option to .info() and .memory_usage() to provide for deep introspection of memory consumption. Note that this can be expensive to compute and therefore is an optional parameter. (GH11595)

```
In [4]: df = DataFrame({'A': ['foo']*1000})
In [5]: df['B'] = df['A'].astype('category')
```
# shows the '+' as we have object dtypes
```
In [6]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000 entries, 0 to 999
Data columns (total 2 columns):
A   1000 non-null object
B   1000 non-null category
dtypes: category(1), object(1)
memory usage: 9.0+KB
```

# we have an accurate memory assessment (but can be expensive to compute this)
```
In [7]: df.info(memory_usage='deep')
```

• Index now has a `fillna` method (GH10089)

```
In [8]: pd.Index([1, np.nan, 3]).fillna(2)
Out[8]: Float64Index([1.0, 2.0, 3.0], dtype='float64')
```

• Series of type `category` now make `.str.<...> and `.dt.<...>` accessor methods / properties available, if the categories are of that type. (GH10661)

```
In [9]: s = pd.Series(list('aabb')).astype('category')
```
```
In [10]: s
Out[10]:
0  a
1  a
2  b
3  b
dtype: category
Categories (2, object): [a, b]
```
```
In [11]: s.str.contains("a")
```
```
 Out[11]:
0   True
1   True
2  False
3  False
dtype: bool
```
```
In [12]: date = pd.Series(pd.date_range('1/1/2015', periods=5)).astype('category')
```
```
In [13]: date
Out[13]:
0  2015-01-01
1  2015-01-01
2  2015-01-02
```
3 2015-01-04
4 2015-01-05
dtype: category
Categories (5, datetime64[ns]): [2015-01-01, 2015-01-02, 2015-01-03, 2015-01-04, ...
   →2015-01-05]

In [14]: date.dt.day

Out[14]:
0 1
1 2
2 3
3 4
4 5
dtype: int64

• **pivot_table** now has a `margins_name` argument so you can use something other than the default of ‘All’ (GH3335)

• Implement export of `datetime64[ns, tz]` dtypes with a fixed HDF5 store (GH1411)

• Pretty printing sets (e.g. in DataFrame cells) now uses set literal syntax `{x, y}` instead of Legacy Python syntax `set([x, y])` (GH1215)

• Improve the error message in `pandas.io.gbq.to_gbq()` when a streaming insert fails (GH11285) and when the DataFrame does not match the schema of the destination table (GH11359)

### 1.13.3 API changes

• Raise `NotImplementedError` in `Index.shift` for non-supported index types (GH8038)

• `min` and `max` reductions on `datetime64` and `timedelta64` dtyped series now result in `NaT` and not `nan` (GH11245).

• Indexing with a null key will raise a `TypeError`, instead of a `ValueError` (GH11356)

• `Series.ptp` will now ignore missing values by default (GH11163)

### 1.13.3.1 Deprecations

• The `pandas.io.ga` module which implements `google-analytics` support is deprecated and will be removed in a future version (GH11308)

• Deprecate the `engine` keyword in `.to_csv()`, which will be removed in a future version (GH11274)

### 1.13.4 Performance Improvements

• Checking monotonic-ness before sorting on an index (GH11080)

• `Series.dropna` performance improvement when its dtype can’t contain NaN (GH11159)

• Release the GIL on most datetime field operations (e.g. `DatetimeIndex.year`, `Series.dt.year`), normalization, and conversion to and from `Period`, `DatetimeIndex.to_period` and `PeriodIndex.to_timestamp` (GH11263)

• Release the GIL on some rolling algs: `rolling_median`, `rolling_mean`, `rolling_max`, `rolling_min`, `rolling_var`, `rolling_kurt`, `rolling_skew` (GH11450)
• Release the GIL when reading and parsing text files in read_csv, read_table (GH11272)
• Improved performance of rolling_median (GH11450)
• Improved performance of to_excel (GH11352)
• Performance bug in repr of Categorical categories, which was rendering the strings before chopping them for display (GH11305)
• Performance improvement in Categorical.remove_unused_categories, (GH11643).
• Improved performance of Series constructor with no data and DatetimeIndex (GH11433)
• Improved performance of shift, cumprod, and cumsum with groupby (GH4095)

1.13.5 Bug Fixes

• SparseArray.__iter__() now does not cause PendingDeprecationWarning in Python 3.5 (GH11622)
• Regression from 0.16.2 for output formatting of long floats/nan, restored in (GH11302)
• Series.sort_index() now correctly handles the inplace option (GH11402)
• Incorrectly distributed .c file in the build on PyPi when reading a csv of floats and passing na_values=<a scalar> would show an exception (GH11374)
• Bug in .to_latex() output broken when the index has a name (GH10660)
• Bug in HDFStore.append with strings whose encoded length exceeded the max unencoded length (GH11234)
• Bug in merging datetime64[ns, tz] dtypes (GH11405)
• Bug in HDFStore.select when comparing with a numpy scalar in a where clause (GH11283)
• Bug in using DataFrame.ix with a multi-index indexer (GH11372)
• Bug in date_range with ambiguous endpoints (GH11626)
• Prevent adding new attributes to the accessors .str, .dt and .cat. Retrieving such a value was not possible, so error out on setting it. (GH10673)
• Bug in tz-conversions with an ambiguous time and .dt accessors (GH11295)
• Bug in output formatting when using an index of ambiguous times (GH11619)
• Bug in comparisons of Series vs list-like (GH11339)
• Bug in DataFrame.replace with a datetime64[ns, tz] and a non-compat to_replace (GH11326, GH11153)
• Bug in isnull where numpy.datetime64('NaT') in a numpy.array was not determined to be null(GH11206)
• Bug in list-like indexing with a mixed-integer Index (GH11320)
• Bug in pivot_table with margins=True when indexes are of Categorical dtype (GH10993)
• Bug in DataFrame.plot cannot use hex strings colors (GH10299)
• Regression in DataFrame.drop_duplicates from 0.16.2, causing incorrect results on integer values (GH11376)
• Bug in pd.eval where unary ops in a list error (GH11235)
• Bug in squeeze() with zero length arrays (GH11230, GH8999)
- Bug in `describe()` dropping column names for hierarchical indexes (GH11517)
- Bug in `DataFrame.pct_change()` not propagating axis keyword on `.fillna` method (GH11150)
- Bug in `.to_csv()` when a mix of integer and string column names are passed as the columns parameter (GH11637)
- Bug in indexing with a range (GH11652)
- Bug in inference of numpy scalars and preserving dtype when setting columns (GH11638)
- Bug in `to_sql` using unicode column names giving UnicodeEncodeError with (GH11431).
- Fix regression in setting of `xticks` in plot (GH11529).
- Bug in `holiday.dates` where observance rules could not be applied to holiday and doc enhancement (GH11477, GH11533)
- Fix plotting issues when having plain `Axes` instances instead of `SubplotAxes` (GH11520, GH11556).
- Bug in `DataFrame.to_latex()` produces an extra rule when header=False (GH7124)
- Bug in `df.groupby(...).apply(func)` when a func returns a Series containing a new datetimelike column (GH11324)
- Bug in pandas.json when file to load is big (GH11344)
- Bugs in `to_excel` with duplicate columns (GH11007, GH10982, GH10970)
- Fixed a bug that prevented the construction of an empty series of dtype datetime64[ns, tz] (GH11245).
- Bug in `read_excel` with multi-index containing integers (GH11317)
- Bug in `to_excel` with openpyxl 2.2+ and merging (GH11408)
- Bug in `DataFrame.to_dict()` produces a np.datetime64 object instead of Timestamp when only datetime is present in data (GH11327)
- Bug in `DataFrame.corr()` raises exception when computes Kendall correlation for DataFrames with boolean and not boolean columns (GH11560)
- Bug in the link-time error caused by C inline functions on FreeBSD 10+ (with clang) (GH10510)
- Bug in `DataFrame.to_csv` in passing through arguments for formatting MultiIndexes, including date_format (GH7791)
- Bug in `DataFrame.join()` with how='right' producing a TypeError (GH11519)
- Bug in `Series.quantile` with empty list results has Index with object dtype (GH11588)
- Bug in `pd.merge` results in empty Int64Index rather than Index(dtype=object) when the merge result is empty (GH11588)
- Bug in `Categorical.remove_unused_categories` when having NaN values (GH11599)
- Bug in `DataFrame.to_sparse()` loses column names for MultiIndexes (GH11600)
- Bug in `DataFrame.round()` with non-unique column index producing a Fatal Python error (GH11611)
- Bug in `DataFrame.round()` with decimals being a non-unique indexed Series producing extra columns (GH11618)
1.14 v0.17.0 (October 9, 2015)

This is a major release from 0.16.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

**Warning:** pandas >= 0.17.0 will no longer support compatibility with Python version 3.2 (GH9118)

**Warning:** The pandas.io.data package is deprecated and will be replaced by the pandas-datareader package. This will allow the data modules to be independently updated to your pandas installation. The API for pandas-datareader v0.1.1 is exactly the same as in pandas v0.17.0 (GH8961, GH10861).

After installing pandas-datareader, you can easily change your imports:

```python
from pandas.io import data, wb
```

becomes

```python
from pandas_datareader import data, wb
```

Highlights include:

- Release the Global Interpreter Lock (GIL) on some cython operations, see here
- Plotting methods are now available as attributes of the .plot accessor, see here
- The sorting API has been revamped to remove some long-time inconsistencies, see here
- Support for a datetime64[ns] with timezones as a first-class dtype, see here
- The default for to_datetime will now be to raise when presented with unparsable formats, previously this would return the original input. Also, date parse functions now return consistent results. See here
- The default for dropna in HDFStore has changed to False, to store by default all rows even if they are all NaN, see here
- Datetime accessor (dt) now supports Series.dt.strftime to generate formatted strings for datet ime-likes, and Series.dt.total_seconds to generate each duration of the timedelta in seconds. See here
- Period and PeriodIndex can handle multiplied freq like 3D, which corresponding to 3 days span. See here
- Development installed versions of pandas will now have PEP440 compliant version strings (GH9518)
- Development support for benchmarking with the Air Speed Velocity library (GH8361)
- Support for reading SAS xport files, see here
- Documentation comparing SAS to pandas, see here
- Removal of the automatic TimeSeries broadcasting, deprecated since 0.8.0, see here
- Display format with plain text can optionally align with Unicode East Asian Width, see here
- Compatibility with Python 3.5 (GH11097)
- Compatibility with matplotlib 1.5.0 (GH11111)

Check the API Changes and deprecations before updating.
What’s new in v0.17.0

• **New features**
  – Datetime with TZ
  – Releasing the GIL
  – Plot submethods
  – Additional methods for `dt` accessor
    * `strftime`
    * `total_seconds`
  – Period Frequency Enhancement
  – Support for SAS XPORT files
  – Support for Math Functions in `.eval()`
  – Changes to Excel with `MultiIndex`
  – Google BigQuery Enhancements
  – Display Alignment with Unicode East Asian Width
  – Other enhancements

• **Backwards incompatible API changes**
  – Changes to sorting API
  – Changes to `to_datetime` and `to_timedelta`
    * Error handling
    * Consistent Parsing
  – Changes to Index Comparisons
  – Changes to Boolean Comparisons vs. None
  – HDFStore dropna behavior
  – Changes to `display.precision` option
  – Changes to `Categorical.unique`
  – Changes to `bool passed as header` in Parsers
  – Other API Changes
  – Deprecations
  – Removal of prior version deprecations/changes

• **Performance Improvements**

• **Bug Fixes**
1.14.1 New features

1.14.1.1 Datetime with TZ

We are adding an implementation that natively supports datetime with timezones. A Series or a DataFrame column previously could be assigned a datetime with timezones, and would work as an object dtype. This had performance issues with a large number of rows. See the docs for more details. (GH8260, GH10763, GH11034).

The new implementation allows for having a single-timezone across all rows, with operations in a performant manner.

```
In [1]: df = DataFrame({'A': date_range('20130101', periods=3),
                    ...: 'B': date_range('20130101', periods=3, tz='US/Eastern'),
                    ...: 'C': date_range('20130101', periods=3, tz='CET'))
...:

In [2]: df
Out[2]:
      A            B            C
0 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00+01:00
1 2013-01-02 00:00:00-05:00 2013-01-02 00:00:00+01:00
2 2013-01-03 00:00:00-05:00 2013-01-03 00:00:00+01:00

In [3]: df.dtypes
\-----
A    datetime64[ns]
B   datetime64[ns, US/Eastern]
C   datetime64[ns, CET]
dtype: object

In [4]: df['B']
Out[4]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
Name: B, dtype: datetime64[ns, US/Eastern]

In [5]: df['B'].dt.tz_localize(None)
\-----
0 2013-01-01
1 2013-01-02
2 2013-01-03
Name: B, dtype: datetime64[ns]

In [6]: df['B'].dtype
Out[6]: datetime64[ns, US/Eastern]

In [7]: type(df['B'].dtype)
\-----
Out[7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

This uses a new-dtype representation as well, that is very similar in look-and-feel to its numpy cousin datetime64[ns]

```
In [6]: df['B'].dtype
Out[6]: datetime64[ns, US/Eastern]

In [7]: type(df['B'].dtype)
\-----
Out[7]: pandas.core.dtypes.dtypes.DatetimeTZDtype
```

Note: There is a slightly different string repr for the underlying DatetimeIndex as a result of the dtype changes, but functionally these are the same.
Previous Behavior:

```
In [1]: pd.date_range('20130101',periods=3,tz='US/Eastern')
Out[1]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
  '2013-01-03 00:00:00-05:00'],
  dtype='datetime64[ns]', freq='D', tz='US/Eastern')
In [2]: pd.date_range('20130101',periods=3,tz='US/Eastern').dtype
Out[2]: dtype('<M8[ns]')
```

New Behavior:

```
In [8]: pd.date_range('20130101',periods=3,tz='US/Eastern')
Out[8]: DatetimeIndex(['2013-01-01 00:00:00-05:00', '2013-01-02 00:00:00-05:00',
  '2013-01-03 00:00:00-05:00'],
  dtype='datetime64[ns, US/Eastern]', freq='D')
In [9]: pd.date_range('20130101',periods=3,tz='US/Eastern').dtype
   --->datetime64[ns, US/Eastern]
```

1.14.1.2 Releasing the GIL

We are releasing the global-interpreter-lock (GIL) on some cython operations. This will allow other threads to run simultaneously during computation, potentially allowing performance improvements from multi-threading. Notably groupby, nsmallest, value_counts and some indexing operations benefit from this. (GH8882)

For example the groupby expression in the following code will have the GIL released during the factorization step, e.g. `df.groupby('key')` as well as the `.sum()` operation.

```
N = 1000000
ngroups = 10
df = DataFrame({'key' : np.random.randint(0,ngroups,size=N),
  'data' : np.random.randn(N)})
df.groupby('key')['data'].sum()
```

Releasing of the GIL could benefit an application that uses threads for user interactions (e.g. QT), or performing multi-threaded computations. A nice example of a library that can handle these types of computation-in-parallel is the dask library.

1.14.1.3 Plot submethods

The Series and DataFrame `.plot()` method allows for customizing plot types by supplying the kind keyword arguments. Unfortunately, many of these kinds of plots use different required and optional keyword arguments, which makes it difficult to discover what any given plot kind uses out of the dozens of possible arguments.

To alleviate this issue, we have added a new, optional plotting interface, which exposes each kind of plot as a method of the `.plot` attribute. Instead of writing `series.plot(kind=<kind>, ...)`, you can now also use `series.plot.<kind>(...)`.
As a result of this change, these methods are now all discoverable via tab-completion:

```
In [12]: df.plot.<TAB>
   df.plot.area   df.plot.barh   df.plot.density   df.plot.hist   df.plot.line
   df.plot.scatter
   df.plot.bar    df.plot.box    df.plot.hexbin    df.plot.kde    df.plot.pie
```

Each method signature only includes relevant arguments. Currently, these are limited to required arguments, but in the future these will include optional arguments, as well. For an overview, see the new Plotting API documentation.

1.14.1.4 Additional methods for `dt` accessor

`strftime`

We are now supporting a `Series.dt.strftime` method for datetime-likes to generate a formatted string (GH10110). Examples:

```
# DatetimeIndex
In [13]: s = pd.Series(pd.date_range('20130101', periods=4))

In [14]: s
Out[14]:
     0  2013-01-01
     1  2013-01-02
     2  2013-01-03
     3  2013-01-04

dtype: datetime64[ns]

In [15]: s.dt.strftime('%Y/%m/%d')
```

```
# PeriodIndex

In [16]: s = pd.Series(pd.period_range('20130101', periods=4))

In [17]: s
Out[17]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: object

In [18]: s.dt.strftime('%Y/%m/%d')

Out[18]:
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object

The string format is as the python standard library and details can be found here

**total_seconds**

pd.Series of type timedelta64 has new method .dt.total_seconds() returning the duration of the timedelta in seconds (GH10817)

# TimedeltaIndex

In [19]: s = pd.Series(pd.timedelta_range('1 minutes', periods=4))

In [20]: s
Out[20]:
0 0 days 00:01:00
1 1 days 00:01:00
2 2 days 00:01:00
3 3 days 00:01:00
dtype: timedelta64[ns]

In [21]: s.dt.total_seconds()

Out[21]:
0    60.0
1   86460.0
2  172860.0
3  259260.0
dtype: float64
1.14.1.5 Period Frequency Enhancement

Period, PeriodIndex and period_range can now accept multiplied freq. Also, Period.freq and PeriodIndex.freq are now stored as a DateOffset instance like DatetimeIndex, and not as str (GH7811)

A multiplied freq represents a span of corresponding length. The example below creates a period of 3 days. Addition and subtraction will shift the period by its span.

```python
In [22]: p = pd.Period('2015-08-01', freq='3D')
In [23]: p
Out[23]: Period('2015-08-01', '3D')
In [24]: p + 1
Out[24]: Period('2015-08-04', '3D')
In [25]: p - 2
Out[25]: Period('2015-07-26', '3D')
In [26]: p.to_timestamp()
Out[26]: Timestamp('2015-08-01 00:00:00')
In [27]: p.to_timestamp(how='E')
Out[27]: Timestamp('2015-08-03 00:00:00')
```

You can use the multiplied freq in PeriodIndex and period_range.

```python
In [28]: idx = pd.period_range('2015-08-01', periods=4, freq='2D')
In [29]: idx
Out[29]: PeriodIndex(['2015-08-01', '2015-08-03', '2015-08-05', '2015-08-07'], dtype='period[2D]', freq='2D')
In [30]: idx + 1
Out[30]: PeriodIndex(['2015-08-03', '2015-08-05', '2015-08-07', '2015-08-09'], dtype='period[2D]', freq='2D')
```

1.14.1.6 Support for SAS XPORT files

read_sas() provides support for reading SAS XPORT format files. (GH4052).

```python
df = pd.read_sas('sas_xport.xpt')
```

It is also possible to obtain an iterator and read an XPORT file incrementally.

```python
for df in pd.read_sas('sas_xport.xpt', chunksize=10000)
    do_something(df)
```

See the docs for more details.
1.14.1.7 Support for Math Functions in .eval()

eval() now supports calling math functions (GH4893)

```python
df = pd.DataFrame({'a': np.random.randn(10)})
df.eval("b = sin(a)")
```

The support math functions are \(\sin, \cos, \exp, \log, \expm1, \log1p, \sqrt, \sinh, \cosh, \tanh, \arcsin, \arccos, \arctan, \arccosh, \arcsinh, \arctanh, \text{abs}\) and \(\text{arctan2}\).

These functions map to the intrinsics for the NumExpr engine. For the Python engine, they are mapped to NumPy calls.

1.14.1.8 Changes to Excel with MultiIndex

In version 0.16.2 a DataFrame with MultiIndex columns could not be written to Excel via to_excel. That functionality has been added (GH10564), along with updating read_excel so that the data can be read back with, no loss of information, by specifying which columns/rows make up the MultiIndex in the header and index_col parameters (GH4679)

See the documentation for more details.

```python
In [31]: df = pd.DataFrame([[1,2,3,4], [5,6,7,8]],
                       columns = pd.MultiIndex.from_product([['foo','bar'],[a,'b']]),
                       names = ['col1', 'col2'])
In [32]: df
Out[32]:
   col1  col2
  foo  bar
 col1  a   b
 col2  a   b
   i1  i2
   j  1  2  3  4
   k  5  6  7  8

In [33]: df.to_excel('test.xlsx')

In [34]: df = pd.read_excel('test.xlsx', header=[0,1], index_col=[0,1])

In [35]: df
Out[35]:
   col1  col2
  foo  bar
 col1  a   b
 col2  a   b
   i1  i2
   j  1  2  3  4
   k  5  6  7  8
```

Previously, it was necessary to specify the has_index_names argument in read_excel, if the serialized data had index names. For version 0.17.0 the output format of to_excel has been changed to make this keyword unnecessary - the change is shown below.
Warning: Excel files saved in version 0.16.2 or prior that had index names will still able to be read in, but the has_index_names argument must specified to True.

1.14.1.9 Google BigQuery Enhancements

- Added ability to automatically create a table/dataset using the `pandas.io.gbq.to_gbq()` function if the destination table/dataset does not exist. (GH8325, GH11121).
- Added ability to replace an existing table and schema when calling the `pandas.io.gbq.to_gbq()` function via the `if_exists` argument. See the docs for more details (GH8325).
- `InvalidColumnOrder` and `InvalidPageToken` in the gbq module will raise `ValueError` instead of `IOError`.
- The `generate_bq_schema()` function is now deprecated and will be removed in a future version (GH11121)
- The gbq module will now support Python 3 (GH11094).
1.14.1.10 Display Alignment with Unicode East Asian Width

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width is corresponding to 2 alphabets. If a DataFrame or Series contains these characters, the default output cannot be aligned properly. The following options are added to enable precise handling for these characters.

- `display.unicode.east_asian_width`: Whether to use the Unicode East Asian Width to calculate the display text width. (GH2612)
- `display.unicode.ambiguous_as_wide`: Whether to handle Unicode characters belong to Ambiguous as Wide. (GH11102)

```python
In [36]: df = pd.DataFrame({u'': ['UK', u''], u'': ['Alice', u'']})

In [37]: df;

>>> df = pd.DataFrame({u'国籍': ['UK', u'日本'], u'名前': ['Alice', u'しのぶ']})

>>> df
<table>
<thead>
<tr>
<th>名前</th>
<th>国籍</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alice</td>
<td>UK</td>
</tr>
<tr>
<td>しのぶ</td>
<td>日本</td>
</tr>
</tbody>
</table>

In [38]: pd.set_option('display.unicode.east_asian_width', True)

In [39]: df;

>>> pd.set_option('display.unicode.east_asian_width', True)

For further details, see [here](#).

1.14.1.11 Other enhancements

- Support for openpyxl >= 2.2. The API for style support is now stable (GH10125)
- `merge` now accepts the argument `indicator` which adds a Categorical-type column (by default called `_merge`) to the output object that takes on the values (GH8790)

<table>
<thead>
<tr>
<th>Observation Origin</th>
<th>_merge value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Merge key only in 'left' frame</td>
<td>left_only</td>
</tr>
<tr>
<td>Merge key only in 'right' frame</td>
<td>right_only</td>
</tr>
<tr>
<td>Merge key in both frames</td>
<td>both</td>
</tr>
</tbody>
</table>

```python
In [40]: df1 = pd.DataFrame({'coll':[0,1], 'col_left':['a','b']})

```
In [41]: df2 = pd.DataFrame({'col1':[1,2,2],'col_right':[2,2,2]})

In [42]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)

Out[42]:
<table>
<thead>
<tr>
<th>col1</th>
<th>col_left</th>
<th>col_right</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>

For more, see the updated docs

- `pd.to_numeric` is a new function to coerce strings to numbers (possibly with coercion) (GH11133)
- `pd.merge` will now allow duplicate column names if they are not merged upon (GH10639).
- `pd.pivot` will now allow passing index as None (GH3962).
- `pd.concat` will now use existing Series names if provided (GH10698).

In [43]: foo = pd.Series([1,2], name='foo')

In [44]: bar = pd.Series([1,2])

In [45]: baz = pd.Series([4,5])

Previous Behavior:

In [1] pd.concat([foo, bar, baz], 1)

Out[1]:
<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>1</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>2</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>baz</td>
<td>4</td>
<td>5</td>
<td></td>
</tr>
</tbody>
</table>

New Behavior:

In [46]: pd.concat([foo, bar, baz], 1)

Out[46]:
foo 0 1
1 1 4
2 2 5

- DataFrame has gained the `nlargest` and `nsmallest` methods (GH10393)
- Add a `limit_direction` keyword argument that works with `limit` to enable `interpolate` to fill NaN values forward, backward, or both (GH9218, GH10420, GH11115)

In [47]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13])

In [48]: ser.interpolate(limit=1, limit_direction='both')

Out[48]:
<table>
<thead>
<tr>
<th></th>
<th>NaN</th>
<th>5.0</th>
<th>5.0</th>
<th>7.0</th>
<th>NaN</th>
<th>11.0</th>
<th>13.0</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>NaN</td>
<td>5.0</td>
<td>5.0</td>
<td>7.0</td>
<td>NaN</td>
<td>11.0</td>
<td>13.0</td>
</tr>
</tbody>
</table>
dtype: float64
• Added a `DataFrame.round` method to round the values to a variable number of decimal places (GH10568).

```python
In [49]: df = pd.DataFrame(np.random.random((3, 3)), columns=['A', 'B', 'C'],
                  index=['first', 'second', 'third'])

In [50]: df
Out[50]:
   A     B     C
first 0.342764 0.304121 0.417022
second 0.681301 0.875457 0.510422
third 0.669314 0.585937 0.624904

In [51]: df.round(2)
   A   B   C
first 0.34 0.30 0.42
second 0.68 0.88 0.51
third 0.67 0.59 0.62

In [52]: df.round({'A': 0, 'C': 2})
   A  B   C
first 0.0 0.304121 0.42
second 1.0 0.875457 0.51
third 1.0 0.585937 0.62

• `drop_duplicates` and `duplicated` now accept a `keep` keyword to target first, last, and all duplicates. The `take_last` keyword is deprecated, see here (GH6511, GH8505)

```python
In [53]: s = pd.Series(['A', 'B', 'C', 'A', 'B', 'D'])

In [54]: s.drop_duplicates()
Out[54]:
0 A
1 B
2 C
5 D
dtype: object

In [55]: s.drop_duplicates(keep='last')
   C
2 0.304121
3 0.875457
5 0.585937
dtype: object

In [56]: s.drop_duplicates(keep=False)
   C
2 0.304121
5 0.585937
dtype: object

• Reindex now has a `tolerance` argument that allows for finer control of Limits on filling while reindexing (GH10411):
In [57]: df = pd.DataFrame({'x': range(5),
                        't': pd.date_range('2000-01-01', periods=5)})

In [58]: df.reindex([0.1, 1.9, 3.5],
                        method='nearest',
                        tolerance=0.2)

Out[58]:
    x     t
0.1  0.0 2000-01-01
1.9  2.0 2000-01-03
3.5  NaN  NaT

When used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with a string:

In [59]: df = df.set_index('t')

In [60]: df.reindex(pd.to_datetime(['1999-12-31']),
                        method='nearest',
                        tolerance='1 day')

Out[60]:
    x     t
1999-12-31  0

tolerance is also exposed by the lower level Index.get_indexer and Index.get_loc methods.

- Added functionality to use the base argument when resampling a TimeDeltaIndex (GH10530)
- DatetimeIndex can be instantiated using strings contains NaT (GH7599)
- to_datetime can now accept the yearfirst keyword (GH7599)
- pandas.tseries.offsets larger than the Day offset can now be used with a Series for addition/subtraction (GH10699). See the docs for more details.
- pd.Timedelta.total_seconds() now returns Timedelta duration to ns precision (previously microsecond precision) (GH10939)
- PeriodIndex now supports arithmetic with np.ndarray (GH10638)
- Support pickling of Period objects (GH10439)
- .as_blocks will now take a copy optional argument to return a copy of the data, default is to copy (no change in behavior from prior versions), (GH9607)
- regex argument to DataFrame.filter now handles numeric column names instead of raising ValueError (GH10384).
- Enable reading gzip compressed files via URL, either by explicitly setting the compression parameter or by inferring from the presence of the HTTP Content-Encoding header in the response (GH8685)
- Enable writing Excel files in memory using StringIO/BytesIO (GH7074)
- Enable serialization of lists and dicts to strings in ExcelWriter (GH8188)
- SQL io functions now accept a SQLAlchemy connectable. (GH7877)
- pd.read_sql and to_sql can accept database URI as con parameter (GH10214)
- read_sql_table will now allow reading from views (GH10750).
**1.14.2 Backwards incompatible API changes**

### 1.14.2.1 Changes to sorting API

The sorting API has had some longtime inconsistencies. (GH9816, GH8239).

Here is a summary of the API PRIOR to 0.17.0:

- `Series.sort` is **INPLACE** while `DataFrame.sort` returns a new object.
- `Series.order` returns a new object
- It was possible to use `Series/DataFrame.sort_index` to sort by **values** by passing the `by` keyword.
- `Series/DataFrame.sortlevel` worked only on a MultiIndex for sorting by index.

To address these issues, we have revamped the API:

- We have introduced a new method, `DataFrame.sort_values()`, which is the merger of `DataFrame.sort()`, `Series.sort()`, and `Series.order()`, to handle sorting of values.
- The existing methods `Series.sort()`, `Series.order()`, and `DataFrame.sort()` have been deprecated and will be removed in a future version.
- The `by` argument of `DataFrame.sort_index()` has been deprecated and will be removed in a future version.
- The existing method `.sort_index()` will gain the `level` keyword to enable level sorting.

We now have two distinct and non-overlapping methods of sorting. A * marks items that will show a `FutureWarning`.

To sort by the **values**:
To sort by the **index**:

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>*Series.sort_index()</td>
<td>Series.sort_index()</td>
</tr>
<tr>
<td>Series.sortlevel(level=...)</td>
<td>Series.sort_index(level=...)</td>
</tr>
<tr>
<td>DataFrame.sort_index()</td>
<td>DataFrame.sort_index()</td>
</tr>
<tr>
<td>DataFrame.sortlevel(level=...)</td>
<td>DataFrame.sort_index(level=...)</td>
</tr>
<tr>
<td>*DataFrame.sort()</td>
<td>DataFrame.sort_index()</td>
</tr>
</tbody>
</table>

We have also deprecated and changed similar methods in two Series-like classes, Index and Categorical.

<table>
<thead>
<tr>
<th>Previous</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>*Index.order()</td>
<td>Index.sort_values()</td>
</tr>
<tr>
<td>*Categorical.order()</td>
<td>Categorical.sort_values()</td>
</tr>
</tbody>
</table>

### 1.14.2.2 Changes to `to_datetime` and `to_timedelta`

**Error handling**

The default for `pd.to_datetime` error handling has changed to `errors='raise'`. In prior versions it was `errors='ignore'`. Furthermore, the `coerce` argument has been deprecated in favor of `errors='coerce'`. This means that invalid parsing will raise rather that return the original input as in previous versions. (GH10636)

**Previous Behavior:**

```python
In [2]: pd.to_datetime(['2009-07-31', 'asd'])
Out[2]: array(['2009-07-31', 'asd'], dtype=object)
```

**New Behavior:**

```python
In [3]: pd.to_datetime(['2009-07-31', 'asd'])
ValueError: Unknown string format.
```

Of course you can coerce this as well.

```python
In [61]: to_datetime(['2009-07-31', 'asd'], errors='coerce')
Out[61]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

To keep the previous behavior, you can use `errors='ignore'`:

```python
In [62]: to_datetime(['2009-07-31', 'asd'], errors='ignore')
Out[62]: array(['2009-07-31', 'asd'], dtype=object)
```

Furthermore, `pd.to_timedelta` has gained a similar API, of `errors='raise'` | `ignore` | `coerce`, and the `coerce` keyword has been deprecated in favor of `errors='coerce'`. 
Consistent Parsing

The string parsing of `to_datetime`, `Timestamp` and `DatetimeIndex` has been made consistent. (GH7599)

Prior to v0.17.0, `Timestamp` and `to_datetime` may parse year-only datetime-string incorrectly using today’s date, otherwise `DatetimeIndex` uses the beginning of the year. `Timestamp` and `to_datetime` may raise `ValueError` in some types of datetime-string which `DatetimeIndex` can parse, such as a quarterly string.

**Previous Behavior:**

```python
In [1]: Timestamp('2012Q2')
Traceback...
ValueError: Unable to parse 2012Q2

# Results in today's date.
In [2]: Timestamp('2014')
Out [2]: 2014-08-12 00:00:00
```

v0.17.0 can parse them as below. It works on `DatetimeIndex` also.

**New Behavior:**

```python
In [63]: Timestamp('2012Q2')
Out[63]: Timestamp('2012-04-01 00:00:00')

In [64]: Timestamp('2014')
Out[64]: Timestamp('2014-01-01 00:00:00')

In [65]: DatetimeIndex(['2012Q2', '2014'])
Out[65]: DatetimeIndex(['2012-04-01', '2014-01-01'], dtype='datetime64[ns]', freq=None)
```

**Note:** If you want to perform calculations based on today’s date, use `Timestamp.now()` and `pandas.tseries.offsets`.

```python
In [66]: import pandas.tseries.offsets as offsets

In [67]: Timestamp.now()
Out[67]: Timestamp('2018-05-02 06:36:06.890801')

In [68]: Timestamp.now() + offsets.DateOffset(years=1)
Out[68]: Timestamp('2019-05-02 06:36:06.891869')
```

1.14.2.3 Changes to Index Comparisons

Operator equal on `Index` should behave similarly to `Series` (GH9947, GH10637)

Starting in v0.17.0, comparing `Index` objects of different lengths will raise a `ValueError`. This is to be consistent with the behavior of `Series`.

**Previous Behavior:**
In [2]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[2]: array([ True, False, False], dtype=bool)

In [3]: pd.Index([1, 2, 3]) == pd.Index([2])
Out[3]: array([False, True, False], dtype=bool)

In [4]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
Out[4]: False

New Behavior:

In [8]: pd.Index([1, 2, 3]) == pd.Index([1, 4, 5])
Out[8]: array([ True, False, False], dtype=bool)

In [9]: pd.Index([1, 2, 3]) == pd.Index([2])
ValueError: Lengths must match to compare

In [10]: pd.Index([1, 2, 3]) == pd.Index([1, 2])
ValueError: Lengths must match to compare

Note that this is different from the numpy behavior where a comparison can be broadcast:

In [69]: np.array([1, 2, 3]) == np.array([1])
Out[69]: array([ True, False, False], dtype=bool)

or it can return False if broadcasting can not be done:

In [70]: np.array([1, 2, 3]) == np.array([1, 2])
Out[70]: False

1.14.2.4 Changes to Boolean Comparisons vs. None

Boolean comparisons of a Series vs None will now be equivalent to comparing with np.nan, rather than raise TypeError. (GH1079).

In [71]: s = Series(range(3))

In [72]: s.iloc[1] = None

In [73]: s
Out[73]:
0   0.0
1   NaN
2   2.0
dtype: float64

Previous Behavior:

In [5]: s==None
TypeError: Could not compare <type 'NoneType'> type with Series

New Behavior:

In [74]: s==None
Out[74]:
0    False
1    False
2    False
dtype: bool

Usually you simply want to know which values are null.

In [75]: s.isnull()
Out[75]:
0    False
1    True
2    False
dtype: bool

Warning: You generally will want to use isnull/notnull for these types of comparisons, as isnull/notnull tells you which elements are null. One has to be mindful that nan's don’t compare equal, but None's do. Note that Pandas/numpy uses the fact that np.nan != np.nan, and treats None like np.nan.

In [76]: None == None
Out[76]: True

In [77]: np.nan == np.nan
\nOut[77]: False

1.14.2.5 HDFStore dropna behavior

The default behavior for HDFStore write functions with format='table' is now to keep rows that are all missing. Previously, the behavior was to drop rows that were all missing save the index. The previous behavior can be replicated using the dropna=True option. (GH9382)

Previous Behavior:

In [78]: df_with_missing = pd.DataFrame({'col1':[0, np.nan, 2],
                                      'col2':[1, np.nan, np.nan]})

In [79]: df_with_missing
Out[79]:
   col1  col2
0    0.0   1.0
1    NaN  NaN
2    2.0   NaN

In [27]: df_with_missing.to_hdf('file.h5',
                           'df_with_missing',
                           format='table',
                           mode='w')

In [28]: pd.read_hdf('file.h5', 'df_with_missing')
Out [28]:
   col1  col2
0  0.00  1.00
1  NaN  NaN
2  2.00  NaN

(continues on next page)
New Behavior:

```python
In [80]: df_with_missing.to_hdf('file.h5', ....: 'df_with_missing', ....: format='table', ....: mode='w')

In [81]: pd.read_hdf('file.h5', 'df_with_missing')
Out[81]:
     col1  col2
0     0.0  1.0
1    NaN  NaN
2     2.0  NaN
```

See the `docs` for more details.

### 1.14.2.6 Changes to `display.precision` option

The `display.precision` option has been clarified to refer to decimal places (GH10451).

Earlier versions of pandas would format floating point numbers to have one less decimal place than the value in `display.precision`.

```python
In [1]: pd.set_option('display.precision', 2)
In [2]: pd.DataFrame({'x': [123.456789]})
Out[2]:
    x
0  123.5
```

If interpreting precision as “significant figures” this did work for scientific notation but that same interpretation did not work for values with standard formatting. It was also out of step with how numpy handles formatting.

Going forward the value of `display.precision` will directly control the number of places after the decimal, for regular formatting as well as scientific notation, similar to how numpy’s `precision` print option works.

```python
In [82]: pd.set_option('display.precision', 2)
In [83]: pd.DataFrame({'x': [123.456789]})
Out[83]:
    x
0  123.46
```

To preserve output behavior with prior versions the default value of `display.precision` has been reduced to 6 from 7.

### 1.14.2.7 Changes to `Categorical.unique`

`Categorical.unique` now returns new `Categoricals` with categories and codes that are unique, rather than returning `np.array` (GH10508)

- unordered category: values and categories are sorted by appearance order.
• ordered category: values are sorted by appearance order, categories keep existing order.

```python
In [84]: cat = pd.Categorical(['C', 'A', 'B', 'C'], categories=['A', 'B', 'C'], ordered=True)

In [85]: cat
Out[85]:
[C, A, B, C]
Categories (3, object): [A < B < C]

In [86]: cat.unique()

Out[86]:
[C, A, B]
Categories (3, object): [A < B < C]

In [87]: cat = pd.Categorical(['C', 'A', 'B', 'C'], categories=['A', 'B', 'C'])

In [88]: cat
Out[88]:
[C, A, B, C]
Categories (3, object): [A, B, C]

In [89]: cat.unique()

Out[89]:
[C, A, B]
Categories (3, object): [C, A, B]
```

### 1.14.2.8 Changes to bool passed as header in Parsers

In earlier versions of pandas, if a bool was passed the header argument of `read_csv`, `read_excel`, or `read_html` it was implicitly converted to an integer, resulting in `header=0` for `False` and `header=1` for `True` (GH6113)

A bool input to `header` will now raise a `TypeError`

```python
In [29]: df = pd.read_csv('data.csv', header=False)
TypeError: Passing a bool to header is invalid. Use header=None for no header or header=int or list-like of ints to specify the row(s) making up the column names
```

### 1.14.2.9 Other API Changes

- Line and kde plot with `subplots=True` now uses default colors, not all black. Specify `color='k'` to draw all lines in black (GH9894)
- Calling the `.value_counts()` method on a Series with a categorical dtype now returns a Series with a CategoricalIndex (GH10704)
- The metadata properties of subclasses of pandas objects will now be serialized (GH10553).
- `groupby` using Categorical follows the same rule as Categorical.unique described above (GH10508)
When constructing DataFrame with an array of complex64 dtype previously meant the corresponding column was automatically promoted to the complex128 dtype. Pandas will now preserve the itemsize of the input for complex data (GH10952)

some numeric reduction operators would return ValueError, rather than TypeError on object types that includes strings and numbers (GH11131)

Passing currently unsupported chunksize argument to read_excel or ExcelFile.parse will now raise NotImplementedError (GH8011)

Allow an ExcelFile object to be passed into read_excel (GH11198)

DatetimeIndex.union does not infer freq if self and the input have None as freq (GH11086)

NaT's methods now either raise ValueError, or return np.nan or NaT (GH9513)

<table>
<thead>
<tr>
<th>Behavior</th>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>return np.nan</td>
<td>weekday, isoweekday</td>
</tr>
<tr>
<td>return NaT</td>
<td>date, now, replace, to_datetime, today</td>
</tr>
<tr>
<td>return np.datetime64('NaT')</td>
<td>to_datetime64 (unchanged)</td>
</tr>
<tr>
<td>raise ValueError</td>
<td>All other public methods (names not beginning with underscores)</td>
</tr>
</tbody>
</table>

1.14.2.10 Deprecations

For Series the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
<tr>
<td>.iget_value(i)</td>
<td>.iloc[i] or .iat[i]</td>
</tr>
</tbody>
</table>

For DataFrame the following indexing functions are deprecated (GH10177).

<table>
<thead>
<tr>
<th>Deprecated Function</th>
<th>Replacement</th>
</tr>
</thead>
<tbody>
<tr>
<td>.irow(i)</td>
<td>.iloc[i]</td>
</tr>
<tr>
<td>.iget_value(i, j)</td>
<td>.iloc[i, j] or .iat[i, j]</td>
</tr>
<tr>
<td>.icol(j)</td>
<td>.iloc[:, j]</td>
</tr>
</tbody>
</table>

Note: These indexing function have been deprecated in the documentation since 0.11.0.

Categorical.name was deprecated to make Categorical more numpy.ndarray like. Use Series(cat, name="whatever") instead (GH10482).

Setting missing values (NaN) in a Categorical's categories will issue a warning (GH10748). You can still have missing values in the values.

drop_duplicates and duplicated's take_last keyword was deprecated in favor of keep. (GH6511, GH8505)

Series.nsmallest and nlargest's take_last keyword was deprecated in favor of keep. (GH10792)

DataFrame.combineAdd and DataFrame.combineMult are deprecated. They can easily be replaced by using the add and mul methods: DataFrame.add(other, fill_value=0) and DataFrame.mul(other, fill_value=1.) (GH10735).
• TimeSeries deprecated in favor of Series (note that this has been an alias since 0.13.0), (GH10890)
• SparsePanel deprecated and will be removed in a future version (GH11157).
• Series.is_time_series deprecated in favor of Series.index.is_all_dates (GH11135)
• Legacy offsets (like 'A@JAN') are deprecated (note that this has been alias since 0.8.0) (GH10878)
• WidePanel deprecated in favor of Panel, LongPanel in favor of DataFrame (note these have been aliases since < 0.11.0), (GH10892)
• DataFrame.convert_objects has been deprecated in favor of type-specific functions pd.to_datetime, pd.to_timestamp and pd.to_numeric (new in 0.17.0) (GH11133).

1.14.2.11 Removal of prior version deprecations/changes

• Removal of na_last parameters from Series.order() and Series.sort(), in favor of
  na_position. (GH5231)
• Remove of percentile_width from .describe(), in favor of percentiles. (GH7088)
• Removal of colSpace parameter from DataFrame.to_string(), in favor of col_space, circa 0.8.0
  version.
• Removal of automatic time-series broadcasting (GH2304)

```
In [90]: np.random.seed(1234)
In [91]: df = DataFrame(np.random.randn(5,2),columns=list('AB'),index=date_range('20130101',periods=5))
In [92]: df
Out[92]:

2013-01-05 0.031393 -2.226989

- Remove table keyword in HDFStore.put/append, in favor of using format= (GH4645)
- Remove kind in read_excel/ExcelFile as its unused (GH4712)
- Remove infer_type keyword from pd.read_html as its unused (GH4770, GH7032)
- Remove offset and timeRule keywords from Series.tshift/shift, in favor of freq (GH4853, GH4864)
- Remove pd.load/pd.save aliases in favor of pd.to_pickle/pd.read_pickle (GH3787)

1.14.3 Performance Improvements

- Development support for benchmarking with the Air Speed Velocity library (GH8361)
- Added vbench benchmarks for alternative ExcelWriter engines and reading Excel files (GH7171)
- Performance improvements in Categorical.value_counts (GH10804)
- Performance improvements in SeriesGroupBy.nunique and SeriesGroupBy.value_counts and SeriesGroupby.transform (GH10820, GH11077)
- Performance improvements in DataFrame.drop_duplicates with integer dtypes (GH10917)
- Performance improvements in DataFrame.duplicated with wide frames. (GH10161, GH11180)
- 4x improvement in timedelta string parsing (GH6755, GH10426)
- 8x improvement in timedelta64 and datetime64 ops (GH6755)
- Significantly improved performance of indexing MultiIndex with slicers (GH10287)
- 8x improvement in iloc using list-like input (GH10791)
- Improved performance of Series.isin for datetimelike/integer Series (GH10287)
- 20x improvement in concat of Categoricals when categories are identical (GH10587)
- Improved performance of to_datetime when specified format string is ISO8601 (GH10178)
- 2x improvement of Series.value_counts for float dtype (GH10821)
- Enable infer_datetime_format in to_datetime when date components do not have 0 padding (GH11142)
- Regression from 0.16.1 in constructing DataFrame from nested dictionary (GH11084)
- Performance improvements in addition/subtraction operations for DateOffset with Series or DatetimeIndex (GH10744, GH11205)
1.14.4 Bug Fixes

- Bug in incorrect computation of `.mean()` on `timedelta64[ns]` because of overflow (GH9442)
- Bug in `.isin` on older numpies (issue: 11232)
- Bug in `DataFrame.to_html(index=False)` renders unnecessary name row (GH10344)
- Bug in `DataFrame.to_latex()` the column_format argument could not be passed (GH9402)
- Bug in `DateTimeIndex` when localizing with `NaT` (GH10477)
- Bug in `Series.dt` ops in preserving meta-data (GH10477)
- Bug in preserving `NaT` when passed in an otherwise invalid `to_datetime` construction (GH10477)
- Bug in `DataFrame.apply` when function returns categorical series. (GH9573)
- Bug in `to_datetime` with invalid dates and formats supplied (GH10154)
- Bug in `Index.drop_duplicates` dropping name(s) (GH10115)
- Bug in `Series.quantile` dropping name (GH10881)
- Bug in `pd.Series` when setting a value on an empty `Series` whose index has a frequency. (GH10193)
- Bug in `pd.Series.interpolate` with invalid order keyword values. (GH10633)
- Bug in `DataFrame.plot` raises `ValueError` when color name is specified by multiple characters (GH10387)
- Bug in `Index` construction with a mixed list of tuples (GH10697)
- Bug in `DataFrame.reset_index` when index contains `NaT`. (GH10388)
- Bug in `ExcelReader` when worksheet is empty (GH6403)
- Bug in `BinGrouper.group_info` where returned values are not compatible with base class (GH10914)
- Bug in clearing the cache on `DataFrame.pop` and a subsequent inplace op (GH10912)
- Bug in indexing with a mixed-integer `Index` causing an `ImportError` (GH10610)
- Bug in `Series.count` when index has nulls (GH10946)
- Bug in pickling of a non-regular freq `DatetimeIndex` (GH11002)
- Bug causing `DataFrame.where` to not respect the axis parameter when the frame has a symmetric shape. (GH9736)
- Bug in `Table.select_column` where name is not preserved (GH10392)
- Bug in `offsets.generate_range` where start and end have finer precision than offset (GH9907)
- Bug in `pd.rolling_*` where `Series.name` would be lost in the output (GH10565)
- Bug in `stack` when index or columns are not unique. (GH10417)
- Bug in setting a `Panel` when an axis has a multi-index (GH10360)
- Bug in `USFederalHolidayCalendar` where `USMemorialDay` and `USMartinLutherKingJr` were incorrect (GH10278 and GH9760)
- Bug in `.sample()` where returned object, if set, gives unnecessary `SettingWithCopyWarning` (GH10738)
- Bug in `.sample()` where weights passed as `Series` were not aligned along axis before being treated positionally, potentially causing problems if weight indices were not aligned with sampled object. (GH10738)
• Regression fixed in (GH9311, GH6620, GH9345), where groupby with a datetime-like converting to float with certain aggregators (GH10979)
• Bug in DataFrame.interpolate with axis=1 and inplace=True (GH10395)
• Bug in io.sql.get_schema when specifying multiple columns as primary key (GH10385).
• Bug in groupby(sort=False) with datetime-like Categorical raises ValueError (GH10505)
• Bug in groupby(axis=1) with filter() throws IndexError (GH11041)
• Bug in test_categorical on big-endian builds (GH10425)
• Bug in Series.shift and DataFrame.shift not supporting categorical data (GH9416)
• Bug in Series.map using categorical Series raises AttributeError (GH10324)
• Bug in MultiIndex.get_level_values including Categorical raises AttributeError (GH10460)
• Bug in pd.get_dummies with sparse=True not returning SparseDataFrame (GH10531)
• Bug in Index subtypes (such as PeriodIndex) not returning their own type for .drop and .insert methods (GH10620)
• Bug in algos.outer_join_indexer when right array is empty (GH10618)
• Bug in filter (regression from 0.16.0) and transform when grouping on multiple keys, one of which is datetime-like (GH10114)
• Bug in to_datetime and to_timedelta causing Index name to be lost (GH10875)
• Bug in len(DataFrame.groupby) causing IndexError when there's a column containing only NaNs (issue: 11016)
• Bug that caused segfault when resampling an empty Series (GH10228)
• Bug in DatetimeIndex and PeriodIndex.value_counts resets name from its result, but retains in result's Index. (GH10150)
• Bug in pd.eval using numexpr engine coerces 1 element numpy array to scalar (GH10546)
• Bug in pd.concat with axis=0 when column is of dtype category (GH10177)
• Bug in read_msgpack where input type is not always checked (GH10369, GH10630)
• Bug in pd.read_csv with kwargs index_col=False, index_col=['a', 'b'] or dtype (GH10413, GH10467, GH10577)
• Bug in Series.from_csv with header kwarg not setting the Series.name or the Series.index. name (GH10483)
• Bug in groupby.var which caused variance to be inaccurate for small float values (GH10448)
• Bug in Series.plot(kind='hist') Y Label not informative (GH10485)
• Bug in read_csv when using a converter which generates a uint8 type (GH9266)
• Bug causes memory leak in time-series line and area plot (GH9003)
• Bug when setting a Panel sliced along the major or minor axes when the right-hand side is a DataFrame (GH11014)
• Bug that returns None and does not raise NotimplementedError when operator functions (e.g. .add) of Panel are not implemented (GH7692)
• Bug in line and kde plot cannot accept multiple colors when subplots=True (GH9894)
Bug in DataFrame.plot raises ValueError when color name is specified by multiple characters (GH10387)

Bug in left and right align of Series with MultiIndex may be inverted (GH10665)

Bug in left and right join of with MultiIndex may be inverted (GH10741)

Bug in read_stata when reading a file with a different order set in columns (GH10757)

Bug in Categorical may not representing properly when category contains tz or Period (GH10713)

Bug in Categorical.__iter__ may not returning correct datetime and Period (GH10713)

Bug in indexing with a PeriodIndex on an object with a PeriodIndex (GH4125)

Bug in read_csv with engine='c': EOF preceded by a comment, blank line, etc. was not handled correctly (GH10728, GH10548)

Reading “famafrench” data via DataReader results in HTTP 404 error because of the website url is changed (GH10591).

Bug in read_msgpack where DataFrame to decode has duplicate column names (GH9618)

Bug in io.common.get_filepath_or_buffer which caused reading of valid S3 files to fail if the bucket also contained keys for which the user does not have read permission (GH10604)

Bug in vectorised setting of timestamp columns with python datetime.date and numpy datetime64 (GH10408, GH10412)

Bug in Index.take may add unnecessary freq attribute (GH10791)

Bug in merge with empty DataFrame may raise IndexError (GH10824)

Bug in to_latex where unexpected keyword argument for some documented arguments (GH10888)

Bug in indexing of large DataFrame where IndexError is uncaught (GH10645 and GH10692)

Bug in read_csv when using the nrows or chunksize parameters if file contains only a header line (GH9535)

Bug in serialization of category types in HDF5 in presence of alternate encodings. (GH10366)

Bug in pd.DataFrame when constructing an empty DataFrame with a string dtype (GH9428)

Bug in pd.DataFrame.diff when DataFrame is not consolidated (GH10907)

Bug in pd.unique for arrays with the datetime64 or timedelta64 dtype that meant an array with object dtype was returned instead the original dtype (GH9431)

Bug in Timedelta raising error when slicing from 0s (GH10583)

Bug in DatetimeIndex.take and TimedeltaIndex.take may not raise IndexError against invalid index (GH10295)

Bug in Series([np.nan]).astype('M8[ms]'), which now returns Series([pd.NaT]) (GH10747)

Bug in PeriodIndex.order reset freq (GH10295)

Bug in date_range when freq divides end as nanos (GH10885)

Bug in iloc allowing memory outside bounds of a Series to be accessed with negative integers (GH10779)

Bug in read_msgpack where encoding is not respected (GH10581)

Bug preventing access to the first index when using iloc with a list containing the appropriate negative integer (GH10547, GH10779)
• Bug in TimedeltaIndex formatter causing error while trying to save DataFrame with TimedeltaIndex using to_csv (GH10833)
• Bug in DataFrame.where when handling Series slicing (GH10218, GH9558)
• Bug where pd.read_gbq throws ValueError when Bigquery returns zero rows (GH10273)
• Bug in to_json which was causing segmentation fault when serializing 0-rank ndarray (GH9576)
• Bug in plotting functions may raise IndexError when plotted on GridSpec (GH10819)
• Bug in plot result may show unnecessary minor ticklabels (GH10657)
• Bug in groupby incorrect computation for aggregation on DataFrame with NaT (E.g first, last, min). (GH10590, GH11010)
• Bug when constructing DataFrame where passing a dictionary with only scalar values and specifying columns did not raise an error (GH10856)
• Bug in .var() causing roundoff errors for highly similar values (GH10242)
• Bug in DataFrame.plot (subplots=True) with duplicated columns outputs incorrect result (GH10962)
• Bug in Index arithmetic may result in incorrect class (GH10638)
• Bug in date_range results in empty if freq is negative annually, quarterly and monthly (GH11018)
• Bug in DatetimeIndex cannot infer negative freq (GH11018)
• Remove use of some deprecated numpy comparison operations, mainly in tests. (GH10569)
• Bug in Index dtype may not applied properly (GH11017)
• Bug in io.gbq when testing for minimum google api client version (GH10652)
• Bug in DataFrame construction from nested dict with timedelta keys (GH11129)
• Bug in .fillna against may raise TypeError when data contains datetime dtype (GH7095, GH11153)
• Bug in .groupby when number of keys to group by is same as length of index (GH11185)
• Bug in convert_objects where converted values might not be returned if all null and coerce (GH9589)
• Bug in convert_objects where copy keyword was not respected (GH9589)

1.15 v0.16.2 (June 12, 2015)

This is a minor bug-fix release from 0.16.1 and includes a a large number of bug fixes along some new features (pipe() method), enhancements, and performance improvements.

We recommend that all users upgrade to this version.

Highlights include:

• A new pipe method, see here
• Documentation on how to use numba with pandas, see here

What’s new in v0.16.2

• New features
  – Pipe
1.15.1 New features

1.15.1.1 Pipe

We’ve introduced a new method DataFrame.pipe(). As suggested by the name, pipe should be used to pipe data through a chain of function calls. The goal is to avoid confusing nested function calls like

```python
# df is a DataFrame
# f, g, and h are functions that take and return DataFrames
f(g(h(df), arg1=1), arg2=2, arg3=3)
```

The logic flows from inside out, and function names are separated from their keyword arguments. This can be rewritten as

```python
(df.pipe(h)
  .pipe(g, arg1=1)
  .pipe(f, arg2=2, arg3=3)
)
```

Now both the code and the logic flow from top to bottom. Keyword arguments are next to their functions. Overall the code is much more readable.

In the example above, the functions f, g, and h each expected the DataFrame as the first positional argument. When the function you wish to apply takes its data anywhere other than the first argument, pass a tuple of (function, keyword) indicating where the DataFrame should flow. For example:

```python
In [1]: import statsmodels.formula.api as sm
In [2]: bb = pd.read_csv('data/baseball.csv', index_col='id')
# sm.ols takes (formula, data)
In [3]: (bb.query('h > 0')
  ...: .assign(ln_h = lambda df: np.log(df.h))
  ...: .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
  ...: .fit()
  ...: .summary()
  ...: )
...:
Out[3]:
<class 'statsmodels.iolib.summary.Summary'>

OLS Regression Results
==============================================================================
Dep. Variable: hr R-squared: 0.685
Model: OLS Adj. R-squared: 0.665
Method: Least Squares F-statistic: 34.28
Date: Wed, 02 May 2018 Prob (F-statistic): 3.48e-15
Time: 06:36:07 Log-Likelihood: -205.92
```

(continues on next page)
The pipe method is inspired by unix pipes, which stream text through processes. More recently dplyr and magrittr have introduced the popular (%>%) pipe operator for R.

See the documentation for more. (GH10129)

1.15.1.2 Other Enhancements

• Added rsplit to Index/Series StringMethods (GH10303)

• Removed the hard-coded size limits on the DataFrame HTML representation in the IPython notebook, and leave this to IPython itself (only for IPython v3.0 or greater). This eliminates the duplicate scroll bars that appeared in the notebook with large frames (GH10231).

Note that the notebook has a toggle output scrolling feature to limit the display of very large frames (by clicking left of the output). You can also configure the way DataFrames are displayed using the pandas options, see here.

• axis parameter of DataFrame.quantile now accepts also index and column. (GH9543)

1.15.2 API Changes

• Holiday now raises NotImplementedError if both offset and observance are used in the constructor instead of returning an incorrect result (GH10217).

1.15.3 Performance Improvements

• Improved Series.resample performance with dtype=datetim64[ns] (GH7754)

• Increase performance of str.split when expand=True (GH10081)
### 1.15.4 Bug Fixes

- Bug in `Series.hist` raises an error when a one row `Series` was given (GH10214)
- Bug where `HDFStore.select` modifies the passed columns list (GH7212)
- Bug in `Categorical repr` with `display.width` of `None` in Python 3 (GH10087)
- Bug in `to_json` with certain orients and a `CategoricalIndex` would segfault (GH10317)
- Bug where some of the `nan` funcs do not have consistent return dtypes (GH10251)
- Bug in `DataFrame.quantile` on checking that a valid axis was passed (GH9543)
- Bug in `groupby.apply` aggregation for Categorical not preserving categories (GH10138)
- Bug in `to_csv` where `date_format` is ignored if the `datetime` is fractional (GH10209)
- Bug in `DataFrame.to_json` with mixed data types (GH10289)
- Bug in cache updating when consolidating (GH10264)
- Bug in `mean()` where integer dtypes can overflow (GH10172)
- Bug where `Panel.from_dict` does not set dtype when specified (GH10058)
- Bug in `Index.union` raises `AttributeError` when passing array-likes. (GH10149)
- Bug in `Timestamp`'s` microsecond, quarter, dayofyear, week and daysinmonth properties return np.int type, not built-in int. (GH10050)
- Bug in `NaT` raises `AttributeError` when accessing to daysinmonth, dayofweek properties. (GH10096)
- Bug in `Index repr` when using the `max_seq_items=None` setting (GH10182).
- Bug in getting timezone data with `dateutil` on various platforms (GH9059, GH8639, GH9663, GH10121)
- Bug in displaying datetimes with mixed frequencies; display ‘ms’ datetimes to the proper precision. (GH10170)
- Bug in `setitem` where type promotion is applied to the entire block (GH10280)
- Bug in `Series.plot` not correctly setting the label (GH10119)
- Bug in `plot` not defaulting to `matplotlib` axes.grid setting (GH9792)
- Bug causing strings containing an exponent, but no decimal to be parsed as `int` instead of `float` in engine='python' for the read_csv parser (GH9565)
- Bug in `Series.align` resets name when `fill_value` is specified (GH10067)
- Bug in `read_csv` causing index name not to be set on an empty DataFrame (GH10184)
- Bug in `SparseSeries.abs` resets name (GH10241)
- Bug in `TimedeltaIndex` slicing may reset freq (GH10292)
- Bug in `GroupBy.get_group` raises `ValueError` when group key contains `NaT` (GH6992)
- Bug in `SparseSeries constructor` ignores input data name (GH10258)
• Bug in `Categorical.remove_categories` causing a `ValueError` when removing the NaN category if underlying dtype is floating-point (GH10156)
• Bug where `infer_freq` infers timerule (WOM-5XXX) unsupported by `to_offset` (GH9425)
• Bug in `DataFrame.to_hdf()` where table format would raise a seemingly unrelated error for invalid (non-string) column names. This is now explicitly forbidden. (GH9057)
• Bug to handle masking empty `DataFrame` (GH10126).
• Bug where MySQL interface could not handle numeric table/column names (GH10255)
• Bug in `read_csv` with a `date_parser` that returned a `datetime64` array of other time resolution than [ns] (GH10245)
• Bug in `Panel.apply` when the result has `ndim=0` (GH10332)
• Bug in `read_hdf` where `auto_close` could not be passed (GH9327).
• Bug in `read_hdf` where open stores could not be used (GH10330).
• Bug in adding empty `DataFrame`'s, now results in a ``DataFrame that `.equals` an empty `DataFrame` (GH10181).
• Bug in `to_hdf` and `HDFStore` which did not check that complib choices were valid (GH4582, GH8874).

1.16 v0.16.1 (May 11, 2015)

This is a minor bug-fix release from 0.16.0 and includes a large number of bug fixes along several new features, enhancements, and performance improvements. We recommend that all users upgrade to this version.

Highlights include:

• Support for a `CategoricalIndex`, a category based index, see [here](#)
• New section on how-to-contribute to `pandas`, see [here](#)
• Revised “Merge, join, and concatenate” documentation, including graphical examples to make it easier to understand each operations, see [here](#)
• New method `sample` for drawing random samples from Series, DataFrames and Panels. See [here](#)
• The default `Index` printing has changed to a more uniform format, see [here](#)
• `BusinessHour` datetime-offset is now supported, see [here](#)
• Further enhancement to the `.str` accessor to make string operations easier, see [here](#)

What’s new in v0.16.1

• Enhancements
  – `CategoricalIndex`
  – `Sample`
  – `String Methods Enhancements`
  – `Other Enhancements`
• API changes
  – `Deprecations`
1.16.1 Enhancements

1.16.1.1 CategoricalIndex

We introduce a CategoricalIndex, a new type of index object that is useful for supporting indexing with duplicates. This is a container around a Categorical (introduced in v0.15.0) and allows efficient indexing and storage of an index with a large number of duplicated elements. Prior to 0.16.1, setting the index of a DataFrame/Series with a category dtype would convert this to regular object-based Index.

```
In [1]: df = DataFrame({'A': np.arange(6),
  ...: 'B': Series(list('aabbca')).astype('category',
  ...: categories=list('cab'))
  ...: })

In [2]: df
Out[2]:
   A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [3]: df.dtypes
Out[3]:
A   int64
B  category
dtype: object

In [4]: df.B.cat.categories
Out[4]: Index(['c', 'a', 'b'], dtype='object')
```

setting the index, will create create a CategoricalIndex

```
In [5]: df2 = df.set_index('B')

In [6]: df2.index
Out[6]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
˓ordered=False, name='B', dtype='category')
```

indexing with __getitem__/.iloc/.loc/.ix works similarly to an Index with duplicates. The indexers MUST be in the category or the operation will raise.
and preserves the `CategoricalIndex`:

```
In [8]: df2.loc['a'].index
Out[8]: CategoricalIndex(["a", 'a', 'a'], categories=['c', 'a', 'b'], ordered=False, 
  name='B', dtype='category')
```

sorting will order by the order of the categories:

```
In [9]: df2.sort_index()
Out[9]:
   A  B
  c 4
  a 0
  a 1
  a 5
  b 2
  b 3
```

groupby operations on the index will preserve the index nature as well:

```
In [10]: df2.groupby(level=0).sum()
Out[10]:
   A  B
  c 4
  a 6
  b 5
```

reindexing operations, will return a resulting index based on the type of the passed indexer, meaning that passing a list will return a plain-old-`Index`; indexing with a `Categorical` will return a `CategoricalIndex`, indexed according to the categories of the PASSED `Categorical` dtype. This allows one to arbitrarily index these even with values NOT in the categories, similarly to how you can reindex ANY pandas index.

```
In [12]: df2.reindex(['a','e'])
Out[12]:
   A  B
  a 0.0
  a 1.0
  a 5.0
  e NaN
```

(continues on next page)
In [14]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))

Out[14]:

A      
B      
a  0.0  
a  1.0  
a  5.0  
e  NaN

In [15]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde'))).index

Out[15]: CategoricalIndex(['a', 'a', 'a', 'e'], categories=['a', 'b', 'c', 'd', 'e'], ordered=False, name='B', dtype='category')

See the documentation for more. (GH7629, GH10038, GH10039)

1.16.1.2 Sample

Series, DataFrames, and Panels now have a new method: sample(). The method accepts a specific number of rows or columns to return, or a fraction of the total number or rows or columns. It also has options for sampling with or without replacement, for passing in a column for weights for non-uniform sampling, and for setting seed values to facilitate replication. (GH2419)

In [1]: example_series = Series([0, 1, 2, 3, 4, 5])

# When no arguments are passed, returns 1
In [2]: example_series.sample()

Out[2]:

3  3

dtype: int64

# One may specify either a number of rows:
In [3]: example_series.sample(n=3)

5  5
1  1
4  4

dtype: int64

# Or a fraction of the rows:
In [4]: example_series.sample(frac=0.5)

4  4
1  1
0  0

dtype: int64

# weights are accepted.
In [5]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [6]: example_series.sample(n=3, weights=example_weights)

Out[6]:

2  2
3  3
5  5
# weights will also be normalized if they do not sum to one, # and missing values will be treated as zeros.

```python
In [7]: example_weights2 = [0.5, 0, 0, None, np.nan]
```  
```python
In [8]: example_series.sample(n=1, weights=example_weights2)
```
```python
Out[8]:
0 0
```
dtype: int64

When applied to a DataFrame, one may pass the name of a column to specify sampling weights when sampling from rows.

```python
In [9]: df = DataFrame({'col1':[9,8,7,6], 'weight_column':[0.5, 0.4, 0.1, 0]})
```
```python
In [10]: df.sample(n=3, weights='weight_column')
```
```python
Out[10]:
col1     weight_column
0   9          0.5
1   8          0.4
2   7          0.1
```

## 1.16.1.3 String Methods Enhancements

*Continuing from v0.16.0*, the following enhancements make string operations easier and more consistent with standard python string operations.

- **Added** `StringMethods (.str accessor) to Index (GH9068)**

  The `.str accessor is now available for both Series and Index.

  ```python
  In [11]: idx = Index(['jack', 'jill', 'jesse', 'frank'])
  ```

  ```python
  In [12]: idx.str.strip()
  ```

  ```python
  Out[12]: Index(['jack', 'jill', 'jesse', 'frank'], dtype='object')
  ```

  One special case for the `.str accessor on Index is that if a string method returns bool, the `.str accessor will return an np.array instead of a boolean Index (GH8875). This enables the following expression to work naturally:

  ```python
  In [13]: idx = Index(['a1', 'a2', 'b1', 'b2'])
  ```

  ```python
  In [14]: s = Series(range(4), index=idx)
  ```

  ```python
  In [15]: s
  ```

  ```python
  Out[15]:
a1  0
  a2  1
  b1  2
  b2  3
  dtype: int64
  ```

  ```python
  In [16]: idx.str.startswith('a')
  ```

  ```python
  Out[16]: array([ True, False, False, False], dtype=bool)
  ```
In [17]: s[s.index.str.startswith('a')]

    →
a1  0
a2  1
dtype: int64

- The following new methods are accessible via .str accessor to apply the function to each values. (GH9766, GH9773, GH10031, GH10045, GH10052)

<table>
<thead>
<tr>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>capitalize()</td>
</tr>
<tr>
<td>swapcase()</td>
</tr>
<tr>
<td>normalize()</td>
</tr>
<tr>
<td>partition()</td>
</tr>
<tr>
<td>rpartition()</td>
</tr>
<tr>
<td>index()</td>
</tr>
<tr>
<td>rindex()</td>
</tr>
<tr>
<td>translate()</td>
</tr>
</tbody>
</table>

- split now takes expand keyword to specify whether to expand dimensionality. return_type is deprecated. (GH9847)

In [18]: s = Series(['a,b', 'a,c', 'b,c'])

# return Series
In [19]: s.str.split(',')

Out[19]:
0    [a, b]
1    [a, c]
2    [b, c]
dtype: object

# return DataFrame
In [20]: s.str.split(',', expand=True)

Out[20]:
     0  1
0    a  b
1    a  c
2    b  c

In [21]: idx = Index(['a,b', 'a,c', 'b,c'])

# return Index
In [22]: idx.str.split(',', expand=True)

Out[22]:
MultiIndex(levels=[['a', 'b'], ['b', 'c']], labels=[[0, 0, 1], [0, 1, 1]])

- Improved extract and get_dummies methods for Index.str (GH9980)

1.16.1.4 Other Enhancements

- BusinessHour offset is now supported, which represents business hours starting from 09:00 - 17:00 on BusinessDay by default. See Here for details. (GH7905)
In [24]: from pandas.tseries.offsets import BusinessHour

In [25]: Timestamp('2014-08-01 09:00') + BusinessHour()
Out[25]: Timestamp('2014-08-01 10:00:00')

In [26]: Timestamp('2014-08-01 07:00') + BusinessHour()
Out[26]: Timestamp('2014-08-01 10:00:00')

In [27]: Timestamp('2014-08-01 16:30') + BusinessHour()
Out[27]: Timestamp('2014-08-04 09:30:00')

- DataFrame.diff now takes an axis parameter that determines the direction of differencing (GH9727)
- Allow clip, clip_lower, and clip_upper to accept array-like arguments as thresholds (This is a regression from 0.11.0). These methods now have an axis parameter which determines how the Series or DataFrame will be aligned with the threshold(s). (GH6966)
- DataFrame.mask() and Series.mask() now support same keywords as where (GH8801)
- drop function can now accept errors keyword to suppress ValueError raised when any of label does not exist in the target data. (GH6736)

In [28]: df = DataFrame(np.random.randn(3, 3), columns=['A', 'B', 'C'])
In [29]: df.drop(['A', 'X'], axis=1, errors='ignore')
Out[29]:
   B    C
0  1.058969 -0.397840
1  1.047579  1.045938
2 -0.122092  0.124713

- Add support for separating years and quarters using dashes, for example 2014-Q1. (GH9688)
- Allow conversion of values with dtype datetime64 or timedelta64 to strings using astype(str) (GH9757)
- get_dummies function now accepts sparse keyword. If set to True, the return DataFrame is sparse, e.g. SparseDataFrame. (GH8823)
- Period now accepts datetime64 as value input. (GH9054)
- Allow timedelta string conversion when leading zero is missing from time definition, ie 0:00:00 vs 00:00:00. (GH9570)
- Allow Panel.shift with axis='items' (GH9890)
- Trying to write an excel file now raises NotImplementedError if the DataFrame has a MultiIndex instead of writing a broken Excel file. (GH9794)
- Allow Categorical.add_categories to accept Series or np.array. (GH9927)
- Add/delete str/dt/cat accessors dynamically from __dir__. (GH9910)
- Add normalize as a dt accessor method. (GH10047)
- DataFrame and Series now have _constructor_expanddim property as overridable constructor for one higher dimensionality data. This should be used only when it is really needed, see here
- pd.lib.infer_dtype now returns 'bytes' in Python 3 where appropriate. (GH10032)
1.16.2 API changes

- When passing in an ax to `df.plot( ..., ax=ax)`, the `sharex` kwarg will now default to `False`. The result is that the visibility of xlabels and xticklabels will not anymore be changed. You have to do that by yourself for the right axes in your figure or set `sharex=True` explicitly (but this changes the visible for all axes in the figure, not only the one which is passed in!). If pandas creates the subplots itself (e.g. no passed in `ax` kwarg), then the default is still `sharex=True` and the visibility changes are applied.

- `assign()` now inserts new columns in alphabetical order. Previously the order was arbitrary. (GH9777)

- By default, `read_csv` and `read_table` will now try to infer the compression type based on the file extension. Set `compression=None` to restore the previous behavior (no decompression). (GH9770)

1.16.2.1 Deprecations

- `Series.str.split`'s `return_type` keyword was removed in favor of `expand` (GH9847)

1.16.3 Index Representation

The string representation of `Index` and its sub-classes have now been unified. These will show a single-line display if there are few values; a wrapped multi-line display for a lot of values (but less than `display.max_seq_items`); if lots of items (> `display.max_seq_items`) will show a truncated display (the head and tail of the data). The formatting for `MultiIndex` is unchanged (a multi-line wrapped display). The display width responds to the option `display.max_seq_items`, which is defaulted to 100. (GH6482)

Previous Behavior

```python
In [2]: pd.Index(range(4), name='foo')
Out[2]: Int64Index([0, 1, 2, 3], dtype='int64')

In [3]: pd.Index(range(104), name='foo')
Out[3]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, ...
                  19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, ...
                  40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, ...
                  61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, ...
                  82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, ...], dtype='int64')

In [4]: pd.date_range('20130101', periods=4, name='foo', tz='US/Eastern')
Out[4]: <class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-01-04 00:00:00-05:00]
Length: 4, Freq: D, Timezone: US/Eastern

In [5]: pd.date_range('20130101', periods=104, name='foo', tz='US/Eastern')
Out[5]: <class 'pandas.tseries.index.DatetimeIndex'>
[2013-01-01 00:00:00-05:00, ..., 2013-04-14 00:00:00-04:00]
Length: 104, Freq: D, Timezone: US/Eastern
```

New Behavior

```python
In [30]: pd.set_option('display.width', 80)

In [31]: pd.Index(range(4), name='foo')
Out[31]: RangeIndex(start=0, stop=4, step=1, name='foo')
```

(continues on next page)
In [32]: pd.Index(range(30), name='foo')
Out[32]: RangeIndex(start=0, stop=30, step=1, name='foo')

In [33]: pd.Index(range(104), name='foo')
Out[33]: RangeIndex(start=0, stop=104, step=1, name='foo')

In [34]: pd.CategoricalIndex(['a','bb','ccc','dddd'], ordered=True, name='foobar')
Out[34]: CategoricalIndex(['a', 'bb', 'ccc', 'dddd'], categories=['a', 'bb', 'ccc', 'dddd'], ordered=True, name='foobar', dtype='category')

In [35]: pd.CategoricalIndex(['a','bb','ccc','dddd']*10, ordered=True, name='foobar')

In [36]: pd.CategoricalIndex(['a','bb','ccc','dddd']*100, ordered=True, name='foobar')

In [37]: pd.date_range('20130101',periods=4, name='foo', tz='US/Eastern')
Out[37]: DatetimeIndex(['2013-01-01 00:00:00-05:00',
                    '2013-01-02 00:00:00-05:00',
                    '2013-01-03 00:00:00-05:00',
                    '2013-01-04 00:00:00-05:00'],
                   dtype='datetime64[ns, US/Eastern]', name='foo', freq='D')

In [38]: pd.date_range('20130101',periods=25, freq='D')

In [39]: pd.date_range('20130101',periods=104, name='foo', tz='US/Eastern')
1.16.4 Performance Improvements

- Improved csv write performance with mixed dtypes, including datetimes by up to 5x (GH9940)
- Improved csv write performance generally by 2x (GH9940)
- Improved the performance of `pd.lib.max_len_string_array` by 5-7x (GH10024)

1.16.5 Bug Fixes

- Bug where labels did not appear properly in the legend of `DataFrame.plot()`, passing `label` arguments works, and Series indices are no longer mutated. (GH9542)
- Bug in json serialization causing a segfault when a frame had zero length. (GH9805)
- Bug in `read_csv` where missing trailing delimiters would cause segfault. (GH5664)
- Bug in retaining index name on appending (GH9862)
- Bug in `scatter_matrix` draws unexpected axis ticklabels (GH5662)
- Fixed bug in `StataWriter` resulting in changes to input `DataFrame` upon save (GH9795).
- Bug in `transform` causing length mismatch when null entries were present and a fast aggregator was being used (GH9697)
- Bug in `equals` causing false negatives when block order differed (GH9330)
- Bug in grouping with multiple `pd.Grouper` where one is non-time based (GH10063)
- Bug in `read_sql_table` error when reading postgres table with timezone (GH7139)
- Bug in `DataFrame` slicing may not retain metadata (GH9776)
- Bug where `TimedeltaIndex` were not properly serialized in fixed `HDFStore` (GH9635)
- Bug with `TimedeltaIndex` constructor ignoring name when given another `TimedeltaIndex` as data (GH10025).
- Bug in `DataFrameFormatter._get_formatted_index` with not applying `max_colwidth` to the `DataFrame` index (GH7856)
- Bug in `.loc` with a read-only ndarray data source (GH10043)
- Bug in `groupby.apply()` that would raise if a passed user defined function either returned only None (for all input). (GH9685)
• Always use temporary files in pytables tests (GH9992)
• Bug in plotting continuously using `secondary_y` may not show legend properly. (GH9610, GH9779)
• Bug in `DataFrame.plot(kind="hist")` results in `TypeError` when DataFrame contains non-numeric columns (GH9853)
• Bug where repeated plotting of `DataFrame` with a `DatetimeIndex` may raise `TypeError` (GH9852)
• Bug in `setup.py` that would allow an incompat cython version to build (GH9827)
• Bug in plotting `secondary_y` incorrectly attaches `right_ax` property to secondary axes specifying itself recursively. (GH9861)
• Bug in `Series.quantile` on empty Series of type `Datetime` or `Timedelta` (GH9675)
• Bug in `where` causing incorrect results when upcasting was required (GH9731)
• Bug in `FloatArrayFormatter` where decision boundary for displaying “small” floats in decimal format is off by one order of magnitude for a given `display.precision` (GH9764)
• Fixed bug where `DataFrame.plot()` raised an error when both `color` and `style` keywords were passed and there was no color symbol in the `style` strings (GH9671)
• Not showing a `DeprecationWarning` on combining list-likes with an `Index` (GH10083)
• Bug in `read_csv` and `read_table` when using `skip_rows` parameter if blank lines are present. (GH9832)
• Bug in `read_csv()` interprets `index_col=True` as 1 (GH9798)
• Bug in index equality comparisons using `==` failing on Index/MultiIndex type incompatibility (GH9785)
• Bug in which `SparseDataFrame` could not take `nan` as a column name (GH8822)
• Bug in `to_msgpack` and `read_msgpack` zlib and blosc compression support (GH9783)
• Bug `GroupBy.size` doesn’t attach index name properly if grouped by `TimeGrouper` (GH9925)
• Bug causing an exception in slice assignments because `length_of_indexer` returns wrong results (GH9995)
• Bug in csv parser causing lines with initial whitespace plus one non-space character to be skipped. (GH9710)
• Bug in C csv parser causing spurious NaNs when data started with newline followed by whitespace. (GH10022)
• Bug causing elements with a null group to spill into the final group when grouping by a `Categorical` (GH9603)
• Bug where `.iloc` and `.loc` behavior is not consistent on empty dataframes (GH9964)
• Bug in invalid attribute access on a `TimedeltaIndex` incorrectly raised `ValueError` instead of `AttributeError` (GH9680)
• Bug in unequal comparisons between categorical data and a scalar, which was not in the categories (e.g. `Series(Categorical(list("abc"), ordered=True)) > "d"`). This returned `False` for all elements, but now raises a `TypeError`. Equality comparisons also now return `False` for `==` and `True` for `!=`. (GH9848)
• Bug in `DataFrame.__setitem__` when right hand side is a dictionary (GH9874)
• Bug in `where` when `dtype` is `datetime64/timedelta64`, but `dtype` of other is not (GH9804)
• Bug in `MultiIndex.sortlevel()` results in unicode level name breaks (GH9856)
• Bug in which `groupby.transform` incorrectly enforced output dtypes to match input dtypes. (GH9807)
• Bug in `DataFrame.constructor` when `columns` parameter is set, and `data` is an empty list (GH9939)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

• Bug in bar plot with log=True raises TypeError if all values are less than 1 (GH9905)
• Bug in horizontal bar plot ignores log=True (GH9905)
• Bug in PyTables queries that did not return proper results using the index (GH8265, GH9676)
• Bug where dividing a dataframe containing values of type Decimal by another Decimal would raise. (GH9787)
• Bug where using DataFrames asfreq would remove the name of the index. (GH9885)
• Bug causing extra index point when resample BM/BQ (GH9756)
• Changed caching in AbstractHolidayCalendar to be at the instance level rather than at the class level as the latter can result in unexpected behaviour. (GH9552)
• Fixed latex output for multi-indexed dataframes (GH9778)
• Bug causing an exception when setting an empty range using DataFrame.loc (GH9596)
• Bug in hiding ticklabels with subplots and shared axes when adding a new plot to an existing grid of axes (GH9158)
• Bug in transform and filter when grouping on a categorical variable (GH9921)
• Bug in transform when groups are equal in number and dtype to the input index (GH9700)
• Google BigQuery connector now imports dependencies on a per-method basis. (GH9713)
• Updated BigQuery connector to no longer use deprecated oauth2client.tools.run() (GH8327)
• Bug in subclassed DataFrame. It may not return the correct class, when slicing or subsetting it. (GH9632)
• Bug in .median() where non-float null values are not handled correctly (GH10040)
• Bug in Series.fillna() where it raises if a numerically convertible string is given (GH10092)

1.17 v0.16.0 (March 22, 2015)

This is a major release from 0.15.2 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• DataFrame.assign method, see here
• Series.to_coo/from_coo methods to interact with scipy.sparse, see here
• Backwards incompatible change to Timedelta to conform the .seconds attribute with datetime. timedelta, see here
• Changes to the .loc slicing API to conform with the behavior of .ix see here
• Changes to the default for ordering in the Categorical constructor, see here
• Enhancement to the .str accessor to make string operations easier, see here
• The pandas.tools.rplot, pandas.sandbox.qtpandas and pandas.rpy modules are deprecated. We refer users to external packages like seaborn, pandas-qt and rpy2 for similar or equivalent functionality, see here

Check the API Changes and deprecations before updating.
What's new in v0.16.0

- **New features**
  - DataFrame Assign
  - Interaction with scipy.sparse
  - String Methods Enhancements
  - Other enhancements
- **Backwards incompatible API changes**
  - Changes in Timedelta
  - Indexing Changes
  - Categorical Changes
  - Other API Changes
  - Deprecations
  - Removal of prior version deprecations/changes
- **Performance Improvements**
- **Bug Fixes**

### 1.17.1 New features

#### 1.17.1.1 DataFrame Assign

Inspired by dplyr's `mutate` verb, DataFrame has a new `assign()` method. The function signature for `assign` is simply `**kwargs`. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a `Series` or NumPy array), or a function of one argument to be called on the DataFrame. The new values are inserted, and the entire DataFrame (with all original and new columns) is returned.

```
In [1]: iris = read_csv('data/iris.data')
In [2]: iris.head()
Out[2]:
          SepalLength  SepalWidth  PetalLength  PetalWidth  Name
0          5.1         3.5          1.4       0.2  Iris-setosa
1          4.9         3.0          1.4       0.2  Iris-setosa
2          4.7         3.2          1.3       0.2  Iris-setosa
3          4.6         3.1          1.5       0.2  Iris-setosa
4          5.0         3.6          1.4       0.2  Iris-setosa

In [3]: iris.assign(sepal_ratio=iris['SepalWidth'] / iris['SepalLength']).head()
```

<table>
<thead>
<tr>
<th></th>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.686275</td>
</tr>
<tr>
<td>1</td>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.612245</td>
</tr>
<tr>
<td>2</td>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.680851</td>
</tr>
<tr>
<td>3</td>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.673913</td>
</tr>
<tr>
<td>4</td>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.720000</td>
</tr>
</tbody>
</table>
Above was an example of inserting a precomputed value. We can also pass in a function to be evaluated.

```python
In [4]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

```
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>1</td>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>2</td>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>3</td>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4</td>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
</tbody>
</table>
```

The power of `assign` comes when used in chains of operations. For example, we can limit the DataFrame to just those with a Sepal Length greater than 5, calculate the ratio, and plot

```python
In [5]: (iris.query('SepalLength > 5')
   ...: .assign(SepalRatio = lambda x: x.SepalWidth / x.SepalLength,
   ...:            PetalRatio = lambda x: x.PetalWidth / x.PetalLength)
   ...: .plot(kind='scatter', x='SepalRatio', y='PetalRatio'))
```

```
Out[5]: <matplotlib.axes._subplots.AxesSubplot at 0x1c289b8ac8>
```

See the documentation for more. (GH9229)

### 1.17.1.2 Interaction with scipy.sparse

Added `SparseSeries.to_coo()` and `SparseSeries.from_coo()` methods (GH8048) for converting to and from `scipy.sparse.coo_matrix` instances (see here). For example, given a SparseSeries with MultiIndex we can convert to a `scipy.sparse.coo_matrix` by specifying the row and column labels as index levels:

```python
In [6]: from numpy import nan
In [7]: s = Series([3.0, nan, 1.0, 3.0, nan, nan])
In [8]: s.index = MultiIndex.from_tuples([(1, 2, 'a', 0),
   ...:                                           (1, 2, 'a', 1),
   ...:                                           (1, 1, 'b', 0),
   ...:                                           (1, 1, 'b', 1),
   ...:                                           (2, 1, 'b', 0),
   ...:                                           (2, 1, 'b', 1)])
```

(continues on next page)
In [9]: s
Out[9]:
A  B  C  D
1  2  a  0  3.0
    1  NaN
1  b  0  1.0
    1  3.0
2  1  b  0  NaN
    1  NaN
dtype: float64

# SparseSeries
In [10]: ss = s.to_sparse()

In [11]: ss
Out[11]:
A  B  C  D
1  2  a  0  3.0
    1  NaN
1  b  0  1.0
    1  3.0
2  1  b  0  NaN
    1  NaN
dtype: float64
BlockIndex
Block locations: array([0, 2], dtype=int32)
Block lengths: array([1, 2], dtype=int32)

In [12]: A, rows, columns = ss.to_coo(row_levels=['A', 'B'],
                                  column_levels=['C', 'D'],
                                  sort_labels=False)

In [13]: A
Out[13]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [14]: A.todense()
    →
    matrix([[ 3.,  0.,  0.,  0.],
             [ 0.,  0.,  1.,  3.],
             [ 0.,  0.,  0.,  0.]])

In [15]: rows
    →[(1, 2), (1, 1), (2, 1)]

In [16]: columns
    →[('a', 0), ('a', 1), ('b', 0), ('b', 1)]
The `from_coo` method is a convenience method for creating a `SparseSeries` from a `scipy.sparse.coo_matrix`:

```python
In [17]: from scipy import sparse

In [18]: A = sparse.coo_matrix(([3.0, 1.0, 2.0], ([1, 0, 0], [0, 2, 3])), shape=(3, 4))

In [19]: A
Out[19]:
<3x4 sparse matrix of type '<class 'numpy.float64'>'
with 3 stored elements in COOrdinate format>

In [20]: A.todense()

matrix([[ 0., 0., 1., 2.],
         [ 3., 0., 0., 0.],
         [ 0., 0., 0., 0.]])

In [21]: ss = SparseSeries.from_coo(A)

In [22]: ss
Out[22]:
0 2 1.0
3 2.0
1 0 3.0
```

### 1.17.1.3 String Methods Enhancements

- Following new methods are accessible via `.str` accessor to apply the function to each values. This is intended to make it more consistent with standard methods on strings. (GH9282, GH9352, GH9386, GH9387, GH9439)

<table>
<thead>
<tr>
<th>Methods</th>
</tr>
</thead>
<tbody>
<tr>
<td>isalnum()</td>
</tr>
<tr>
<td>isalpha()</td>
</tr>
<tr>
<td>isdigit()</td>
</tr>
<tr>
<td>isdigit()</td>
</tr>
<tr>
<td>isspace()</td>
</tr>
<tr>
<td>islower()</td>
</tr>
<tr>
<td>isupper()</td>
</tr>
<tr>
<td>istitle()</td>
</tr>
<tr>
<td>isnumeric()</td>
</tr>
<tr>
<td>isdecimal()</td>
</tr>
<tr>
<td>find()</td>
</tr>
<tr>
<td>rfind()</td>
</tr>
<tr>
<td>ljust()</td>
</tr>
<tr>
<td>rjust()</td>
</tr>
<tr>
<td>zfill()</td>
</tr>
</tbody>
</table>

```python
In [23]: s = Series(['abcd', '3456', 'EFGH'])

In [24]: s.str.isalpha()
Out[24]:
0  True
1  False
2  True
dtype: bool

In [25]: s.str.find('ab')
Out[25]:
0 0
```

(continues on next page)
• Series.str.pad() and Series.str.center() now accept fillchar option to specify filling character (GH9352)

```
In [26]: s = Series(['12', '300', '25'])

In [27]: s.str.pad(5, fillchar='_')
Out[27]:
0   ___12
1   ___300
2   ___25
dtype: object
```

• Added Series.str.slice_replace(), which previously raised NotImplementedError (GH8888)

```
In [28]: s = Series(['ABCD', 'EFGH', 'IJK'])

In [29]: s.str.slice_replace(1, 3, 'X')
Out[29]:
0  AXD
1  EXH
2   IX
dtype: object
```

# replaced with empty char
```
In [30]: s.str.slice_replace(0, 1)
```

```
Out[30]:
0  BCD
1  FGH
2   JK
dtype: object
```

### 1.17.1.4 Other enhancements

• Reindex now supports method='nearest' for frames or series with a monotonic increasing or decreasing index (GH9258):

```
In [31]: df = pd.DataFrame({'x': range(5)})

In [32]: df.reindex([0.2, 1.8, 3.5], method='nearest')
Out[32]:
   x
0.2  0
1.8  2
3.5  4
```

This method is also exposed by the lower level Index.get_indexer and Index.get_loc methods.

• The read_excel() function's sheetname argument now accepts a list and None, to get multiple or all sheets respectively. If more than one sheet is specified, a dictionary is returned. (GH9450)

```
# Returns the 1st and 4th sheet, as a dictionary of DataFrames.
pd.read_excel('path_to_file.xls', sheetname=['Sheet1', 3])
```
• Allow Stata files to be read incrementally with an iterator; support for long strings in Stata files. See the docs here (GH9493). 
• Paths beginning with ~ will now be expanded to begin with the user’s home directory (GH9066)
• Added time interval selection in get_data_yahoo (GH9071)
• Added Timestamp.to_datetime64() to complement Timedelta.to_timedelta64() (GH9255)
• tseries.frequencies.to_offset() now accepts Timedelta as input (GH9064)
• Lag parameter was added to the autocorrelation method of Series, defaults to lag-1 autocorrelation (GH9192)
• Timedelta will now accept nanoseconds keyword in constructor (GH9273)
• SQL code now safely escapes table and column names (GH8986)
• Added auto-complete for Series.str.<tab>, Series.dt.<tab> and Series.cat.<tab> (GH9322)
• Index.get_indexer now supports method='pad' and method='backfill' even for any target array, not just monotonic targets. These methods also work for monotonic decreasing as well as monotonic increasing indexes (GH9258).
• Index.asof now works on all index types (GH9258).
• A verbose argument has been augmented in io.read_excel(), defaults to False. Set to True to print sheet names as they are parsed. (GH9450)
• Added days_in_month (compatibility alias daysinmonth) property to Timestamp, DatetimeIndex, Period, PeriodIndex, and Series.dt (GH9572)
• Added decimal option in to_csv to provide formatting for non-’.’ decimal separators (GH781)
• Added normalize option for Timestamp to normalized to midnight (GH8794)
• Added example for DataFrame import to R using HDF5 file and rhdf5 library. See the documentation for more (GH9636).

1.17.2 Backwards incompatible API changes

1.17.2.1 Changes in Timedelta

In v0.15.0 a new scalar type Timedelta was introduced, that is a sub-class of datetime.timedelta. Mentioned here was a notice of an API change w.r.t. the .seconds accessor. The intent was to provide a user-friendly set of accessors that give the ‘natural’ value for that unit, e.g. if you had a Timedelta('1 day, 10:11:12'), then .seconds would return 12. However, this is at odds with the definition of datetime.timedelta, which defines .seconds as 10 * 3600 + 11 * 60 + 12 == 36672.

So in v0.16.0, we are restoring the API to match that of datetime.timedelta. Further, the component values are still available through the .components accessor. This affects the .seconds and .microseconds accessors, and removes the .hours, .minutes, .milliseconds accessors. These changes affect TimedeltaIndex and the Series .dt accessor as well. (GH9185, GH9139)

Previous Behavior

```
In [2]: t = pd.Timedelta('1 day, 10:11:12.100123')
In [3]: t.days
Out[3]: 1
```
In [4]: t.seconds
Out[4]: 12

In [5]: t.microseconds
Out[5]: 123

New Behavior

In [33]: t = pd.Timedelta('1 day, 10:11:12.100123')

In [34]: t.days
Out[34]: 1

In [35]: t.seconds
Out[35]: 36672

In [36]: t.microseconds
Out[36]: 100123

Using .components allows the full component access

In [37]: t.components
Out[37]: Components(days=1, hours=10, minutes=11, seconds=12, milliseconds=100,
    microseconds=123, nanoseconds=0)

In [38]: t.components.seconds
Out[38]: 12

1.17.2.2 Indexing Changes

The behavior of a small sub-set of edge cases for using .loc have changed (GH8613). Furthermore we have improved the content of the error messages that are raised:

- Slicing with .loc where the start and/or stop bound is not found in the index is now allowed; this previously would raise a KeyError. This makes the behavior the same as .ix in this case. This change is only for slicing, not when indexing with a single label.

In [39]: df = DataFrame(np.random.randn(5,4),
    index=date_range('20130101',periods=5))

In [40]: df
Out[40]:
          A          B          C          D
2013-01-01 -0.322795  0.841675  2.390961  0.076200
2013-01-02 -0.566446  0.036142 -2.074978  0.247792
2013-01-03 -0.897157 -0.136795  0.018289  0.755414
2013-01-04  0.215269  0.841009 -1.445810 -1.401973
2013-01-05 -0.100918 -0.548242 -0.144620  0.354020

In [41]: s = Series(range(5),[-2,-1,1,2,3])

In [42]: s
(continues on next page)
Previous Behavior

In [4]: df.loc['2013-01-02':'2013-01-10']
KeyError: 'stop bound [2013-01-10] is not in the [index]'

In [6]: s.loc[-10:3]
KeyError: 'start bound [-10] is not the [index]'

New Behavior

In [43]: df.loc['2013-01-02':'2013-01-10']
Out[43]:
   A    B    C    D
2013-01-02 -0.566446 0.036142 -2.074978 0.247792
2013-01-03 -0.897157 -0.136795  0.018289  0.755414
2013-01-04  0.215269  0.841009 -1.445810 -1.401973
2013-01-05 -0.100918 -0.548242 -0.144620  0.354020

In [44]: s.loc[-10:3]
Out[44]:
-2  0
-1  1
  1  2
  2  3
  3  4
dtype: int64

- Allow slicing with float-like values on an integer index for .ix. Previously this was only enabled for .loc:

Previous Behavior

In [8]: s.ix[-1.0:2]
TypeError: the slice start value [-1.0] is not a proper indexer for this index

New Behavior

In [2]: s.ix[-1.0:2]
Out[2]:
-1  1
  1  2
  2  3
dtype: int64

- Provide a useful exception for indexing with an invalid type for that index when using .loc. For example trying to use .loc on an index of type DatetimeIndex or PeriodIndex or TimedeltaIndex, with an integer (or a float).

Previous Behavior
In [4]: df.loc[2:3]
KeyError: 'start bound [2] is not the [index]'

New Behavior

In [4]: df.loc[2:3]
TypeError: Cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with <type 'int'> keys

1.17.2.3 Categorical Changes

In prior versions, Categoricals that had an unspecified ordering (meaning no ordered keyword was passed) were defaulted as ordered Categoricals. Going forward, the ordered keyword in the Categorical constructor will default to False. Ordering must now be explicit.

Furthermore, previously you could change the ordered attribute of a Categorical by just setting the attribute, e.g. cat.ordered=True; This is now deprecated and you should use cat.as_ordered() or cat.as_unordered(). These will by default return a new object and not modify the existing object. (GH9347, GH9190)

Previous Behavior

In [3]: s = Series([0,1,2], dtype='category')

In [4]: s
Out[4]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [5]: s.cat.ordered
Out[5]: True

In [6]: s.cat.ordered = False

In [7]: s
Out[7]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]

New Behavior

In [45]: s = Series([0,1,2], dtype='category')

In [46]: s
Out[46]:
0 0
1 1
2 2
dtype: category
Categories (3, int64): [0, 1, 2]
In [47]: s.cat.ordered
    False
In [48]: s = s.cat.as_ordered()

In [49]: s
Out[49]:
0   0
1   1
2   2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [50]: s.cat.ordered
    True

# you can set in the constructor of the Categorical
In [51]: s = Series(Categorical([0,1,2],ordered=True))

In [52]: s
Out[52]:
0   0
1   1
2   2
dtype: category
Categories (3, int64): [0 < 1 < 2]

In [53]: s.cat.ordered
    True

For ease of creation of series of categorical data, we have added the ability to pass keywords when calling .astype(). These are passed directly to the constructor.

In [54]: s = Series(['a','b','c','a']).astype('category',ordered=True)

In [55]: s
Out[55]:
0   a
1   b
2   c
3   a
dtype: category
Categories (3, object): [a < b < c]

In [56]: s = Series(['a','b','c','a']).astype('category',categories=list('abcdef'),
    ordered=False)

In [57]: s
Out[57]:
0   a
1   b
2   c
3 a
dtype: category
Categories (6, object): [a, b, c, d, e, f]

1.17.2.4 Other API Changes

- `Index.duplicated` now returns `np.array(dtype=bool)` rather than `Index(dtype=object)` containing `bool` values. (GH8875)

- `DataFrame.to_json` now returns accurate type serialisation for each column for frames of mixed dtype (GH9037)

    Previously data was coerced to a common dtype before serialisation, which for example resulted in integers being serialised to floats:

    ```
    In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
    Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1.0,"1":2.0}}'
    ```

    Now each column is serialised using its correct dtype:

    ```
    In [2]: pd.DataFrame({'i': [1,2], 'f': [3.0, 4.2]}).to_json()
    Out[2]: '{"f":{"0":3.0,"1":4.2},"i":{"0":1,"1":2}}'
    ```

- `DatetimeIndex`, `PeriodIndex` and `TimedeltaIndex.summary` now output the same format. (GH9116)

- `TimedeltaIndex.freqstr` now output the same string format as `DatetimeIndex`. (GH9116)

- Bar and horizontal bar plots no longer add a dashed line along the info axis. The prior style can be achieved with matplotlib’s `axhline` or `axvline` methods (GH9088).

- `Series` accessors `.dt`, `.cat` and `.str` now raise `AttributeError` instead of `TypeError` if the series does not contain the appropriate type of data (GH9617). This follows Python’s built-in exception hierarchy more closely and ensures that tests like `hasattr(s, 'cat')` are consistent on both Python 2 and 3.

- `Series` now supports bitwise operation for integral types (GH9016). Previously even if the input dtypes were integral, the output dtype was coerced to `bool`.

    Previous Behavior

    ```
    In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
    Out[2]:
    a  True
    b  True
    c  True
    d  True
dtype: bool
    ```

    New Behavior. If the input dtypes are integral, the output dtype is also integral and the output values are the result of the bitwise operation.

    ```
    In [2]: pd.Series([0,1,2,3], list('abcd')) | pd.Series([4,4,4,4], list('abcd'))
    Out[2]:
    a  4
    b  5
    c  6
    ```
During division involving a Series or DataFrame, 0/0 and 0//0 now give np.nan instead of np.inf. (GH9144, GH8445)

Previous Behavior

```
In [2]: p = pd.Series([0, 1])
In [3]: p / 0
Out[3]:
0   inf
1   inf
dtype: float64

In [4]: p // 0
Out[4]:
0   inf
1   inf
dtype: float64
```

New Behavior

```
In [54]: p = pd.Series([0, 1])
In [55]: p / 0
Out[55]:
0   NaN
1   inf
dtype: float64

In [56]: p // 0
Out[56]:
0   NaN
1   inf
dtype: float64
```

- Series.values_counts and Series.describe for categorical data will now put NaN entries at the end. (GH9443)
- Series.describe for categorical data will now give counts and frequencies of 0, not NaN, for unused categories (GH9443)
- Due to a bug fix, looking up a partial string label with DatetimeIndex.asof now includes values that match the string, even if they are after the start of the partial string label (GH9258).

Old behavior:

```
In [4]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[4]: Timestamp('2000-01-31 00:00:00')
```

Fixed behavior:

```
In [57]: pd.to_datetime(['2000-01-31', '2000-02-28']).asof('2000-02')
Out[57]: Timestamp('2000-02-28 00:00:00')
```
To reproduce the old behavior, simply add more precision to the label (e.g., use 2000-02-01 instead of 2000-02).

### 1.17.2.5 Deprecations

- The `rplot` trellis plotting interface is deprecated and will be removed in a future version. We refer to external packages like `seaborn` for similar but more refined functionality (GH3445). The documentation includes some examples how to convert your existing code using `rplot` to `seaborn`: `rplot docs`.
- The `pandas.sandbox.qtpandas` interface is deprecated and will be removed in a future version. We refer users to the external package `pandas-qt` (GH9615).
- The `pandas.rpy` interface is deprecated and will be removed in a future version. Similar functionality can be accessed thru the `rpy2` project (GH9602).
- Adding `DatetimeIndex/PeriodIndex` to another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to a `TypeError` in a future version. `.union()` should be used for the union set operation. (GH9094)
- Subtracting `DatetimeIndex/PeriodIndex` from another `DatetimeIndex/PeriodIndex` is being deprecated as a set-operation. This will be changed to an actual numeric subtraction yielding a `TimeDeltaIndex` in a future version. `.difference()` should be used for the differencing set operation. (GH9094)

### 1.17.2.6 Removal of prior version deprecations/changes

- `DataFrame.pivot_table` and `crosstab`'s `rows` and `cols` keyword arguments were removed in favor of `index` and `columns` (GH6581)
- `DataFrame.to_excel` and `DataFrame.to_csv` `cols` keyword argument was removed in favor of `columns` (GH6581)
- Removed `convert_dummies` in favor of `get_dummies` (GH6581)
- Removed `value_range` in favor of `describe` (GH6581)

### 1.17.3 Performance Improvements

- Fixed a performance regression for `.loc` indexing with an array or list-like (GH9126).
- `DataFrame.to_json` 30x performance improvement for mixed dtype frames. (GH9037)
- Performance improvements in `MultiIndex.duplicated` by working with labels instead of values (GH9125)
- Improved the speed of `nunique` by calling `unique` instead of `value_counts` (GH9129, GH7771)
- Performance improvement of up to 10x in `DataFrame.count` and `DataFrame.dropna` by taking advantage of homogeneous/heterogeneous dtypes appropriately (GH9136)
- Performance improvement of up to 20x in `DataFrame.count` when using a `MultiIndex` and the `level` keyword argument (GH9163)
- Performance and memory usage improvements in `merge` when key space exceeds `int64` bounds (GH9151)
- Performance improvements in multi-key `groupby` (GH9429)
- Performance improvements in `MultiIndex.sortlevel` (GH9445)
- Performance and memory usage improvements in `DataFrame.duplicated` (GH9398)

**1.17. v0.16.0 (March 22, 2015)**
• Cythonized Period (GH9440)
• Decreased memory usage on to_hdf (GH9648)

1.17.4 Bug Fixes

• Changed .to_html to remove leading/trailing spaces in table body (GH9487)
• Fixed issue using read_csv on s3 with Python 3 (GH9452)
• Fixed compatibility issue in DatetimeIndex affecting architectures where numpy.int_ defaults to numpy.int32 (GH9493)
• Bug in Panel indexing with an object-like (GH9140)
• Bug in the returned Series.dt.components index was reset to the default index (GH9247)
• Bug in Categorical.__getitem__/__setitem__ with listlike input getting incorrect results from indexer coercion (GH9469)
• Bug in partial setting with a DatetimeIndex (GH9478)
• Bug in groupby for integer and datetime64 columns when applying an aggregator that caused the value to be changed when the number was sufficiently large (GH9311, GH6620)
• Fixed bug in to_sql when mapping a Timestamp object column (datetime column with timezone info) to the appropriate sqlalghemey type (GH9085).
• Fixed bug in to_sql dtype argument not accepting an instantiated SQLAlchemy type (GH9083).
• Bug in .loc partial setting with a np.datetime64 (GH9516)
• Incorrect dtypes inferred on datetimelike looking Series & on .xs slices (GH9477)
• Items in Categorical.unique() (and s.unique() if s is of dtype category) now appear in the order in which they are originally found, not in sorted order (GH9331). This is now consistent with the behavior for other dtypes in pandas.
• Fixed bug on big endian platforms which produced incorrect results in StataReader (GH8688).
• Bug in MultiIndex.has_duplicates when having many levels causes an indexer overflow (GH9075, GH5873)
• Bug in pivot and unstack where nan values would break index alignment (GH4862, GH7401, GH7403, GH7405, GH7466, GH9497)
• Bug in left join on multi-index with sort=True or null values (GH9210).
• Bug in MultiIndex where inserting new keys would fail (GH9250).
• Bug in groupby when key space exceeds int64 bounds (GH9096).
• Bug in unstack with TimedeltaIndex or DatetimeIndex and nulls (GH9491).
• Bug in rank where comparing floats with tolerance will cause inconsistent behaviour (GH8365).
• Fixed character encoding bug in read_stata and StataReader when loading data from a URL (GH9231).
• Bug in adding offsets.Nano to other offsets raises TypeError (GH9284)
• Bug in DatetimeIndex iteration, related to (GH8890), fixed in (GH9100)
• Bugs in resample around DST transitions. This required fixing offset classes so they behave correctly on DST transitions. (GH5172, GH8744, GH8653, GH9173, GH9468).
• Bug in binary operator method (eg .mul()) alignment with integer levels (GH9463).
- Bug in boxplot, scatter and hexbin plot may show an unnecessary warning (GH8877)
- Bug in subplot with `layout kw` may show unnecessary warning (GH9464)
- Bug in using groupers that need passed thru arguments (e.g. `axis`), when using wrapped function (e.g. `fillna`), (GH9221)
- DataFrame now properly supports simultaneous `copy` and `dtype` arguments in constructor (GH9099)
- Bug in `read_csv` when using `skiprows` on a file with CR line endings with the `c` engine. (GH9079)
- `isnull` now detects `NaT` in `PeriodIndex` (GH9129)
- Bug in `groupby .nth()` with a multiple column groupby (GH8979)
- Bug in `DataFrame.where` and `Series.where` coerce numerics to string incorrectly (GH9280)
- Accessing `Series.str` methods on with non-string values now raises `TypeError` instead of producing incorrect results (GH9184)
- Bug in `DatetimeIndex.__contains__` when index has duplicates and is not monotonic increasing (GH9512)
- Fixed division by zero error for `Series.kurt()` when all values are equal (GH9197)
- Fixed issue in the `xlswriter` engine where it added a default ‘General’ format to cells if no other format was applied. This prevented other row or column formatting being applied. (GH9167)
- Fixes issue with `index_col=False` when `usecols` is also specified in `read_csv`. (GH9082)
- Bug where `wide_to_long` would modify the input subnames list (GH9204)
- Bug in `to_sql` not storing float64 values using double precision. (GH9009)
- `SparseSeries` and `SparsePanel` now accept zero argument constructors (same as their non-sparse counterparts) (GH9272).
- Regression in merging `Categorical` and `object` dtypes (GH9426)
- Bug in `read_csv` with buffer overflows with certain malformed input files (GH9205)
- Bug in `groupby` MultiIndex with missing pair (GH9049, GH9344)
- Fixed bug in `Series.groupby` where grouping on `MultiIndex` levels would ignore the sort argument (GH9444)
- Fix bug in `DataFrame.Groupby` where `sort=False` is ignored in the case of `Categorical` columns. (GH8868)
- Fixed bug with reading CSV files from Amazon S3 on python 3 raising a `TypeError` (GH9452)
- Bug in the Google BigQuery reader where the ‘jobComplete’ key may be present but False in the query results (GH8728)
- Bug in `Series.values_counts` with excluding `NaN` for categorical type `Series` with `dropna=True` (GH9443)
- Fixed missing numeric_only option for `DataFrame.std/var/sem` (GH9201)
- Support constructing `Panel` or `Panel4D` with scalar data (GH8285)
- Series text representation disconnected from `max_rows/max_columns` (GH7508).
• Series number formatting inconsistent when truncated (GH8532).

Previous Behavior

```python
In [2]: pd.options.display.max_rows = 10
In [3]: s = pd.Series([1,1,1,1,1,1,1,1,1,1,0.9999,1,1]*10)
In [4]: s
Out[4]:
0 1
1 1
2 1
... 127 0.9999
128 1.0000
129 1.0000
Length: 130, dtype: float64
```

New Behavior

```python
0 1.0000
1 1.0000
2 1.0000
3 1.0000
4 1.0000
... 125 1.0000
126 1.0000
127 0.9999
128 1.0000
129 1.0000
dtype: float64
```

• A Spurious SettingWithCopy Warning was generated when setting a new item in a frame in some cases (GH8730)

The following would previously report a SettingWithCopy Warning.

```python
In [1]: df1 = DataFrame({'x': Series(['a','b','c']), 'y': Series(['d','e','f'])})
In [2]: df2 = df1[['x']]
In [3]: df2['y'] = ['g', 'h', 'i']
```

### 1.18 v0.15.2 (December 12, 2014)

This is a minor release from 0.15.1 and includes a large number of bug fixes along with several new features, enhancements, and performance improvements. A small number of API changes were necessary to fix existing bugs. We recommend that all users upgrade to this version.

- **Enhancements**
- **API Changes**
- **Performance Improvements**
- **Bug Fixes**
1.18.1 API changes

- Indexing in MultiIndex beyond lex-sort depth is now supported, though a lexically sorted index will have a better performance. (GH2646)

```python
In [1]: df = pd.DataFrame({'jim':[0, 0, 1, 1],
                      'joe': ['x', 'x', 'z', 'y'],
                      'jolie': np.random.rand(4)).set_index(['jim', 'joe'])

In [2]: df
Out[2]:
        jolie
    jim  joe
   0     x     0.123943
       x     0.119381
   1     z     0.738523
       y     0.587304

In [3]: df.index.lexsort_depth
    \------
    → 1
    # in prior versions this would raise a KeyError
    # will now show a PerformanceWarning

In [4]: df.loc[(1, 'z')]
    \------
    →
    jolie
    jim  joe
   1     z     0.738523

# lexically sorting
In [5]: df2 = df.sort_index()

In [6]: df2
Out[6]:
        jolie
    jim  joe
   0     x     0.123943
       x     0.119381
   1     y     0.587304
       z     0.738523

In [7]: df2.index.lexsort_depth
    \------
    → 2

In [8]: df2.loc[(1, 'z')]
    \------
    →
    jolie
    jim  joe
   1     z     0.738523
```

- Bug in unique of Series with category dtype, which returned all categories regardless whether they were “used” or not (see GH8559 for the discussion). Previous behaviour was to return all categories:
In [3]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])

In [4]: cat
Out[4]:
[a, b, a]
Categories (3, object): [a < b < c]

In [5]: cat.unique()
Out[5]:
array(['a', 'b', 'c'], dtype=object)

Now, only the categories that do effectively occur in the array are returned:

In [9]: cat = pd.Categorical(['a', 'b', 'a'], categories=['a', 'b', 'c'])
In [10]: cat.unique()
Out[10]:
[a, b]
Categories (2, object): [a, b]

• Series.all and Series.any now support the level and skipna parameters. Series.all, Series.any, Index.all, and Index.any no longer support the out and keepdims parameters, which existed for compatibility with ndarray. Various index types no longer support the all and any aggregation functions and will now raise TypeError.(GH8302).

• Allow equality comparisons of Series with a categorical dtype and object dtype; previously these would raise TypeError.(GH8938)

• Bug in NDFrame: conflicting attribute/column names now behave consistently between getting and setting. Previously, when both a column and attribute named y existed, data.y would return the attribute, while data.y = z would update the column (GH8994)

In [11]: data = pd.DataFrame({'x':[1, 2, 3]})
In [12]: data.y = 2
In [13]: data['y'] = [2, 4, 6]

In [14]: data
Out[14]:
   x  y
0  1  2
1  2  4
2  3  6

# this assignment was inconsistent
In [15]: data.y = 5

Old behavior:

In [6]: data.y
Out[6]: 2

In [7]: data['y'].values
Out[7]: array([5, 5, 5])

New behavior:
```
In [16]: data.y
Out[16]: 5

In [17]: data['y'].values
Out[17]: array([2, 4, 6])
```

- `Timestamp('now')` is now equivalent to `Timestamp.now()` in that it returns the local time rather than UTC. Also, `Timestamp('today')` is now equivalent to `Timestamp.today()` and both have `tz` as a possible argument. (GH9000)

- Fix negative step support for label-based slices (GH8753)

  Old behavior:

  ```
  In [1]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
  Out[1]:
  a 0
  b 1
  c 2
dtype: int64

  In [2]: s.loc['c':'a':-1]
  Out[2]:
  c 2
dtype: int64
  ```

  New behavior:

  ```
  In [18]: s = pd.Series(np.arange(3), ['a', 'b', 'c'])
  In [19]: s.loc['c':'a':-1]
  Out[19]:
  c 2
  b 1
  a 0
dtype: int64
  ```

### 1.18.2 Enhancements

**Categorical enhancements:**

- Added ability to export Categorical data to Stata (GH8633). See [here](#) for limitations of categorical variables exported to Stata data files.

- Added flag `order_categoricals` to `StataReader` and `read_stata` to select whether to order imported categorical data (GH8836). See [here](#) for more information on importing categorical variables from Stata data files.

- Added ability to export Categorical data to to/from HDF5 (GH7621). Queries work the same as if it was an object array. However, the `category` dtyped data is stored in a more efficient manner. See [here](#) for an example and caveats w.r.t. prior versions of pandas.

- Added support for `searchsorted()` on `Categorical` class (GH8420).

**Other enhancements:**

- Added the ability to specify the SQL type of columns when writing a DataFrame to a database (GH8778). For example, specifying to use the `sqlalchemy String` type instead of the default `Text` type for string columns:
**Series.all** and **Series.any** now support the level and skipna parameters (GH8302):

```python
In [20]: s = pd.Series([False, True, False], index=[0, 0, 1])
In [21]: s.any(level=0)
Out[21]:
0    True
1     False
dtype: bool
```

**Panel** now supports the all and any aggregation functions. (GH8302):

```python
In [22]: p = pd.Panel(np.random.rand(2, 5, 4) > 0.1)
In [23]: p.all()
Out[23]:
          0  1
0    True  True
1    True  True
2   False  False
3    True  True
```

• Added support for `utcfromtimestamp()`, `fromtimestamp()`, and `combine()` on `Timestamp` class (GH5351).

• Added Google Analytics (`pandas.io.ga`) basic documentation (GH8835). See [here](#).

• Timedelta arithmetic returns `NotImplemented` in unknown cases, allowing extensions by custom classes (GH8813).

• Timedelta now supports arithmetic with `numpy.ndarray` objects of the appropriate dtype (`numpy` 1.8 or newer only) (GH8884).

• Added `Timedelta.to_timedelta64()` method to the public API (GH8884).

• Added `gbq.generate_bq_schema()` function to the `gbq` module (GH8325).

• **Series** now works with map objects the same way as generators (GH8909).

• Added context manager to `HDFStore` for automatic closing (GH8791).

• `to_datetime` gains an `exact` keyword to allow for a format to not require an exact match for a provided format string (if its `False`). `exact` defaults to `True` (meaning that exact matching is still the default) (GH8904).

• Added `axvlines` boolean option to `parallel_coordinates` plot function, determines whether vertical lines will be printed, default is `True`.

• Added ability to read table footers to `read_html` (GH8552).

• **to_sql** now infers datatypes of non-NA values for columns that contain NA values and have dtype `object` (GH8778).

### 1.18.3 Performance

• Reduce memory usage when skiprows is an integer in `read_csv` (GH8681)
• Performance boost for `to_datetime` conversions with a passed `format=`, and the `exact=False` (GH8904)

### 1.18.4 Bug Fixes

• Bug in concat of Series with category dtype which were coercing to object. (GH8641)  
• Bug in Timestamp-Timestamp not returning a Timedelta type and datelike-datelike ops with timezones (GH8865)  
• Made consistent a timezone mismatch exception (either tz operated with None or incompatible timezone), will now return `TypeError` rather than `ValueError` (a couple of edge cases only), (GH8865)  
• Bug in using a `pd.Grouper(key=...)` with no level/axis or level only (GH8795, GH8866)  
• Report a `TypeError` when invalid/no parameters are passed in a groupby (GH8015)  
• Bug in packaging pandas with `py2app/cx_Freeze` (GH8602, GH8831)  
• Bug in groupby signatures that didn’t include `*args` or `**kwargs` (GH8733).  
• `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).  
• Unclear error message in csv parsing when passing dtype and names and the parsed data is a different data type (GH8833)  
• Bug in slicing a multi-index with an empty list and at least one boolean indexer (GH8781)  
• `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo (GH8761).  
• `Timedelta` `kwargs` may now be `numpy` ints and floats (GH8757).  
• Fixed several outstanding bugs for `Timedelta` arithmetic and comparisons (GH8813, GH5963, GH5436).  
• `sql_schema` now generates dialect appropriate `CREATE TABLE` statements (GH8697)  
• `slice` string method now takes step into account (GH8754)  
• Bug in `BlockManager` where setting values with different type would break block integrity (GH8850)  
• Bug in `DatetimeIndex` when using `time` object as key (GH8667)  
• Bug in `merge` where how='left' and sort=False would not preserve left frame order (GH7331)  
• Bug in `MultiIndex.reindex` where reindexing at level would not reorder labels (GH4088)  
• Bug in certain operations with dateutil timezones, manifesting with dateutil 2.3 (GH8639)  
• Regression in `DatetimeIndex` iteration with a Fixed/Local offset timezone (GH8890)  
• Bug in `to_datetime` when parsing a nanoseconds using the `%f` format (GH8989)  
• `io.data.Options` now raises `RemoteDataError` when no expiry dates are available from Yahoo and when it receives no data from Yahoo (GH8761), (GH8783).  
• Fix: The font size was only set on x axis if vertical or the y axis if horizontal. (GH8765)  
• Fixed division by 0 when reading big csv files in python 3 (GH8621)  
• Bug in outputting a `Multindex` with `to_html, index=False` which would add an extra column (GH8452)  
• Imported categorical variables from Stata files retain the ordinal information in the underlying data (GH8836).  
• Defined `.size` attribute across `NDFrame` objects to provide compat with `numpy` >= 1.9.1; buggy with `np.array_split` (GH8846)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- Skip testing of histogram plots for matplotlib <= 1.2 (GH8648).
- Bug where `get_data_google` returned object dtypes (GH3995)
- Bug in `DataFrame.stack(..., dropna=False)` when the DataFrame’s columns is a MultiIndex whose labels do not reference all its levels. (GH8844)
- Bug in that Option context applied on `__enter__` (GH8514)
- Bug in resample that causes a ValueError when resampling across multiple days and the last offset is not calculated from the start of the range (GH8683)
- Bug where `DataFrame.plot(kind='scatter')` fails when checking if an np.array is in the DataFrame (GH8852)
- Bug in `pd.infer_freq/DataFrame.inferred_freq` that prevented proper sub-daily frequency inference when the index contained DST days (GH8772).
- Bug where index name was still used when plotting a series with `use_index=False` (GH8558).
- Bugs when trying to stack multiple columns, when some (or all) of the level names are numbers (GH8584).
- Bug in `MultiIndex` where `__contains__` returns wrong result if index is not lexically sorted or unique (GH7724)
- BUG CSV: fix problem with trailing whitespace in skipped rows, (GH8679), (GH8661), (GH8983)
- Regression in `Timestamp` does not parse ‘Z’ zone designator for UTC (GH8771)
- Bug in `StataWriter` the produces writes strings with 244 characters irrespective of actual size (GH8969)
- Fixed ValueError raised by cummin/cummax when datetime64 Series contains NaT. (GH8965)
- Bug in `DataReader` returns object dtype if there are missing values (GH8980)
- Bug in plotting if sharex was enabled and index was a timeseries, would show labels on multiple axes (GH3964).
- Bug where passing a unit to the TimedeltaIndex constructor applied the to nano-second conversion twice. (GH9011).
- Bug in plotting of a period-like array (GH9012)

1.19 v0.15.1 (November 9, 2014)

This is a minor bug-fix release from 0.15.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

- Enhancements
- API Changes
- Bug Fixes

1.19.1 API changes

- `s.dt.hour` and other `.dt` accessors will now return `np.nan` for missing values (rather than previously -1), (GH8689)
In [1]: s = Series(date_range('20130101', periods=5, freq='D'))

In [2]: s.iloc[2] = np.nan

In [3]: s
Out[3]:
0 2013-01-01
1 2013-01-02
2 NaT
3 2013-01-04
4 2013-01-05
dtype: datetime64[ns]

previous behavior:

In [6]: s.dt.hour
Out[6]:
0 0
1 0
2 -1
3 0
4 0
dtype: int64

current behavior:

In [4]: s.dt.hour
Out[4]:
0 0.0
1 0.0
2 NaN
3 0.0
4 0.0
dtype: float64

• groupby with as_index=False will not add erroneous extra columns to result (GH8582):

In [5]: np.random.seed(2718281)
In [6]: df = pd.DataFrame(np.random.randint(0, 100, (10, 2)), columns=['jim', 'joe'])
In [7]: df.head()
Out[7]:
   jim  joe
0   61   81
1   96   49
2   55   65
3   72   51
4   77   12

In [8]: ts = pd.Series(5 * np.random.randint(0, 3, 10))
In [4]: df.groupby(ts, as_index=False).max()
Out [4]:
    NaN  jim  joe
0  0   72  83
1  5   77  84
2 10   96  65

Current behavior:

In [9]: df.groupby(ts, as_index=False).max()
Out [9]:
    jim  joe
0  72  83
1  77  84
2  96  65

• groupby will not erroneously exclude columns if the column name conflicts with the grouper name (GH8112):

In [10]: df = pd.DataFrame({'jim': range(5), 'joe': range(5, 10)})
In [11]: df
Out [11]:
    jim  joe
0   0   5
1   1   6
2   2   7
3   3   8
4   4   9

In [12]: gr = df.groupby(df['jim'] < 2)

Previous behavior (excludes 1st column from output):

In [4]: gr.apply(sum)
Out [4]:
    joe
    jim
False 24
True  1

Current behavior:

In [13]: gr.apply(sum)
Out [13]:
    joe
    jim
    False  9  24
    True   1  11

• Support for slicing with monotonic decreasing indexes, even if start or stop is not found in the index (GH7860):

In [14]: s = pd.Series(['a', 'b', 'c', 'd'], [4, 3, 2, 1])
In [15]: s
Out [15]:
    a
previous behavior:

```python
In [8]: s.loc[3.5:1.5]
KeyError: 3.5
```

current behavior:

```python
In [16]: s.loc[3.5:1.5]
Out[16]:
3   b
2   c
dtype: object
```

- `io.data.Options` has been fixed for a change in the format of the Yahoo Options page (GH8612), (GH8741)

Note: As a result of a change in Yahoo’s option page layout, when an expiry date is given, `Options` methods now return data for a single expiry date. Previously, methods returned all data for the selected month.

The `month` and `year` parameters have been undeprecated and can be used to get all options data for a given month.

If an expiry date that is not valid is given, data for the next expiry after the given date is returned.

Option data frames are now saved on the instance as `callsYYMMDD` or `putsYYMMDD`. Previously they were saved as `callsMMYY` and `putsMMYY`. The next expiry is saved as `calls` and `puts`.

New features:

- The expiry parameter can now be a single date or a list-like object containing dates.
- A new property `expiry_dates` was added, which returns all available expiry dates.

Current behavior:

```python
In [17]: from pandas.io.data import Options
In [18]: aapl = Options('aapl','yahoo')
In [19]: aapl.get_call_data().iloc[0:5,0:1]
Out[19]:
   Strike  Expiry   Type  Symbol
     80  2014-11-14  call     AAPL141114C00080000  29.05
     84  2014-11-14  call     AAPL141114C00084000  24.80
     85  2014-11-14  call     AAPL141114C00085000  24.05
     86  2014-11-14  call     AAPL141114C00086000  22.76
     87  2014-11-14  call     AAPL141114C00087000  21.74

In [20]: aapl.expiry_dates
Out[20]:
[datetime.date(2014, 11, 14),
```
In [21]: aapl.get_near_stock_price(expiry=aapl.expiry_dates[0:3]).iloc[0:5,0:1]
Out[21]:

<table>
<thead>
<tr>
<th>Strike</th>
<th>Expiry</th>
<th>Type</th>
<th>Symbol</th>
</tr>
</thead>
<tbody>
<tr>
<td>109</td>
<td>2014-11-22</td>
<td>call</td>
<td>AAPL141122C00109000 1.48</td>
</tr>
<tr>
<td>110</td>
<td>2014-11-14</td>
<td>call</td>
<td>AAPL141114C00110000 0.55</td>
</tr>
</tbody>
</table>

- pandas now also registers the `datetime64` dtype in matplotlib's units registry to plot such values as datetimes. This is activated once pandas is imported. In previous versions, plotting an array of `datetime64` values will have resulted in plotted integer values. To keep the previous behaviour, you can do `del matplotlib.units.registry[np.datetime64]` (GH8614).

### 1.19.2 Enhancements

- `concat` permits a wider variety of iterables of pandas objects to be passed as the first parameter (GH8645):

```python
In [17]: from collections import deque
In [18]: df1 = pd.DataFrame([1, 2, 3])
In [19]: df2 = pd.DataFrame([4, 5, 6])

previous behavior:
In [7]: pd.concat((df1, df2))
```

```
TypeError: first argument must be a list-like of pandas objects, you passed an object of type "deque"
```

```python
current behavior:
In [20]: pd.concat(deque((df1, df2)))
```

```
Out[20]:
   0  1
   1  2
   2  3
   0  4
   1  5
   2  6
```
• Represent MultiIndex labels with a dtype that utilizes memory based on the level size. In prior versions, the memory usage was a constant 8 bytes per element in each level. In addition, in prior versions, the reported memory usage was incorrect as it didn’t show the usage for the memory occupied by the underlying data array. (GH8456)

```python
In [21]: dfi = DataFrame(1,index=pd.MultiIndex.from_product([['a'],range(1000)]),
                   columns=['A'])
```

previous behavior:

```python
# this was underreported in prior versions
In [1]: dfi.memory_usage(index=True)
Out[1]:
Index 8000 # took about 24008 bytes in < 0.15.1
A 8000
dtype: int64
```

current behavior:

```python
In [22]: dfi.memory_usage(index=True)
Out [22]:
Index 52080
A 8000
dtype: int64
```

• Added Index properties `is_monotonic_increasing` and `is_monotonic_decreasing` (GH8680).
• Added option to select columns when importing Stata files (GH7935)
• Qualify memory usage in DataFrame.info() by adding `+` if it is a lower bound (GH8578)
• Raise errors in certain aggregation cases where an argument such as `numeric_only` is not handled (GH8592).
• Added support for 3-character ISO and non-standard country codes in `io.wb.download()` (GH8482)
• World Bank data requests now will warn/raise based on an `errors` argument, as well as a list of hard-coded country codes and the World Bank’s JSON response. In prior versions, the error messages didn’t look at the World Bank’s JSON response. Problem-inducing input were simply dropped prior to the request. The issue was that many good countries were cropped in the hard-coded approach. All countries will work now, but some bad countries will raise exceptions because some edge cases break the entire response. (GH8482)
• Added option to `Series.str.split()` to return a DataFrame rather than a Series (GH8428)
• Added option to `df.info(null_counts=None|True|False)` to override the default display options and force showing of the null-counts (GH8701)

### 1.19.3 Bug Fixes

• Bug in unpickling of a CustomBusinessDay object (GH8591)
• Bug in coercing Categorical to a records array, e.g. `df.to_records()` (GH8626)
• Bug in Categorical not created properly with Series.to_frame() (GH8626)
• Bug in coercing in astype of a Categorical of a passed pd.Categorical (this now raises TypeError correctly), (GH8626)
• Bug in cut/qcut when using Series and `retbins=True` (GH8589)
• Bug in writing Categorical columns to an SQL database with `to_sql` (GH8624).
• Bug in comparing Categorical of datetime raising when being compared to a scalar datetime (GH8687)
• Bug in selecting from a Categorical with .iloc (GH8623)
• Bug in groupby-transform with a Categorical (GH8623)
• Bug in duplicated/drop_duplicates with a Categorical (GH8623)
• Bug in Categorical reflected comparison operator raising if the first argument was a numpy array scalar (e.g. np.int64) (GH8658)
• Bug in Panel indexing with a list-like (GH8710)
• Compat issue is DataFrame.dtypes when options.mode.use_inf_as_null is True (GH8722)
• Bug in read_csv, dialect parameter would not take a string (:issue: 8703)
• Bug in slicing a multi-index level with an empty-list (GH8737)
• Bug in numeric index operations of add/sub with Float/Index Index with numpy arrays (GH8608)
• Bug in setitem with empty indexer and unwanted coercion of dtypes (GH8669)
• Bug in ix/loc block splitting on setitem (manifests with integer-like dtypes, e.g. datetime64) (GH8607)
• Bug when doing label based indexing with integers not found in the index for non-unique but monotonic indexes (GH8680).
• Bug when indexing a Float64Index with np.nan on numpy 1.7 (GH8980).
• Fix shape attribute for MultiIndex (GH8609)
• Bug in GroupBy where a name conflict between the grouper and columns would break groupby operations (GH7115, GH8112)
• Fixed a bug where plotting a column y and specifying a label would mutate the index name of the original DataFrame (GH8494)
• Fix regression in plotting of a DatetimeIndex directly with matplotlib (GH8614).
• Bug in date_range where partially-specified dates would incorporate current date (GH6961)
• Bug in Setting by indexer to a scalar value with a mixed-dtype Panel4d was failing (GH8702)
• Bug where DataReader's would fail if one of the symbols passed was invalid. Now returns data for valid symbols and np.nan for invalid (GH8494)
• Bug in get_quote_yahoo that wouldn’t allow non-float return values (GH5229).

1.20 v0.15.0 (October 18, 2014)

This is a major release from 0.14.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Warning: pandas >= 0.15.0 will no longer support compatibility with NumPy versions < 1.7.0. If you want to use the latest versions of pandas, please upgrade to NumPy >= 1.7.0 (GH7711)

• Highlights include:
  – The Categorical type was integrated as a first-class pandas type, see here
  – New scalar type Timedelta, and a new index type TimedeltaIndex, see here
– New datetimelike properties accessor .dt for Series, see Datetimelike Properties
– New DataFrame default display for df.info() to include memory usage, see Memory Usage
– read_csv will now by default ignore blank lines when parsing, see here
– API change in using Indexes in set operations, see here
– Enhancements in the handling of timezones, see here
– A lot of improvements to the rolling and expanding moment functions, see here
– Internal refactoring of the Index class to no longer sub-class ndarray, see Internal Refactoring
– dropping support for PyTables less than version 3.0.0, and numexpr less than version 2.1 (GH7990)
– Split indexing documentation into Indexing and Selecting Data and MultiIndex / Advanced Indexing
– Split out string methods documentation into Working with Text Data

• Check the API Changes and deprecations before updating

• Other Enhancements
• Performance Improvements
• Bug Fixes

Warning: In 0.15.0 Index has internally been refactored to no longer sub-class ndarray but instead subclass PandasObject, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (See the Internal Refactoring)

Warning: The refactorings in Categorical changed the two argument constructor from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use Categorical directly, please audit your code before updating to this pandas version and change it to use the from_codes() constructor. See more on Categorical here

1.20.1 New features

1.20.1.1 Categoricals in Series/DataFrame

Categorical can now be included in Series and DataFrames and gained new methods to manipulate. Thanks to Jan Schulz for much of this API/implementation. (GH3943, GH5313, GH5314, GH7444, GH7839, GH7848, GH7864, GH7914, GH7768, GH8006, GH3678, GH8075, GH8076, GH8143, GH8453, GH8518).

For full docs, see the categorical introduction and the API documentation.

1.20. v0.15.0 (October 18, 2014) 287
In [4]: df["grade"].cat.categories = ["very good", "good", "very bad"]

# Reorder the categories and simultaneously add the missing categories
In [5]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [6]: df["grade"]
Out[6]:
0 very good
1 good
2 good
3 very good
4 very good
5 very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]

In [7]: df.sort_values("grade")

In [8]: df.groupby("grade").size()
1.20.1.2 TimedeltaIndex/Scalar

We introduce a new scalar type Timedelta, which is a subclass of datetime.timedelta, and behaves in a similar manner, but allows compatibility with np.timedelta64 types as well as a host of custom representation, parsing, and attributes. This type is very similar to how Timestamp works for datetimes. It is a nice-API box for the type. See the docs. (GH3009, GH4533, GH8209, GH8187, GH8190, GH7869, GH7661, GH8345, GH8471)

**Warning:** Timedelta scalars (and TimedeltaIndex) component fields are **not the same** as the component fields on a datetime.timedelta object. For example, .seconds on a datetime.timedelta object returns the total number of seconds combined between hours, minutes and seconds. In contrast, the pandas Timedelta breaks out hours, minutes, microseconds and nanoseconds separately.

```python
# Timedelta accessor
In [9]: tds = Timedelta('31 days 5 min 3 sec')

In [10]: tds.minutes
Out[10]: 5L

In [11]: tds.seconds
Out[11]: 3L

# datetime.timedelta accessor
# this is 5 minutes * 60 + 3 seconds
In [12]: tds.to_pytimedelta().seconds
Out[12]: 303
```

**Note:** this is no longer true starting from v0.16.0, where full compatibility with datetime.timedelta is introduced. See the 0.16.0 whatsnew entry

**Warning:** Prior to 0.15.0 pd.to_timedelta would return a Series for list-like/Series input, and a np.timedelta64 for scalar input. It will now return a TimedeltaIndex for list-like input, Series for Series input, and Timedelta for scalar input.

The arguments to pd.to_timedelta are now (arg,unit='ns',box=True,coerce=False), previously were (arg,box=True,unit='ns') as these are more logical.

Construct a scalar

```python
In [9]: Timedelta('1 days 06:05:01.00003')
Out[9]: Timedelta('1 days 06:05:01.000030')

In [10]: Timedelta('15.5us')
   → Timedelta('0 days 00:00:00.000015')

In [11]: Timedelta('1 hour 15.5us')
   → Timedelta('0 days 01:00:00.000015')

# negative Timedeltas have this string repr
# to be more consistent with datetime.timedelta conventions
In [12]: Timedelta('-1us')
   → Timedelta('-1 days +23:59:59.999999')
```

(continues on next page)
# a NaT
```
In [13]: Timedelta('nan')
NaT
```

Access fields for a Timedelta
```
In [14]: td = Timedelta('1 hour 3m 15.5us')
In [15]: td.seconds
Out[15]: 3780
In [16]: td.microseconds
Out[16]: 16
In [17]: td.nanoseconds
Out[17]: 500
```

Construct a TimedeltaIndex
```
In [18]: TimedeltaIndex(["1 days","1 days, 00:00:05", ....:
                      np.timedelta64(2,'D'),timedelta(days=2,seconds=2)])
Out[18]: TimedeltaIndex(["1 days 00:00:00", '1 days 00:00:05', '2 days 00:00:00', '2 days 00:00:02'],
                      dtype='timedelta64[ns]', freq=None)
```

Constructing a TimedeltaIndex with a regular range
```
In [19]: timedelta_range('1 days',periods=5,freq='D')
Out[19]: TimedeltaIndex(["1 days", '2 days', '3 days', '4 days', '5 days'], dtype="timedelta64[ns]", freq='D')
```
```
In [20]: timedelta_range(start='1 days',end='2 days',freq='30T')
```
```
```
```
You can now use a TimedeltaIndex as the index of a pandas object

```python
In [21]: s = Series(np.arange(5),
       index=timedelta_range('1 days', periods=5, freq='s'))

In [22]: s
Out[22]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
1 days 00:00:03    3
1 days 00:00:04    4
Freq: S, dtype: int64
```

You can select with partial string selections

```python
In [23]: s['1 day 00:00:02']
Out[23]: 2

In [24]: s['1 day':'1 day 00:00:02']
Out[24]:
1 days 00:00:00    0
1 days 00:00:01    1
1 days 00:00:02    2
Freq: S, dtype: int64
```

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

```python
In [25]: tdi = TimedeltaIndex(['1 days', pd.NaT, '2 days'])

In [26]: tdi.tolist()
Out[26]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]

In [27]: dti = date_range('20130101', periods=3)

In [28]: dti.tolist()
Out[28]: [Timestamp('2013-01-01 00:00:00', freq='D'),
        Timestamp('2013-01-02 00:00:00', freq='D'),
        Timestamp('2013-01-03 00:00:00', freq='D')]

In [29]: (dti + tdi).tolist()
Out[29]: [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]

In [30]: (dti - tdi).tolist()
Out[30]: [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

• iteration of a Series e.g. list(Series(...)) of timedelta64[ns] would prior to v0.15.0 return np.timedelta64 for each element. These will now be wrapped in Timedelta.

### 1.20.1.3 Memory Usage

Implemented methods to find memory usage of a DataFrame. See the FAQ for more. (GH6852).
A new display option `display.memory_usage` (see *Options and Settings*) sets the default behavior of the `memory_usage` argument in the `df.info()` method. By default `display.memory_usage` is `True`.

```
In [31]: dtypes = ['int64', 'float64', 'datetime64[ns]', 'timedelta64[ns]',
           ...:    'complex128', 'object', 'bool']
           ...
In [32]: n = 5000
In [33]: data = dict((t, np.random.randint(100, size=n).astype(t))
            ...:          for t in dtypes)
            ...
In [34]: df = DataFrame(data)
In [35]: df['categorical'] = df['object'].astype('category')
In [36]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 5000 entries, 0 to 4999
Data columns (total 8 columns):
int64 5000 non-null int64
float64 5000 non-null float64
datetime64[ns] 5000 non-null datetime64[ns]
timedelta64[ns] 5000 non-null timedelta64[ns]
complex128 5000 non-null complex128
object 5000 non-null object
bool 5000 non-null bool
categorical 5000 non-null category
dtypes: bool(1), category(1), complex128(1), datetime64[ns](1), float64(1), int64(1),
        object(1), timedelta64[ns](1)
memory usage: 289.1+KB
```

Additionally `memory_usage()` is an available method for a dataframe object which returns the memory usage of each column.

```
In [37]: df.memory_usage(index=True)
Out[37]:
             Index     80
        int64  40000
        float64 40000
       datetime64[ns]  40000
       timedelta64[ns] 40000
           complex128  80000
          object    40000
           bool       5000
       categorical  10920
dtype: int64
```

### 1.20.1.4 .dt accessor

Series has gained an accessor to succinctly return datetime like properties for the *values* of the Series, if its a datetime/period like Series. (GH7207) This will return a Series, indexed like the existing Series. See the *docs*.

```
# datetime
In [38]: s = Series(date_range('20130101 09:10:12', periods=4))
```
In [39]: s
Out[39]:
  0  2013-01-01 09:10:12  
  1  2013-01-02 09:10:12  
  2  2013-01-03 09:10:12  
  3  2013-01-04 09:10:12
dtype: datetime64[ns]

In [40]: s.dt.hour
   
   0   9  
   1   9  
   2   9  
   3   9  
dtype: int64

In [41]: s.dt.second
   
   0   12  
   1   12  
   2   12  
   3   12  
dtype: int64

In [42]: s.dt.day
   
   0   1  
   1   2  
   2   3  
   3   4  
dtype: int64

In [43]: s.dt.freq
   
   'D'

This enables nice expressions like this:

In [44]: s[s.dt.day==2]
Out[44]:
  1  2013-01-02 09:10:12
dtype: datetime64[ns]

You can easily produce tz aware transformations:

In [45]: stz = s.dt.tz_localize('US/Eastern')

In [46]: stz
Out[46]:
  0  2013-01-01 09:10:12-05:00  
  1  2013-01-02 09:10:12-05:00  
  2  2013-01-03 09:10:12-05:00  
  3  2013-01-04 09:10:12-05:00  

(continues on next page)
You can also chain these types of operations:

```python
In [48]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[48]:
   0  2013-01-01 04:10:12-05:00
   1  2013-01-02 04:10:12-05:00
   2  2013-01-03 04:10:12-05:00
   3  2013-01-04 04:10:12-05:00
 dtype: datetime64[ns, US/Eastern]
```

The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [49]: s = Series(period_range('20130101', periods=4, freq='D'))

In [50]: s
Out[50]:
   0  2013-01-01
   1  2013-01-02
   2  2013-01-03
   3  2013-01-04
 dtype: object

In [51]: s.dt.year
   →
   0  2013
   1  2013
   2  2013
   3  2013
 dtype: int64

In [52]: s.dt.day
   →
   0  1
   1  2
   2  3
   3  4
 dtype: int64
```

```python
# timedelta
In [53]: s = Series(timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [54]: s
Out[54]:
   0  1 days 00:00:05
   1  1 days 00:00:06
   2  1 days 00:00:07
   3  1 days 00:00:08
```
1.20.1.5 Timezone handling improvements

- `tz_localize(None)` for `tz-aware` Timestamp and DatetimeIndex now removes timezone holding local time, previously this resulted in Exception or TypeError (GH7812)
**tz_localize** now accepts the ambiguous keyword which allows for passing an array of bools indicating whether the date belongs in DST or not, 'NaT' for setting transition times to NaT, 'infer' for inferring DST/non-DST, and 'raise' (default) for an AmbiguousTimeError to be raised. See the docs for more details (GH7943)

Dataframe.tz_localize and Dataframe.tz_convert now accepts an optional level argument for localizing a specific level of a MultiIndex (GH7846)

Timestamp.tz_localize and Timestamp.tz_convert now raise TypeError in error cases, rather than Exception (GH8025)

a timeseries/index localized to UTC when inserted into a Series/Dataframe will preserve the UTC timezone (rather than being a naive datetime64[ns]) as object dtype (GH8411)

Timestamp.__repr__ displays dateutil.tz.tzoffset info (GH7907)

### 1.20.1.6 Rolling/Expanding Moments improvements

- rolling_min(), rolling_max(), rolling_cov(), and rolling_corr() now return objects with all NaN when len(arg) < min_periods <= window rather than raising. (This makes all rolling functions consistent in this behavior). (GH7766)

Prior to 0.15.0

In [64]: s = Series([10, 11, 12, 13])

In [15]: pd.rolling_min(s, window=10, min_periods=5)
ValueError: min_periods (5) must be <= window (4)

New behavior

In [4]: pd.rolling_min(s, window=10, min_periods=5)
Out [4]:
   0  NaN
   1  NaN
   2  NaN
   3  NaN
dtype: float64

- rolling_max(), rolling_min(), rolling_sum(), rolling_mean(), rolling_median(), rolling_std(), rolling_var(), rolling_skew(), rolling_kurt(), rolling_quantile(), rolling_cov(), rolling_corr(), rolling_corr_pairwise(), rolling_window(), and rolling_apply() with center=True previously would return a result of the same structure as the input arg with NaN in the final \( \frac{(window-1)}{2} \) entries.

Now the final \( \frac{(window-1)}{2} \) entries of the result are calculated as if the input arg were followed by \( \frac{(window-1)}{2} \) NaN values (or with shrinking windows, in the case of rolling_apply()). (GH7925, GH8269)
Prior behavior (note final value is NaN):

```python
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
```

```
Out[7]:
0   1
1   3
2   6
3  NaN
dtype: float64
```

New behavior (note final value is 5 = sum([2, 3, NaN])):

```python
In [7]: rolling_sum(Series(range(4)), window=3, min_periods=0, center=True)
```

```
Out[7]:
0   1
1   3
2   6
3   5
dtype: float64
```

- `rolling_window()` now normalizes the weights properly in rolling mean mode (`mean=True`) so that the calculated weighted means (e.g. ‘triang’, ‘gaussian’) are distributed about the same means as those calculated without weighting (i.e. ‘boxcar’). See the note on normalization for further details. (GH7618)

Behavior prior to 0.15.0:

```python
In [39]: rolling_window(s, window=3, win_type='triang', center=True)
```

```
Out[39]:
0    NaN
1   6.583333
2   6.883333
3   6.683333
4    NaN
dtype: float64
```

New behavior

```python
In [10]: pd.rolling_window(s, window=3, win_type='triang', center=True)
```

```
Out[10]:
0    NaN
1   9.875
2  10.325
3  10.025
4    NaN
dtype: float64
```

- Removed `center` argument from all `expanding_` functions (see list), as the results produced when `center=True` did not make much sense. (GH7925)
- Added optional `ddof` argument to `expanding_cov()` and `rolling_cov()`. The default value of 1 is backwards-compatible. (GH8279)
- Documented the `ddof` argument to `expanding_var()`, `expanding_std()`, `rolling_var()`, and `rolling_std()`. These functions’ support of a `ddof` argument (with a default value of 1) was previously undocumented. (GH8064)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now interpret `min_periods` in the same manner that the `rolling_*()` and `expanding_*()` functions do: a given result entry will be NaN if the (expanding, in this case) window does not contain at least `min_periods` values. The previous behavior was to set to NaN the `min_periods` entries starting with the first non-NaN value. (GH7977)

Prior behavior (note values start at index 2, which is `min_periods` after index 0 (the index of the first non-empty value)):

```python
In [66]: s = Series([1, None, None, None, 2, 3])
In [51]: ewma(s, com=3., min_periods=2)
Out[51]:
   0     NaN
   1     NaN
   2  1.000000
   3  1.000000
   4  1.571429
   5  2.189189
dtype: float64
```

New behavior (note values start at index 4, the location of the 2nd (since `min_periods=2`) non-empty value):

```python
In [2]: pd.ewma(s, com=3., min_periods=2)
Out[2]:
   0     NaN
   1     NaN
   2     NaN
   3     NaN
   4  1.759644
   5  2.383784
dtype: float64
```

- `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `adjust` argument, just like `ewma()` does, affecting how the weights are calculated. The default value of `adjust` is `True`, which is backwards-compatible. See Exponentially weighted moment functions for details. (GH7911)

- `ewma()`, `ewmstd()`, `ewmvol()`, `ewmvar()`, `ewmcov()`, and `ewmcorr()` now have an optional `ignore_na` argument. When `ignore_na=False` (the default), missing values are taken into account in the weights calculation. When `ignore_na=True` (which reproduces the pre-0.15.0 behavior), missing values are ignored in the weights calculation. (GH7543)

```python
In [7]: pd.ewma(Series([None, 1., 8.]), com=2.)
Out[7]:
   0     NaN
   1  1.000000
   2  5.200000
   3     NaN
   4  1.759644
   5  2.383784
dtype: float64

In [8]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=True)  # pre-0.15.0 behavior
Out[8]:
   0  1.000000
   1  1.000000
   2  5.200000
dtype: float64

In [9]: pd.ewma(Series([1., None, 8.]), com=2., ignore_na=False)  # new default
```

(continues on next page)
Warning: By default (ignore_na=False) the ewm*() functions’ weights calculation in the presence of missing values is different than in pre-0.15.0 versions. To reproduce the pre-0.15.0 calculation of weights in the presence of missing values one must specify explicitly ignore_na=True.

- Bug in expanding_cov(), expanding_corr(), rolling_cov(), rolling_cor(), ewmcov(), and ewmcorr() returning results with columns sorted by name and producing an error for non-unique columns: now handles non-unique columns and returns columns in original order (except for the case of two DataFrames with pairwise=False, where behavior is unchanged) (GH7542)
- Bug in rolling_count() and expanding_*() functions unnecessarily producing error message for zero-length data (GH8056)
- Bug in rolling_apply() and expanding_apply() interpreting min_periods=0 as min_periods=1 (GH8080)
- Bug in expanding_std() and expanding_var() for a single value producing a confusing error message (GH7900)
- Bug in rolling_std() and rolling_var() for a single value producing 0 rather than NaN (GH7900)
- Bug in ewmstd(), ewmvol(), ewmvar(), and ewmcov() calculation of de-biasing factors when bias=False (the default). Previously an incorrect constant factor was used, based on adjust=True, ignore_na=True, and an infinite number of observations. Now a different factor is used for each entry, based on the actual weights (analogous to the usual N/(N-1) factor). In particular, for a single point a value of NaN is returned when bias=False, whereas previously a value of (approximately) 0 was returned.

For example, consider the following pre-0.15.0 results for ewmvar(..., bias=False), and the corresponding debiasing factors:

```python
In [67]: s = Series([1., 2., 0., 4.])

In [89]: ewmvar(s, com=2., bias=False)
Out[89]:
   0   -2.775558e-16
   1    3.000000e-01
   2    9.556787e-01
   3    3.585799e+00
dtype: float64

In [90]: ewmvar(s, com=2., bias=False) / ewmvar(s, com=2., bias=True)
Out[90]:
   0   1.25
   1   1.25
   2   1.25
   3   1.25
dtype: float64
```

Note that entry 0 is approximately 0, and the debiasing factors are a constant 1.25. By comparison, the following 0.15.0 results have a NaN for entry 0, and the debiasing factors are decreasing (towards 1.25):
```python
In [14]: pd.ewmvar(s, com=2., bias=False)
Out[14]:
   0    NaN
   1  0.500000
   2  1.210526
   3  4.089069
   dtype: float64

In [15]: pd.ewmvar(s, com=2., bias=False) / pd.ewmvar(s, com=2., bias=True)
Out[15]:
   0    NaN
   1  2.083333
   2  1.583333
   3  1.425439
dtype: float64
```

See *Exponentially weighted moment functions* for details. (GH7912)

### 1.2.0.1.7 Improvements in the sql io module

- Added support for a `chunksize` parameter to `to_sql` function. This allows DataFrame to be written in chunks and avoid packet-size overflow errors (GH8062).
- Added support for a `chunksize` parameter to `read_sql` function. Specifying this argument will return an iterator through chunks of the query result (GH2908).
- Added support for writing `datetime.date` and `datetime.time` object columns with `to_sql` (GH6932).
- Added support for specifying a `schema` to read from/write to with `read_sql_table` and `to_sql` (GH7441, GH7952). For example:

```python
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

- Added support for writing NaN values with `to_sql` (GH2754).
- Added support for writing datetime64 columns with `to_sql` for all database flavors (GH7103).

### 1.2.0.2 Backwards incompatible API changes

#### 1.2.0.2.1 Breaking changes

API changes related to `Categorical` (see [here](#) for more details):

- The `Categorical` constructor with two arguments changed from “codes/labels and levels” to “values and levels (now called ‘categories’)”. This can lead to subtle bugs. If you use `Categorical` directly, please audit your code by changing it to use the `from_codes()` constructor.

  An old function call like (prior to 0.15.0):

```python
pd.Categorical([0,1,0,2,1], levels=['a', 'b', 'c'])
```

will have to adapted to the following to keep the same behaviour:
API changes related to the introduction of the Timedelta scalar (see above for more details):

- Prior to 0.15.0 to_timedelta() would return a Series for list-like/Series input, and a np.timedelta64 for scalar input. It will now return a TimedeltaIndex for list-like input, Series for Series input, and Timedelta for scalar input.

For API changes related to the rolling and expanding functions, see detailed overview above.

Other notable API changes:

- Consistency when indexing with .loc and a list-like indexer when no values are found.

In [68]: df = DataFrame([['a'], ['b']], index=[1, 2])
In [69]: df
Out[69]:
   0
  1 a
  2 b

In prior versions there was a difference in these two constructs:

- df.loc[[3]] would return a frame reindexed by 3 (with all np.nan values)
- df.loc[[3],:] would raise KeyError.

Both will now raise a KeyError. The rule is that at least 1 indexer must be found when using a list-like and .loc (GH7999)

Furthermore in prior versions these were also different:

- df.loc[[1,3]] would return a frame reindexed by [1,3]
- df.loc[[1,3],:] would raise KeyError.

Both will now return a frame reindex by [1,3]. E.g.

In [3]: df.loc[[1,3]]
Out[3]:
   0  
   1 a
   3 NaN

In [4]: df.loc[[1,3],:]
Out[4]:
   0  
   1 a
   3 NaN

This can also be seen in multi-axis indexing with a Panel.

In [70]: p = Panel(np.arange(2*3*4).reshape(2,3,4),
     ....:     items=['ItemA','ItemB'],
     ....:     major_axis=[1,2,3],
     ....:     minor_axis=['A','B','C','D'])
     ....:

(continues on next page)
In [71]: p
Out[71]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 3 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemB
Major_axis axis: 1 to 3
Minor_axis axis: A to D

The following would raise KeyError prior to 0.15.0:

In [5]:
Out[5]:
ItemA  ItemD
  1   3  NaN
  2   7  NaN
  3  11  NaN

Furthermore, .loc will raise If no values are found in a multi-index with a list-like indexer:

In [72]: s = Series(np.arange(3,dtype='int64'),
....:     index=MultiIndex.from_product([['A'],['foo','bar','baz']],
....:     names=['one','two']).sort_index()
....:
In [73]: s
Out[73]:
one two
   A   bar  1
   baz  2
   foo  0
dtype: int64
In [74]: try:
....:     s.loc[['D']]
....: except KeyError as e:
....:     print("KeyError: " + str(e))
   \"[\'D\'] not in index\"

- Assigning values to None now considers the dtype when choosing an ‘empty’ value (GH7941).
  Previously, assigning to None in numeric containers changed the dtype to object (or errored, depending on the call). It now uses NaN:

In [75]: s = Series([1, 2, 3])
In [76]: s.loc[0] = None
In [77]: s
Out[77]:
0   NaN
1   2.0
2   3.0
dtype: float64
NaT is now used similarly for datetime containers.

For object containers, we now preserve None values (previously these were converted to NaN values).

```
In [78]: s = Series(["a", "b", "c"])
In [79]: s.loc[0] = None
In [80]: s
Out[80]:
0  None
1   b
2   c
dtype: object
```

To insert a NaN, you must explicitly use np.nan. See the docs.

- In prior versions, updating a pandas object inplace would not reflect in other python references to this object. (GH8511, GH5104)

```
In [81]: s = Series([1, 2, 3])
In [82]: s2 = s
In [83]: s += 1.5
```

```
Behavior prior to v0.15.0
# the original object
In [5]: s
Out[5]:
0  2.5
1  3.5
2  4.5
dtype: float64

# a reference to the original object
In [7]: s2
Out[7]:
0   1
1   2
2   3
dtype: int64
```

This is now the correct behavior

```
# the original object
In [84]: s
Out[84]:
0  2.5
1  3.5
2  4.5
dtype: float64

# a reference to the original object
In [85]: s2
Out[85]:
0  2.5
```

(continues on next page)
• Made both the C-based and Python engines for `read_csv` and `read_table` ignore empty lines in input as well as whitespace-filled lines, as long as `sep` is not whitespace. This is an API change that can be controlled by the keyword parameter `skip_blank_lines`. See the docs (GH4466).

• A timeseries/index localized to UTC when inserted into a Series/DataFrame will preserve the UTC timezone and inserted as `object` dtype rather than being converted to a naive `datetime64[ns]` (GH8411).

• Bug in passing a `DatetimeIndex` with a timezone that was not being retained in DataFrame construction from a dict (GH7822).

In prior versions this would drop the timezone, now it retains the timezone, but gives a column of `object` dtype:

```python
i = date_range('1/1/2011', periods=3, freq='10s', tz = 'US/Eastern')
```

```python
In [86]: i = date_range('1/1/2011', periods=3, freq='10s', tz = 'US/Eastern')

In [87]: i
Out[87]:
DatetimeIndex(['2011-01-01 00:00:00-05:00', '2011-01-01 00:00:10-05:00',
               '2011-01-01 00:00:20-05:00'],
              dtype='datetime64[ns, US/Eastern]', freq='10S')
```

```python
In [88]: df = DataFrame( {'a' : i } )

In [89]: df
Out[89]:
a
0 2011-01-01 00:00:00-05:00
1 2011-01-01 00:00:10-05:00
2 2011-01-01 00:00:20-05:00
```

Previously this would have yielded a column of `datetime64` dtype, but without timezone info.

The behaviour of assigning a column to an existing dataframe as `df['a'] = i` remains unchanged (this already returned an `object` column with a timezone).

• When passing multiple levels to `stack()`, it will now raise a `ValueError` when the levels aren’t all level names or all level numbers (GH7660). See Reshaping by stacking and unstacking.

• Raise a `ValueError` in `df.to_hdf` with ‘fixed’ format, if `df` has non-unique columns as the resulting file will be broken (GH7761)

• `SettingWithCopy` raise/warnings (according to the option `mode.chained_assignment`) will now be issued when setting a value on a sliced mixed-dtype DataFrame using chained-assignment. (GH7845, GH7950)
In [3]: df.iloc[0:5]['group'] = 'a'
/usr/local/bin/ipython:1: SettingWithCopyWarning:
A value is trying to be set on a copy of a slice from a DataFrame. 
Try using .loc[row_indexer,col_indexer] = value instead

See the caveats in the documentation: http://pandas.pydata.org/pandas-docs/stable/
˓→indexing.html#indexing-view-versus-copy

• merge, DataFrame.merge, and ordered_merge now return the same type as the left argument (GH7737).

• Previously an enlargement with a mixed-dtype frame would act unlike .append which will preserve dtypes (related GH2578, GH8176):

In [91]: df = DataFrame([[True, 1],[False, 2]],
   ....:     columns=['female','fitness'])
   ....:

In [92]: df
Out[92]:
   female fitness
   0   True    1
   1  False    2

In [93]: df.dtypes
Out[93]:
female  bool
fitness  int64
dtype: object

# dtypes are now preserved

In [95]: df
Out[95]:
   female fitness
   0   True    1
   1  False    2
   2  False    2

In [96]: df.dtypes
Out[96]:
   female  bool
   fitness  int64
dtype: object

• Series.to_csv() now returns a string when path=None, matching the behaviour of DataFrame. to_csv() (GH8215).

• read_hdf now raises IOError when a file that doesn’t exist is passed in. Previously, a new, empty file was created, and a KeyError raised (GH7715).

• DataFrame.info() now ends its output with a newline character (GH8114)

• Concatenating no objects will now raise a ValueError rather than a bare Exception.

• Merge errors will now be sub-classes of ValueError rather than raw Exception (GH8501)
• DataFrame.plot and Series.plot keywords are now have consistent orders (GH8037)

1.20.2.2 Internal Refactoring

In 0.15.0 Index has internally been refactored to no longer sub-class ndarray but instead subclass PandasObject, similarly to the rest of the pandas objects. This change allows very easy sub-classing and creation of new index types. This should be a transparent change with only very limited API implications (GH5080, GH7439, GH7796, GH8024, GH8367, GH7997, GH8522):

- you may need to unpickle pandas version < 0.15.0 pickles using pd.read_pickle rather than pickle.load. See pickle docs
- when plotting with a PeriodIndex, the matplotlib internal axes will now be arrays of Period rather than a PeriodIndex (this is similar to how a DatetimeIndex passes arrays of datetimes now)
- MultiIndexes will now raise similarly to other pandas objects w.r.t. truth testing, see here (GH7897).
- When plotting a DatetimeIndex directly with matplotlib’s plot function, the axis labels will no longer be formatted as dates but as integers (the internal representation of a datetime64). UPDATE This is fixed in 0.15.1, see here.

1.20.2.3 Deprecations

- The attributes Categorical labels and levels attributes are deprecated and renamed to codes and categories.
- The outtype argument to pd.DataFrame.to_dict has been deprecated in favor of orient. (GH7840)
- The convert_dummies method has been deprecated in favor of get_dummies (GH8140)
- The infer_dst argument in tz_localize will be deprecated in favor of ambiguous to allow for more flexibility in dealing with DST transitions. Replace infer_dst=True with ambiguous='infer' for the same behavior (GH7943). See the docs for more details.
- The top-level pd.value_range has been deprecated and can be replaced by .describe() (GH8481)
- The Index set operations + and - were deprecated in order to provide these for numeric type operations on certain index types. + can be replaced by .union() or |, and - by .difference(). Further the method name Index.diff() is deprecated and can be replaced by Index.difference() (GH8226)

```
# +
Index(['a','b','c']) + Index(['b','c','d'])
# should be replaced by
Index(['a','b','c']).union(Index(['b','c','d']))

# -
Index(['a','b','c']) - Index(['b','c','d'])
# should be replaced by
Index(['a','b','c']).difference(Index(['b','c','d']))
```

- The infer_types argument to read_html() now has no effect and is deprecated (GH7762, GH7032).

1.20.2.4 Removal of prior version deprecations/changes

- Remove DataFrame.delevel method in favor of DataFrame.reset_index
1.20.3 Enhancements

Enhancements in the importing/exporting of Stata files:

- Added support for bool, uint8, uint16 and uint32 datatypes in `to_stata` (GH7097, GH7365)
- Added conversion option when importing Stata files (GH8527)
- `DataFrame.to_stata` and `StataWriter` check string length for compatibility with limitations imposed in dta files where fixed-width strings must contain 244 or fewer characters. Attempting to write Stata dta files with strings longer than 244 characters raises a `ValueError` (GH7858)
- `read_stata` and `StataReader` can import missing data information into a `DataFrame` by setting the argument `convert_missing` to True. When using this options, missing values are returned as `StataMissingValue` objects and columns containing missing values have `object` data type. (GH8045)

Enhancements in the plotting functions:

- Added `layout` keyword to `DataFrame.plot`. You can pass a tuple of `(rows, columns)`, one of which can be -1 to automatically infer (GH6667, GH8071).
- Allow to pass multiple axes to `DataFrame.plot`, `hist` and `boxplot` (GH5353, GH6970, GH7069)
- Added support for `c`, `colormap` and `colorbar` arguments for `DataFrame.plot` with `kind='scatter'` (GH7780)
- Histogram from `DataFrame.plot` with `kind='hist'` (GH7809), See the docs.
- Boxplot from `DataFrame.plot` with `kind='box'` (GH7998), See the docs.

Other:

- `read_csv` now has a keyword parameter `float_precision` which specifies which floating-point converter the C engine should use during parsing, see here (GH8002, GH8044)
- Added `searchsorted` method to `Series` objects (GH7447)
- `describe()` on mixed-types DataFrames is more flexible. Type-based column filtering is now possible via the `include/exclude` arguments. See the docs (GH8164).

```
In [97]: df = DataFrame({'catA': ['foo', 'foo', 'bar'] * 8,
...:                  'catB': ['a', 'b', 'c', 'd'] * 6,
...:                  'numC': np.arange(24),
...:                  'numD': np.arange(24.) + .5})

In [98]: df.describe(include=['object'])
Out[98]:
        catA     catB
count 24.0  24.0
unique 2.0  4.0
top foo    c
freq 16.0  6.0

In [99]: df.describe(include=['number', 'object'], exclude=['float'])
```

(continues on next page)
mean NaN NaN 11.500000
std NaN NaN 7.071068
min NaN NaN 0.000000
25% NaN NaN 5.750000
50% NaN NaN 11.500000
75% NaN NaN 17.250000
max NaN NaN 23.000000

Requesting all columns is possible with the shorthand ‘all’

In [100]: df.describe(include='all')
Out[100]:
<table>
<thead>
<tr>
<th></th>
<th>catA</th>
<th>catB</th>
<th>numC</th>
<th>numD</th>
</tr>
</thead>
<tbody>
<tr>
<td>count</td>
<td>24</td>
<td>24</td>
<td>24.000000</td>
<td>24.000000</td>
</tr>
<tr>
<td>unique</td>

<td>23.500000</td>
</tr>
</tbody>
</table>

Without those arguments, ‘describe’ will behave as before, including only numerical columns or, if none are, only categorical columns. See also the docs

- Added `split` as an option to the orient argument in `pd.DataFrame.to_dict` (GH7840)
- The `get_dummies` method can now be used on DataFrames. By default only catagorical columns are encoded as 0’s and 1’s, while other columns are left untouched.

In [101]: df = DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'], 'C': [1, 2, 3]})

In [102]: pd.get_dummies(df)
Out[102]:
<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>A_a</th>
<th>A_b</th>
<th>B_b</th>
<th>B_c</th>
</tr>

<td>1</td>
</tr>
<tr>
<td>2</td>
<td>3</td>
<td>1</td>
<td>0</td>
<td>1</td>
<td>0</td>
</tr>
</tbody>
</table>

- `PeriodIndex` supports resolution as the same as `DatetimeIndex` (GH7708)
- `pandas.tseries.holiday` has added support for additional holidays and ways to observe holidays (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a list of offsets in Python3 (GH7070)
- `pandas.tseries.holiday.Holiday` now supports a `days_of_week` parameter (GH7070)
- `GroupBy.nth()` now supports selecting multiple nth values (GH7910)

In [103]: business_dates = date_range(start='4/1/2014', end='6/30/2014', freq='B')
In [104]: df = DataFrame(1, index=business_dates, columns=['a', 'b'])
# get the first, 4th, and last date index for each month
In [105]: df.groupby((df.index.year, df.index.month)).nth([0, 3, -1])

Out[105]:
   a  b
2014 4 1 1
   4 1 1
   4 1 1
   5 1 1
   5 1 1
   5 1 1
   6 1 1
   6 1 1
   6 1 1

• Period and PeriodIndex supports addition/subtraction with timedelta-likes (GH7966)

  If Period freq is D, H, T, S, L, U, N, Timedelta-like can be added if the result can have same freq. Otherwise, only the same offsets can be added.

In [106]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')

In [107]: idx
Out[107]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
             '2014-07-01 12:00', '2014-07-01 13:00'],
            dtype='period[H]', freq='H')

In [108]: idx + pd.offsets.Hour(2)

Out[108]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
             '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [109]: idx + Timedelta('120m')

Out[109]:
PeriodIndex(['2014-07-01 11:00', '2014-07-01 12:00', '2014-07-01 13:00',
             '2014-07-01 14:00', '2014-07-01 15:00'],
            dtype='period[H]', freq='H')

In [110]: idx = pd.period_range('2014-07', periods=5, freq='M')

In [111]: idx
Out[111]:
            dtype='period[M]', freq='M')

In [112]: idx + pd.offsets.MonthEnd(3)

Out[112]:
            dtype='period[M]', freq='M')

• Added experimental compatibility with openpyxl for versions >= 2.0. The DataFrame.to_excel method engine keyword now recognizes openpyxl1 and openpyxl2 which will explicitly require openpyxl v1 and v2 respectively, failing if the requested version is not available. The openpyxl engine is a now a meta-engine that automatically uses whichever version of openpyxl is installed. (GH7177)
- DataFrame.fillna can now accept a DataFrame as a fill value (GH8377)
- Passing multiple levels to stack() will now work when multiple level numbers are passed (GH7660). See Reshaping by stacking and unstacking.
- set_names(), set_labels(), and set_levels() methods now take an optional level keyword argument to all modification of specific level(s) of a MultiIndex. Additionally set_names() now accepts a scalar string value when operating on an Index or on a specific level of a MultiIndex (GH7792)

```
In [113]: idx = MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [114]: idx.set_names('qux', level=0)
Out[114]:
MultiIndex(levels=[['a'], [0, 1], ['p', 'q', 'r']],
labels=[[0, 0, 0, 0, 0, 0, 0, 0, 0], [0, 0, 0, 1, 1, 1, 2, 2, 2], [0, 0, 0, 1, 1, 1, 2, 2, 2]],
names=['qux', 'bar', 'baz'])

In [115]: idx.set_names(['qux','corge'], level=[0,1])

In [116]: idx.set_levels(['a','b','c'], level='bar')

In [117]: idx.set_levels([[0, 1], [0, 1, 2], [1, 2, 3]], level=[1,2])

```
- Index.isin now supports a level argument to specify which index level to use for membership tests (GH7892, GH7890)

```
In [1]: idx = MultiIndex.from_product([[0, 1], ['a', 'b', 'c']])

In [2]: idx.values
Out[2]:
array(
[(0, 'a'), (0, 'b'), (0, 'c'), (1, 'a'), (1, 'b'), (1, 'c')],
dtype=object)

In [3]: idx.isin(['a', 'c', 'e'], level=1)
Out[3]:
array([ True, False, True, True, False, True], dtype=bool)

```
- Index now supports duplicated and drop_duplicates. (GH4060)

```
In [118]: idx = Index([1, 2, 3, 4, 1, 2])

(continues on next page)
In [119]: idx
Out[119]: Int64Index([1, 2, 3, 4, 1, 2], dtype='int64')

In [120]: idx.duplicated()
Out[120]: array([False, False, False, True, True], dtype=bool)

In [121]: idx.drop_duplicates()
Out[121]: Int64Index([1, 2, 3, 4], dtype='int64')

- add copy=True argument to pd.concat to enable pass thru of complete blocks (GH8252)
- Added support for numpy 1.8+ data types (bool_, int_, float_, string_) for conversion to R dataframe (GH8400)

1.20.4 Performance

- Performance improvements in DatetimeIndex.__iter__ to allow faster iteration (GH7683)
- Performance improvements in Period creation (and PeriodIndex setitem) (GH5155)
- Improvements in Series.transform for significant performance gains (revised) (GH6496)
- Performance improvements in StataReader when reading large files (GH8040, GH8073)
- Performance improvements in StataWriter when writing large files (GH8079)
- Performance and memory usage improvements in multi-key groupby (GH8128)
- Performance improvements in groupby .agg and .apply where builtins max/min were not mapped to numpy/cythonized versions (GH7722)
- Performance improvement in writing to sql (to_sql) of up to 50% (GH8208).
- Performance benchmarking of groupby for large value of ngroups (GH6787)
- Performance improvement in CustomBusinessDay,CustomBusinessMonth (GH8236)
- Performance improvement for MultiIndex.values for multi-level indexes containing datetimes (GH8543)

1.20.5 Bug Fixes

- Bug in pivot_table, when using margins and a dict aggfunc (GH8349)
- Bug in read_csv where squeeze=True would return a view (GH8217)
- Bug in checking of table name in read_sql in certain cases (GH7826).
- Bug in DataFrame.groupby where Grouper does not recognize level when frequency is specified (GH7885)
- Bug in multiindexes dtypes getting mixed up when DataFrame is saved to SQL table (GH8021)
- Bug in Series 0-division with a float and integer operand dtypes (GH7785)
- Bug in Series.astype("unicode") not calling unicode on the values correctly (GH7758)
- Bug in DataFrame.as_matrix() with mixed datetime64[ns] and timedelta64[ns] dtypes (GH7778)
• Bug in HDFStore.select_column() not preserving UTC timezone info when selecting a DatetimeIndex (GH7777)
• Bug in to_datetime when format='%Y%m%d' and coerce=True are specified, where previously an object array was returned (rather than a coerced time-series with NaT), (GH7930)
• Bug in DatetimeIndex and PeriodIndex in-place addition and subtraction cause different result from normal one (GH6527)
• Bug in adding and subtracting PeriodIndex with PeriodIndex raise TypeError (GH7741)
• Bug in combine_first with PeriodIndex data raises TypeError (GH3367)
• Bug in multi-index slicing with missing indexers (GH7866)
• Bug in multi-index slicing with various edge cases (GH8132)
• Regression in multi-index indexing with a non-scalar type object (GH7914)
• Bug in Timestamp comparisons with == and int64 dtype (GH8058)
• Bug in pickles contains DateOffset may raise AttributeError when normalize attribute is referred internally (GH7748)
• Bug in Panel when using major_xs and copy=False is passed (deprecation warning fails because of missing warnings)(GH8152).
• Bug in pickle deserialization that failed for pre-0.14.1 containers with dup items trying to avoid ambiguity when matching block and manager items, when there’s only one block there’s no ambiguity (GH7794)
• Bug in putting a PeriodIndex into a Series would convert to int64 dtype, rather than object of Periods (GH7932)
• Bug in HDFStore iteration when passing a where (GH8014)
• Bug in DataFrameGroupby.transform when transforming with a passed non-sorted key (GH8046, GH8430)
• Bug in repeated timeseries line and area plot may result in ValueError or incorrect kind (GH7733)
• Bug in inference in a MultiIndex with datetime.date inputs (GH7888)
• Bug in get where an IndexError would not cause the default value to be returned (GH7725)
• Bug in offsets.apply, rollforward and rollback may reset nanosecond (GH7697)
• Bug in offsets.apply, rollforward and rollback may raise AttributeError if Timestamp has dateutil tzinfo (GH7697)
• Bug in sorting a multi-index frame with a Float64Index (GH8017)
• Bug in inconsistent panel setitem with a rhs of a DataFrame for alignment (GH7763)
• Bug in is_superperiod and is_subperiod cannot handle higher frequencies than S (GH7760, GH7772, GH7803)
• Bug in 32-bit platforms with Series.shift (GH8129)
• Bug in PeriodIndex.unique returns int64 np.ndarray (GH7540)
• Bug in groupby.apply with a non-affecting mutation in the function (GH8467)
• Bug in DataFrame.reset_index which has MultiIndex contains PeriodIndex or DatetimeIndex with tz raises ValueError (GH7746, GH7793)
• Bug in DataFrame.plot with subplots=True may draw unnecessary minor xticks and yticks (GH7801)
- Bug in StataReader which did not read variable labels in 117 files due to difference between Stata documentation and implementation (GH7816)
- Bug in StataReader where strings were always converted to 244 characters-fixed width irrespective of underlying string size (GH7858)
- Bug in DataFrame.plot and Series.plot may ignore rot and fontsize keywords (GH7844)
- Bug in DateTimeIndex.value_counts doesn’t preserve tz (GH7735)
- Bug in PeriodIndex.value_counts results in Int64Index (GH7735)
- Bug in DataFrame.join when doing left join on index and there are multiple matches (GH5391)
- Bug in GroupBy.transform() where int groups with a transform that didn’t preserve the index were incorrectly truncated (GH7972).
- Bug in groupby where callable objects without name attributes would take the wrong path, and produce a DataFrame instead of a Series (GH7929)
- Bug in groupby error message when a DataFrame grouping column is duplicated (GH7511)
- Bug in read_html where the infer_types argument forced coercion of date-likes incorrectly (GH7762, GH7032).
- Bug in Series.str.cat with an index which was filtered as to not include the first item (GH7857)
- Bug in Timestamp cannot parse nanosecond from string (GH7878)
- Bug in Timestamp with string offset and tz results incorrect (GH7833)
- Bug in tslib.tz_convert and tslib.tz_convert_single may return different results (GH7798)
- Bug in DatetimeIndex.intersection of non-overlapping timestamps with tz raises IndexError (GH7880)
- Bug in alignment with TimeOps and non-unique indexes (GH8363)
- Bug in GroupBy.filter() where fast path vs. slow path made the filter return a non scalar value that appeared valid but wasn’t (GH7870).
- Bug in date_range() / DatetimeIndex() when the timezone was inferred from input dates yet incorrect times were returned when crossing DST boundaries (GH7835, GH7901).
- Bug in to_excel() where a negative sign was being prepended to positive infinity and was absent for negative infinity (GH7949)
- Bug in area plot draws legend with incorrect alpha when stacked=True (GH8027)
- Period and PeriodIndex addition/subtraction with np.timedelta64 results in incorrect internal representations (GH7740)
- Bug in Holiday with no offset or observance (GH7987)
- Bug in DataFrame.to_latex formatting when columns or index is a MultiIndex (GH7982).
- Bug in DateOffset around Daylight Savings Time produces unexpected results (GH5175).
- Bug in DataFrame.shift where empty columns would throw ZeroDivisionError on numpy 1.7 (GH8019)
- Bug in installation where html_encoding/*.html wasn’t installed and therefore some tests were not running correctly (GH7927).
- Bug in read_html where bytes objects were not tested for in _read (GH7927).
- Bug in DataFrame.stack() when one of the column levels was a datelike (GH8039)
• Bug in broadcasting numpy scalars with DataFrame (GH8116)
• Bug in pivot_table performed with nameless index and columns raises KeyError (GH8103)
• Bug in DataFrame.plot(kind='scatter') draws points and errorbars with different colors when the color is specified by c keyword (GH8081)
• Bug in Float64Index where iat and at were not testing and were failing (GH8092).
• Bug in DataFrame.boxplot() where y-limits were not set correctly when producing multiple axes (GH7528, GH5517).
• Bug in read_csv where line comments were not handled correctly given a custom line terminator or delim_whitespace=True (GH8122).
• Bug in read_html where empty tables caused a StopIteration (GH7575)
• Bug in casting when setting a column in a same-dtype block (GH7704)
• Bug in accessing groups from a GroupBy when the original grouper was a tuple (GH8121).
• Bug in .at that would accept integer indexers on a non-integer index and do fallback (GH7814)
• Bug with kde plot and NaNs (GH8182)
• Bug in GroupBy.count with float32 data type were nan values were not excluded (GH8169).
• Bug with stacked barplots and NaNs (GH8175).
• Bug in resample with non evenly divisible offsets (e.g. ‘7s’) (GH8371)
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug with DatetimeIndex.asof incorrectly matching partial strings and returning the wrong date (GH8245).
• Bug in plotting methods modifying the global matplotlib rcParams (GH8242).
• Bug in DataFrame.__setitem__ that caused errors when setting a dataframe column to a sparse array (GH8131)
• Bug where DataFrame.boxplot() failed when entire column was empty (GH8181).
• Bug with messed variables in radviz visualization (GH8199).
• Bug in interpolation methods with the limit keyword when no values needed interpolating (GH7173).
• Bug where col_space was ignored in DataFrame.to_string() when header=False (GH8230).
• Bug in to_clipboard that would clip long column data (GH8305)
• Bug in DataFrame terminal display: Setting max_column/max_rows to zero did not trigger auto-resizing of dfs to fit terminal width/height (GH7180).
• Bug in OLS where running with “cluster” and “nw_lags” parameters did not work correctly, but also did not throw an error (GH5884).
• Bug in DataFrame.dropna that interpreted non-existent columns in the subset argument as the ‘last column’ (GH8303)
• Bug in Index.intersection on non-monotonic non-unique indexes (GH8362).
• Bug in masked series assignment where mismatching types would break alignment (GH8387)
• Bug in NDFrame.equals gives false negatives with dtype=object (GH8437)
• Bug in assignment with indexer where type diversity would break alignment (GH8258)
• Bug in `NDFrame.loc` indexing when row/column names were lost when target was a list/ndarray (GH6552)
• Regression in `NDFrame.loc` indexing when rows/columns were converted to Float64Index if target was an empty list/ndarray (GH7774)
• Bug in `Series` that allows it to be indexed by a `DataFrame` which has unexpected results. Such indexing is no longer permitted (GH8444)
• Bug in item assignment of a `DataFrame` with multi-index columns where right-hand-side columns were not aligned (GH7655)
• Suppress FutureWarning generated by NumPy when comparing object arrays containing NaN for equality (GH7065)
• Bug in `DataFrame.eval()` where the dtype of the `not` operator (~) was not correctly inferred as `bool`.

1.21 v0.14.1 (July 11, 2014)

This is a minor release from 0.14.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

• Highlights include:
  – New methods `select_dtypes()` to select columns based on the dtype and `sem()` to calculate the standard error of the mean.
  – Support for dateutil timezones (see docs).
  – Support for ignoring full line comments in the `read_csv()` text parser.
  – New documentation section on `Options and Settings`.
  – Lots of bug fixes.

• Enhancements
• API Changes
• Performance Improvements
• Experimental Changes
• Bug Fixes

1.21.1 API changes

• Openpyxl now raises a ValueError on construction of the openpyxl writer instead of warning on pandas import (GH7284).
• For `StringMethods.extract`, when no match is found, the result - only containing NaN values - now also has `dtype=object` instead of `float` (GH7242)
• `Period` objects no longer raise a `TypeError` when compared using `==` with another object that isn’t a `Period`. Instead when comparing a `Period` with another object using `==` if the other object isn’t a `Period False` is returned. (GH7376)
• Previously, the behaviour on resetting the time or not in offsets.apply, rollforward and rollback operations differed between offsets. With the support of the normalize keyword for all offsets(see below) with a default value of False (preserve time), the behaviour changed for certain offsets (BusinessMonthBegin, MonthEnd, BusinessMonthEnd, CustomBusinessMonthEnd, BusinessYearBegin, LastWeekOfMonth, FY5253Quarter, LastWeekOfMonth, Easter):

In [6]: from pandas.tseries import offsets
In [7]: d = pd.Timestamp('2014-01-01 09:00')
# old behaviour < 0.14.1
In [8]: d + offsets.MonthEnd()
Out[8]: Timestamp('2014-01-31 00:00:00')

Starting from 0.14.1 all offsets preserve time by default. The old behaviour can be obtained with normalize=True

# new behaviour
In [1]: d + offsets.MonthEnd()
Out[1]: Timestamp('2014-01-31 09:00:00')
In [2]: d + offsets.MonthEnd(normalize=True)

Note that for the other offsets the default behaviour did not change.
• Add back #N/A N/A as a default NA value in text parsing, (regression from 0.12) (GH5521)
• Raise a TypeError on inplace-setting with a .where and a non np.nan value as this is inconsistent with a set-item expression like df[mask] = None (GH7656)

1.21.2 Enhancements

• Add dropna argument to value_counts and nunique (GH5569).
• Add select_dtypes() method to allow selection of columns based on dtype (GH7316). See the docs.
• All offsets supports the normalize keyword to specify whether offsets.apply, rollforward and rollback resets the time (hour, minute, etc) or not (default False, preserves time) (GH7156):

In [3]: import pandas.tseries.offsets as offsets
In [4]: day = offsets.Day()
In [5]: day.apply(Timestamp('2014-01-01 09:00'))
Out[5]: Timestamp('2014-01-02 09:00:00')
In [6]: day = offsets.Day(normalize=True)
In [7]: day.apply(Timestamp('2014-01-01 09:00'))

• PeriodIndex is represented as the same format as DatetimeIndex (GH7601)
• StringMethods now work on empty Series (GH7242)
• The file parsers read_csv and read_table now ignore line comments provided by the parameter comment, which accepts only a single character for the C reader. In particular, they allow for comments before file data begins (GH2685)
• Add `NotImplementedError` for simultaneous use of `chunksize` and `nrows` for `read_csv()` (GH6774).
• Tests for basic reading of public S3 buckets now exist (GH7281).
• `read_html` now sports an `encoding` argument that is passed to the underlying parser library. You can use this to read non-ascii encoded web pages (GH7323).
• `read_excel` now supports reading from URLs in the same way that `read_csv` does. (GH6809)
• Support for dateutil timezones, which can now be used in the same way as pytz timezones across pandas. (GH4688)

```python
In [8]: rng = date_range('3/6/2012 00:00', periods=10, freq='D', tz='dateutil/Europe/London')
...:
...

In [9]: rng.tz
Out[9]: tzfile('/usr/share/zoneinfo/Europe/London')
```

See the docs.
• Implemented `sem` (standard error of the mean) operation for `Series`, `DataFrame`, `Panel`, and `Groupby` (GH6897)
• Add `nlargest` and `nsmallest` to the `Series` groupby whitelist, which means you can now use these methods on a `SeriesGroupBy` object (GH7053).
• All offsets `apply`, `rollforward` and `rollback` can now handle `np.datetime64`, previously results in `ApplyTypeError` (GH7452)
• `Period` and `PeriodIndex` can contain `NaT` in its values (GH7485)
• Support pickling `Series`, `DataFrame` and `Panel` objects with non-unique labels along `item` axis (index, columns and items respectively) (GH7370).
• Improved inference of datetime/timedelta with mixed null objects. Regression from 0.13.1 in interpretation of an object Index with all null elements (GH7431)

1.21.3 Performance

• Improvements in dtype inference for numeric operations involving yielding performance gains for dtypes: `int64`, `timedelta64`, `datetime64` (GH7223)
• Improvements in `Series.transform` for significant performance gains (GH6496)
• Improvements in `DataFrame.transform` with ufuncs and built-in grouper functions for significant performance gains (GH7383)
• Regression in `groupby` aggregation of `datetime64` dtypes (GH7555)
• Improvements in `MultiIndex.from_product` for large iterables (GH7627)

1.21.4 Experimental

• `pandas.io.data.Options` has a new method, `get_all_data` method, and now consistently returns a multi-indexed `DataFrame` (GH5602)
• `io.gbq.read_gbq` and `io.gbq.to_gbq` were refactored to remove the dependency on the Google `bq.py` command line client. This submodule now uses `httplib2` and the Google `apiclient` and `oauth2client` API client libraries which should be more stable and, therefore, reliable than `bq.py`. See the docs. (GH6937).
1.21.5 Bug Fixes

- Bug in `DataFrame.where` with a symmetric shaped frame and a passed other of a DataFrame (GH7506)
- Bug in `Panel` indexing with a multi-index axis (GH7516)
- Regression in datetimelike slice indexing with a duplicated index and non-exact end-points (GH7523)
- Bug in `setitem` with list-of-lists and single vs mixed types (GH7551)
- Bug in `timeops` with non-aligned Series (GH7500)
- Bug in `timedelta` inference when assigning an incomplete Series (GH7592)
- Bug in `groupby .nth` with a Series and integer-like column name (GH7559)
- Bug in `Series.get` with a boolean accessor (GH7407)
- Bug in `value_counts` where `NaT` did not qualify as missing (NaN) (GH7423)
- Bug in `to_timedelta` that accepted invalid units and misinterpreted ‘m/h’ (GH7611, GH6423)
- Bug in line plot doesn’t set correct xlim if `secondary_y=True` (GH7459)
- Bug in grouped `hist` and `scatter` plots use old `figsize` default (GH7394)
- Bug in plotting subplots with `DataFrame.plot`, `hist` clears passed `ax` even if the number of subplots is one (GH7391).
- Bug in plotting subplots with `DataFrame.boxplot` with `by kw` raises `ValueError` if the number of subplots exceeds 1 (GH7391).
- Bug in subplots displays `ticklabels` and `labels` in different rule (GH5897)
- Bug in `Panel.apply` with a multi-index as an axis (GH7469)
- Bug in `DatetimeIndex.insert` doesn’t preserve name and tz (GH7299)
- Bug in `DatetimeIndex.asobject` doesn’t preserve name (GH7299)
- Bug in multi-index slicing with datetimelike ranges (strings and Timestamps), (GH7429)
- Bug in `Index.min` and `max` doesn’t handle `nan` and `NaT` properly (GH7261)
- Bug in `PeriodIndex.min/max results in int` (GH7609)
- Bug in `resample` where `fill_method` was ignored if you passed `how` (GH2073)
- Bug in `TimeGrouper` doesn’t exclude column specified by key (GH7227)
- Bug in `DataFrame` and `Series` `bar` and `barh` plot raises `TypeError` when `bottom` and `left` keyword is specified (GH7226)
- Bug in `DataFrame.hist` raises `TypeError` when it contains non numeric column (GH7277)
- Bug in `Index.delete` does not preserve name and `freq` attributes (GH7302)
- Bug in `DataFrame.query()`/`eval` where local string variables with the @ sign were being treated as temporaries attempting to be deleted (GH7300).
- Bug in `Float64Index` which didn’t allow duplicates (GH149).
- Bug in `DataFrame.replace()` where truthy values were being replaced (GH7140).
- Bug in `StringMethods.extract()` where a single match group Series would use the matcher’s name instead of the group name (GH7313).
- Bug in `isnull()` when `mode.use_inf_as_null == True` where `isnull` wouldn’t test `True` when it encountered an `inf/-inf` (GH7315).
• Bug in inferred_freq results in None for eastern hemisphere timezones (GH7310)
• Bug in Easter returns incorrect date when offset is negative (GH7195)
• Bug in broadcasting with .div, integer dtypes and divide-by-zero (GH7325)
• Bug in CustomBusinessDay.apply raises NameError when np.datetime64 object is passed (GH7196)
• Bug in MultiIndex.append, concat and pivot_table don’t preserve timezone (GH6606)
• Bug in .loc with a list of indexers on a single-multi index level (that is not nested) (GH7349)
• Bug in Series.map when mapping a dict with tuple keys of different lengths (GH7333)
• Bug all StringMethods now work on empty Series (GH7242)
• Fix delegation of read_sql to read_sql_query when query does not contain ‘select’ (GH7324).
• Bug where a string column name assignment to a DataFrame with a Float64Index raised a TypeError during a call to np.isnan (GH7366).
• Bug where NDFrame.replace() didn’t correctly replace objects with Period values (GH7379).
• Bug in .ix getitem should always return a Series (GH7150)
• Bug in multi-index slicing with incomplete indexers (GH7399)
• Bug in multi-index slicing with a step in a sliced level (GH7400)
• Bug where negative indexers in DatetimeIndex were not correctly sliced (GH7408)
• Bug where NaT wasn’t repr’d correctly in a MultiIndex (GH7406, GH7409).
• Bug where bool objects were converted to nan in convert_objects (GH7416).
• Bug in quantile ignoring the axis keyword argument (issue7306)
• Bug where nanops._maybe_null_out doesn’t work with complex numbers (GH7353)
• Bug in several nanops functions when axis==0 for 1-dimensional nan arrays (GH7354)
• Bug where nanops.nanmedian doesn’t work when axis==None (GH7352)
• Bug where nanops._has_infs doesn’t work with many dtypes (GH7357)
• Bug in StataReader.data where reading a 0-observation dta failed (GH7369)
• Bug in StataReader when reading Stata 13 (117) files containing fixed width strings (GH7360)
• Bug in StataWriter where encoding was ignored (GH7286)
• Bug in DatetimeIndex comparison doesn’t handle NaT properly (GH7529)
• Bug in passing input with tzinfo to some offsets apply, rollforward or rollback resets tzinfo or raises ValueError (GH7465)
• Bug in DatetimeIndex.to_period, PeriodIndex.asobject, PeriodIndex.to_timestamp doesn’t preserve name (GH7485)
• Bug in DatetimeIndex.to_period and PeriodIndex.to_timestamp handle NaT incorrectly (GH7228)
• Bug in offsets.apply, rollforward and rollback may return normal datetime (GH7502)
• Bug in resample raises ValueError when target contains NaT (GH7227)
• Bug in Timestamp.tz_localize resets nanosecond info (GH7534)
• Bug in DatetimeIndex.asobject raises ValueError when it contains NaT (GH7539)
• Bug in Timestamp.__new__ doesn’t preserve nanosecond properly (GH7610)
• Bug in Index.astype(float) where it would return an object dtype Index (GH7464).
• Bug in DataFrame.reset_index loses tz (GH3950)
• Bug in DatetimeIndex.freqstr raises AttributeError when freq is None (GH7606)
• Bug in GroupBy.size created by TimeGrouper raises AttributeError (GH7453)
• Bug in single column bar plot is misaligned (GH7498).
• Bug in area plot with tz-aware time series raises ValueError (GH7471)
• Bug in non-monotonic Index.union may preserve name incorrectly (GH7458)
• Bug in DatetimeIndex.intersection doesn’t preserve timezone (GH4690)
• Bug in rolling_var where a window larger than the array would raise an error(GH7297)
• Bug with last plotted timeseries dictating xlim (GH2960)
• Bug with secondary_y axis not being considered for timeseries xlim (GH3490)
• Bug in Float64Index assignment with a non scalar indexer (GH7586)
• Bug in pandas.core.strings.str_contains does not properly match in a case insensitive fashion when regex=False and case=False (GH7505)
• Bug in expanding_cov, expanding_corr, rolling_cov, and rolling_corr for two arguments with mismatched index (GH7512)
• Bug in to_sql taking the boolean column as text column (GH7678)
• Bug in grouped hist doesn’t handle rot kw and sharex kw properly (GH7234)
• Bug in .loc performing fallback integer indexing with object dtype indices (GH7496)
• Bug (regression) in PeriodIndex constructor when passed Series objects (GH7701).

1.22 v0.14.0 (May 31, 2014)

This is a major release from 0.13.1 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

• Highlights include:
  – Officially support Python 3.4
  – SQL interfaces updated to use sqlalchemy, See Here.
  – Display interface changes, See Here
  – MultiIndexing Using Slicers, See Here.
  – Ability to join a singly-indexed DataFrame with a multi-indexed DataFrame, see Here
  – More consistency in groupby results and more flexible groupby specifications, See Here
  – Holiday calendars are now supported in CustomBusinessDay, see Here
  – Several improvements in plotting functions, including: hexbin, area and pie plots, see Here.
  – Performance doc section on I/O operations, See Here

• Other Enhancements
Warning: In 0.14.0 all NDFrame based containers have undergone significant internal refactoring. Before that each block of homogeneous data had its own labels and extra care was necessary to keep those in sync with the parent container’s labels. This should not have any visible user/API behavior changes (GH6745)

1.22.1 API changes

- read_excel uses 0 as the default sheet (GH6573)

- iloc will now accept out-of-bounds indexers for slices, e.g. a value that exceeds the length of the object being indexed. These will be excluded. This will make pandas conform more with python/numpy indexing of out-of-bounds values. A single indexer that is out-of-bounds and drops the dimensions of the object will still raise IndexError (GH6296, GH6299). This could result in an empty axis (e.g. an empty DataFrame being returned)

```python
In [1]: dfl = DataFrame(np.random.randn(5,2),columns=list('AB'))

In [2]: dfl
Out[2]:
       A    B
0  1.583584 -0.438313
1 -0.402537 -0.780572
2 -0.141685  0.542241
3  0.370966 -0.251642
4  0.787484  1.666563

In [3]: dfl.iloc[:,2:3]
Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [4]: dfl.iloc[:,1:3]
       B
0  -0.438313
1  -0.780572
2   0.542241
3  -0.251642
4   1.666563
```
In [5]: df1.iloc[4:6]

\[\begin{array}{cc}
A & B \\
4 & 0.787484 & 1.666563 \\
\end{array}\]

These are out-of-bounds selections

```python
df1.iloc[[4, 5, 6]]
IndexError: positional indexers are out-of-bounds
```

```python
df1.iloc[:, 4]
IndexError: single positional indexer is out-of-bounds
```

- Slicing with negative start, stop & step values manages corner cases better (GH6531):
  - df.iloc[:~len(df)] now empty
  - df.iloc[len(df)::-1] now enumerates all elements in reverse

- The DataFrame.interpolate() keyword downcast default has been changed from infer to None. This is to preserve the original dtype unless explicitly requested otherwise (GH6290).

- When converting a data frame to HTML it used to return `Empty DataFrame`. This special case has been removed, instead a header with the column names is returned (GH6062).

- Series and Index now internall share more common operations, e.g. `factorize()`, `nunique()`, `value_counts()` are now supported on Index types as well. The Series.weekday property from is removed from Series for API consistency. Using a `DateTimeIndex/PeriodIndex` method on a Series will now raise a `TypeError`. (GH4551, GH4056, GH5519, GH6380, GH7206).

- Add `is_month_start`, `is_month_end`, `is_quarter_start`, `is_quarter_end`, `is_year_start`, `is_year_end` accessors for `DateTimeIndex / Timestamp` which return a boolean array of whether the timestamp(s) are at the start/end of the month/quarter/year defined by the frequency of the `DateTimeIndex / Timestamp` (GH4565, GH6998).

- Local variable usage has changed in `pandas.eval()` / `DataFrame.eval()` / `DataFrame.query()` (GH5987). For the `DataFrame` methods, two things have changed
  - Column names are now given precedence over locals
  - Local variables must be referred to explicitly. This means that even if you have a local variable that is not a column you must still refer to it with the '@' prefix.
  - You can have an expression like `df.query('@a < a')` with no complaints from `pandas` about ambiguity of the name a.
  - The top-level `pandas.eval()` function does not allow you use the '@' prefix and provides you with an error message telling you so.
  - `NameResolutionError` was removed because it isn’t necessary anymore.

- Define and document the order of column vs index names in query/eval (GH6676)

- `concat` will now concatenate mixed Series and DataFrames using the Series name or numbering columns as needed (GH2385). See the docs

- Slicing and advanced/boolean indexing operations on Index classes as well as `Index.delete()` and `index.drop()` methods will no longer change the type of the resulting index (GH6440, GH7040)
In [6]: i = pd.Index([1, 2, 3, 'a', 'b', 'c'])
In [7]: i[[0,1,2]]
Out[7]: Index([1, 2, 3], dtype='object')
In [8]: i.drop(['a', 'b', 'c'])
Out[8]: Index([1, 2, 3], dtype='object')

Previously, the above operation would return Int64Index. If you’d like to do this manually, use Index.astype()

In [9]: i[[0,1,2]].astype(np.int_)
Out[9]: Int64Index([1, 2, 3], dtype='int64')

• set_index no longer converts MultiIndexes to an Index of tuples. For example, the old behavior returned an Index in this case (GH6459):

# Old behavior, casted MultiIndex to an Index
In [10]: tuple_ind
Out[10]: Index([('a', 'c'), ('a', 'd'), ('b', 'c'), ('b', 'd')], dtype='object')
In [11]: df_multi.set_index(tuple_ind)
Out[11]:
                           0     1
(a, c) 0.471435 -1.190976
(a, d) 1.432707 -0.312652
(b, c) -0.720589  0.887163
(b, d)  0.859588 -0.636524

# New behavior
In [12]: mi
Out[12]: MultiIndex(levels=[['a', 'b'], ['c', 'd']],
labels=[[0, 0, 1, 1], [0, 1, 0, 1]])
In [13]: df_multi.set_index(mi)
Out[13]:
                           0     1
 a c  0.471435 -1.190976
d   1.432707 -0.312652
b c -0.720589  0.887163
d   0.859588 -0.636524

This also applies when passing multiple indices to set_index:

# Old output, 2-level MultiIndex of tuples
In [14]: df_multi.set_index([df_multi.index, df_multi.index])
Out[14]:
             0     1
(a, c) (a, c) 0.471435 -1.190976
(a, d) (a, d) 1.432707 -0.312652
(b, c) (b, c) -0.720589  0.887163
(b, d) (b, d)  0.859588 -0.636524

(continues on next page)
```python
In [15]: df_multi.set_index([df_multi.index, df_multi.index])
Out[15]:
       0   1
a  c     a   c  0.471435 -1.190976
   d     a   d  1.432707 -0.312652
b  c     b   c -0.720589  0.887163
d  b     d   b  0.859588 -0.636524

• pairwise keyword was added to the statistical moment functions rolling_cov, rolling_corr,
evwcov, ewmcorr, expanding_cov, expanding_corr to allow the calculation of moving window
covariance and correlation matrices (GH4950). See Computing rolling pairwise covariances and correlations
in the docs.
```

```python
In [1]: df = DataFrame(np.random.randn(10,4),columns=list('ABCD'))
In [4]: covs = pd.rolling_cov(df[['A','B','C']], df[['B','C','D']], 5,
   pairwise=True)
In [5]: covs[df.index[-1]]
Out[5]:
       B     C     D
A  0.035310  0.326593 -0.505430
B  0.137748 -0.006888 -0.005383
C -0.006888  0.861040  0.020762
```

• Series.iteritems() is now lazy (returns an iterator rather than a list). This was the documented behavior
prior to 0.14. (GH6760)

• Added nunique and value_counts functions to Index for counting unique elements. (GH6734)

• stack and unstack now raise a ValueError when the level keyword refers to a non-unique item in the
Index (previously raised a KeyError). (GH6738)

• drop unused order argument from Series.sort; args now are in the same order as Series.order; add
na_position arg to conform to Series.order (GH6847)

• default sorting algorithm for Series.order is now quicksort, to conform with Series.sort (and
numpy defaults)

• add inplace keyword to Series.order/sort to make them inverses (GH6859)

• DataFrame.sort now places NaNs at the beginning or end of the sort according to the na_position
parameter. (GH3917)

• accept TextFileReader in concat, which was affecting a common user idiom (GH6583), this was a
regression from 0.13.1

• Added factorize functions to Index and Series to get indexer and unique values (GH7090)

• describe on a DataFrame with a mix of Timestamp and string like objects returns a different Index (GH7088).
Previously the index was unintentionally sorted.

• Arithmetic operations with only bool dtypes now give a warning indicating that they are evaluated in Python
space for +, -, and * operations and raise for all others (GH7011, GH6762, GH7015, GH7210)
x / y  # this raises because it doesn't make sense

NotImplementedError: operator '/' not implemented for bool dtypes

- In HDFStore, `select_as_multiple` will always raise a KeyError, when a key or the selector is not found (GH6177)
- `df['col'] = value` and `df.loc[:, 'col'] = value` are now completely equivalent; previously the `.loc` would not necessarily coerce the dtype of the resultant series (GH6149)
- `dtypes` and `ftypes` now return a series with `dtype=object` on empty containers (GH5740)
- `df.to_csv` will now return a string of the CSV data if neither a target path nor a buffer is provided (GH6061)
- `pd.infer_freq()` will now raise a `TypeError` if given an invalid `Series/Index` type (GH6407, GH6463)
- A tuple passed to DataFrame.sort_index will be interpreted as the levels of the index, rather than requiring a list of tuple (GH4370)
- All offset operations now return `Timestamp` types (rather than `datetime`), Business/Week frequencies were incorrect (GH4069)
- `to_excel` now converts `np.inf` into a string representation, customizable by the `inf_rep` keyword argument (Excel has no native `inf` representation) (GH6782)
- Replace `pandas.compat.scipy.scoreatpercentile` with `numpy.percentile` (GH6810)
- `.quantile` on a `datetime[ns]` series now returns `Timestamp` instead of `np.datetime64` objects (GH6810)
- `AssertionError` to `TypeError` for invalid types passed to `concat` (GH6583)
- Raise a `TypeError` when `DataFrame` is passed an iterator as the `data` argument (GH5357)

### 1.22.2 Display Changes

- The default way of printing large DataFrames has changed. DataFrames exceeding `max_rows` and/or `max_columns` are now displayed in a centrally truncated view, consistent with the printing of a `pandas.Series` (GH5603).

In previous versions, a DataFrame was truncated once the dimension constraints were reached and an ellipse (...) signaled that part of the data was cut off.
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: pd.options.display.max_rows = 6
In [4]: pd.options.display.max_columns = 6
In [5]: index = pd.DatetimeIndex(start='20010101', freq='D', periods=10)
In [6]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
Out[6]:
                      0  1  2  3  4  5
2001-01-01       0  1  2  3  4  5 ...  
2001-01-02   10  11  12  13  14  15 ...  
2001-01-03    20  21  22  23  24  25 ...  
2001-01-04    30  31  32  33  34  35 ...  
2001-01-05    40  41  42  43  44  45 ...  
2001-01-06    50  51  52  53  54  55 ...  
                        ...  ...
[10 rows x 10 columns]

In the current version, large DataFrames are centrally truncated, showing a preview of head and tail in both dimensions.

In [24]: pd.DataFrame(np.arange(10*10).reshape((10,10)), index=index)
Out[24]:
                      0  1  2 ...  7  8  9
2001-01-01       0  1  2 ...  7  8  9
2001-01-02   10  11  12 ...  17 18 19
2001-01-03    20  21  22 ...  27 28 29
                      ...  ...
2001-01-08    70  71  72 ...  77 78 79
2001-01-09    80  81  82 ...  87 88 89
2001-01-10    90  91  92 ...  97 98 99
[10 rows x 10 columns]

• allow option 'truncate' for display.show_dimensions to only show the dimensions if the frame is truncated (GH6547).

The default for display.show_dimensions will now be truncate. This is consistent with how Series display length.

In [16]: dfd = pd.DataFrame(np.arange(25).reshape(-1,5), index=[0,1,2,3,4],
                         columns=[0,1,2,3,4])
# show dimensions since this is truncated
In [17]: with pd.option_context('display.max_rows', 2, 'display.max_columns', 2,
                           'display.show_dimensions', 'truncate'):
    ...:     print(dfd)
    ...:
    0  1  2  3  4
2001-01-01  0  1  2  3  4
2001-01-02 10 11 12 13 14
2001-01-03 20 21 22 23 24
2001-01-04 30 31 32 33 34
2001-01-05 40 41 42 43 44
2001-01-06 50 51 52 53 54
...  ...
(continues on next page)
• Regression in the display of a MultiIndexed Series with \texttt{display.max_rows} is less than the length of the series (GH7101)

• Fixed a bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the \texttt{large_repr} set to ‘info’ (GH7105)

• The \texttt{verbose} keyword in \texttt{DataFrame.info()}, which controls whether to shorten the info representation, is now \texttt{None} by default. This will follow the global setting in \texttt{display.max_info_columns}. The global setting can be overridden with \texttt{verbose=True} or \texttt{verbose=False}.

• Fixed a bug with the \texttt{info} repr not honoring the \texttt{display.max_info_columns} setting (GH6939)

• Offset/freq info now in Timestamp \texttt{__repr__} (GH4553)

### 1.22.3 Text Parsing API Changes

\texttt{read_csv()}/\texttt{read_table()} will now be noisier w.r.t invalid options rather than falling back to the PythonParser.

• Raise \texttt{ValueError} when \texttt{sep} specified with \texttt{delim_whitespace=True} in \texttt{read_csv()}/\texttt{read_table()} (GH6607)

• Raise \texttt{ValueError} when \texttt{engine='c'} specified with unsupported options in \texttt{read_csv()}/\texttt{read_table()} (GH6607)

• Raise \texttt{ValueError} when fallback to python parser causes options to be ignored (GH6607)

• Produce \texttt{ParserWarning} on fallback to python parser when no options are ignored (GH6607)

• Translate \texttt{sep='\s+'} to \texttt{delim_whitespace=True} in \texttt{read_csv()}/\texttt{read_table()} if no other C-unsupported options specified (GH6607)

### 1.22.4 Groupby API Changes

More consistent behaviour for some groupby methods:

• \texttt{groupby head} and \texttt{tail} now act more like \texttt{filter} rather than an aggregation:
In [19]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])
In [20]: g = df.groupby('A')
In [21]: g.head(1)  # filters DataFrame
Out[21]:
   A  B
0  1  2
2  5  6
In [22]: g.apply(lambda x: x.head(1))  # used to simply fall-through

In [23]: g[['B']].head(1)
Out[23]:
   B
0  2
2  6

• groupby head and tail respect column selection:

• groupby nth now reduces by default; filtering can be achieved by passing as_index=False. With an optional dropna argument to ignore NaN. See the docs.

Reducing

In [24]: df = DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [25]: g = df.groupby('A')
In [26]: g.nth(0)
Out[26]:
   B
0  NaN
2  6.0

# this is equivalent to g.first()
In [27]: g.nth(0, dropna='any')
Out[27]:
   B
0   4.0
2  6.0

# this is equivalent to g.last()
In [28]: g.nth(-1, dropna='any')
Out[28]:
   B
0   4.0
2  6.0
Filtering

In [29]: gf = df.groupby('A', as_index=False)

In [30]: gf.nth(0)
Out[30]:
   A  B
0  1  NaN
2  5  6.0

In [31]: gf.nth(0, dropna='any')

Out[31]:
   A  B
1  1  4.0
5  5  6.0

- groupby will now not return the grouped column for non-cython functions (GH5610, GH5614, GH6732), as its already the index

In [32]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])

In [33]: g = df.groupby('A')

In [34]: g.count()
Out[34]:
   B
A
1  1
5  2

In [35]: g.describe()

Out[35]:
   B
A
1  1.0 4.0 NaN 4.0 4.0 4.0 4.0 4.0
5  2.0 7.0 1.414214 6.0 6.5 7.0 7.5 8.0

- passing as_index will leave the grouped column in-place (this is not change in 0.14.0)

In [36]: df = DataFrame([[1, np.nan], [1, 4], [5, 6], [5, 8]], columns=['A', 'B'])

In [37]: g = df.groupby('A', as_index=False)

In [38]: g.count()
Out[38]:
   A  B
0  1  1
1  5  2

In [39]: g.describe()

Out[39]:
   count mean  std  min  25%  50%  75%  max
A
1  2.0 1.0 0.0 1.0 1.0 1.0 1.0 1.0
5  4.0 4.0 4.0 4.0 4.0

(continues on next page)
1.2.5 SQL

The SQL reading and writing functions now support more database flavors through SQLAlchemy (GH2717, GH4163, GH5950, GH6292). All databases supported by SQLAlchemy can be used, such as PostgreSQL, MySQL, Oracle, Microsoft SQL server (see documentation of SQLAlchemy on included dialects).

The functionality of providing DBAPI connection objects will only be supported for sqlite3 in the future. The 'mysql' flavor is deprecated.

The new functions `read_sql_query()` and `read_sql_table()` are introduced. The function `read_sql()` is kept as a convenience wrapper around the other two and will delegate to specific function depending on the provided input (database table name or sql query).

In practice, you have to provide a SQLAlchemy engine to the sql functions. To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For an in-memory sqlite database:

```
In [40]: from sqlalchemy import create_engine
   # Create your connection.
In [41]: engine = create_engine('sqlite:///:memory:)
```

This engine can then be used to write or read data to/from this database:

```
In [42]: df = pd.DataFrame({'A': [1,2,3], 'B': ['a', 'b', 'c']})
In [43]: df.to_sql('db_table', engine, index=False)
```

You can read data from a database by specifying the table name:

```
In [44]: pd.read_sql_table('db_table', engine)
Out[44]:
   A  B
0  1  a
1  2  b
2  3  c
```

or by specifying a sql query:
Some other enhancements to the sql functions include:

- support for writing the index. This can be controlled with the `index` keyword (default is True).
- specify the column label to use when writing the index with `index_label`.
- specify string columns to parse as datetimes with the `parse_dates` keyword in `read_sql_query()` and `read_sql_table()`.

**Warning:** Some of the existing functions or function aliases have been deprecated and will be removed in future versions. This includes: `tquery`, `uquery`, `read_frame`, `frame_query`, `write_frame`.

**Warning:** The support for the ‘mysql’ flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).

### 1.22.6 MultiIndexing Using Slicers

In 0.14.0 we added a new way to slice multi-indexed objects. You can slice a multi-index by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as `slice(None)`.

As usual, **both sides** of the slicers are included as this is label indexing.

See the docs See also issues (GH6134, GH4036, GH3057, GH2598, GH5641, GH7106)

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the `index` and for the `columns`. Their are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

```
df.loc[{'slice('A1','A3'),....},:]
```

rather than this:

```
df.loc[{'slice('A1','A3'),....}]
```

**Warning:** You will need to make sure that the selection axes are fully lexsorted!
In [46]: def mklbl(prefix,n):
    ....:     return ['%s%s' % (prefix,i) for i in range(n)]
    ....:

In [47]: index = MultiIndex.from_product([mklbl('A',4),
    ....:                                   mklbl('B',2),
    ....:                                   mklbl('C',4),
    ....:                                   mklbl('D',2)])
    ....:

In [48]: columns = MultiIndex.from_tuples([('a','foo'),('a','bar'),
    ....:                                ('b','foo'),('b','bah')],
    ....:                                names=['lvl0', 'lvl1'])
    ....:

In [49]: df = DataFrame(np.arange(len(index)*len(columns)).reshape((len(index),
    ....:                                                     len(columns))),
    ....:                                index=index,
    ....:                                columns=columns).sort_index().sort_index(axis=1)
    ....:

In [50]: df
Out[50]:
lvl0   a   b

C1  D0  233  232  235  234
  D1  237  236  239  238
C2  D0  241  240  243  242
  D1  245  244  247  246
C3  D0  249  248  251  250
  D1  253  252  255  254
[64 rows x 4 columns]

Basic multi-index slicing using slices, lists, and labels.

In [51]: df.loc[(slice('A1','A3'),slice(None), ['C1','C3'],:),:]
Out[51]:
lvl0   a   b
lvl1
A1  B0  C1  D0  73   72   75   74
  D1   77   76   79   78
C3  D0  89   88   91   90
  D1   93   92   95   94
B1  C1  D0  105  104  107  106
  D1  109  108  111  110
C3  D0  121  120  123  122
  ... ... ... ...
A3  B1  C1  D1  229  228  231  230
C1  D0  233  232  235  234
  D1  237  236  239  238
C2  D0  241  240  243  242
  D1  245  244  247  246
C3  D0  249  248  251  250
  D1  253  252  255  254
... ... ... ... ...
(continues on next page)
You can use a `pd.IndexSlice` to shortcut the creation of these slices

```
In [52]: idx = pd.IndexSlice

In [53]: df.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[53]:
   lvl0  a  b
  lvl1 foo foo
   A0  B0  C1  D0  8  10
      D1  12  14
   C3  D0  24  26
      D1  28  30
   B1  C1  D0  40  42
      D1  44  46
   C3  D0  56  58
   ... ... ...
   A3  B0  C1  D1  204  206
   C3  D0  216  218
      D1  220  222
   B1  C1  D0  232  234
      D1  236  238
   C3  D0  248  250
      D1  252  254
```

[32 rows x 2 columns]

It is possible to perform quite complicated selections using this method on multiple axes at the same time.

```
In [54]: df.loc[['A1', (slice(None), 'foo')]]
Out[54]:
   lvl0  a  b
  lvl1 foo foo
   B0  C0  D0  64  66
      D1  68  70
   C1  D0  72  74
      D1  76  78
   C2  D0  80  82
      D1  84  86
   C3  D0  88  90
   ... ... ...
   B1  C0  D1  100  102
   C1  D0  104  106
      D1  108  110
   C2  D0  112  114
      D1  116  118
   C3  D0  120  122
      D1  124  126
```

(continues on next page)
Using a boolean indexer you can provide selection related to the values.

\[
\text{In [56]: mask = df[('a','foo')] > 200}
\]

\[
\text{In [57]: df.loc[idx[mask,:,:,[}'C1','C3']},idx[:,'foo']\}
\]

\[
\text{Out[57]:}
\]

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>8</td>
<td>10</td>
</tr>
<tr>
<td>D1</td>
<td>12</td>
<td>14</td>
</tr>
<tr>
<td>C3</td>
<td>24</td>
<td>26</td>
</tr>
<tr>
<td>D1</td>
<td>28</td>
<td>30</td>
</tr>
<tr>
<td>B1</td>
<td>40</td>
<td>42</td>
</tr>
<tr>
<td>D1</td>
<td>44</td>
<td>46</td>
</tr>
<tr>
<td>C3</td>
<td>56</td>
<td>58</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A3</td>
<td>204</td>
<td>206</td>
</tr>
<tr>
<td>C3</td>
<td>216</td>
<td>218</td>
</tr>
<tr>
<td>D1</td>
<td>220</td>
<td>222</td>
</tr>
<tr>
<td>B1</td>
<td>232</td>
<td>234</td>
</tr>
<tr>
<td>D1</td>
<td>236</td>
<td>238</td>
</tr>
<tr>
<td>C3</td>
<td>248</td>
<td>250</td>
</tr>
<tr>
<td>D1</td>
<td>252</td>
<td>254</td>
</tr>
</tbody>
</table>

You can also specify the axis argument to .loc to interpret the passed slicers on a single axis.

\[
\text{In [58]: df.loc(axis=0)[:,:,[}'C1','C3']}
\]

\[
\text{Out[58]:}
\]

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>A0</td>
<td>9</td>
<td>8</td>
</tr>
<tr>
<td>D1</td>
<td>13</td>
<td>12</td>
</tr>
<tr>
<td>C3</td>
<td>25</td>
<td>24</td>
</tr>
<tr>
<td>D1</td>
<td>29</td>
<td>28</td>
</tr>
<tr>
<td>B1</td>
<td>41</td>
<td>40</td>
</tr>
<tr>
<td>D1</td>
<td>45</td>
<td>44</td>
</tr>
<tr>
<td>C3</td>
<td>57</td>
<td>56</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A3</td>
<td>205</td>
<td>204</td>
</tr>
<tr>
<td>A3</td>
<td>205</td>
<td>204</td>
</tr>
<tr>
<td>A3</td>
<td>205</td>
<td>204</td>
</tr>
<tr>
<td>A3</td>
<td>205</td>
<td>204</td>
</tr>
<tr>
<td>A3</td>
<td>205</td>
<td>204</td>
</tr>
</tbody>
</table>
Furthermore you can set the values using these methods

```python
In [59]: df2 = df.copy()

In [60]: df2.loc(axis=0)[:, :, ['C1', 'C3']] = -10

In [61]: df2
```

```
   a   b
  ---- ----
A0  1   0
  5   4
C0  -10 -10
  -10 -10
D0  17  16
  21  20
C1  241 240
  245 244
D1  241 240
  245 244
C2  -10 -10
  -10 -10
D2  17  16
  21  20
C3  241 240
  245 244
D3  -10 -10
  -10 -10
...   ...   ...
A3  47  46
  51  50
C1  229 228
  233 232
D1  229 228
  233 232
C2  241 240
  245 244
D2  229 228
  233 232
C3  25000 24000
  25500 25400
D3  229 228
  233 232
```

[64 rows x 4 columns]

You can use a right-hand-side of an alignable object as well.

```python
In [62]: df2 = df.copy()

In [63]: df2.loc[idx[:, :, ['C1', 'C3']], :]] = df2*1000

In [64]: df2
```

```
   a   b
  ---- ----
A0  1   0
  5   4
C0  9000 8000
  11000 10000
D0  13000 12000
  15000 14000
C1  17  16
  19  18
D1  21  20
  23  22
C2  25000 24000
  27000 26000
D2  229 228
  233 232

  235000 234000
D3  229 228
  233 232
```

[64 rows x 4 columns]
1.22.7 Plotting

- Hexagonal bin plots from DataFrame.plot with kind='hexbin' (GH5478), See the docs.

- DataFrame.plot and Series.plot now supports area plot with specifying kind='area' (GH6656), See the docs

- Pie plots from Series.plot and DataFrame.plot with kind='pie' (GH6976), See the docs.

- Plotting with Error Bars is now supported in the .plot method of DataFrame and Series objects (GH3796, GH6834), See the docs.

- DataFrame.plot and Series.plot now support a table keyword for plotting matplotlib.Table, See the docs. The table keyword can receive the following values.
  - False: Do nothing (default).
  - True: Draw a table using the DataFrame or Series called plot method. Data will be transposed to meet matplotlib’s default layout.
  - DataFrame or Series: Draw matplotlib.table using the passed data. The data will be drawn as displayed in print method (not transposed automatically). Also, helper function pandas.tools.plotting.table is added to create a table from DataFrame and Series, and add it to an matplotlib.Axes.

- plot(legend='reverse') will now reverse the order of legend labels for most plot kinds. (GH6014)

- Line plot and area plot can be stacked by stacked=True (GH6656)

- Following keywords are now acceptable for DataFrame.plot() with kind='bar' and kind='barh':
  - width: Specify the bar width. In previous versions, static value 0.5 was passed to matplotlib and it cannot be overwritten. (GH6604)
  - align: Specify the bar alignment. Default is center (different from matplotlib). In previous versions, pandas passes align='edge' to matplotlib and adjust the location to center by itself, and it results align keyword is not applied as expected. (GH4525)
  - position: Specify relative alignments for bar plot layout. From 0 (left/bottom-end) to 1(right/top-end). Default is 0.5 (center). (GH6604)

Because of the default align value changes, coordinates of bar plots are now located on integer values (0.0, 1.0, 2.0 ...). This is intended to make bar plot be located on the same coordinates as line plot. However, bar plot may differs unexpectedly when you manually adjust the bar location or drawing area, such as using set_xlim, set_ylim, etc. In this cases, please modify your script to meet with new coordinates.

- The parallel_coordinates() function now takes argument color instead of colors. A FutureWarning is raised to alert that the old colors argument will not be supported in a future release. (GH6956)

- The parallel_coordinates() and andrews_curves() functions now take positional argument frame instead of data. A FutureWarning is raised if the old data argument is used by name. (GH6956)
• DataFrame.boxplot() now supports layout keyword (GH6769)
• DataFrame.boxplot() has a new keyword argument, return_type. It accepts 'dict', 'axes', or 'both', in which case a namedtuple with the matplotlib axes and a dict of matplotlib Lines is returned.

### 1.22.8 Prior Version Deprecations/Changes

There are prior version deprecations that are taking effect as of 0.14.0.

• Remove DateRange in favor of DatetimeIndex (GH6816)
• Remove column keyword from DataFrame.sort (GH4370)
• Remove precision keyword from set_eng_float_format() (GH395)
• Remove force_unicode keyword from DataFrame.to_string(), DataFrame.to_latex(), and DataFrame.to_html(); these function encode in unicode by default (GH2224, GH2225)
• Remove nanRep keyword from DataFrame.to_csv() and DataFrame.to_string() (GH275)
• Remove unique keyword from HDFStore.select_column() (GH3256)
• Remove inferTimeRule keyword from Timestamp.offset() (GH391)
• Remove name keyword from get_data_yahoo() and get_data_google() (commit b921d1a)
• Remove offset keyword from DatetimeIndex constructor (commit 3136390)
• Remove time_rule from several rolling-moment statistical functions, such as rolling_sum() (GH1042)
• Removed neg – boolean operations on numpy arrays in favor of inv ~, as this is going to be deprecated in numpy 1.9 (GH6960)

### 1.22.9 Deprecations

• The pivot_table()/DataFrame.pivot_table() and crosstab() functions now take arguments index and columns instead of rows and cols. A FutureWarning is raised to alert that the old rows and cols arguments will not be supported in a future release (GH5505)
• The DataFrame.drop_duplicates() and DataFrame.duplicated() methods now take argument subset instead of cols to better align with DataFrame.dropna(). A FutureWarning is raised to alert that the old cols arguments will not be supported in a future release (GH6680)
• The DataFrame.to_csv() and DataFrame.to_excel() functions now take argument columns instead of cols. A FutureWarning is raised to alert that the old cols arguments will not be supported in a future release (GH6645)
• Indexers will warn FutureWarning when used with a scalar indexer and a non-floating point Index (GH4892, GH6960)

```python
# non-floating point indexes can only be indexed by integers / labels
In [1]: Series(1, np.arange(5))[3.0]
   pandas/core/index.py:469: FutureWarning: scalar indexers for index type
   Int64Index should be integers and not floating point
Out[1]: 1

In [2]: Series(1, np.arange(5)).iloc[3.0]
   pandas/core/index.py:469: FutureWarning: scalar indexers for index type
   Int64Index should be integers and not floating point
Out[2]: 1
```

(continues on next page)
In [3]: Series(1, np.arange(5)).iloc[3.0:4]
pandas/core/index.py:527: FutureWarning: slice indexers when using iloc should be integers and not floating point

Out[3]:
3  1
   dtype: int64

# these are Float64Indexes, so integer or floating point is acceptable
In [4]: Series(1, np.arange(5.))[3]
Out[4]: 1

In [5]: Series(1, np.arange(5.))[3.0]
Out[6]: 1

- Numpy 1.9 compat w.r.t. deprecation warnings (GH6960)
- Panel.shift() now has a function signature that matches DataFrame.shift(). The old positional argument lags has been changed to a keyword argument periods with a default value of 1. A FutureWarning is raised if the old argument lags is used by name. (GH6910)
- The order keyword argument of factorize() will be removed. (GH6926).
- Remove the copy keyword from DataFrame.xs(), Panel.major_xs(), Panel.minor_xs(). A view will be returned if possible, otherwise a copy will be made. Previously the user could think that copy=False would ALWAYS return a view. (GH6894)
- The parallel_coordinates() function now takes argument color instead of colors. A FutureWarning is raised to alert that the old colors argument will not be supported in a future release. (GH6956)
- The parallel_coordinates() and andrews_curves() functions now take positional argument frame instead of data. A FutureWarning is raised if the old data argument is used by name. (GH6956)
- The support for the 'mysql' flavor when using DBAPI connection objects has been deprecated. MySQL will be further supported with SQLAlchemy engines (GH6900).
- The following io.sql functions have been deprecated: tquery, uquery, read_frame, frame_query, write_frame.
- The percentile_width keyword argument in describe() has been deprecated. Use the percentiles keyword instead, which takes a list of percentiles to display. The default output is unchanged.
- The default return type of boxplot() will change from a dict to a matpltolib Axes in a future release. You can use the future behavior now by passing return_type='axes' to boxplot.

1.22.10 Known Issues

- OpenPyXL 2.0.0 breaks backwards compatibility (GH7169)

1.22.11 Enhancements

- DataFrame and Series will create a MultiIndex object if passed a tuples dict, See the docs (GH3323)
In [65]: Series(((‘a’, ‘b’): 1, (‘a’, ‘a’): 0, 
       ....:     (‘a’, ‘c’): 2, (‘b’, ‘a’): 3, (‘b’, ‘b’): 4}) 
       ....: 
Out[65]:
   a   b
  a   1
  c   2
  b  a  3
  b  4
dtype: int64

In [66]: DataFrame(((‘a’, ‘b’): {(‘A’, ‘B’): 1, (‘A’, ‘C’): 2}, 
       ....:     (‘a’, ‘c’): {(‘A’, ‘B’): 5, (‘A’, ‘C’): 6}, 
       ....:     (‘b’, ‘b’): {(‘A’, ‘D’): 9, (‘A’, ‘B’): 10}})
       ....: 
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\n
• Added the sym_diff method to Index (GH5543)
• DataFrame.to_latex now takes a longtable keyword, which if True will return a table in a longtable environment. (GH6617)
• Add option to turn off escaping in DataFrame.to_latex (GH6472)
• pd.read_clipboard will, if the keyword sep is unspecified, try to detect data copied from a spreadsheet and parse accordingly. (GH6223)
• Joining a singly-indexed DataFrame with a multi-indexed DataFrame (GH3662)

See the docs. Joining multi-index DataFrames on both the left and right is not yet supported ATM.
In [71]: household.join(portfolio, how='inner')

Out[71]:

</tbody>
</table>

• `quotechar`, `doublequote`, and `escapechar` can now be specified when using `DataFrame.to_csv` (GH5414, GH4528)

• Partially sort by only the specified levels of a MultiIndex with the `sort_remaining` boolean kwarg. (GH9384)

• Added `to_julian_date` to `TimeStamp` and `DatetimeIndex`. The Julian Date is used primarily in astronomy and represents the number of days from noon, January 1, 4713 BC. Because nanoseconds are used to define the time in pandas the actual range of dates that you can use is 1678 AD to 2262 AD. (GH4041)

• `DataFrame.to_stata` will now check data for compatibility with Stata data types and will upcast when needed. When it is not possible to losslessly upcast, a warning is issued (GH6327)

• `DataFrame.to_stata` and `StataWriter` will accept keyword arguments `time_stamp` and `data_label` which allow the time stamp and dataset label to be set when creating a file. (GH6545)

• `pandas.io.gbq` now handles reading unicode strings properly. (GH5940)

• `Holidays Calendars` are now available and can be used with the `CustomBusinessDay` offset (GH6719)

• `Float64Index` is now backed by a `float64` dtype ndarray instead of an `object` dtype array (GH6471).

• Implemented `Panel.pct_change` (GH6904)

• Added how option to rolling-moment functions to dictate how to handle resampling; `rolling_max()` defaults to max, `rolling_min()` defaults to min, and all others default to mean (GH6297)

• `CustomBusinessMonthBegin` and `CustomBusinessMonthEnd` are now available (GH6866)
• Series.quantile() and DataFrame.quantile() now accept an array of quantiles.
• describe() now accepts an array of percentiles to include in the summary statistics (GH4196)
• pivot_table can now accept Grouper by index and columns keywords (GH6913)

```
In [72]: import datetime
In [73]: df = DataFrame({
     ...:     'Branch': 'A A A A B'.split(),
     ...:     'Buyer': 'Carl Mark Carl Joe Joe'.split(),
     ...:     'Quantity': [1, 3, 5, 1, 8, 1],
     ...:     'Date': [datetime.datetime(2013,11,1,13,0), datetime.datetime(2013,9,1,13,5),

• **read_excel** can now read milliseconds in Excel dates and times with xlrd >= 0.9.3. (GH5945)
• **pd.stats.moments.rolling_var** now uses Welford’s method for increased numerical stability (GH6817)
• **pd.expanding_apply** and **pd.rolling_apply** now take args and kwargs that are passed on to the func (GH6289)
• **DataFrame.rank()** now has a percentage rank option (GH5971)
• **Series.rank()** now has a percentage rank option (GH5971)
• **Series.rank()** and **DataFrame.rank()** now accept method='dense' for ranks without gaps (GH6514)
• Support passing **encoding** with **xlwt** (GH3710)
• Refactor **Block** classes removing **Block.items** attributes to avoid duplication in item handling (GH6745, GH6988).
• Testing statements updated to use specialized asserts (GH6175)
1.22.12 Performance

- Performance improvement when converting `DatetimeIndex` to floating ordinals using `DatetimeConverter` (GH6636)
- Performance improvement for `DataFrame.shift` (GH5609)
- Performance improvement in indexing into a multi-indexed Series (GH5567)
- Performance improvements in single-dtyped indexing (GH6484)
- Improve performance of `DataFrame` construction with certain offsets, by removing faulty caching (e.g. MonthEnd, BusinessMonthEnd), (GH6479)
- Improve performance of `CustomBusinessDay` (GH6584)
- Improve performance of slice indexing on Series with string keys (GH6341, GH6372)
- Performance improvement for `DataFrame.from_records` when reading a specified number of rows from an iterable (GH6700)
- Performance improvements in timedelta conversions for integer dtypes (GH6754)
- Improved performance of compatible pickles (GH6899)
- Improve performance in certain reindexing operations by optimizing `take_2d` (GH6749)
- `GroupBy.count()` is now implemented in Cython and is much faster for large numbers of groups (GH7016).

1.22.13 Experimental

There are no experimental changes in 0.14.0

1.22.14 Bug Fixes

- Bug in Series `ValueError` when index doesn’t match data (GH6532)
- Prevent segfault due to MultiIndex not being supported in HDFStore table format (GH1848)
- Bug in `pd.DataFrame.sort_index` where `mergesort` wasn’t stable when `ascending=False` (GH6399)
- Bug in `pd.tseries.frequencies.to_offset` when argument has leading zeroes (GH6391)
- Bug in version string gen. for dev versions with shallow clones / install from tarball (GH6127)
- Inconsistent tz parsing `Timestamp/to_datetime` for current year (GH5958)
- Indexing bugs with reordered indexes (GH6252, GH6254)
- Bug in `.xs` with a Series multiindex (GH6258, GH5684)
- Bug in conversion of a string types to a DatetimeIndex with a specified frequency (GH6273, GH6274)
- Bug in `eval` where type-promotion failed for large expressions (GH6205)
- Bug in `interpolate` with `inplace=True` (GH6281)
- `HDFStore.remove` now handles start and stop (GH6177)
- `HDFStore.select_as_multiple` handles start and stop the same way as `select` (GH6177)
- `HDFStore.select_as_coordinates` and `select_column` works with a where clause that results in filters (GH6177)
• Regression in join of non_unique_indexes (GH6329)
• Issue with groupby agg with a single function and a mixed-type frame (GH6337)
• Bug in DataFrame.replace() when passing a non-bool to_replace argument (GH6332)
• Raise when trying to align on different levels of a multi-index assignment (GH3738)
• Bug in setting complex dtypes via boolean indexing (GH6345)
• Bug in TimeGrouper/resample when presented with a non-monotonic DatetimeIndex that would return invalid results. (GH4161)
• Bug in index name propagation in TimeGrouper/resample (GH4161)
• TimeGrouper has a more compatible API to the rest of the groupers (e.g. groups was missing) (GH3881)
• Bug in multiple grouping with a TimeGrouper depending on target column order (GH6764)
• Bug in pd.eval when parsing strings with possible tokens like ' & ' (GH6351)
• Bug correctly handle placements of -inf in Panels when dividing by integer 0 (GH6178)
• DataFrame.shift with axis=1 was raising (GH6371)
• Disabled clipboard tests until release time (run locally with nosetests -A disabled) (GH6048).
• Bug in DataFrame.replace() when passing a nested dict that contained keys not in the values to be replaced (GH6342)
• str.match ignored the na flag (GH6609).
• Bug in take with duplicate columns that were not consolidated (GH6240)
• Bug in interpolate changing dtypes (GH6290)
• Bug in Series.get was using a buggy access method (GH6383)
• Bug in hdfstore queries of the form where=[('date', '>=', datetime(2013,1,1)), ('date', '<=', datetime(2014,1,1))] (GH6313)
• Bug in DataFrame.dropna with duplicate indices (GH6355)
• Regression in chained getitem indexing with embedded list-like from 0.12 (GH6394)
• Float64Index with nans not comparing correctly (GH6401)
• eval/query expressions with strings containing the @ character will now work (GH6366).
• Bug in Series.reindex when specifying a method with some nan values was inconsistent (noted on a resample) (GH6418)
• Bug in DataFrame.replace() where nested dicts were erroneously depending on the order of dictionary keys and values (GH5338).
• Perf issue in concatting with empty objects (GH3259)
• Clarify sorting of sym_diff on Index objects with NaN values (GH6444)
• Regression in MultiIndex.from_product with a DatetimeIndex as input (GH6439)
• Bug in str.extract when passed a non-default index (GH6348)
• Bug in str.split when passed pat=None and n=1 (GH6466)
• Bug in io.data.DataReader when passed "F-F_Momentum_Factor" and data_source="famafrench" (GH6460)
• Bug in sum of a timedelta64 [ns] series (GH6462)
• Bug in `resample` with a timezone and certain offsets (GH6397)
• Bug in `iat/ilocs` with duplicate indices on a Series (GH6493)
• Bug in `read_html` where nan’s were incorrectly being used to indicate missing values in text. Should use the empty string for consistency with the rest of pandas (GH5129).
• Bug in `read_html` tests where redirected invalid URLs would make one test fail (GH6445).
• Bug in multi-axis indexing using `.loc` on non-unique indices (GH6504)
• Bug that caused `_ref_locs` corruption when slice indexing across columns axis of a DataFrame (GH6525)
• Regression from 0.13 in the treatment of numpy `datetime64` non-ns dtypes in Series creation (GH6529)
• `.names` attribute of MultiIndexes passed to `set_index` are now preserved (GH6459).
• Bug in `setitem` with a duplicate index and an alignable rhs (GH6541)
• Bug in `setitem` with `.loc` on mixed integer Indexes (GH6546)
• Bug in `pd.read_stata` which would use the wrong data types and missing values (GH6327)
• Bug in `DataFrame.to_stata` that lead to data loss in certain cases, and could be exported using the wrong data types and missing values (GH6335)
• `StataWriter` replaces missing values in string columns by empty string (GH6802)
• Inconsistent types in `Timestamp` addition/subtraction (GH6543)
• Bug in preserving frequency across `Timestamp` addition/subtraction (GH4547)
• Bug in empty list lookup caused `IndexError` exceptions (GH6536, GH6551)
• `Series.quantile` raising on an object dtype (GH6555)
• Bug in `.xs` with a `nan` in level when dropped (GH6574)
• Bug in `fillna` with `method='bfill/ffill'` and `datetime64[ns]` dtype (GH6587)
• Bug in sql writing with mixed dtypes possibly leading to data loss (GH6509)
• Bug in `Series.pop` (GH6600)
• Bug in `iloc` indexing when positional indexer matched `Int64Index` of the corresponding axis and no re-ordering happened (GH6612)
• Bug in `fillna` with `limit` and `value` specified
• Bug in `DataFrame.to_stata` when columns have non-string names (GH4558)
• Bug in `compat` with `np.compress`, surfaced in (GH6658)
• Bug in binary operations with a rhs of a Series not aligning (GH6681)
• Bug in `DataFrame.to_stata` which incorrectly handles nan values and ignores `with_index` keyword argument (GH6685)
• Bug in `resample` with extra bins when using an evenly divisible frequency (GH4076)
• Bug in consistency of groupby aggregation when passing a custom function (GH6715)
• Bug in `resample` when `how=None` resample freq is the same as the axis frequency (GH5955)
• Bug in downcasting inference with empty arrays (GH6733)
• Bug in `obj.blocks` on sparse containers dropping all but the last items of same for dtype (GH6748)
• Bug in unpickling `NaT` (NaTType) (GH4606)
- Bug in `DataFrame.replace()` where regex metacharacters were being treated as regexes even when `regex=False` (GH6777).
- Bug in timedelta ops on 32-bit platforms (GH6808)
- Bug in setting a tz-aware index directly via `.index` (GH6785)
- Bug in expressions.py where `numexpr` would try to evaluate arithmetic ops (GH6762).
- Bug in Makefile where it didn’t remove Cython generated C files with `make clean` (GH6768)
- Bug with `numpy < 1.7.2` when reading long strings from `HDFStore` (GH6166)
- Bug in `DataFrame._reduce` where non bool-like (0/1) integers were being converted into bools. (GH6806)
- Regression from 0.13 with `fillna` and a Series on datetime-like (GH6344)
- Bug in adding `np.timedelta64` to `DatetimeIndex` with timezone outputs incorrect results (GH6818)
- Bug in `DataFrame.replace()` where changing a dtype through replacement would only replace the first occurrence of a value (GH6689)
- Better error message when passing a frequency of ‘MS’ in `Period` construction (GH5332)
- Bug in `Series.__unicode__` when `max_rows=None` and the Series has more than 1000 rows. (GH6863)
- Bug in `groupby.get_group` where a datetlike wasn’t always accepted (GH5267)
- Bug in `groupBy.get_group` created by `TimeGrouper` raises `AttributeError` (GH6914)
- Bug in `DatetimeIndex.tz_localize` and `DatetimeIndex.tz_convert` converting NaT incorrectly (GH5546)
- Bug in arithmetic operations affecting NaT (GH6873)
- Bug in `Series.str.extract` where the resulting Series from a single group match wasn’t renamed to the group name
- Bug in `DataFrame.to_csv` where setting `index=False` ignored the header kwarg (GH6186)
- Bug in `DataFrame.plot` and `Series.plot`, where the legend behave inconsistently when plotting to the same axes repeatedly (GH6678)
- Internal tests for patching `__finalize__` / bug in merge not finalizing (GH6923, GH6927)
- accept `TextFileReader` in `concat`, which was affecting a common user idiom (GH6583)
- Bug in C parser with leading whitespace (GH3374)
- Bug in C parser with `delim_whitespace=True` and \r-delimited lines
- Bug in python parser with explicit multi-index in row following column header (GH6893)
- Bug in `Series.rank` and `DataFrame.rank` that caused small floats (<1e-13) to all receive the same rank (GH6886)
- Bug in `DataFrame.apply` with functions that used `*args` or `**kwargs` and returned an empty result (GH6952)
- Bug in sum/mean on 32-bit platforms on overflows (GH6915)
- Moved `Panel.shift` to `NDFrame.slice_shift` and fixed to respect multiple dtypes. (GH6959)
- Bug in enabling `subplots=True` in `DataFrame.plot` only has single column raises `TypeError`, and `Series.plot` raises `AttributeError` (GH6951)
- Bug in `DataFrame.plot` draws unnecessary axes when enabling `subplots` and `kind=scatter` (GH6951)
bug in read_csv from a filesystem with non-utf-8 encoding (GH6807)
* Bug in iloc when setting / aligning (GH6766)
* Bug causing UnicodeEncodeError when get_dummies called with unicode values and a prefix (GH6885)
* Bug in timeseries-with-frequency plot cursor display (GH5453)
* Bug surfaced in groupby.plot when using a Float64Index (GH7025)
* Stopped tests from failing if options data isn’t able to be downloaded from Yahoo (GH7034)
* Bug in parallel_coordinates and radviz where reordering of class column caused possible color/class mismatch (GH6956)
* Bug in radviz and andrews_curves where multiple values of ‘color’ were being passed to plotting method (GH6956)
* Bug in Float64Index.isin() where containing nans would make indices claim that they contained all the things (GH7066). 
* Bug in DataFrame.boxplot where it failed to use the axis passed as the ax argument (GH3578)
* Bug in the XlsxWriter and XlwtWriter implementations that resulted in datetime columns being formatted without the time (GH7075) were being passed to plotting method
* read_fwf() treats None in colspec like regular python slices. It now reads from the beginning or until the end of the line when colspec contains a None (previously raised a TypeError)
* Bug in cache coherence with chained indexing and slicing: add _is_view property to NDFrame to correctly predict views; mark is_copy on xs only if its an actual copy (and not a view) (GH7084)
* Bug in DatetimeIndex creation from string ndarray with dayfirst=True (GH5917)
* Bug in MultiIndex.from_arrays created from DatetimeIndex doesn’t preserve freq and tz (GH7090)
* Bug in unstack raises ValueError when MultiIndex contains PeriodIndex (GH4342)
* Bug in boxplot and hist draws unnecessary axes (GH6769)
* Regression in groupby.nth() for out-of-bounds indexers (GH6621)
* Bug in quantile with datetime values (GH6965)
* Bug in Dataframe.set_index, reindex and pivot don’t preserve DatetimeIndex and PeriodIndex attributes (GH3950, GH5878, GH6631)
* Bug in MultiIndex.get_level_values doesn’t preserve DatetimeIndex and PeriodIndex attributes (GH7092)
* Bug in Groupby doesn’t preserve tz (GH3950)
* Bug in PeriodIndex partial string slicing (GH6716)
* Bug in the HTML repr of a truncated Series or DataFrame not showing the class name with the large_repr set to ‘info’ (GH7105)
* Bug in DatetimeIndex specifying freq raises ValueError when passed value is too short (GH7098)
* Fixed a bug with the info repr not honoring the display.max_info_columns setting (GH6939)
* Bug PeriodIndex string slicing with out of bounds values (GH5407)
* Fixed a memory error in the hashtable implementation/factorizer on resizing of large tables (GH7157)
* Bug in isnull when applied to 0-dimensional object arrays (GH7176)
• Bug in `query/eval` where global constants were not looked up correctly (GH7178)
• Bug in recognizing out-of-bounds positional list indexers with `iloc` and a multi-axis tuple indexer (GH7189)
• Bug in setitem with a single value, multi-index and integer indices (GH7190, GH7218)
• Bug in expressions evaluation with reversed ops, showing in series-dataframe ops (GH7198, GH7192)
• Bug in multi-axis indexing with > 2 ndim and a multi-index (GH7199)
• Fix a bug where invalid eval/query operations would blow the stack (GH5198)

1.23 v0.13.1 (February 3, 2014)

This is a minor release from 0.13.0 and includes a small number of API changes, several new features, enhancements, and performance improvements along with a large number of bug fixes. We recommend that all users upgrade to this version.

Highlights include:

• Added `infer_datetime_format` keyword to `read_csv/to_datetime` to allow speedups for homogeneously formatted datetimes.
• Will intelligently limit display precision for datetime/timedelta formats.
• Enhanced Panel `apply()` method.
• Suggested tutorials in new `Tutorials` section.
• Our pandas ecosystem is growing. We now feature related projects in a new `Pandas Ecosystem` section.
• Much work has been taking place on improving the docs, and a new `Contributing` section has been added.
• Even though it may only be of interest to devs, we <3 our new CI status page: ScatterCI.

**Warning:** 0.13.1 fixes a bug that was caused by a combination of having numpy < 1.8, and doing chained assignment on a string-like array. Please review the docs, chained indexing can have unexpected results and should generally be avoided.

This would previously segfault:

```
In [1]: df = DataFrame(dict(A = np.array(['foo','bar','bah','foo','bar'])))
In [2]: df['A'].iloc[0] = np.nan
In [3]: df
Out[3]:
   A
0  NaN
1  bar
2  bah
3  foo
4  bar
```

The recommended way to do this type of assignment is:
1.23.1 Output Formatting Enhancements

- `df.info()` view now display dtype info per column (GH5682)
- `df.info()` now honors the option `max_info_rows`, to disable null counts for large frames (GH5974)

```
In [7]: max_info_rows = pd.get_option('max_info_rows')

In [8]: df = DataFrame(dict(A = np.random.randn(10),
                       B = np.random.randn(10),
                       C = date_range('20130101',periods=10)))

In [9]: df.iloc[3:6,[0,2]] = np.nan

# set to not display the null counts
In [10]: pd.set_option('max_info_rows',0)

In [11]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A   float64
B   float64
C   datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0bytes
```

```
# this is the default (same as in 0.13.0)
In [12]: pd.set_option('max_info_rows',max_info_rows)

In [13]: df.info()
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 10 entries, 0 to 9
Data columns (total 3 columns):
A   7 non-null float64
B   10 non-null float64
C   7 non-null datetime64[ns]
dtypes: datetime64[ns](1), float64(2)
memory usage: 320.0bytes
```

- Add `show_dimensions` display option for the new DataFrame repr to control whether the dimensions print.

1.23.  v0.13.1 (February 3, 2014)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

```python
In [14]: df = DataFrame([[1, 2], [3, 4]])
In [15]: pd.set_option('show_dimensions', False)
In [16]: df
Out[16]:
   0  1
0  1  2
1  3  4

In [17]: pd.set_option('show_dimensions', True)
In [18]: df
Out[18]:
   0  1
0  1  2
1  3  4
[2 rows x 2 columns]
```

- The `ArrayFormatter` for `datetime` and `timedelta64` now intelligently limit precision based on the values in the array (GH3401).

Previously output might look like:

<table>
<thead>
<tr>
<th>age</th>
<th>today</th>
<th>diff</th>
</tr>
</thead>
<tbody>
<tr>
<td>2001-01-01 00:00:00</td>
<td>2013-04-19 00:00:00</td>
<td>4491 days, 00:00:00</td>
</tr>
<tr>
<td>2004-06-01 00:00:00</td>
<td>2013-04-19 00:00:00</td>
<td>3244 days, 00:00:00</td>
</tr>
</tbody>
</table>

Now the output looks like:

```python
In [19]: df = DataFrame([ Timestamp('20010101'),
                      Timestamp('20040601') ], columns=['age'])
In [20]: df['today'] = Timestamp('20130419')
In [21]: df['diff'] = df['today']-df['age']
In [22]: df
Out[22]:
     age       today      diff
0 2001-01-01 2001-01-01 4491 days
1 2004-06-01 2004-06-01 3244 days
[2 rows x 3 columns]
```

### 1.23.2 API changes

- Add `-NaN` and `-nan` to the default set of NA values (GH5952). See NA Values.
- Added `Series.str.get_dummies` vectorized string method (GH6021), to extract dummy/indicator variables for separated string columns:

```python
In [23]: s = Series(['a', 'a|b', np.nan, 'a|c'])
```
In [24]: s.str.get_dummies(sep='|')
Out[24]:
a  b  c
0  1  0  0
1  1  1  0
2  0  0  0
3  1  0  1

[4 rows x 3 columns]

- Added the `NDFrame.equals()` method to compare if two NDFrames are equal have equal axes, dtypes, and values. Added the `array_equivalent` function to compare if two ndarrays are equal. NaNs in identical locations are treated as equal. (GH5283) See also the docs for a motivating example.

In [25]: df = DataFrame({'col': ['foo', 0, np.nan]})
In [26]: df2 = DataFrame({'col': [np.nan, 0, 'foo']}, index=[2, 1, 0])
In [27]: df.equals(df2)
Out[27]: False
In [28]: df.equals(df2.sort_index())
Out[28]: True
In [29]: import pandas.core.common as com
In [30]: com.array_equivalent(np.array([0, np.nan]), np.array([0, np.nan]))
AttributeError: module 'pandas.core.common' has no attribute 'array_equivalent'

- `DataFrame.apply` will use the `reduce` argument to determine whether a `Series` or a `DataFrame` should be returned when the `DataFrame` is empty (GH6007).

Previously, calling `DataFrame.apply` an empty `DataFrame` would return either a `DataFrame` if there were no columns, or the function being applied would be called with an empty `Series` to guess whether a `Series` or `DataFrame` should be returned:

In [32]: def applied_func(col):
        ....:     print("Apply function being called with: ", col)
        ....:     return col.sum()
        ....:
In [33]: empty = DataFrame(columns=['a', 'b'])
In [34]: empty.apply(applied_func)
Apply function being called with: Series([], Length: 0, dtype: float64)
Out[34]:
a  NaN
Now, when apply is called on an empty DataFrame: if the reduce argument is True a Series will returned, if it is False a DataFrame will be returned, and if it is None (the default) the function being applied will be called with an empty series to try and guess the return type.

```
In [35]: empty.apply(applied_func, reduce=True)
Out[35]:
a  NaN
b  NaN
Length: 2, dtype: float64

In [36]: empty.apply(applied_func, reduce=False)
Out[36]:
Empty DataFrame
Columns: [a, b]
Index: []
[0 rows x 2 columns]
```

### 1.23.3 Prior Version Deprecations/Changes

There are no announced changes in 0.13 or prior that are taking effect as of 0.13.1

### 1.23.4 Deprecations

There are no deprecations of prior behavior in 0.13.1

### 1.23.5 Enhancements

- `pd.read_csv` and `pd.to_datetime` learned a new `infer_datetime_format` keyword which greatly improves parsing perf in many cases. Thanks to @lexual for suggesting and @danbirken for rapidly implementing. (GH5490, GH6021)

  If `parse_dates` is enabled and this flag is set, pandas will attempt to infer the format of the datetime strings in the columns, and if it can be inferred, switch to a faster method of parsing them. In some cases this can increase the parsing speed by ~5-10x.

```
# Try to infer the format for the index column
def = pd.read_csv('foo.csv', index_col=0, parse_dates=True, infer_datetime_format=True)
```

- `date_format` and `datetime_format` keywords can now be specified when writing to excel files (GH4133)

- `MultiIndex.from_product` convenience function for creating a MultiIndex from the cartesian product of a set of iterables (GH6055):

```
In [32]: shades = ['light', 'dark']
In [33]: colors = ['red', 'green', 'blue']
```
In [34]: MultiIndex.from_product([shades, colors], names=['shade', 'color'])
Out[34]:
MultiIndex(levels=[['dark', 'light'], ['blue', 'green', 'red']],
labels=[[1, 1, 1, 0, 0, 0], [2, 1, 0, 2, 1, 0]],
names=['shade', 'color'])

• Panel apply() will work on non-ufuncs. See the docs.

In [35]: import pandas.util.testing as tm
In [36]: panel = tm.makePanel(5)
In [37]: panel
Out[37]:
<class 'pandas.core.panel.Panel'>

2000-01-06 -0.962029
2000-01-07 -2.085266
[5 rows x 4 columns]

A similar reduction type operation

In [40]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[40]:
ItemA  ItemB  ItemC
A  2.579643  3.062757  0.379252
B  1.416120  -1.960855  0.923558
C  0.595222  -1.079772  -3.118269
D  1.487226  -0.734611  -1.979310
[4 rows x 3 columns]
This is equivalent to

```
In [41]: panel.sum('major_axis')
Out[41]:
        ItemA  ItemB  ItemC
A   2.579643  3.062757  0.379252
B   1.416120 -1.960855  0.923558
C   0.595222 -1.079772 -3.118269
D   1.487226 -0.734611 -1.979310
[4 rows x 3 columns]
```

A transformation operation that returns a Panel, but is computing the z-score across the major_axis

```
In [42]: result = panel.apply(
                      ....: lambda x: (x-x.mean())/x.std(),
                      ....: axis='major_axis')
                      ...

In [43]: result
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [44]: result['ItemA']
```

```

### 1.23.6 Performance

Performance improvements for 0.13.1

- Series datetime/timedelta binary operations ([GH5801](https://github.com/pandas-dev/pandas/issues/5801))
- DataFrame `count/dropna` for `axis=1`
- Series.str.contains now has a `regex=False` keyword which can be faster for plain (non-regex) string patterns. ([GH5879](https://github.com/pandas-dev/pandas/issues/5879))
- Series.str.extract ([GH5944](https://github.com/pandas-dev/pandas/issues/5944))
- dtypes/ftypes methods ([GH5968](https://github.com/pandas-dev/pandas/issues/5968))
- indexing with object dtypes ([GH5968](https://github.com/pandas-dev/pandas/issues/5968))
- DataFrame.apply ([GH6013](https://github.com/pandas-dev/pandas/issues/6013))
- Regression in JSON IO ([GH5765](https://github.com/pandas-dev/pandas/issues/5765))
- Index construction from Series ([GH6150](https://github.com/pandas-dev/pandas/issues/6150))
1.23.7 Experimental

There are no experimental changes in 0.13.1

1.23.8 Bug Fixes

See V0.13.1 Bug Fixes for an extensive list of bugs that have been fixed in 0.13.1.

See the full release notes or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

1.24 v0.13.0 (January 3, 2014)

This is a major release from 0.12.0 and includes a number of API changes, several new features and enhancements along with a large number of bug fixes.

Highlights include:

- support for a new index type Float64Index, and other Indexing enhancements
- HDFStore has a new string based syntax for query specification
- support for new methods of interpolation
- updated timedelta operations
- a new string manipulation method extract
- Nanosecond support for Offsets
- isin for DataFrames

Several experimental features are added, including:

- new eval/query methods for expression evaluation
- support for msgpack serialization
- an i/o interface to Google’s BigQuery

There are several new or updated docs sections including:

- Comparison with SQL, which should be useful for those familiar with SQL but still learning pandas.
- Comparison with R, idiom translations from R to pandas.
- Enhancing Performance, ways to enhance pandas performance with eval/query.

Warning: In 0.13.0 Series has internally been refactored to no longer sub-class ndarray but instead subclass NDFrame, similar to the rest of the pandas containers. This should be a transparent change with only very limited API implications. See Internal Refactoring

1.24.1 API changes

- read_excel now supports an integer in its sheetname argument giving the index of the sheet to read in (GH4301).
• Text parser now treats anything that reads like inf ("inf", "Inf", "-Inf", "iNf", etc.) as infinity. (GH4220, GH4219), affecting read_table, read_csv, etc.

• pandas now is Python 2/3 compatible without the need for 2to3 thanks to @jtratner. As a result, pandas now uses iterators more extensively. This also led to the introduction of substantive parts of the Benjamin Peterson’s six library into compat. (GH4384, GH4375, GH4372)

• pandas.util.compat and pandas.util.py3compat have been merged into pandas.compat. pandas.compat now includes many functions allowing 2/3 compatibility. It contains both list and iterator versions of range, filter, map and zip, plus other necessary elements for Python 3 compatibility. lmap, lzip, lrange and lfilter all produce lists instead of iterators, for compatibility with numpy, subscripting and pandas constructors. (GH4384, GH4375, GH4372)

• Series.get with negative indexers now returns the same as [] (GH4390)

• Changes to how Index and MultiIndex handle metadata (levels, labels, and names) (GH4039):

```python
# previously, you would have set levels or labels directly
index.levels = [[1, 2, 3, 4], [1, 2, 4, 4]]

# now, you use the set_levels or set_labels methods
index = index.set_levels([[1, 2, 3, 4], [1, 2, 4, 4]])

# similarly, for names, you can rename the object
# but setting names is not deprecated
index = index.set_names(["bob", "cranberry"])

# and all methods take an inplace kwarg - but return None
index.set_names(["bob", "cranberry"], inplace=True)
```

• All division with NDFrame objects is now truedivision, regardless of the future import. This means that operating on pandas objects will by default use floating point division, and return a floating point dtype. You can use // and floordiv to do integer division.

Integer division

```python
In [3]: arr = np.array([1, 2, 3, 4])

In [4]: arr2 = np.array([5, 3, 2, 1])

In [5]: arr / arr2
Out[5]: array([0, 0, 1, 4])

In [6]: Series(arr) // Series(arr2)
Out[6]:
0 0
1 0
2 1
3 4
dtype: int64
```

True Division

```python
In [7]: pd.Series(arr) / pd.Series(arr2) # no future import required
Out[7]:
0 0.200000
1 0.666667
2 1.500000
```

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

(continued from previous page)

3 4.000000
dtype: float64

- Infer and downcast dtype if downcast='infer' is passed to fillna/ffill/bfill (GH4604)
- __nonzero__ for all NDFrame objects, will now raise a ValueError, this reverts back to (GH1073, GH4633) behavior. See gotchas for a more detailed discussion.

This prevents doing boolean comparison on entire pandas objects, which is inherently ambiguous. These all will raise a ValueError.

```python
if df:
    ...
df1 and df2
s1 and s2
```

Added the .bool() method to NDFrame objects to facilitate evaluating of single-element boolean Series:

```python
In [1]: Series([True]).bool()
Out[1]: True

In [2]: Series([False]).bool()
   ...: Out[2]: False

In [3]: DataFrame([[True]]).bool()
   ...: Out[3]: True

In [4]: DataFrame([[False]]).bool()
   ...: Out[4]: False
```

- All non-Index NDFrames (Series, DataFrame, Panel, Panel4D, SparsePanel, etc.), now support the entire set of arithmetic operators and arithmetic flex methods (add, sub, mul, etc.). SparsePanel does not support pow or mod with non-scalars. (GH3765)
- Series and DataFrame now have a mode() method to calculate the statistical mode(s) by axis/Series. (GH5367)
- Chained assignment will now by default warn if the user is assigning to a copy. This can be changed with the option mode.chained_assignment, allowed options are raise/warn/None. See the docs.

```python
In [5]: dfc = DataFrame({'A':['aaa','bbb','ccc'],'B':[1,2,3]})
In [6]: pd.set_option('chained_assignment', 'warn')
```

The following warning / exception will show if this is attempted.

```python
In [7]: dfc.loc[0]['A'] = 1111
```

```
Traceback (most recent call last)
  ...:
SettingWithCopyWarning:
  A value is trying to be set on a copy of a slice from a DataFrame.
  Try using .loc[row_index,col_indexer] = value instead
```

Here is the correct method of assignment.
In [8]: dfc.loc[0,'A'] = 11

In [9]: dfc
Out[9]:
   A  B
0  11 1
1  bbb 2
2  ccc 3
[3 rows x 2 columns]

- Panel.reindex has the following call signature Panel.reindex(items=None, major_axis=None, minor_axis=None, **kwargs) to conform with other NDFrame objects. See Internal Refactoring for more information.
- Series.argmin and Series.argmax are now aliased to Series.idxmin and Series.idxmax. These return the index of the min or max element respectively. Prior to 0.13.0 these would return the position of the min / max element. (GH6214)

1.24.2 Prior Version Deprecations/Changes

These were announced changes in 0.12 or prior that are taking effect as of 0.13.0

- Remove deprecated Factor (GH3650)
- Remove deprecated set_printoptions/reset_printoptions (GH3046)
- Remove deprecated _verbose_info (GH3215)
- Remove deprecated read_clipboard/to_clipboard/ExcelFile/ExcelWriter from pandas.io.parsers (GH3717) These are available as functions in the main pandas namespace (e.g. pd.read_clipboard)
- default for tupleize_cols is now False for both to_csv and read_csv. Fair warning in 0.12 (GH3604)
- default for display.max_seq_len is now 100 rather then None. This activates truncated display (“…” ) of long sequences in various places. (GH3391)

1.24.3 Deprecations

Deprecated in 0.13.0

- deprecated iterkv, which will be removed in a future release (this was an alias of iteritems used to bypass 2to3’s changes). (GH4384, GH4375, GH4372)
- deprecated the string method match, whose role is now performed more idiomatically by extract. In a future release, the default behavior of match will change to become analogous to contains, which returns a boolean indexer. (Their distinction is strictness: match relies on re.match while contains relies on re.search.) In this release, the deprecated behavior is the default, but the new behavior is available through the keyword argument as_indexer=True.

1.24.4 Indexing API Changes

Prior to 0.13, it was impossible to use a label indexer (.loc/.ix) to set a value that was not contained in the index of a particular axis. (GH2578). See the docs

In the Series case this is effectively an appending operation

1.24. v0.13.0 (January 3, 2014)
In [10]: s = Series([1,2,3])

In [11]: s
Out[11]:
0    1
1    2
2    3
Length: 3, dtype: int64

In [13]: s
Out[13]:
0   1.0
1   2.0
2   3.0
5   5.0
Length: 4, dtype: float64

In [14]: dfi = DataFrame(np.arange(6).reshape(3,2),
   ....: columns=['A','B'])
   ....:

In [15]: dfi
Out[15]:
   A  B
0  0  1
1  2  3
2  4  5
[3 rows x 2 columns]

This would previously KeyError

In [16]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

In [17]: dfi
Out[17]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
[3 rows x 3 columns]

This is like an append operation.

In [18]: dfi.loc[3] = 5

In [19]: dfi
Out[19]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5

(continues on next page)
A Panel setting operation on an arbitrary axis aligns the input to the Panel

```
In [20]: p = pd.Panel(np.arange(16).reshape(2,4,2),
                ....:     items=['Item1','Item2'],
                ....:     major_axis=pd.date_range('2001/1/12',periods=4),
                ....:     minor_axis=['A','B'],dtype='float64')

In [21]: p
Out[21]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to B
```

```
In [22]: p.loc[:,:,'C'] = Series([30,32],index=p.items)

In [23]: p
Out[23]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2001-01-12 00:00:00 to 2001-01-15 00:00:00
Minor_axis axis: A to C
```

```
In [24]: p.loc[:,:,'C']
Out[24]:
   Item1  Item2
2001-01-12  30.0  32.0
2001-01-13  30.0  32.0
2001-01-14  30.0  32.0
2001-01-15  30.0  32.0
```

### 1.24.5 Float64Index API Change

- Added a new index type, Float64Index. This will be automatically created when passing floating values in index creation. This enables a pure label-based slicing paradigm that makes [],ix,loc for scalar indexing and slicing work exactly the same. See the docs, (GH263)

Construction is by default for floating type values.

```
In [25]: index = Index([1.5, 2, 3, 4.5, 5])

In [26]: index
Out[26]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')

In [27]: s = Series(range(5),index=index)

In [28]: s
```

(continues on next page)
Scalar selection for [], .ix, .loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0)

\[
\begin{align*}
\text{In [29]} &: s[3] \\
\text{Out [29]} &: 2 \\
\text{In [30]} &: s.loc[3] \\
\text{Out [30]} &: 2
\end{align*}
\]

The only positional indexing is via iloc

\[
\begin{align*}
\text{In [31]} &: s.iloc[3] \\
\text{Out [31]} &: 3
\end{align*}
\]

A scalar index that is not found will raise KeyError

Slicing is ALWAYS on the values of the index, for [], ix, loc and ALWAYS positional with iloc

\[
\begin{align*}
\text{In [32]} &: s[2:4] \\
\text{Out [32]} &: 2.0 \ 1 \\
& 3.0 \ 2 \\
& \text{Length: 2, dtype: int64} \\
\text{In [33]} &: s.loc[2:4] \\
& \text{Out [33]}: 2.0 \ 1 \\
& 3.0 \ 2 \\
& \text{Length: 2, dtype: int64} \\
\text{In [34]} &: s.iloc[2:4] \\
& 3.0 \ 2 \\
& 4.5 \ 3 \\
& \text{Length: 2, dtype: int64}
\end{align*}
\]

In float indexes, slicing using floats are allowed

\[
\begin{align*}
\text{In [35]} &: s[2.1:4.6] \\
\text{Out [35]} &: 3.0 \ 2 \\
& 4.5 \ 3 \\
& \text{Length: 2, dtype: int64} \\
\text{In [36]} &: s.loc[2.1:4.6] \\
& \text{Out [36]}: 3.0 \ 2
\end{align*}
\]
Indexing on other index types are preserved (and positional fallback for [], ix), with the exception, that floating point slicing on indexes on non Float64Index will now raise a TypeError.

```
In [1]: Series(range(5))[3.5]
TypeError: the label [3.5] is not a proper indexer for this index type
   →(Int64Index)
In [1]: Series(range(5))[3.5:4.5]
TypeError: the slice start [3.5] is not a proper indexer for this index type
   →(Int64Index)
```

Using a scalar float indexer will be deprecated in a future version, but is allowed for now.

```
In [3]: Series(range(5))[3.0]
Out[3]: 3
```

### 1.24.6 HDFStore API Changes

- Query Format Changes. A much more string-like query format is now supported. See the docs.

```
In [37]: path = 'test.h5'
In [38]: dfq = DataFrame(randn(10,4),
   ....:     columns=list('ABCD'),
   ....:     index=date_range('20130101',periods=10))
   ....:
In [39]: dfq.to_hdf(path,'dfq',format='table',data_columns=True)
```

Use boolean expressions, with in-line function evaluation.

```
In [40]: read_hdf(path,'dfq',
   ....:     where="index>Timestamp('20130104') & columns=['A', 'B']")
   ....:
Out[40]:
   A   B
2013-01-05  1.057633 -0.791489
2013-01-06  1.910759  0.787965
2013-01-07  1.043945  2.107785
2013-01-08  0.749185  0.675521
2013-01-09 -0.276646  1.924533
2013-01-10  0.226363 -2.078618
[6 rows x 2 columns]
```

Use an inline column reference

```
In [41]: read_hdf(path,'dfq',
   ....:     where="A>0 or C>0")
   ....:
Out[41]:
   A   B   C   D
```
The format keyword now replaces the table keyword; allowed values are fixed(f) or table(t) the same defaults as prior < 0.13.0 remain, e.g. put implies fixed format and append implies table format. This default format can be set as an option by setting io.hdf.default_format.

In [42]: path = 'test.h5'
In [43]: df = pd.DataFrame(np.random.randn(10,2))
In [44]: df.to_hdf(path, 'df_table', format='table')
In [45]: df.to_hdf(path, 'df_table2', append=True)
In [46]: df.to_hdf(path, 'df_fixed')
In [47]: with pd.HDFStore(path) as store:
   ....:    print(store)
   ....:
<class 'pandas.io.pytables.HDFStore'>
File path: test.h5

• Significant table writing performance improvements
• handle a passed Series in table format (GH4330)
• can now serialize a timedelta64[ns] dtype in a table (GH3577). See the docs.
• added an is_open property to indicate if the underlying file handle is_open; a closed store will now report 'CLOSED' when viewing the store (rather than raising an error) (GH4409)
• a close of a HDFStore now will close that instance of the HDFStore but will only close the actual file if the ref count (by PyTables) w.r.t. all of the open handles are 0. Essentially you have a local instance of HDFStore referenced by a variable. Once you close it, it will report closed. Other references (to the same file) will continue to operate until they themselves are closed. Performing an action on a closed file will raise ClosedFileError

In [48]: path = 'test.h5'
In [49]: df = DataFrame(randn(10,2))
In [50]: store1 = HDFStore(path)
In [51]: store2 = HDFStore(path)
In [52]: store1.append('df', df)
In [53]: store2.append('df2',df)

In [54]: store1
Out[54]: <class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [55]: store2
Out[55]: <class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [56]: store1.close()

In [57]: store2
Out[57]: <class 'pandas.io.pytables.HDFStore'>
File path: test.h5

In [58]: store2.close()

In [59]: store2
Out[59]: <class 'pandas.io.pytables.HDFStore'>
File path: test.h5

• removed the _quiet attribute, replace by a DuplicateWarning if retrieving duplicate rows from a table (GH4367)

• removed the warn argument from open. Instead a PossibleDataLossError exception will be raised if you try to use mode='w' with an OPEN file handle (GH4367)

• allow a passed locations array or mask as a where condition (GH4467). See the docs for an example.

• add the keyword dropna=True to append to change whether ALL nan rows are not written to the store (default is True, ALL nan rows are NOT written), also settable via the option io.hdf.dropna_table (GH4625)

• pass thru store creation arguments; can be used to support in-memory stores

1.24.7 DataFrame repr Changes

The HTML and plain text representations of DataFrame now show a truncated view of the table once it exceeds a certain size, rather than switching to the short info view (GH4886, GH5550). This makes the representation more consistent as small DataFrames get larger.
To get the info view, call `DataFrame.info()`. If you prefer the info view as the repr for large DataFrames, you can set this by running `set_option('display.large_repr', 'info')`.

### 1.24.8 Enhancements

- `df.to_clipboard()` learned a new `excel` keyword that lets you paste df data directly into Excel (enabled by default). (GH5070).
- `read_html` now raises a `URLError` instead of catching and raising a `ValueError` (GH4303, GH4305)
- Added a test for `read_clipboard()` and `to_clipboard()` (GH4282)
- Clipboard functionality now works with PySide (GH4282)
- Added a more informative error message when plot arguments contain overlapping color and style arguments (GH4402)
- `to_dict` now takes `records` as a possible outtype. Returns an array of column-keyed dictionaries. (GH4936)
- NaN handing in `get_dummies` (GH4446) with `dummy_na`

```python
# previously, nan was erroneously counted as 2 here
# now it is not counted at all
In [60]: get_dummies([1, 2, np.nan])
Out[60]:
   1.0  2.0
0  1  0
1  0  1
2  0  0
[3 rows x 2 columns]

# unless requested
In [61]: get_dummies([1, 2, np.nan], dummy_na=True)
            1.0  2.0  NaN
Out[61]: 
0 1 0 0
1 0 1 0
2 0 0 1
[3 rows x 3 columns]
```

- `timedelta64[ns]` operations. See the docs.
**Warning**: Most of these operations require `numpy >= 1.7`

Using the new top-level `to_timedelta`, you can convert a scalar or array from the standard timedelta format (produced by `to_csv`) into a timedelta type (`np.timedelta64` in nanoseconds).

```
In [62]: to_timedelta('1 days 06:05:01.00003')
Out[62]: Timedelta('1 days 06:05:01.000030')

In [63]: to_timedelta('15.5us')
Out[63]: Timedelta('0 days 00:00:00.000015')

In [64]: to_timedelta(['1 days 06:05:01.00003','15.5us','nan'])
Out[64]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT], dtype='timedelta64[ns]', freq=None)

In [65]: to_timedelta(np.arange(5),unit='s')
Out[65]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'], dtype='timedelta64[ns]', freq=None)

In [66]: to_timedelta(np.arange(5),unit='d')
Out[66]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'], dtype='timedelta64[ns]', freq=None)
```

A Series of dtype `timedelta64[ns]` can now be divided by another `timedelta64[ns]` object, or astyped to yield a `float64` dtyped Series. This is frequency conversion. See the docs for the docs.

```
In [67]: from datetime import timedelta

In [68]: td = Series(date_range('20130101',periods=4))-Series(date_range('20121201',periods=4))

In [69]: td[2] += np.timedelta64(timedelta(minutes=5,seconds=3))

In [70]: td[3] = np.nan

In [71]: td
Out[71]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3   NaT
Length: 4, dtype: timedelta64[ns]

# to days
In [72]: td / np.timedelta64(1,'D')
```

(continues on next page)
Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series

```
In [76]: td * -1
Out[76]:
0   -31 days 00:00:00
1   -31 days 00:00:00
2   -32 days 23:54:57
3      NaT
Length: 4, dtype: timedelta64[ns]
```

```
In [77]: td * Series([1,2,3,4])
Out[77]:
0  31 days 00:00:00
1  62 days 00:00:00
2  93 days 00:15:09
3      NaT
Length: 4, dtype: timedelta64[ns]
```

Absolute `DateOffset` objects can act equivalently to `timedeltas`

```
In [78]: from pandas import offsets

In [79]: td + offsets.Minute(5) + offsets.Milli(5)
Out[79]:
0  31 days 00:05:00.005000
1  31 days 00:05:00.005000
2  31 days 00:10:03.005000
3      NaT
```

(continues on next page)
Fillna is now supported for timedeltas

```python
In [80]: td.fillna(0)
Out[80]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3   0 days 00:00:00
Length: 4, dtype: timedelta64[ns]
```

```python
In [81]: td.fillna(timedelta(days=1,seconds=5))
Out[81]:
0  31 days 00:00:00
1  31 days 00:00:00
2  31 days 00:05:03
3  1 days 00:00:05
Length: 4, dtype: timedelta64[ns]
```

You can do numeric reduction operations on timedeltas.

```python
In [82]: td.mean()
Out[82]: Timedelta('31 days 00:01:41')
```

```python
In [83]: td.quantile(.1)
Out[83]: Timedelta('31 days 00:00:00')
```

- `plot(kind='kde')` now accepts the optional parameters `bw_method` and `ind`, passed to `scipy.stats.gaussian_kde()` (for scipy >= 0.11.0) to set the bandwidth, and to `gkde.evaluate()` to specify the indices at which it is evaluated, respectively. See scipy docs. (GH4298)

- DataFrame constructor now accepts a numpy masked record array (GH3478)

- The new vectorized string method `extract` return regular expression matches more conveniently.

```python
In [84]: Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)')
Out[84]:
0  a 1
1  b 2
2  NaN
[3 rows x 1 columns]
```

Elements that do not match return NaN. Extracting a regular expression with more than one group returns a DataFrame with one column per group.

```python
In [85]: Series(['a1', 'b2', 'c3']).str.extract('(^[ab])(\d)')
Out[85]:
0  a 1
1  b 2
2  NaN NaN
```

(continues on next page)
Elements that do not match return a row of NaN. Thus, a Series of messy strings can be converted into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating get() to access tuples or re.match objects.

Named groups like

```python
In [86]: Series(['a1', 'b2', 'c3']).str.extract(  
       ....:    '(?P<letter>[ab])(?P<digit>\d)')  
       ....:
Out[86]:
   letter digit
0    a    1
1    b    2
2  NaN  NaN
[3 rows x 2 columns]
```

and optional groups can also be used.

```python
In [87]: Series(['a1', 'b2', '3']).str.extract(  
       ....:    '(?P<letter>[ab]?)(?P<digit>\d)')  
       ....:
Out[87]:
   letter digit
0    a    1
1    b    2
2  NaN    3
[3 rows x 2 columns]
```

• `read_stata` now accepts Stata 13 format (GH4291)

• `read_fwf` now infers the column specifications from the first 100 rows of the file if the data has correctly separated and properly aligned columns using the delimiter provided to the function (GH4488).

• support for nanosecond times as an offset

**Warning:** These operations require `numpy >= 1.7`

Period conversions in the range of seconds and below were reworked and extended up to nanoseconds. Periods in the nanosecond range are now available.

```python
In [88]: date_range('2013-01-01', periods=5, freq='5N')
Out[88]:
DatetimeIndex([  
    '2013-01-01 00:00:00',
    '2013-01-01 00:00:00.000000005',
    '2013-01-01 00:00:00.000000010',
    '2013-01-01 00:00:00.000000015',
    '2013-01-01 00:00:00.000000020'],
   dtype='datetime64[ns]', freq='5N')
```

or with frequency as offset
In [89]: date_range('2013-01-01', periods=5, freq=pd.offsets.Nano(5))
Out[89]:
DatetimeIndex([ '2013-01-01 00:00:00',
'2013-01-01 00:00:00.000000005',
'2013-01-01 00:00:00.000000010',
'2013-01-01 00:00:00.000000015',
'2013-01-01 00:00:00.000000020'],
dtype='datetime64[ns]', freq='5N')

Timestamps can be modified in the nanosecond range

In [90]: t = Timestamp('20130101 09:01:02')
In [91]: t + pd.tseries.offsets.Nano(123)
Out[91]: Timestamp('2013-01-01 09:01:02.000000123')

• A new method, isin for DataFrames, which plays nicely with boolean indexing. The argument to isin, what we’re comparing the DataFrame to, can be a DataFrame, Series, dict, or array of values. See the docs for more.

To get the rows where any of the conditions are met:

In [92]: dfi = DataFrame({'A': [1, 2, 3, 4], 'B': ['a', 'b', 'f', 'n']})
In [93]: dfi
Out[93]:
   A  B
0 1  a
1 2  b
2 3  f
3 4  n

[4 rows x 2 columns]
In [94]: other = DataFrame({'A': [1, 3, 3, 7], 'B': ['e', 'f', 'f', 'e']})
In [95]: mask = dfi.isin(other)
In [96]: mask
Out[96]:
   A  B
0  True False
1  False False
2  True  True
3  False False

[4 rows x 2 columns]
In [97]: dfi[mask.any(1)]

   A  B
0 1  a
2 3  f

[2 rows x 2 columns]

• Series now supports a to_frame method to convert it to a single-column DataFrame (GH5164)
• All R datasets listed here http://stat.ethz.ch/R-manual/R-devel/library/datasets/html/00Index.html can now be
loaded into Pandas objects

```python
# note that pandas.rpy was deprecated in v0.16.0
import pandas.rpy.common as com
com.load_data('Titanic')
```

- `tz_localize` can infer a fall daylight savings transition based on the structure of the unlocalized data (GH4230), see the docs
- `DatetimeIndex` is now in the API documentation, see the docs
- `json_normalize()` is a new method to allow you to create a flat table from semi-structured JSON data. See the docs (GH1067)
- Added PySide support for the qtpandas DataFrameModel and DataFrameWidget.
- Python csv parser now supports usecols (GH4335)
- Frequencies gained several new offsets:
  - `LastWeekOfMonth` (GH4637)
  - `FY5253`, and `FY5253Quarter` (GH4511)
- DataFrame has a new `interpolate` method, similar to Series (GH4434, GH1892)

```python
In [98]: df = DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
                   ....: 'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
In [99]: df.interpolate()
```

Additionally, the `method` argument to `interpolate` has been expanded to include `'nearest'`, `'zero'`, `'slinear'`, `'bicubic'`, `'krogh'`, `'piecewise_polynomial'`, `'pchip'`, `'polynomial'`, `'spline'` The new methods require scipy. Consult the Scipy reference guide and documentation for more information about when the various methods are appropriate. See the docs.

Interpolate now also accepts a `limit` keyword argument. This works similar to `fillna`'s limit:

```python
In [100]: ser = Series([1, 3, np.nan, np.nan, np.nan, 11])
In [101]: ser.interpolate(limit=2)
```

Interpolate now also accepts a `limit` keyword argument. This works similar to `fillna`'s limit:
• Added `wide_to_long` panel data convenience function. See the docs.

```python
In [102]: np.random.seed(123)

In [103]: df = pd.DataFrame({
        "A1970": {0: "a", 1: "b", 2: "c"},
        "A1980": {0: "d", 1: "e", 2: "f"},
        "B1970": {0: 2.5, 1: 1.2, 2: .7},
        "B1980": {0: 3.2, 1: 1.3, 2: .1},
        "X": dict(zip(range(3), np.random.randn(3)))
    })

In [104]: df["id"] = df.index

In [105]: df
Out[105]:
0     a     d  2.50  3.20 -1.10  0
1     b     e  1.20  1.30  0.00  1
2     c     f  0.70  0.10  0.30  2

[3 rows x 6 columns]
```

```python
In [106]: wide_to_long(df, ["A", "B"], i="id", j="year")

In [107]:

→ X A B id year
0 1970 -1.085631 a 2.5
1 1970 0.997345 b 1.2
2 1970 0.282978 c 0.7
3 1980 -1.085631 d 3.2
4 1980 0.997345 e 1.3
5 1980 0.282978 f 0.1

[6 rows x 3 columns]
```

• `to_csv` now takes a `date_format` keyword argument that specifies how output datetime objects should be formatted. Datetimes encountered in the index, columns, and values will all have this formatting applied. (GH4313)

• `DataFrame.plot` will scatter plot x versus y by passing `kind='scatter'` (GH2215)

• Added support for Google Analytics v3 API segment IDs that also supports v2 IDs. (GH5271)

### 1.24.9 Experimental

• The new `eval()` function implements expression evaluation using `numexpr` behind the scenes. This results in large speedups for complicated expressions involving large DataFrames/Series. For example,

```python
In [107]: nrows, ncols = 20000, 100

In [108]: df1, df2, df3, df4 = [DataFrame(randn(nrows, ncols))
        for _ in range(4)]

```
# eval with NumExpr backend

```python
In [109]: %timeit pd.eval('df1 + df2 + df3 + df4')
7.05 ms +- 224 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

# pure Python evaluation

```python
In [110]: %timeit df1 + df2 + df3 + df4
9.4 ms +- 330 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

For more details, see the [docs](#).

- Similar to pandas.eval, DataFrame has a new DataFrame.eval method that evaluates an expression in the context of the DataFrame. For example,

```python
In [111]: df = DataFrame(randn(10, 2), columns=['a', 'b'])
```

```python
In [112]: df.eval('a + b')
```

```
Out[112]:
   a   b
0 -0.685204  1.589745
1  1.589745 -0.685204
2  0.325441 -1.784153
3 -1.784153  0.325441
4  0.171850 -0.432893
5 -0.432893  0.171850
6 -1.895919  3.065587
7  3.065587 -1.895919
8 -0.092759  1.391365
9  1.391365 -0.092759
Length: 10, dtype: float64
```

- query() method has been added that allows you to select elements of a DataFrame using a natural query syntax nearly identical to Python syntax. For example,

```python
In [113]: n = 20
```

```python
In [114]: df = DataFrame(np.random.randint(n, size=(n, 3)), columns=['a', 'b', 'c'])
```

```python
In [115]: df.query('a < b < c')
```

```
Out[115]:
     a  b  c
11  1  5  8
15  8 16 19
```

selects all the rows of df where \(a < b < c\) evaluates to True. For more details see the [docs](#).

- pd.read_msgpack() and pd.to_msgpack() are now a supported method of serialization of arbitrary pandas (and python objects) in a lightweight portable binary format. See [docs](#).

**Warning:** Since this is an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

```python
In [116]: df = DataFrame(np.random.rand(5,2),columns=list('AB'))
```

(continues on next page)
In [117]: df.to_msgpack('foo.msg')

In [118]: pd.read_msgpack('foo.msg')
Out[118]:
   A     B
0 0.251082 0.017357
1 0.347915 0.929879
2 0.546233 0.203368
3 0.064942 0.031722
4 0.355309 0.524575

[5 rows x 2 columns]

In [119]: s = Series(np.random.rand(5),index=date_range('20130101',periods=5))

In [120]: pd.to_msgpack('foo.msg', df, s)

In [121]: pd.read_msgpack('foo.msg')
Out[121]:
   A     B
0 0.251082 0.017357
1 0.347915 0.929879
2 0.546233 0.203368
3 0.064942 0.031722
4 0.355309 0.524575

[5 rows x 2 columns], 2013-01-01 0.022321
2013-01-02 0.227025
2013-01-03 0.383282
2013-01-04 0.193225
2013-01-05 0.110977
Freq: D, Length: 5, dtype: float64

You can pass iterator=True to iterator over the unpacked results

In [122]: for o in pd.read_msgpack('foo.msg', iterator=True):
    ..........: print(o)
    ..........:

• pandas.io.gbq provides a simple way to extract from, and load data into, Google’s BigQuery Data Sets by way of pandas DataFrames. BigQuery is a high performance SQL-like database service, useful for performing ad-hoc queries against extremely large datasets. See the docs
from pandas.io import gbq

# A query to select the average monthly temperatures in the
# in the year 2000 across the USA. The dataset,
# publicata:samples.gsod, is available on all BigQuery accounts,
# and is based on NOAA gsod data.
query = """SELECT station_number as STATION,
month as MONTH, AVG(mean_temp) as MEAN_TEMP
FROM publicdata:samples.gsod
WHERE YEAR = 2000
GROUP BY STATION, MONTH
ORDER BY STATION, MONTH ASC""

# Fetch the result set for this query
# Your Google BigQuery Project ID
# To find this, see your dashboard:
# https://console.developers.google.com/iam-admin/projects?authuser=0
projectid = xxxxxxxxx;
df = gbq.read_gbq(query, project_id = projectid)

# Use pandas to process and reshape the dataset
df2 = df.pivot(index='STATION', columns='MONTH', values='MEAN_TEMP')
df3 = pandas.concat((df2.min(), df2.mean(), df2.max()),
axis=1, keys=['Min Tem', 'Mean Temp', 'Max Temp'])

The resulting DataFrame is:

<table>
<thead>
<tr>
<th>MONTH</th>
<th>Min Tem</th>
<th>Mean Temp</th>
<th>Max Temp</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>-53.336667</td>
<td>39.827892</td>
<td>89.770968</td>
</tr>

</tbody>
</table>

Warning: To use this module, you will need a BigQuery account. See <https://cloud.google.com/products/big-query> for details.
As of 10/10/13, there is a bug in Google’s API preventing result sets from being larger than 100,000 rows. A patch is scheduled for the week of 10/14/13.
1.24.10 Internal Refactoring

In 0.13.0 there is a major refactor primarily to subclass Series from NDFrame, which is the base class currently for DataFrame and Panel, to unify methods and behaviors. Series formerly subclassed directly from ndarray. (GH4080, GH3862, GH816)

**Warning:** There are two potential incompatibilities from < 0.13.0

- Using certain numpy functions would previously return a Series if passed a Series as an argument. This seems only to affect np.ones_like, np.empty_like, np.diff and np.where. These now return ndarrays.

```python
In [123]: s = Series([1, 2, 3, 4])
```

**Numpy Usage**

```python
In [124]: np.ones_like(s)
Out[124]: array([1, 1, 1, 1])
```

```python
In [125]: np.diff(s)
Out[125]: array([1, 1, 1])
```

```python
In [126]: np.where(s>1,s,np.nan)
Out[126]: array([ NaN, 2., 3., 4.])
```

**Pandonic Usage**

```python
In [127]: Series(1,index=s.index)
Out[127]:
0  1
1  1
2  1
3  1
Length: 4, dtype: int64
```

```python
In [128]: s.diff()
Out[128]:
0  NaN
1  1.0
2  1.0
3  1.0
Length: 4, dtype: float64
```

```python
In [129]: s.where(s>1)
Out[129]:
0  NaN
1  2.0
2  3.0
3  4.0
Length: 4, dtype: float64
```

- Passing a Series directly to a cython function expecting an ndarray type will no long work directly, you must pass Series.values, See Enhancing Performance
- Series(0.5) would previously return the scalar 0.5, instead this will return a 1-element Series
- This change breaks rpy2<2.3.8, an Issue has been opened against rpy2 and a workaround is detailed in GH5698. Thanks @JanSchulz.
• Pickle compatibility is preserved for pickles created prior to 0.13. These must be unpickled with pd.read_pickle, see Pickling.
• Refactor of series.py/frame.py/panel.py to move common code to generic.py
  – added _setup_axes to created generic NDFrame structures
  – moved methods
  * from_axes,_wrap_array,axes,ix,loc,lloc,shape,empty,swapaxes,transpose,pop
  * __iter__,keys,__contains__,__len__,__neg__,__invert__
  * convert_objects,as_blocks,as_matrix,values
  * __getstate__,__setstate__ (compat remains in frame/panel)
  * __getattr__,__setattr__
  * _indexed_same,reindex_like,align,where,mask
  * fillna,replace(Series replace is now consistent with DataFrame)
  * filter (also added axis argument to selectively filter on a different axis)
  * reindex,reindex_axis,take
  * truncate (moved to become part of NDFrame)
• These are API changes which make Panel more consistent with DataFrame
  – swapaxes on a Panel with the same axes specified now return a copy
  – support attribute access for setting
  – filter supports the same API as the original DataFrame filter
• Reindex called with no arguments will now return a copy of the input object
• TimeSeries is now an alias for Series. the property is_time_series can be used to distinguish (if desired)
• Refactor of Sparse objects to use BlockManager
  – Created a new block type in internals, SparseBlock, which can hold multi-dtypes and is non-consolidatable. SparseSeries and SparseDataFrame now inherit more methods from there hierarchy (Series/DataFrame), and no longer inherit from SparseArray (which instead is the object of the SparseBlock)
  – Sparse suite now supports integration with non-sparse data. Non-float sparse data is supportable (partially implemented)
  – Operations on sparse structures within DataFrames should preserve sparseness, merging type operations will convert to dense (and back to sparse), so might be somewhat inefficient
  – enable setitem on SparseSeries for boolean/integer/slices
  – SparsePanels implementation is unchanged (e.g. not using BlockManager, needs work)
• added ftypes method to Series/DataFrame, similar to dtypes, but indicates if the underlying is sparse/dense (as well as the dtype)
• All NDFrame objects can now use __finalize__() to specify various values to propagate to new objects from an existing one (e.g. name in Series will follow more automatically now)
• Internal type checking is now done via a suite of generated classes, allowing isinstance(value, klass) without having to directly import the klass, courtesy of @jratner
• Bug in Series update where the parent frame is not updating its cache based on changes (GH4080) or types (GH3217), fillna (GH3386)
• Indexing with dtype conversions fixed (GH4463, GH4204)
• Refactor Series.update to core/generic.py (GH4604, GH4618), allow method= in reindexing on a Series to work
• Series.copy no longer accepts the order parameter and is now consistent with NDFrame copy
• Refactor rename methods to core/generic.py; fixes Series.rename for (GH4605), and adds rename with the same signature for Panel
• Refactor clip methods to core/generic.py (GH4798)
• Refactor of _get_numeric_data/_get_bool_data to core/generic.py, allowing Series/Panel functionality
• Series (for index) / Panel (for items) now allow attribute access to its elements (GH1903)

```
In [130]: s = Series([1,2,3],index=list('abc'))
In [131]: s.b
Out[131]: 2
In [132]: s.a = 5
In [133]: s
Out[133]:
   a  5
   b  2
   c  3
Length: 3, dtype: int64
```

1.24.11 Bug Fixes

See V0.13.0 Bug Fixes for an extensive list of bugs that have been fixed in 0.13.0.

See the full release notes or issue tracker on GitHub for a complete list of all API changes, Enhancements and Bug Fixes.

1.25 v0.12.0 (July 24, 2013)

This is a major release from 0.11.0 and includes several new features and enhancements along with a large number of bug fixes.

Highlights include a consistent I/O API naming scheme, routines to read html, write multi-indexes to csv files, read & write STATA data files, read & write JSON format files, Python 3 support for HDFStore, filtering of groupby expressions via filter, and a revamped replace routine that accepts regular expressions.

1.25.1 API changes

• The I/O API is now much more consistent with a set of top level reader functions accessed like pd.read_csv() that generally return a pandas object.

```python
read_csv()
```
- read_excel
- read_hdf
- read_sql
- read_json
- read_html
- read_stata
- read_clipboard

The corresponding writer functions are object methods that are accessed like df.to_csv()

- to_csv
- to_excel
- to_hdf
- to_sql
- to_json
- to_html
- to_stata
- to_clipboard

• Fix modulo and integer division on Series, DataFrames to act similarly to float dtypes to return np.nan or np.inf as appropriate (GH3590). This correct a numpy bug that treats integer and float dtypes differently.

```
In [1]: p = DataFrame({ 'first' : [4,5,8], 'second' : [0,0,3] })
In [2]: p % 0
Out[2]:
            first  second
0       NaN      NaN
1       NaN      NaN
2       NaN      NaN
[3 rows x 2 columns]
In [3]: p % p
   →
            first  second
0   0.0      NaN
1   0.0      NaN
2   0.0      0.0
[3 rows x 2 columns]
In [4]: p / p
   →
            first  second
0   1.0      NaN
1   1.0      NaN
2   1.0      1.0
```

(continues on next page)
• Add **squeeze** keyword to **groupby** to allow reduction from DataFrame -> Series if groups are unique. This is a Regression from 0.10.1. We are reverting back to the prior behavior. This means groupby will return the same shaped objects whether the groups are unique or not. Revert this issue (GH2893) with (GH3596).

```python
In [6]: df2 = DataFrame([("val1": 1, "val2" : 20), {"val1":1, "val2": 19},  
...:              {"val1":1, "val2": 27}, {"val1":1, "val2": 12})]

In [7]: def func(dataf):  
...:     return dataf["val2"] - dataf["val2"].mean()

In [8]: df2.groupby("val1", squeeze=True).apply(func)
```

```
Out[8]:  
0  0.5  
1 -0.5  
2  7.5  
3 -7.5  
Name: 1, Length: 4, dtype: float64
```

• Raise on **iloc** when boolean indexing with a label based indexer mask e.g. a boolean Series, even with integer labels, will raise. Since **iloc** is purely positional based, the labels on the Series are not alignable (GH3631). This case is rarely used, and there are plenty of alternatives. This preserves the **iloc** API to be purely positional based.

```python
In [10]: df = DataFrame(lrange(5), list('ABCDE'), columns=['a'])

In [11]: mask = (df.a%2 == 0)

In [12]: mask
Out[12]:  
   A   True
```
B  False
C   True
D  False
E   True
Name: a, Length: 5, dtype: bool

# this is what you should use
In [13]: df.loc[mask]

    a  
A  0  
C  2  
E  4  
[3 rows x 1 columns]

# this will work as well
In [14]: df.iloc[mask.values]

    a  
A  0  
C  2  
E  4  
[3 rows x 1 columns]

def.iloc[mask] will raise a ValueError

• The raise_on_error argument to plotting functions is removed. Instead, plotting functions raise a
  TypeError when the dtype of the object is object to remind you to avoid object arrays whenever
  possible and thus you should cast to an appropriate numeric dtype if you need to plot something.

• Add colormap keyword to DataFrame plotting methods. Accepts either a matplotlib colormap object (ie,
  matplotlib.cm.jet) or a string name of such an object (ie, ‘jet’). The colormap is sampled to select the color for
  each column. Please see Colormaps for more information. (GH3860)

• DataFrame.interpolate() is now deprecated. Please use DataFrame.fillna() and
  DataFrame.replace() instead. (GH3582, GH3675, GH3676)

• the method and axis arguments of DataFrame.replace() are deprecated

• DataFrame.replace's infer_types parameter is removed and now performs conversion by default.  
  (GH3907)

• Add the keyword allow_duplicates to DataFrame.insert to allow a duplicate column to be inserted
  if True, default is False (same as prior to 0.12) (GH3679)

• Implement __nonzero__ for NDFrame objects (GH3691, GH3696)

• IO api
  – added top-level function read_excel to replace the following. The original API is deprecated and will
    be removed in a future version

```python
from pandas.io.parsers import ExcelFile
xls = ExcelFile('path_to_file.xls')
xls.parse('Sheet1', index_col=None, na_values=['NA'])
```
With

```python
import pandas as pd
pd.read_excel('path_to_file.xls', 'Sheet1', index_col=None, na_values=['NA'])
```

- added top-level function `read_sql` that is equivalent to the following

```python
from pandas.io.sql import read_frame
read_frame(..)
```

- `DataFrame.to_html` and `DataFrame.to_latex` now accept a path for their first argument (GH3702)
- Do not allow astypes on `datetime64[ns]` except to `object`, and `timedelta64[ns]` to `object/int` (GH3425)
- The behavior of `datetime64` dtypes has changed with respect to certain so-called reduction operations (GH3726). The following operations now raise a `TypeError` when performed on a `Series` and return an empty `Series` when performed on a `DataFrame` similar to performing these operations on, for example, a `DataFrame` of slice objects:
  - sum, prod, mean, std, var, skew, kurt, corr, and cov
- `read_html` now defaults to `None` when reading, and falls back on `bs4 + html5lib` when `lxml` fails to parse. a list of parsers to try until success is also valid
- The internal `pandas` class hierarchy has changed (slightly). The previous `PandasObject` now is called `PandasContainer` and a new `PandasObject` has become the baseclass for `PandasContainer` as well as `Index`, `Categorical`, `GroupBy`, `SparseList`, and `SparseArray` (+ their base classes). Currently, `PandasObject` provides string methods (from `StringMixin`). (GH4090, GH4092)
- New `StringMixin` that, given a `__unicode__` method, gets python 2 and python 3 compatible string methods (`__str__`, `__bytes__`, and `__repr__`). Plus string safety throughout. Now employed in many places throughout the pandas library. (GH4090, GH4092)

### 1.25.2 I/O Enhancements

- `pd.read_html()` can now parse HTML strings, files or urls and return DataFrames, courtesy of @cpcloud. (GH3477, GH3605, GH3606, GH3616). It works with a single parser backend: BeautifulSoup4 + html5lib. See the docs

You can use `pd.read_html()` to read the output from `DataFrame.to_html()` like so

```python
In [15]: df = DataFrame({'a': range(3), 'b': list('abc'))

In [16]: print(df)
   a  b
0  0  a
1  1  b
2  2  c

[3 rows x 2 columns]

In [17]: html = df.to_html()

In [18]: alist = pd.read_html(html, index_col=0)

In [19]: print(df == alist[0])
```
Note that a list here is a Python list so `pd.read_html()` and `DataFrame.to_html()` are not inverses.

- `pd.read_html()` no longer performs hard conversion of date strings (GH3656).

**Warning:** You may have to install an older version of BeautifulSoup4, *See the installation docs*

- Added module for reading and writing Stata files: `pandas.io.stata` (GH1512) accessible via `read_stata` top-level function for reading, and `to_stata` DataFrame method for writing, *See the docs*

- Added module for reading and writing json format files: `pandas.io.json` accessible via `read_json` top-level function for reading, and `to_json` DataFrame method for writing, *See the docs* various issues (GH1226, GH3804, GH3876, GH3867, GH1305)

- MultiIndex column support for reading and writing csv format files

  - The header option in `read_csv` now accepts a list of the rows from which to read the index.

  - The option, `tupleize_cols` can now be specified in both `to_csv` and `read_csv`, to provide compatibility for the pre 0.12 behavior of writing and reading MultiIndex columns via a list of tuples. The default in 0.12 is to write lists of tuples and *not* interpret list of tuples as a MultiIndex column.

  Note: The default behavior in 0.12 remains unchanged from prior versions, but starting with 0.13, the default to write and read MultiIndex columns will be in the new format. (GH3571, GH1651, GH3141)

  - If an `index_col` is not specified (e.g. you don’t have an index, or wrote it with `df.to_csv(..., index=False)`), then any names on the columns index will be lost.

```
In [20]: from pandas.util.testing import makeCustomDataFrame as mkdf
In [21]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)
In [22]: df.to_csv('mi.csv')
In [23]: print(open('mi.csv').read())
C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,R_l0_g0,R_l1_g0,R0C0,R0C1,R0C2
R_l0_g1,R_l1_g1,R1C0,R1C1,R1C2
R_l0_g2,R_l1_g2,R2C0,R2C1,R2C2
R_l0_g3,R_l1_g3,R3C0,R3C1,R3C2
R_l0_g4,R_l1_g4,R4C0,R4C1,R4C2
```

```
In [24]: pd.read_csv('mi.csv', header=[0,1,2,3], index_col=[0,1])
```

---

(continues on next page)
• Support for HDFStore (via PyTables 3.0.0) on Python3

• Iterator support via read_hdf that automatically opens and closes the store when iteration is finished. This is only for tables

```python
In [25]: path = 'store_iterator.h5'
In [26]: DataFrame(randn(10,2)).to_hdf(path,'df',table=True)
In [27]: for df in read_hdf(path,'df', chunksize=3):
   ....:   print df
   ....:
   0  1
   0  0.713216 -0.778461
   1 -0.661062  0.862877
   2  0.344342  0.149565
   3 -0.626968 -0.875772
   4 -0.930687 -0.218983
   5  0.949965 -0.442354
   6 -0.402985  1.111358
   7 -0.241527 -0.670477
   8  0.049355  0.632633
   9 -1.502767 -1.225492
```

• read_csv will now throw a more informative error message when a file contains no columns, e.g., all newline characters

1.25.3 Other Enhancements

• DataFrame.replace() now allows regular expressions on contained Series with object dtype. See the examples section in the regular docs Replacing via String Expression

For example you can do

```python
In [25]: df = DataFrame({'a': list('ab..'), 'b': [1, 2, 3, 4]})
In [26]: df.replace(regex=r'\s*\.', value=np.nan)
Out[26]:
     a  b
0   a  1
1   b  2
```

(continues on next page)
to replace all occurrences of the string ' . ' with zero or more instances of surrounding whitespace with NaN.

Regular string replacement still works as expected. For example, you can do

```python
In [27]: df.replace('.', np.nan)
Out[27]:
  a  b
0  a  1
1  b  2
2  NaN  3
3  NaN  4
[4 rows x 2 columns]
```

to replace all occurrences of the string ' . ' with NaN.

- `pd.melt()` now accepts the optional parameters `var_name` and `value_name` to specify custom column names of the returned DataFrame.
- `pd.set_option()` now allows N option, value pairs (GH3667).

Let's say that we had an option 'a.b' and another option 'b.c'. We can set them at the same time:

```python
In [28]: pd.get_option('a.b')
Out[28]: 2

In [29]: pd.get_option('b.c')
Out[29]: 3

In [30]: pd.set_option('a.b', 1, 'b.c', 4)
In [31]: pd.get_option('a.b')
Out[31]: 1

In [32]: pd.get_option('b.c')
Out[32]: 4
```

- The `filter` method for group objects returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [33]: sf = Series([1, 1, 2, 3, 3, 3])
In [34]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[34]:
3  3
4  3
5  3
Length: 3, dtype: int64
```

The argument of `filter` must a function that, applied to the group as a whole, returns `True` or `False`. Another useful operation is filtering out elements that belong to groups with only a couple members.
In 

In [35]: df = DataFrame({'A': np.arange(8), 'B': list('aabbbbcc')})

In [36]: df.groupby('B').filter(lambda x: len(x) > 2)

Out[36]:
    A B
  2 2 b
  3 3 b
  4 4 b
  5 5 b

[4 rows x 2 columns]

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

In [37]: df.groupby('B').filter(lambda x: len(x) > 2, dropna=False)

Out[37]:
    A  B
  0  NaN NaN
  1  NaN NaN
  2  2.0 b
  3  3.0 b
  4  4.0 b
  5  5.0 b
  6  NaN NaN
  7  NaN NaN

[8 rows x 2 columns]

• Series and DataFrame hist methods now take a figsize argument (GH3834)
• DatetimeIndexes no longer try to convert mixed-integer indexes during join operations (GH3877)
• Timestamp.min and Timestamp.max now represent valid Timestamp instances instead of the default date-time.min and datetime.max (respectively), thanks @SleepingPills
• read_html now raises when no tables are found and BeautifulSoup==4.2.0 is detected (GH4214)

1.25.4 Experimental Features

• Added experimental CustomBusinessDay class to support DateOffsets with custom holiday calendars and custom weekmasks. (GH2301)

Note: This uses the numpy.busdaycalendar API introduced in Numpy 1.7 and therefore requires Numpy 1.7.0 or newer.
# add that for a couple of years
In [41]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01')]

In [42]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [43]: dt = datetime(2013, 4, 30)

In [44]: print(dt + 2 * bday_egypt)
2013-05-05 00:00:00

In [45]: dts = date_range(dt, periods=5, freq=bday_egypt)

In [46]: print(Series(dts.weekday, dts).map(Series('Mon Tue Wed Thu Fri Sat Sun'.split())))

1.25.5 Bug Fixes

- Plotting functions now raise a TypeError before trying to plot anything if the associated objects have have a dtype of object (GH1818, GH3572, GH3911, GH3912), but they will try to convert object arrays to numeric arrays if possible so that you can still plot, for example, an object array with floats. This happens before any drawing takes place which eliminates any spurious plots from showing up.

- fillna methods now raise a TypeError if the value parameter is a list or tuple.

- Series.str now supports iteration (GH3638). You can iterate over the individual elements of each string in the Series. Each iteration yields yields a Series with either a single character at each index of the original Series or NaN. For example,

In [47]: strs = 'go', 'bow', 'joe', 'slow'

In [48]: ds = Series(strs)

In [49]: for s in ds.str:
   ....:     print(s)
   ....:
0  g
1  b
2  j
3  s
Length: 4, dtype: object
0  o
1  o
2  o
3  l
Length: 4, dtype: object
0  NaN
1  w
The last element yielded by the iterator will be a `Series` containing the last element of the longest string in the `Series` with all other elements being `NaN`. Here since 'slow' is the longest string and there are no other strings with the same length 'w' is the only non-null string in the yielded `Series`.

- `HDFStore` will retain index attributes (freq,tz,name) on recreation (GH3499)
- will warn with a `AttributeConflictWarning` if you are attempting to append an index with a different frequency than the existing, or attempting to append an index with a different name than the existing
- support datelike columns with a timezone as `data_columns` (GH2852)

- Non-unique index support clarified (GH3468).
  - Fix assigning a new index to a duplicate index in a DataFrame would fail (GH3468)
  - Fix construction of a DataFrame with a duplicate index
  - `ref_locs` support to allow duplicative indices across dtypes, allows `iget` support to always find the index (even across dtypes) (GH2194)
  - `applymap` on a DataFrame with a non-unique index now works (removed warning) (GH2786), and fix (GH3230)
  - Fix to `.csv` to handle non-unique columns (GH3495)
  - Duplicate indexes with `getitem` will return items in the correct order (GH3455, GH3457) and handle missing elements like unique indices (GH3561)
  - Duplicate indexes with and empty DataFrame.from_records will return a correct frame (GH3562)
  - Concat to produce a non-unique columns when duplicates are across dtypes is fixed (GH3602)
  - Allow `insert/delete` to non-unique columns (GH3679)
  - Non-unique indexing with a slice via `loc` and friends fixed (GH3659)
  - Allow `insert/delete` to non-unique columns (GH3679)

pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- Extend reindex to correctly deal with non-unique indices (GH3679)
- DataFrame.itertuples() now works with frames with duplicate column names (GH3873)
- Bug in non-unique indexing via iloc (GH4017); added takeable argument to reindex for location-based taking
- Allow non-unique indexing in series via .ix/.loc and __getitem__ (GH4246)
- Fixed non-unique indexing memory allocation issue with .ix/.loc (GH4280)
- DataFrame.from_records did not accept empty recarrays (GH3682)
- read_html now correctly skips tests (GH3741)
- Fixed a bug where DataFrame.replace with a compiled regular expression in the to_replace argument wasn’t working (GH3907)
- Improved network test decorator to catch IOError (and therefore URLError as well). Added with_connectivity_check decorator to allow explicitly checking a website as a proxy for seeing if there is network connectivity. Plus, new optional_args decorator factory for decorators. (GH3910, GH3914)
- Fixed testing issue where too many sockets where open thus leading to a connection reset issue (GH3982, GH3985, GH4028, GH4054)
- Fixed failing tests in test_yahoo, test_google where symbols were not retrieved but were being accessed (GH3982, GH3985, GH4028, GH4054)
- Series.hist will now take the figure from the current environment if one is not passed
- Fixed bug where a 1xN DataFrame would barf on a 1xN mask (GH4071)
- Fixed running of tox under python3 where the pickle import was getting rewritten in an incompatible way (GH4062, GH4063)
- Fixed bug where sharex and sharey were not being passed to grouped_hist (GH4089)
- Fixed bug in DataFrame.replace where a nested dict wasn’t being iterated over when regex=False (GH4115)
- Fixed bug in the parsing of microseconds when using the format argument in to_datetime (GH4152)
- Fixed bug in PandasAutoDateLocator where invert_xaxis triggered incorrectly MilliSecondLocator (GH3990)
- Fixed bug in plotting that wasn’t raising on invalid colormap for matplotlib 1.1.1 (GH4215)
- Fixed the legend displaying in DataFrame.plot(kind='kde') (GH4216)
- Fixed bug where Index slices weren’t carrying the name attribute (GH4226)
- Fixed bug in initializing DatetimeIndex with an array of strings in a certain time zone (GH4229)
- Fixed bug where html5lib wasn’t being properly skipped (GH4265)
- Fixed bug where get_data_famafrench wasn’t using the correct file edges (GH4281)

See the full release notes or issue tracker on GitHub for a complete list.

1.26 v0.11.0 (April 22, 2013)

This is a major release from 0.10.1 and includes many new features and enhancements along with a large number of bug fixes. The methods of Selecting Data have had quite a number of additions, and Dtype support is now full-fledged. There are also a number of important API changes that long-time pandas users should pay close attention to.
There is a new section in the documentation, *10 Minutes to Pandas*, primarily geared to new users.

There is a new section in the documentation, *Cookbook*, a collection of useful recipes in pandas (and that we want contributions!).

There are several libraries that are now *Recommended Dependencies*

### 1.26.1 Selection Choices

Starting in 0.11.0, object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- **.loc** is strictly label based, will raise *KeyError* when the items are not found, allowed inputs are:
  - A single label, e.g. 5 or 'a', (note that 5 is interpreted as a *label* of the index. This use is *not* an integer position along the index)
  - A list or array of labels ['a', 'b', 'c']
  - A slice object with labels 'a':'f', (note that contrary to usual python slices, both the start and the stop are included!)
  - A boolean array

  See more at *Selection by Label*

- **.iloc** is strictly integer position based (from 0 to length-1 of the axis), will raise *IndexError* when the requested indices are out of bounds. Allowed inputs are:
  - An integer e.g. 5
  - A list or array of integers [4, 3, 0]
  - A slice object with ints 1:7
  - A boolean array

  See more at *Selection by Position*

- **.ix** supports mixed integer and label based access. It is primarily label based, but will fallback to integer positional access. **.ix** is the most general and will support any of the inputs to **.loc** and **.iloc**, as well as support for floating point label schemes. **.ix** is especially useful when dealing with mixed positional and label based hierarchial indexes.

  As using integer slices with **.ix** have different behavior depending on whether the slice is interpreted as position based or label based, it’s usually better to be explicit and use **.iloc** or **.loc**.

  See more at *Advanced Indexing* and *Advanced Hierarchical*.

### 1.26.2 Selection Deprecations

Starting in version 0.11.0, these methods *may* be deprecated in future versions.

- **irow**
- **icol**
- **iget_value**

See the section *Selection by Position* for substitutes.
1.26.3 Dtypes

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the \texttt{dtype} keyword, a passed \texttt{ndarray}, or a passed \texttt{Series}, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will \textbf{NOT} be combined. The following example will give you a taste.

```python
In [1]: df1 = DataFrame(randn(8, 1), columns = ['A'], dtype = 'float32')

In [2]: df1
Out[2]:
   A
0  1.392665
1 -0.123497
2 -0.402761
3 -0.246604
4 -0.288433
5 -0.763434
6  2.069526
7 -1.203569

[8 rows x 1 columns]

In [3]: df1.dtypes

A  float32
Length: 1, dtype: object

In [4]: df2 = DataFrame(dict( A = Series(randn(8),dtype='float16'),
                          B = Series(randn(8)),
                          C = Series(randn(8),dtype='uint8') ))

In [5]: df2
Out[5]:
   A   B   C
0  0.591797 -0.038605 0
1  0.841309 -0.460478 1
2 -0.500977 -0.310458 0
3 -0.816406  0.866493 254
4 -0.207031  0.245972 0
5 -0.664062  0.319442 1
6  0.580566  1.378512 1
7 -0.965820  0.292502 255

[8 rows x 3 columns]

In [6]: df2.dtypes

A  float16
B  float64
C  uint8
Length: 3, dtype: object

# here you get some upcasting
In [7]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2
```
In [8]: df3

Out[8]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>1.984462</td>

</table>

[8 rows x 3 columns]

In [9]: df3.dtypes

Out[9]:

˓→

A  float32
B  float64
C  float64

Length: 3, dtype: object

### 1.26.4 Dtype Conversion

This is lower-common-denominator upcasting, meaning you get the dtype which can accommodate all of the types

In [10]: df3.values.dtype

Out[10]: dtype('float64')

Conversion

In [11]: df3.astype('float32').dtypes

Out[11]:

A  float32
B  float32
C  float32

Length: 3, dtype: object

Mixed Conversion

In [12]: df3['D'] = '1.'

In [13]: df3['E'] = '1'

In [14]: df3.convert_objects(convert_numeric=True).dtypes

Out[14]:

A  float32
B  float64
C  float64
D  float64
E  int64

Length: 5, dtype: object

# same, but specific dtype conversion
In [15]: df3['D'] = df3['D'].astype('float16')
In [16]: df3['E'] = df3['E'].astype('int32')

In [17]: df3.dtypes
Out[17]:
A    float32
B    float64
C    float64
D    float16
E     int32
Length: 5, dtype: object

Forcing Date coercion (and setting NaT when not datelike)

In [18]: from datetime import datetime

In [19]: s = Series([datetime(2001,1,1,0,0), 'foo', 1.0, 1, Timestamp('20010104'), '20010105'],dtype='O')

In [20]: s.convert_objects(convert_dates='coerce')
Out[20]:
0  2001-01-01
1       NaT
2       NaT
3       NaT
4  2001-01-04
5  2001-01-05
Length: 6, dtype: datetime64[ns]

1.26.5 Dtype Gotchas

Platform Gotchas

Starting in 0.11.0, construction of DataFrame/Series will use default dtypes of int64 and float64, regardless of platform. This is not an apparent change from earlier versions of pandas. If you specify dtypes, they WILL be respected, however (GH2837)

The following will all result in int64 dtypes

In [21]: DataFrame([[1,2]],columns=['a']).dtypes
Out[21]:
a    int64
Length: 1, dtype: object

In [22]: DataFrame({'a' : [1,2] }).dtypes
Out[22]:
a    int64
Length: 1, dtype: object

In [23]: DataFrame({'a' : 1 }, index=range(2)).dtypes
Out[23]:
˓→a    int64
Length: 1, dtype: object
Keep in mind that `DataFrame(np.array([1, 2]))` **WILL** result in `int32` on 32-bit platforms!

### Upcasting Gotchas

Performing indexing operations on integer type data can easily upcast the data. The `dtype` of the input data will be preserved in cases where `nans` are not introduced.

```
In [24]: dfi = df3.astype('int32')
In [25]: dfi['D'] = dfi['D'].astype('int64')
In [26]: dfi
Out[26]:
     A   B  C  D  E
0  1.0 0.0 0.0 1.0 1.0
1  0.0 0.0 0.0 1.0 1.0
2  0.0 0.0 0.0 1.0 1.0
3 -1.0 254.0 1.0 1.0 1.0
4  0.0 0.0 0.0 1.0 1.0
5 -1.0  1.0 1.0 1.0 1.0
6  2.0  1.0  1.0 1.0 1.0
7 -2.0 255.0 1.0 1.0 1.0
[8 rows x 5 columns]
```

```
In [27]: dfi.dtypes
\nA    int32
B    int32
C    int32
D    int64
E    int32
Length: 5, dtype: object

In [28]: casted = dfi[dfi>0]
In [29]: casted
Out[29]:
     A   B   C   D  E
0  1.0  NaN NaN  1.0 1.0
1  NaN  NaN  1.0  1.0 1.0
2  NaN  NaN  NaN  1.0 1.0
3  NaN  NaN  254.0  1.0 1.0
4  NaN  NaN  NaN  1.0 1.0
5  NaN  NaN  1.0  1.0 1.0
6  2.0  1.0  1.0  1.0 1.0
7  NaN  NaN  255.0  1.0 1.0
[8 rows x 5 columns]
```

```
In [30]: casted.dtypes
\nA    float64
B    float64
C    float64
D    int64
E    int32
```
While float dtypes are unchanged.

```python
In [31]: df4 = df3.copy()
In [32]: df4['A'] = df4['A'].astype('float32')
In [33]: df4.dtypes
Out[33]:
A float32
B float64
C float64
D float16
E int32
Length: 5, dtype: object
```

```python
In [34]: casted = df4[df4>0]
In [35]: casted
Out[35]:
A  B  C  D  E
0 1.984462  NaN  NaN 1.0 1
1 0.717812  NaN  1.0 1.0 1
2  NaN  NaN  NaN 1.0 1
3  NaN 0.866493  254.0 1.0 1
4  NaN 0.245972  NaN 1.0 1
5  NaN 0.319442  1.0 1.0 1
6 2.650092  1.378512  1.0 1.0 1
7  NaN 0.292502  255.0 1.0 1
[8 rows x 5 columns]
```

```python
In [36]: casted.dtypes
```

1.26.6 Datetimes Conversion

Datetime64[ns] columns in a DataFrame (or a Series) allow the use of np.nan to indicate a nan value, in addition to the traditional NaT, or not-a-time. This allows convenient nan setting in a generic way. Furthermore datetime64[ns] columns are created by default, when passed datetimelike objects (this change was introduced in 0.10.1) (GH2809, GH2810)

```python
In [37]: df = DataFrame(randn(6,2),date_range('20010102',periods=6),columns=['A','B'])
In [38]: df['timestamp'] = Timestamp('20010103')
In [39]: df
```

(continues on next page)

Astype conversion on datetime64[ns] to object, implicitly converts NaT to np.nan

In [43]: import datetime

In [44]: s = Series([datetime.datetime(2001, 1, 2, 0, 0) for i in range(3)])

In [45]: s.dtype

Out[45]:

dtype('<M8[ns]')

In [46]: s[1] = np.nan

In [47]: s

Out[47]:

0 2001-01-02
1 NaT
2 2001-01-02
Length: 3, dtype: datetime64[ns]

In [48]: s.dtype

Out[48]:

dtype('<M8[ns]')

In [49]: s = s.astype('O')
1.26.7 API changes

- Added to_series() method to indices, to facilitate the creation of indexers (GH3275)
- HDFStore
  - added the method select_column to select a single column from a table as a Series.
  - deprecated the unique method, can be replicated by select_column(key, column).unique()
  - min_itemsize parameter to append will now automatically create data_columns for passed keys

1.26.8 Enhancements

- Improved performance of df.to_csv() by up to 10x in some cases. (GH3059)
- Numexpr is now a Recommended Dependencies, to accelerate certain types of numerical and boolean operations
- Bottleneck is now a Recommended Dependencies, to accelerate certain types of nan operations
- HDFStore
  - support read_hdf/to_hdf API similar to read_csv/to_csv

  \[
  \text{In } [52]: \text{ df = DataFrame(dict}(A=lrange(5), B=lrange(5))) \\
  \text{In } [53]: \text{ df.to_hdf('store.h5','table',append=True)} \\
  \text{In } [54]: \text{ read_hdf('store.h5', 'table', where = ['index>2'])} \\
  \text{Out}[54]: \begin{array}
  \text{A} \\
  3 \\
  4 \\
  \end{array}
  \begin{array}
  \text{B} \\
  3 \\
  4 \\
  \end{array}
  \]

  - provide dotted attribute access to get from stores, e.g. store.df == store['df']
  - new keywords iterator=boolean, and chunksize=number_in_a_chunk are provided to support iteration on select and select_as_multiple (GH3076)

- You can now select timestamps from an unordered timeseries similarly to an ordered timeseries (GH2437)
- You can now select with a string from a DataFrame with a datelike index, in a similar way to a Series (GH3070)
In [55]: idx = date_range("2001-10-1", periods=5, freq='M')
In [56]: ts = Series(np.random.rand(len(idx)), index=idx)

• In pd.io.data.Options,
– Fix bug when trying to fetch data for the current month when already past expiry.
– Now using lxml to scrape html instead of BeautifulSoup (lxml was faster).
– New instance variables for calls and puts are automatically created when a method that creates them is called. This works for current month where the instance variables are simply calls and puts. Also works for future expiry months and save the instance variable as callsMMYY or putsMMYY, where MMYY are, respectively, the month and year of the option’s expiry.
– Options.get_near_stock_price now allows the user to specify the month for which to get relevant options data.
– Options.get_forward_data now has optional kwargs near and above_below. This allows the user to specify if they would like to only return forward looking data for options near the current stock price. This just obtains the data from Options.get_near_stock_price instead of Options.get_xxx_data() (GH2758).

• Cursor coordinate information is now displayed in time-series plots.
• added option display.max_seq_items to control the number of elements printed per sequence pprinting it. (GH2979)
• added option display.chop_threshold to control display of small numerical values. (GH2739)
• added option display.max_info_rows to prevent verbose_info from being calculated for frames above 1M rows (configurable). (GH2807, GH2918)
• value_counts() now accepts a “normalize” argument, for normalized histograms. (GH2710).
• DataFrame.from_records now accepts not only dicts but any instance of the collections.Mapping ABC.
• added option display.mpl_style providing a sleeker visual style for plots. Based on https://gist.github.com/huyng/816622 (GH3075).
• Treat boolean values as integers (values 1 and 0) for numeric operations. (GH2641)
• to_html() now accepts an optional “escape” argument to control reserved HTML character escaping (enabled by default) and escapes &., in addition to < and >. (GH2919)

See the full release notes or issue tracker on GitHub for a complete list.

1.27 v0.10.1 (January 22, 2013)

This is a minor release from 0.10.0 and includes new features, enhancements, and bug fixes. In particular, there is substantial new HDFStore functionality contributed by Jeff Reback.

An undesired API breakage with functions taking the inplace option has been reverted and deprecation warnings added.

1.27.1 API changes

• Functions taking an inplace option return the calling object as before. A deprecation message has been added
• Groupby aggregations Max/Min no longer exclude non-numeric data (GH2700)
• Resampling an empty DataFrame now returns an empty DataFrame instead of raising an exception (GH2640)
• The file reader will now raise an exception when NA values are found in an explicitly specified integer column instead of converting the column to float (GH2631)
• DatetimeIndex.unique now returns a DatetimeIndex with the same name and
• timezone instead of an array (GH2563)

1.27.2 New features

• MySQL support for database (contribution from Dan Allan)

1.27.3 HDFStore

You may need to upgrade your existing data files. Please visit the compatibility section in the main docs.

You can designate (and index) certain columns that you want to be able to perform queries on a table, by passing a list to data_columns

```
In [1]: store = HDFStore('store.h5')
In [2]: df = DataFrame(randn(8, 3), index=date_range('1/1/2000', periods=8), columns=['A', 'B', 'C'])
In [3]: df['string'] = 'foo'
In [4]: df.loc[df.index[4:6], 'string'] = np.nan
In [5]: df.loc[df.index[7:9], 'string'] = 'bar'
In [6]: df['string2'] = 'cool'
In [7]: df
Out[7]:
        A         B         C      string       string2
0  1.885136 -0.183873  2.550850      foo         cool
1  0.180759 -1.117089  0.061462      foo         cool
2 -0.294467 -0.591411 -0.876691      foo         cool
3  3.127110  1.451130  0.045152      foo         cool
4 -0.242846  1.195819  1.533294      NaN         cool
5  0.820521 -0.281201  1.651561      NaN         cool
6 -0.034086  0.252394 -0.498772      foo         cool
7 -2.290958 -1.601262 -0.256718     bar         cool
[8 rows x 5 columns]
```

# on-disk operations
```
In [8]: store.append('df', df, data_columns = ['B','C','string','string2'])
In [9]: store.select('df', 'B>0 and string==''foo''')
Out[9]:
        A     B     C  string       string2
0  3.127110  1.451130  0.045152      foo         cool
1 -0.034086  0.252394 -0.498772      foo         cool
[2 rows x 5 columns]
```

# this is in-memory version of this type of selection
```
In [10]: df[(df.B > 0) & (df.string == 'foo')]
```

(continues on next page)
Retrieving unique values in an indexable or data column.

```python
# note that this is deprecated as of 0.14.0
# can be replicated by: store.select_column('df','index').unique()
store.unique('df','index')
store.unique('df','string')
```

You can now store `datetime64` in data columns

```python
In [11]: df_mixed = df.copy()
In [12]: df_mixed['datetime64'] = Timestamp('20010102')
In [13]: df_mixed.loc[df_mixed.index[3:4], ['A','B']] = np.nan
In [14]: store.append('df_mixed', df_mixed)
In [15]: df_mixed1 = store.select('df_mixed')
In [16]: df_mixed1
```

```
   A      B      C   string  string2  datetime64
0  2000-01-01  1.885136 -0.183873  foo   cool  2001-01-02
1  2000-01-02  0.180759 -1.117089  foo   cool  2001-01-02
2  2000-01-03 -0.294467  -0.591411  foo   cool  2001-01-02
3  2000-01-04     NaN       NaN        NaN     NaN  2001-01-02
4  2000-01-06  0.820521 -0.281201  NaN  cool  2001-01-02
5  2000-01-07 -0.034086  0.252394  foo   cool  2001-01-02
6  2000-01-08 -2.290958 -1.601262  bar   cool  2001-01-02
```

```
In [17]: df_mixed1.get_dtype_counts()
```

```
\---
<table>
<thead>
<tr>
<th>dtype</th>
<th>count</th>
</tr>
</thead>
<tbody>
<tr>
<td>float64</td>
<td>3</td>
</tr>
<tr>
<td>object</td>
<td>2</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>1</td>
</tr>
<tr>
<td>Length: 3, dtype: int64</td>
<td></td>
</tr>
</tbody>
</table>
```

You can pass `columns` keyword to select to filter a list of the return columns, this is equivalent to passing a `Term('columns',list_of_columns_to_filter)`

```python
In [18]: store.select('df',columns = ['A','B'])
```

```
   A      B
0  2000-01-01  1.885136 -0.183873
1  2000-01-02  0.180759 -1.117089
2  2000-01-03 -0.294467  -0.591411
3  2000-01-04  -0.242846  1.195819
4  2000-01-06  0.820521 -0.281201
5  2000-01-07 -0.034086  0.252394
6  2000-01-08 -2.290958 -1.601262
```

(continues on next page)
HDFStore now serializes multi-index dataframes when appending tables.

In [19]: index = MultiIndex(levels=[['foo', 'bar', 'baz', 'qux'],  
                        ['one', 'two', 'three']],  
                   labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],  
                          [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],  
                   names=['foo', 'bar'])

In [20]: df = DataFrame(np.random.randn(10, 3), index=index,  
                   columns=['A', 'B', 'C'])

In [21]: df
Out[21]:
       A       B       C
foo  bar
  one   0.239369  0.174122 -1.131794
  two  -1.948006  0.980347 -0.674429
  three -0.361633 -0.761218  1.768215
bar  one   0.152288 -0.862613 -0.210968
  two  -0.859278  1.498195  0.462413
baz  two  -0.647604  1.511487 -0.727189
  three -0.342928 -0.007364  1.427674
qux  one   0.104020  2.052171 -1.230963
  two  -0.019240 -1.713238  0.838912
  three -0.637855  0.215109 -1.515362

[10 rows x 3 columns]

In [22]: store.append('mi', df)

In [23]: store.select('mi')
Out[23]:
       A       B       C
foo  bar
  one   0.239369  0.174122 -1.131794
  two  -1.948006  0.980347 -0.674429
  three -0.361633 -0.761218  1.768215
bar  one   0.152288 -0.862613 -0.210968
  two  -0.859278  1.498195  0.462413
baz  two  -0.647604  1.511487 -0.727189
  three -0.342928 -0.007364  1.427674
qux  one   0.104020  2.052171 -1.230963
  two  -0.019240 -1.713238  0.838912
  three -0.637855  0.215109 -1.515362

[10 rows x 3 columns]
# the levels are automatically included as data columns

In [24]: store.select('mi', "foo='bar'")

\→
|   | A   | B   | C     |
|---|--|---|--|---|
|foo| bar|   |   |
|   |   |   |   |
|   |   |   |   |

[2 rows x 3 columns]

Multi-table creation via append_to_multiple and selection via select_as_multiple can create/select from multiple tables and return a combined result, by using where on a selector table.

In [25]: df_mt = DataFrame(randn(8, 6), index=date_range('1/1/2000', periods=8),
                   columns=['A', 'B', 'C', 'D', 'E', 'F'])

In [26]: df_mt['foo'] = 'bar'

# you can also create the tables individually

In [27]: store.append_to_multiple({ 'df1_mt' : ['A','B'], 'df2_mt' : None }, df_mt,
                          selector = 'df1_mt')

In [28]: store

Out[28]:
<class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# individual tables were created

In [29]: store.select('df1_mt')

\→
|   | A   | B     |
|---|--|---|---|
|   |   |   |   |
|   |   |   |   |
|   |   |   |   |

[8 rows x 2 columns]

In [30]: store.select('df2_mt')

\→
<table>
<thead>
<tr>
<th></th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
<th>foo</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

(continues on next page)
[8 rows x 5 columns]

# as a multiple

```python
In [31]: store.select_as_multiple(['df1_mt','df2_mt'], where = [ 'A>0','B>0' ],
selector = 'df1_mt')
```

```
      A       B      C     D      E     F   foo
2000-01-03 1.249874 1.458210 -0.710542 0.825392 1.557329 1.993441 bar
2000-01-07 1.239198 0.185437 -0.540770 -0.370038 1.298390 1.662964 bar
[2 rows x 7 columns]
```

Enhancements

- **HDFStore** now can read native PyTables table format tables
- You can pass `nan_rep = 'my_nan_rep'` to append, to change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.
- You can pass `index` to append. This defaults to `True`. This will automagically create indicies on the `indexables` and `data columns` of the table
- You can pass `chunksize=an integer` to append, to change the writing chunksize (default is 50000). This will significantly lower your memory usage on writing.
- You can pass `expectedrows=an integer` to the first append, to set the TOTAL number of expectedrows that PyTables will expected. This will optimize read/write performance.
- `Select` now supports passing `start` and `stop` to provide selection space limiting in selection.
- Greatly improved ISO8601 (e.g., yyyy-mm-dd) date parsing for file parsers (GH2698)
- Allow DataFrame.merge to handle combinatorial sizes too large for 64-bit integer (GH2690)
- Series now has unary negation (-series) and inversion (~series) operators (GH2686)
- DataFrame.plot now includes a `logx` parameter to change the x-axis to log scale (GH2327)
- Series arithmetic operators can now handle constant and ndarray input (GH2574)
- ExcelFile now takes a `kind` argument to specify the file type (GH2613)
- A faster implementation for Series.str methods (GH2602)

Bug Fixes

- **HDFStore** tables can now store `float32` types correctly (cannot be mixed with `float64` however)
- Fixed Google Analytics prefix when specifying request segment (GH2713).
- Function to reset Google Analytics token store so users can recover from improperly setup client secrets (GH2687).
- Fixed groupby bug resulting in segfault when passing in MultiIndex (GH2706)
- Fixed bug where passing a Series with datetime64 values into `to_datetime` results in bogus output values (GH2699)
- Fixed bug in `pattern` in HDFStore expressions when pattern is not a valid regex (GH2694)
- Fixed performance issues while aggregating boolean data (GH2692)
When given a boolean mask key and a Series of new values, Series __setitem__ will now align the incoming values with the original Series (GH2686)

- Fixed MemoryError caused by performing counting sort on sorting MultiIndex levels with a very large number of combinatorial values (GH2684)
- Fixed bug that causes plotting to fail when the index is a DatetimeIndex with a fixed-offset timezone (GH2683)
- Corrected businessday subtraction logic when the offset is more than 5 bdays and the starting date is on a weekend (GH2680)
- Fixed C file parser behavior when the file has more columns than data (GH2668)
- Fixed file reader bug that misaligned columns with data in the presence of an implicit column and a specified usecols value
- DataFrames with numerical or datetime indices are now sorted prior to plotting (GH2609)
- Fixed DataFrame.from_records error when passed columns, index, but empty records (GH2633)
- Several bug fixed for Series operations when dtype is datetime64 (GH2689, GH2629, GH2626)

See the full release notes or issue tracker on GitHub for a complete list.

1.28 v0.10.0 (December 17, 2012)

This is a major release from 0.9.1 and includes many new features and enhancements along with a large number of bug fixes. There are also a number of important API changes that long-time pandas users should pay close attention to.

1.28.1 File parsing new features

The delimited file parsing engine (the guts of read_csv and read_table) has been rewritten from the ground up and now uses a fraction the amount of memory while parsing, while being 40% or more faster in most use cases (in some cases much faster).

There are also many new features:

- Much-improved Unicode handling via the encoding option.
- Column filtering (usecols)
- Dtype specification (dtype argument)
- Ability to specify strings to be recognized as True/False
- Ability to yield NumPy record arrays (as_recarray)
- High performance delim_whitespace option
- Decimal format (e.g. European format) specification
- Easier CSV dialect options: escapechar, lineterminator, quotechar, etc.
- More robust handling of many exceptional kinds of files observed in the wild
1.28.2 API changes

Deprecated DataFrame BINOP TimeSeries special case behavior

The default behavior of binary operations between a DataFrame and a Series has always been to align on the DataFrame’s columns and broadcast down the rows, except in the special case that the DataFrame contains time series. Since there are now methods for each binary operator enabling you to specify how you want to broadcast, we are phasing out this special case (Zen of Python: Special cases aren’t special enough to break the rules). Here’s what I’m talking about:

```python
In [1]: import pandas as pd

In [2]: df = pd.DataFrame(np.random.randn(6, 4),
                          index=pd.date_range('1/1/2000', periods=6))

In [3]: df
Out[3]:
   0    1    2    3
2000-01-01 -0.134024 -0.205969 1.348944 -1.198246
2000-01-02  1.626124  0.982041  0.059493 -0.460111
2000-01-03 -1.565401 -0.025706  0.942864  2.502156
2000-01-04 -0.302741  0.261551 -0.066342  0.897097
2000-01-05  0.268766 -1.225092  0.582752 -1.490764
2000-01-06 -0.639757 -0.952750 -0.892402  0.505987

[6 rows x 4 columns]

# deprecated now

In [4]: df - df[0]

   0    1    2    3
2000-01-01 NaN NaN NaN NaN
2000-01-02 NaN NaN NaN NaN
2000-01-03 NaN NaN NaN NaN
2000-01-04 NaN NaN NaN NaN

[6 rows x 10 columns]

# Change your code to

In [5]: df.sub(df[0], axis=0) # align on axis 0 (rows)
```

(continues on next page)
Altered resample default behavior

The default time series resample binning behavior of daily `D` and higher frequencies has been changed to `closed='left', label='left'`. Lower frequencies are unaffected. The prior defaults were causing a great deal of confusion for users, especially resampling data to daily frequency (which labeled the aggregated group with the end of the interval: the next day).

```python
In [1]: dates = pd.date_range('1/1/2000', '1/5/2000', freq='4h')
In [2]: series = Series(np.arange(len(dates)), index=dates)
In [3]: series
Out[3]:

Freq: D, dtype: int64

- Infinity and negative infinity are no longer treated as NA by isnull and notnull. That they ever were was a relic of early pandas. This behavior can be re-enabled globally by the mode.use_inf_as_null option:

In [6]: s = pd.Series([1.5, np.inf, 3.4, -np.inf])
In [7]: pd.isnull(s)
Out[7]:
0  False
1  False
2  False
3  False
Length: 4, dtype: bool
In [8]: s.fillna(0)
Out[8]:
0  1.500000
1  inf
2  3.400000
3  -inf
Length: 4, dtype: float64
In [9]: pd.set_option('use_inf_as_null', True)
In [10]: pd.isnull(s)
Out[10]:
0  False
1  True
2  False
3  True
Length: 4, dtype: bool
In [11]: s.fillna(0)
Out[11]:
0  1.5
1  0.0
2  3.4
3  0.0
Length: 4, dtype: float64
In [12]: pd.reset_option('use_inf_as_null')

- Methods with the inplace option now all return None instead of the calling object. E.g. code written like df = df.fillna(0, inplace=True) may stop working. To fix, simply delete the unnecessary variable assignment.

- pandas.merge no longer sorts the group keys (sort=False) by default. This was done for performance reasons: the group-key sorting is often one of the more expensive parts of the computation and is often unnec-
- The default column names for a file with no header have been changed to the integers 0 through \( N - 1 \). This is to create consistency with the DataFrame constructor with no columns specified. The v0.9.0 behavior (names \( X0, X1, \ldots \)) can be reproduced by specifying prefix='X':

```python
In [6]: data = 'a,b,c
1,Yes,2
3,No,4'
In [7]: print(data)
a,b,c
1,Yes,2
3,No,4
In [8]: pd.read_csv(StringIO(data), header=None)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[8]:
   0  1  2
0  a  b  c
1  1  Yes 2
2  3  No  4
[3 rows x 3 columns]
In [9]: pd.read_csv(StringIO(data), header=None, prefix='X')
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[9]:
   → X0 X1 X2
0  a  b  c
1  1  Yes 2
2  3  No  4
[3 rows x 3 columns]
```

- Values like 'Yes' and 'No' are not interpreted as boolean by default, though this can be controlled by new `true_values` and `false_values` arguments:

```python
In [10]: print(data)
a,b,c
1,Yes,2
3,No,4
In [11]: pd.read_csv(StringIO(data))
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[11]:
   a  b  c
0  1  Yes 2
1  3  No  4
[2 rows x 3 columns]
In [12]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[12]:
   → a  b  c
0  1  True 2
1  3  False 4
[2 rows x 3 columns]
```

- The file parsers will not recognize non-string values arising from a converter function as NA if passed in the `na_values` argument. It's better to do post-processing using the `replace` function instead.
• Calling `fillna` on Series or DataFrame with no arguments is no longer valid code. You must either specify a fill value or an interpolation method:

```python
In [13]: s = Series([np.nan, 1., 2., np.nan, 4])

In [14]: s
Out[14]:
0   NaN
1     1
2     2
3   NaN
4     4
Length: 5, dtype: float64

In [15]: s.fillna(0)
\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\\...
\\→
0    0.0

Length: 5, dtype: float64

In [16]: s.fillna(method='pad')
\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\:\\...
\\→
0   NaN
1     1
2     2
3     2
4     4
Length: 5, dtype: float64
```

Convenience methods `ffill` and `bfill` have been added:

```python
In [17]: s.ffill()
Out[17]:
0   NaN
1     1
2     2
3     2
4     4
Length: 5, dtype: float64
```

• `Series.apply` will now operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame

```python
In [18]: def f(x):
   ....:     return Series([ x, x**2 ], index = ['x', 'x^2'])
   ....:

In [19]: s = Series(np.random.rand(5))

In [20]: s
Out[20]:
0  0.717478
1  0.815199
```

(continues on next page)
2 0.452478
3 0.848385
4 0.235477
Length: 5, dtype: float64

In [21]: s.apply(f)

Out[21]:
\[ x \ \ x^2 \\
0 0.717478 0.514775 \\
1 0.815199 0.664550 \\
2 0.452478 0.204737 \\
3 0.848385 0.719757 \\
4 0.235477 0.055449 \\
\] [5 rows x 2 columns]

• New API functions for working with pandas options (GH2097):
  - `get_option` / `set_option` - get/set the value of an option. Partial names are accepted.
  - `reset_option` - reset one or more options to their default value. Partial names are accepted.
  - `describe_option` - print a description of one or more options. When called with no arguments, print all registered options.

Note: `set_printoptions`/`reset_printoptions` are now deprecated (but functioning), the print options now live under “display.XYZ”. For example:

In [22]: get_option("display.max_rows")
Out[22]: 15

• `to_string()` methods now always return unicode strings (GH2224).

1.28.3 New features

1.28.4 Wide DataFrame Printing

Instead of printing the summary information, pandas now splits the string representation across multiple rows by default:

In [23]: wide_frame = DataFrame(randn(5, 16))

In [24]: wide_frame
Out[24]:
\[ 0 1 2 3 4 5 ... 10 11 12 13 14 15 \\
0 -0.681624 0.191356 1.180274 -0.834179 0.703043 0.166568 ... 1.209871 -0.976847 \\
0 941235 -0.336232 -0.976847 0.033862 \\
1 0.441522 -0.316864 -0.017062 1.570114 -0.360875 -0.880096 ... -1.621234 -0.976847 \\
1 906840 1.014601 -0.475108 -0.358944 1.262942 \\
2 -0.412451 -0.462580 0.422194 0.288403 -0.487393 -0.776739 ... 0.965887 0.033862 \\
2 246354 -0.727728 -0.094414 -0.276854 0.158399 \\
3 -0.272725 1.331263 0.585174 -0.568825 -0.719412 1.191340 ... -1.195795 -1.033607 \\
3 425911 -0.548829 0.774225 0.740501 1.510263 \\
4 -1.642511 0.432560 1.218080 -0.564705 -0.581790 0.286071 ... 0.241963 -0.976847 \\
4 471786 0.314510 -0.059986 -2.069319 -1.151040 \\
\] (continues on next page)
The old behavior of printing out summary information can be achieved via the `expand_frame_repr` print option:

```python
In [25]: pd.set_option('expand_frame_repr', False)
In [26]: wide_frame
Out[26]:
   0    1    2    3    4    5    6    7
  → 8  9  10  11  12  13  14  15
0 -0.681624 0.191356 1.180274 -0.834179 0.703043 0.166568 -0.583599 -1.201796 -1.
1  0.441522 -0.316864 -0.017062 1.570114 -0.360875 -0.880096 0.235532 0.207232 -1.
2 -0.412451 -0.462580 0.422194 0.288403 -0.487393 -0.777639 0.055865 1.383381 0.
3 -0.277255 1.331263 0.585174 -0.568825 -0.719412 1.191340 -0.456362 0.089931 0.
4 -1.642511 0.432560 1.218080 -0.564705 -0.581790 1.218080 -0.564705 -0.581790 0.
[5 rows x 16 columns]
```

The width of each line can be changed via `line_width` (80 by default):

```python
In [27]: pd.set_option('line_width', 40)
---------------------------------------------------------------------------
OptionError Traceback (most recent call last)

[8 rows x 5 columns]
```

```python
In [55]: df1.get_dtype_counts()
```

(continues on next page)
• performance improvements on table writing
• support for arbitrarily indexed dimensions
• SparseSeries now has a density property (GH2384)
• enable Series.str.strip/lstrip/rstrip methods to take an input argument to strip arbitrary characters (GH2411)
• implement value_vars in melt to limit values to certain columns and add melt to pandas namespace (GH2412)

Bug Fixes
• added Term method of specifying where conditions (GH1996).
• del store['df'] now call store.remove('df') for store deletion
• deleting of consecutive rows is much faster than before
• min_itemsize parameter can be specified in table creation to force a minimum size for indexing columns (the previous implementation would set the column size based on the first append)
• indexing support via create_table_index (requires PyTables >= 2.3) (GH698).
• appending on a store would fail if the table was not first created via put
• fixed issue with missing attributes after loading a pickled dataframe (GH2431)
• minor change to select and remove: require a table ONLY if where is also provided (and not None)

Compatibility
0.10 of HDFStore is backwards compatible for reading tables created in a prior version of pandas, however, query terms using the prior (undocumented) methodology are unsupported. You must read in the entire file and write it out using the new format to take advantage of the updates.

1.28.6 N Dimensional Panels (Experimental)

Adding experimental support for Panel4D and factory functions to create n-dimensional named panels. Here is a taste of what to expect.

```python
In [58]: p4d = Panel4D(randn(2, 2, 5, 4),
        ....:     labels=['Label1','Label2'],
        ....:     items=['Item1', 'Item2'],
        ....:     major_axis=date_range('1/1/2000', periods=5),
        ....:     minor_axis=['A', 'B', 'C', 'D'])

In [59]: p4d
Out[59]:
<class 'pandas.core.panelnd.Panel4D'>
Dimensions: 2 (labels) x 2 (items) x 5 (major_axis) x 4 (minor_axis)
Labels axis: Label1 to Label2
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

See the full release notes or issue tracker on GitHub for a complete list.
1.29 v0.9.1 (November 14, 2012)

This is a bugfix release from 0.9.0 and includes several new features and enhancements along with a large number of bug fixes. The new features include by-column sort order for DataFrame and Series, improved NA handling for the rank method, masking functions for DataFrame, and intraday time-series filtering for DataFrame.

1.29.1 New features

- **Series.sort**, **DataFrame.sort**, and **DataFrame.sort_index** can now be specified in a per-column manner to support multiple sort orders (GH928)

```
In [2]: df = DataFrame(np.random.randint(0, 2, (6, 3)), columns=['A', 'B', 'C'])
In [3]: df.sort(['A', 'B'], ascending=[1, 0])
```

```
Out[3]:
    A  B  C
0  0  0  0
1  0  0  0
2  0  1  1
3  0  1  1
4  1  0  0
5  1  0  0
```

- **DataFrame.rank** now supports additional argument values for the **na_option** parameter so missing values can be assigned either the largest or the smallest rank (GH1508, GH2159)

```
In [1]: df = DataFrame(np.random.randn(6, 3), columns=['A', 'B', 'C'])
In [3]: df.rank()
```

```
Out[3]:
    A  B  C
0  3.0 1.0 3.0
1  1.0 3.0 2.0
2  NaN NaN NaN
3  NaN NaN NaN
4  NaN NaN NaN
5  2.0 2.0 1.0
```

```
In [4]: df.rank(na_option='top')
```

```
Out[4]:
    A  B  C
0  6.0 4.0 6.0
1  4.0 6.0 5.0
2  2.0 2.0 2.0
3  2.0 2.0 2.0
4  2.0 2.0 2.0
5  5.0 5.0 4.0
```

(continues on next page)
In [5]: df.rank(na_option='bottom')

    A  B  C
0  3.0 1.0 3.0
1  1.0 3.0 2.0
2  5.0 5.0 5.0
3  5.0 5.0 5.0
4  5.0 5.0 5.0
5  2.0 2.0 1.0
[6 rows x 3 columns]

- DataFrame has new `where` and `mask` methods to select values according to a given boolean mask (GH2109, GH2151)

DataFrame currently supports slicing via a boolean vector the same length as the DataFrame (inside the []). The returned DataFrame has the same number of columns as the original, but is sliced on its index.

In [6]: df = DataFrame(np.random.randn(5, 3), columns=['A','B','C'])

In [7]: df
Out[7]:
   A   B   C
0 -1.10 1.19 0.63
1  2.37 0.33 -0.87
2  1.12 -0.22 0.64
3  0.96 -1.85 0.44
4  1.23 1.62 -0.30
[5 rows x 3 columns]

In [8]: df[df['A'] > 0]

    A  B  C
0  NaN NaN 0.63
1  2.37 0.33 NaN
2  1.12 NaN 0.64
3  0.96 -1.85 NaN
4  1.23 1.62 NaN
[4 rows x 3 columns]

If a DataFrame is sliced with a DataFrame based boolean condition (with the same size as the original DataFrame), then a DataFrame the same size (index and columns) as the original is returned, with elements that do not meet the boolean condition as `NaN`. This is accomplished via the new method `DataFrame.where`. In addition, `where` takes an optional `other` argument for replacement.

In [9]: df[df>0]
Out[9]:
   A   B   C
0  NaN NaN 0.63
1  2.37 0.33 NaN
2  1.12 NaN 0.64
(continues on next page)
Furthermore, `where` now aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `.ix` (but on the contents rather than the axis labels)

```python
In [12]: df2 = df.copy()

In [13]: df2[df2[1:4] > 0] = 3

In [14]: df2
Out[14]:
          A      B      C
0 -1.101581 -1.187831 0.630693
1  3.000000  3.000000 -0.870464
2  3.000000  0.224382  0.642489
3  3.000000 -1.848369  0.440883
4  1.235390  1.615529 -0.303272

[5 rows x 3 columns]
```

`DataFrame.mask` is the inverse boolean operation of `where`.

```python
In [15]: df.mask(df<=0)
Out[15]:
          A      B      C
0    NaN    NaN  0.630693
1  2.369983  0.333769    NaN
2  1.118760    NaN  0.642489
3  0.961751    NaN  0.440883
4  1.235390  1.615529    NaN

[5 rows x 3 columns]
```
• Enable referencing of Excel columns by their column names (GH1936)

```
In [16]: xl = ExcelFile('data/test.xls')
```

```
In [17]: xl.parse('Sheet1', index_col=0, parse_dates=True, 
   ....:    parse_cols='A:D')
   ....:
Out[17]:
```

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-03</td>
<td>0.980269</td>
<td>3.685731</td>
<td>-0.364217</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>1.047916</td>
<td>-0.041232</td>

</tr>
</tbody>
</table>

[7 rows x 4 columns]
```

• Added option to disable pandas-style tick locators and formatters using `series.plot(x_compat=True)` or `pandas.plot_params['x_compat'] = True` (GH2205)

• Existing TimeSeries methods `at_time` and `between_time` were added to DataFrame (GH2149)

• DataFrame.dot can now accept ndarrays (GH2042)

• DataFrame.drop now supports non-unique indexes (GH2101)

• Panel.shift now supports negative periods (GH2164)

• DataFrame now support unary ~ operator (GH2110)

### 1.29.2 API changes

• Upsampling data with a PeriodIndex will result in a higher frequency TimeSeries that spans the original time window

```
In [1]: prng = period_range('2012Q1', periods=2, freq='Q')
```

```
In [2]: s = Series(np.random.randn(len(prng)), prng)
```

```
In [4]: s.resample('M')
```

```
Out[4]:
```

| 2012-01 | -1.471992 |
| 2012-02 | NaN |
| 2012-03 | NaN |
| 2012-04 | -0.493593 |
| 2012-05 | NaN |
| 2012-06 | NaN |
Freq: M, dtype: float64
```

• Period.end_time now returns the last nanosecond in the time interval (GH2124, GH2125, GH1764)
In [18]: p = Period('2012')
In [19]: p.end_time
Out[19]: Timestamp('2012-12-31 23:59:59.999999999')

• File parsers no longer coerce to float or bool for columns that have custom converters specified (GH2184)

In [20]: data = 'A,B,C
00001,001,5
00002,002,6'
In [21]: read_csv(StringIO(data), converters={'A': lambda x: x.strip()})
Out[21]:
<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
</tr>
<tr>

<td>2</td>
<td>6</td>
</tr>
</tbody>
</table>
[2 rows x 3 columns]

See the full release notes or issue tracker on GitHub for a complete list.

1.30 v0.9.0 (October 7, 2012)

This is a major release from 0.8.1 and includes several new features and enhancements along with a large number of bug fixes. New features include vectorized unicode encoding/decoding for Series.str, to_latex method to DataFrame, more flexible parsing of boolean values, and enabling the download of options data from Yahoo! Finance.

1.30.1 New features

• Add encode and decode for unicode handling to vectorized string processing methods in Series.str (GH1706)
• Add DataFrame.to_latex method (GH1735)
• Add convenient expanding window equivalents of all rolling_* ops (GH1785)
• Add Options class to pandas.io.data for fetching options data from Yahoo! Finance (GH1748, GH1739)
• More flexible parsing of boolean values (Yes, No, TRUE, FALSE, etc) (GH1691, GH1295)
• Add level parameter to Series.reset_index
• TimeSeries.between_time can now select times across midnight (GH1871)
• Series constructor can now handle generator as input (GH1679)
• DataFrame.dropna can now take multiple axes (tuple/list) as input (GH924)
• Enable skip_footer parameter in ExcelFile.parse (GH1843)

1.30.2 API changes

• The default column names when header=None and no columns names passed to functions like read_csv has changed to be more Pythonic and amenable to attribute access:
In [3]: df
Out[3]:
   0  1  2
 0  0  0  1
 1  1  1  0
 2  0  1  0
[3 rows x 3 columns]

- Creating a Series from another Series, passing an index, will cause reindexing to happen inside rather than treating the Series like an ndarray. Technically improper usages like `Series(df[col1], index=df[col2])` that worked before “by accident” (this was never intended) will lead to all NA Series in some cases. To be perfectly clear:

    In [4]: s1 = Series([1, 2, 3])
    In [5]: s1
    Out[5]:
   0  1
   1  2
   2  3
   Length: 3, dtype: int64
    In [6]: s2 = Series(s1, index=['foo', 'bar', 'baz'])
    In [7]: s2
    Out[7]:
   foo   NaN
   bar   NaN
   baz   NaN
   Length: 3, dtype: float64

- Deprecated `day_of_year` API removed from PeriodIndex, use `dayofyear` (GH1723)
- Don’t modify NumPy suppress printoption to True at import time
- The internal HDF5 data arrangement for DataFrames has been transposed. Legacy files will still be readable by HDFStore (GH1834, GH1824)
- Legacy cruft removed: pandas.stats.misc.quantileTS
- Use ISO8601 format for Period repr: monthly, daily, and on down (GH1776)
- Empty DataFrame columns are now created as object dtype. This will prevent a class of TypeErrors that was occurring in code where the dtype of a column would depend on the presence of data or not (e.g. a SQL query having results) (GH1783)
- Setting parts of DataFrame/Panel using ix now aligns input Series/DataFrame (GH1630)
- `first` and `last` methods in GroupBy no longer drop non-numeric columns (GH1809)
- Resolved inconsistencies in specifying custom NA values in text parser. `na_values` of type dict no longer override default NAs unless `keep_default_na` is set to false explicitly (GH1657)
- `DataFrame.dot` will not do data alignment, and also work with Series (GH1915)

See the full release notes or issue tracker on GitHub for a complete list.
1.31 v0.8.1 (July 22, 2012)

This release includes a few new features, performance enhancements, and over 30 bug fixes from 0.8.0. New features include notably NA friendly string processing functionality and a series of new plot types and options.

1.31.1 New features

- Add vectorized string processing methods accessible via Series.str (GH620)
- Add option to disable adjustment in EWMA (GH1584)
- Radviz plot (GH1566)
- Parallel coordinates plot
- Bootstrap plot
- Per column styles and secondary y-axis plotting (GH1559)
- New datetime converters millisecond plotting (GH1599)
- Add option to disable “sparse” display of hierarchical indexes (GH1538)
- Series/DataFrame’s set_index method can append levels to an existing Index/MultiIndex (GH1569, GH1577)

1.31.2 Performance improvements

- Improved implementation of rolling min and max (thanks to Bottleneck !)
- Add accelerated ‘median’ GroupBy option (GH1358)
- Significantly improve the performance of parsing ISO8601-format date strings with DatetimeIndex or to_datetime (GH1571)
- Improve the performance of GroupBy on single-key aggregations and use with Categorical types
- Significant datetime parsing performance improvements

1.32 v0.8.0 (June 29, 2012)

This is a major release from 0.7.3 and includes extensive work on the time series handling and processing infrastructure as well as a great deal of new functionality throughout the library. It includes over 700 commits from more than 20 distinct authors. Most pandas 0.7.3 and earlier users should not experience any issues upgrading, but due to the migration to the NumPy datetime64 dtype, there may be a number of bugs and incompatibilities lurking. Lingering incompatibilities will be fixed ASAP in a 0.8.1 release if necessary. See the full release notes or issue tracker on GitHub for a complete list.

1.32.1 Support for non-unique indexes

All objects can now work with non-unique indexes. Data alignment / join operations work according to SQL join semantics (including, if application, index duplication in many-to-many joins)
1.32.2 NumPy datetime64 dtype and 1.6 dependency

Time series data are now represented using NumPy’s datetime64 dtype; thus, pandas 0.8.0 now requires at least NumPy 1.6. It has been tested and verified to work with the development version (1.7+) of NumPy as well which includes some significant user-facing API changes. NumPy 1.6 also has a number of bugs having to do with nanosecond resolution data, so I recommend that you steer clear of NumPy 1.6’s datetime64 API functions (though limited as they are) and only interact with this data using the interface that pandas provides.

See the end of the 0.8.0 section for a “porting” guide listing potential issues for users migrating legacy codebases from pandas 0.7 or earlier to 0.8.0.

Bug fixes to the 0.7.x series for legacy NumPy < 1.6 users will be provided as they arise. There will be no more further development in 0.7.x beyond bug fixes.

1.32.3 Time series changes and improvements

Note: With this release, legacy scikits.timeseries users should be able to port their code to use pandas.

Note: See documentation for overview of pandas timeseries API.

- New datetime64 representation speeds up join operations and data alignment, reduces memory usage, and improve serialization / deserialization performance significantly over datetime.datetime

- High performance and flexible resample method for converting from high-to-low and low-to-high frequency. Supports interpolation, user-defined aggregation functions, and control over how the intervals and result labeling are defined. A suite of high performance Cython/C-based resampling functions (including Open-High-Low-Close) have also been implemented.

- Revamp of frequency aliases and support for frequency shortcuts like ‘15min’, or ‘1h30min’

- New DatetimeIndex class supports both fixed frequency and irregular time series. Replaces now deprecated DateRange class

- New PeriodIndex and Period classes for representing time spans and performing calendar logic, including the 12 fiscal quarterly frequencies <timeseries.quarterly>. This is a partial port of, and a substantial enhancement to, elements of the scikits.timeseries codebase. Support for conversion between PeriodIndex and DatetimeIndex

- New Timestamp data type subclasses datetime.datetime, providing the same interface while enabling working with nanosecond-resolution data. Also provides easy time zone conversions.

- Enhanced support for time zones. Add tz_convert and tz_localize methods to TimeSeries and DataFrame. All timestamps are stored as UTC; Timestamps from DatetimeIndex objects with time zone set will be localized to localtime. Time zone conversions are therefore essentially free. User needs to know very little about pytz library now; only time zone names as as strings are required. Time zone-aware timestamps are equal if and only if their UTC timestamps match. Operations between time zone-aware time series with different time zones will result in a UTC-indexed time series.

- Time series string indexing conveniences / shortcuts: slice years, year and month, and index values with strings

- Enhanced time series plotting; adaptation of scikits.timeseries matplotlib-based plotting code

- New date_range, bdate_range, and period_range factory functions

- Robust frequency inference function infer_freq and inferred_freq property of DatetimeIndex, with option to infer frequency on construction of DatetimeIndex
• **to_datetime** function efficiently parses array of strings to DatetimeIndex. DatetimeIndex will parse array or list of strings to datetime64

*Optimized* support for datetime64-dtype data in Series and DataFrame columns

New NaT (Not-a-Time) type to represent NA in timestamp arrays

Optimize Series.asof for looking up “as of” values for arrays of timestamps

Milli, Micro, Nano date offset objects

Can index time series with datetime.time objects to select all data at particular time of day (TimeSeries.at_time) or between two times (TimeSeries.between_time)

Add `tshift` method for leading/lagging using the frequency (if any) of the index, as opposed to a naive lead/lag using shift

### 1.32.4 Other new features

• New `cut` and `qcut` functions (like R’s cut function) for computing a categorical variable from a continuous variable by binning values either into value-based (`cut`) or quantile-based (`qcut`) bins

• Rename `Factor` to `Categorical` and add a number of usability features

• Add `limit` argument to fillna/reindex

• More flexible multiple function application in GroupBy, and can pass list (name, function) tuples to get result in particular order with given names

• Add flexible `replace` method for efficiently substituting values

• Enhanced `read_csv/read_table` for reading time series data and converting multiple columns to dates

• Add `comments` option to parser functions: `read_csv`, etc.

• Add `:ref:`dayfirst `<io.dayfirst>` option to parser functions for parsing international DD/MM/YYYY dates

• Allow the user to specify the CSV reader `dialect` to control quoting etc.

• Handling `thousands` separators in `read_csv` to improve integer parsing.

• Enable unstacking of multiple levels in one shot. Alleviate `pivot_table` bugs (empty columns being introduced)

• Move to klib-based hash tables for indexing; better performance and less memory usage than Python’s dict

• Add `ordered_merge` function

• Add flexible `comparison` instance methods `eq`, `ne`, `lt`, `gt`, etc. to DataFrame, Series

• Improve `scatter_matrix` plotting function and add histogram or kernel density estimates to diagonal

• Add `kde` plot option for density plots

• Support for converting DataFrame to R `data.frame` through rpy2

• Improved support for complex numbers in Series and DataFrame

• Add `pct_change` method to all data structures

• Add `max_colwidth` configuration option for DataFrame console output

• Interpolate Series values using index values

• Can select multiple columns from GroupBy
• Add **update** methods to Series/DataFrame for updating values in place
• Add **any** and **all** method to DataFrame

### 1.32.5 New plotting methods

**Series.plot** now supports a **secondary_y** option:

```python
In [1]: plt.figure()
Out[1]: <Figure size 640x480 with 0 Axes>

In [2]: fx['FR'].plot(style='g')
Out[2]: <matplotlib.axes._subplots.AxesSubplot at 0x11c82474e0>

In [3]: fx['IT'].plot(style='k--', secondary_y=True)
Out[3]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3733d860>
```

Vytautas Jancauskas, the 2012 GSOC participant, has added many new plot types. For example, 'kde' is a new option:

```python
In [4]: s = Series(np.concatenate((np.random.randn(1000),
                        np.random.randn(1000) * 0.5 + 3)))

In [5]: plt.figure()
Out[5]: <Figure size 640x480 with 0 Axes>

In [6]: s.hist(normed=True, alpha=0.2)
Out[6]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37bc7240>

In [7]: s.plot(kind='kde')
Out[7]: <matplotlib.axes._subplots.AxesSubplot at 0x1c37bc7240>
```

See the *plotting page* for much more.

### 1.32.6 Other API changes

• Deprecation of **offset**, **time_rule**, and **timeRule** arguments names in time series functions. Warnings will be printed until pandas 0.9 or 1.0.

### 1.32.7 Potential porting issues for pandas <= 0.7.3 users

The major change that may affect you in pandas 0.8.0 is that time series indexes use NumPy's `datetime64` data type instead of `dtype=object` arrays of Python's built-in `datetime.datetime` objects. `DateRange` has been replaced by `DatetimeIndex` but otherwise behaved identically. But, if you have code that converts `DateRange` or `Index` objects that used to contain `datetime.datetime` values to plain NumPy arrays, you may have bugs lurking with code using scalar values because you are handing control over to NumPy:
In [8]: import datetime

In [9]: rng = date_range('1/1/2000', periods=10)

In [10]: rng[5]
Out[10]: Timestamp('2000-01-06 00:00:00', freq='D')

In [11]: isinstance(rng[5], datetime.datetime)
Out[11]: True

In [12]: rng_asarray = np.asarray(rng)

In [13]: scalar_val = rng_asarray[5]

In [14]: type(scalar_val)
Out[14]: numpy.datetime64

pandas’s Timestamp object is a subclass of datetime.datetime that has nanosecond support (the nanosecond field store the nanosecond value between 0 and 999). It should substitute directly into any code that used datetime.datetime values before. Thus, I recommend not casting DatetimeIndex to regular NumPy arrays.

If you have code that requires an array of datetime.datetime objects, you have a couple of options. First, the astype(object) method of DatetimeIndex produces an array of Timestamp objects:

In [15]: stamp_array = rng.astype(object)

In [16]: stamp_array
Out[16]:
Index([2000-01-01 00:00:00, 2000-01-02 00:00:00, 2000-01-03 00:00:00,
       2000-01-04 00:00:00, 2000-01-05 00:00:00, 2000-01-06 00:00:00,
       2000-01-07 00:00:00, 2000-01-08 00:00:00, 2000-01-09 00:00:00,
       2000-01-10 00:00:00],
dtype='object')

In [17]: stamp_array[5]
˓→Timestamp('2000-01-06 00:00:00', freq='D')

To get an array of proper datetime.datetime objects, use the to_pydatetime method:

In [18]: dt_array = rng.to_pydatetime()

In [19]: dt_array
Out[19]:
datetime.datetime(2000, 1, 1, 0, 0),
datetime.datetime(2000, 1, 2, 0, 0),
datetime.datetime(2000, 1, 3, 0, 0),
datetime.datetime(2000, 1, 4, 0, 0),
datetime.datetime(2000, 1, 5, 0, 0),
datetime.datetime(2000, 1, 6, 0, 0),
datetime.datetime(2000, 1, 7, 0, 0),
datetime.datetime(2000, 1, 8, 0, 0),
datetime.datetime(2000, 1, 9, 0, 0),
datetime.datetime(2000, 1, 10, 0, 0)], dtype=object)

In [20]: dt_array[5]
matplotlib knows how to handle \texttt{datetime.datetime} but not Timestamp objects. While I recommend that you plot time series using \texttt{TimeSeries.plot}, you can either use \texttt{to_pydatetime} or register a converter for the Timestamp type. See matplotlib documentation for more on this.

\begin{verbatim}
In [21]: rng = date_range('1/1/2000', periods=10)
In [22]: rng
Out[22]:
              '2000-01-09', '2000-01-10'],
dtype='datetime64[ns]', freq='D')
In [23]: np.asarray(rng)

In [24]: converted = np.asarray(rng, dtype=object)
In [25]: converted[5]
Out[25]: 947116800000000000
\end{verbatim}

\textbf{Warning:} There are bugs in the user-facing API with the nanosecond datetime64 unit in NumPy 1.6. In particular, the string version of the array shows garbage values, and conversion to \texttt{dtype=object} is similarly broken.

\textbf{Trust me: don't panic.} If you are using NumPy 1.6 and restrict your interaction with datetime64 values to pandas’s API you will be just fine. There is nothing wrong with the data-type (a 64-bit integer internally); all of the important data processing happens in pandas and is heavily tested. I strongly recommend that you do not work directly with datetime64 arrays in NumPy 1.6 and only use the pandas API.

\textbf{Support for non-unique indexes:} In the latter case, you may have code inside a \texttt{try:... catch:} block that failed due to the index not being unique. In many cases it will no longer fail (some method like \texttt{append} still check for uniqueness unless disabled). However, all is not lost: you can inspect \texttt{index.is_unique} and raise an exception explicitly if it is \texttt{False} or go to a different code branch.

\section*{1.33 v.0.7.3 (April 12, 2012)}

This is a minor release from 0.7.2 and fixes many minor bugs and adds a number of nice new features. There are also a couple of API changes to note; these should not affect very many users, and we are inclined to call them “bug fixes” even though they do constitute a change in behavior. See the full release notes or issue tracker on GitHub for a complete list.
1.33.1 New features

- New fixed width file reader, `read_fwf`
- New `scatter_matrix` function for making a scatter plot matrix

```python
from pandas.tools.plotting import scatter_matrix
scatter_matrix(df, alpha=0.2)
```

- Add stacked argument to Series and DataFrame's `plot` method for stacked bar plots.

```python
df.plot(kind='bar', stacked=True)
```
Add log x and y *scaling options* to DataFrame.plot and Series.plot

Add *kurt* methods to Series and DataFrame for computing kurtosis

1.33.2 NA Boolean Comparison API Change

Reverted some changes to how NA values (represented typically as `NaN` or `None`) are handled in non-numeric Series:

In [1]: series = Series(['Steve', np.nan, 'Joe'])

In [2]: series == 'Steve'

Out[2]:
0   True
1   False

(continues on next page)
In comparisons, NA / NaN will always come through as `False` except with `!=` which is `True`. *Be very careful* with boolean arithmetic, especially negation, in the presence of NA data. You may wish to add an explicit NA filter into boolean array operations if you are worried about this:

```python
In [4]: mask = series == 'Steve'
```

```python
In [5]: series[mask & series.notnull()]
```

Out[5]:

```
0  Steve
```

While propagating NA in comparisons may seem like the right behavior to some users (and you could argue on purely technical grounds that this is the right thing to do), the evaluation was made that propagating NA everywhere, including in numerical arrays, would cause a large amount of problems for users. Thus, a “practicality beats purity” approach was taken. This issue may be revisited at some point in the future.

### 1.3.3.3 Other API Changes

When calling `apply` on a grouped Series, the return value will also be a Series, to be more consistent with the `groupby` behavior with DataFrame:

```python
In [6]: df = DataFrame({'A' : ['foo', 'bar', 'foo', 'bar',
                     'foo', 'bar', 'foo', 'foo'],
                     'B' : ['one', 'one', 'two', 'three',
                     'two', 'two', 'one', 'three'],
                     'C' : np.random.randn(8), 'D' : np.random.randn(8))
```

```
                           A       B        C        D
0   foo        one -0.841015  0.459840
1   bar        one  0.114219 -0.253040
2   foo        two -0.405617 -0.261128
3   bar        three 1.240678  0.406604
4   foo        two -1.222828 -1.022256
5   bar        two  1.525196 -0.882785
6   foo        one  0.520047  1.793331
7   foo        three 0.163834 -0.429688
```

[8 rows x 4 columns]

```python
In [8]: grouped = df.groupby('A')['C']
```

```
In [9]: grouped.describe()  
```
Out[9]:
<table>

Name: C, Length: 4, dtype: float64

### 1.34 v.0.7.2 (March 16, 2012)

This release targets bugs in 0.7.1, and adds a few minor features.

#### 1.34.1 New features

- Add additional tie-breaking methods in DataFrame.rank (GH874)
- Add ascending parameter to rank in Series, DataFrame (GH875)
- Add coerce_float option to DataFrame.from_records (GH893)
- Add sort_columns parameter to allow unsorted plots (GH918)
- Enable column access via attributes on GroupBy (GH882)
- Can pass dict of values to DataFrame.fillna (GH661)
- Can select multiple hierarchical groups by passing list of values in .ix (GH134)
- Add axis option to DataFrame.fillna (GH174)
- Add level keyword to drop for dropping values from a level (GH159)

#### 1.34.2 Performance improvements

- Use khash for Series.value_counts, add raw function to algorithms.py (GH861)
- Intercept __builtin__.__sum in groupby (GH885)

### 1.35 v.0.7.1 (February 29, 2012)

This release includes a few new features and addresses over a dozen bugs in 0.7.0.
### 1.35.1 New features

- Add `to_clipboard` function to pandas namespace for writing objects to the system clipboard (GH774)
- Add `itertuples` method to DataFrame for iterating through the rows of a dataframe as tuples (GH818)
- Add ability to pass `fill_value` and method to DataFrame and Series align method (GH806, GH807)
- Add `fill_value` option to reindex, align methods (GH784)
- Enable `concat` to produce DataFrame from Series (GH787)
- Add `between` method to Series (GH802)
- Add HTML representation hook to DataFrame for the IPython HTML notebook (GH773)
- Support for reading Excel 2007 XML documents using openpyxl

### 1.35.2 Performance improvements

- Improve performance and memory usage of `fillna` on DataFrame
- Can concatenate a list of Series along axis=1 to obtain a DataFrame (GH787)

### 1.36 v.0.7.0 (February 9, 2012)

#### 1.36.1 New features

- New unified `merge function` for efficiently performing full gamut of database / relational-algebra operations. Refactored existing join methods to use the new infrastructure, resulting in substantial performance gains (GH220, GH249, GH267)
- New unified concatenation function for concatenating Series, DataFrame or Panel objects along an axis. Can form union or intersection of the other axes. Improves performance of `Series.append` and `DataFrame.append` (GH468, GH479, GH273)
- Can pass multiple DataFrames to `DataFrame.append` to concatenate (stack) and multiple Series to `Series.append` too
- Can pass list of dicts (e.g., a list of JSON objects) to DataFrame constructor (GH526)
- You can now `set multiple columns` in a DataFrame via `__getitem__`, useful for transformation (GH342)
- Handle differently-indexed output values in `DataFrame.apply` (GH498)

```python
In [1]: df = DataFrame(randn(10, 4))
In [2]: df.apply(lambda x: x.describe())
Out[2]:
        0       1       2       3
count 10.000000 10.000000 10.000000 10.000000
mean  0.424980  0.115056  0.452000 -0.103829
std   0.898046  0.712034  0.867316  0.830197
min  -1.337024 -0.779344 -1.206466 -1.022360
25%  -0.000996 -0.344789 -0.120217 -0.744313
50%   0.860419  0.098422  0.540168 -0.387554
75%   1.094236  0.375137  1.076331  0.674952
max   1.207725  1.601703  1.663859  1.096187
```

(continues on next page)
Add reorder_levels method to Series and DataFrame (GH534)
Add dict-like get function to DataFrame and Panel (GH521)
Add DataFrame.iterrows method for efficiently iterating through the rows of a DataFrame
Add DataFrame.to_panel with code adapted from LongPanel.to_long
Add reindex_axis method added to DataFrame
Add level option to binary arithmetic functions on DataFrame and Series
Add level option to the reindex and align methods on Series and DataFrame for broadcasting values across a level (GH542, GH552, others)
Add attribute-based item access to Panel and add IPython completion (GH563)
Add logy option to Series.plot for log-scaling on the Y axis
Add index and header options to DataFrame.to_string
Can pass multiple DataFrames to DataFrame.join to join on index (GH115)
Can pass multiple Panels to Panel.join (GH115)
Added justify argument to DataFrame.to_string to allow different alignment of column headers
Add sort option to GroupBy to allow disabling sorting of the group keys for potential speedups (GH595)
Can pass MaskedArray to Series constructor (GH563)
Add Panel item access via attributes and IPython completion (GH554)
Implement DataFrame.lookup, fancy-indexing analogue for retrieving values given a sequence of row and column labels (GH338)
Can pass a list of functions to aggregate with groupby on a DataFrame, yielding an aggregated result with hierarchical columns (GH166)
Can call cummin and cummax on Series and DataFrame to get cumulative minimum and maximum, respectively (GH647)
value_range added as utility function to get min and max of a dataframe (GH288)
Added encoding argument to read_csv, read_table, to_csv and from_csv for non-ascii text (GH717)
Added abs method to pandas objects
Added crosstab function for easily computing frequency tables
Added isin method to index objects
Added level argument to xs method of DataFrame.

1.36.2 API Changes to integer indexing

One of the potentially riskiest API changes in 0.7.0, but also one of the most important, was a complete review of how integer indexes are handled with regard to label-based indexing. Here is an example:
In [3]: s = Series(randn(10), index=range(0, 20, 2))

In [4]: s
Out[4]:
   0  0.446246
   2 -0.500268
   4  0.814725
   6 -0.312744
   8  1.098892
  10  1.306330
  12 -0.366970
  14 -0.030890
  16  1.608095
  18 -0.023287
Length: 10, dtype: float64

In [5]: s[0]
Out[5]:
   → 0.44624598505731339

In [6]: s[2]
Out[6]:
   → -0.500268093241102

In [7]: s[4]
Out[7]:
   → 0.8147247587659604

This is all exactly identical to the behavior before. However, if you ask for a key not contained in the Series, in versions 0.6.1 and prior, Series would fall back on a location-based lookup. This now raises a KeyError:

In [2]: s[1]
KeyError: 1

This change also has the same impact on DataFrame:

In [3]: df = DataFrame(randn(8, 4), index=range(0, 16, 2))

In [4]: df
Out[4]:
    0    1    2    3
   0  0.88427  0.3363 -0.1787  0.03162
   2  0.14451 -0.1415  0.2504  0.58374
   4 -1.44779 -0.9186 -1.4996  0.27163
   6 -0.26598 -2.4184 -0.2658  0.11503
   8 -0.58776  0.3144 -0.8566  0.61941
  10  0.10940 -0.7175 -1.0108  0.47990
  12 -1.16919 -0.3087 -0.6049 -0.43544
  14 -0.07337  0.3410  0.0424 -0.16037

In [5]: df.ix[3]
KeyError: 3

In order to support purely integer-based indexing, the following methods have been added:
### 1.36.3 API tweaks regarding label-based slicing

Label-based slicing using `ix` now requires that the index be sorted (monotonic) **unless** both the start and endpoint are contained in the index:

```python
In [1]: s = Series(randn(6), index=list('gmkaec'))
```

```python
In [2]: s
Out[2]:
g   -1.182230
m   -0.276183
k   -0.243550
   1.628992
   0.073308
   -0.539890
dtype: float64
```

Then this is OK:

```python
In [3]: s.ix['k':'e']
Out[3]:
k   -0.243550
   1.628992
   0.073308
dtype: float64
```

But this is not:

```python
In [12]: s.ix['b':'h']
KeyError 'b'
```

If the index had been sorted, the “range selection” would have been possible:

```python
In [4]: s2 = s.sort_index()
```

```python
In [5]: s2
Out[5]:
a   1.628992
c   -0.539890
e   0.073308
g   -1.182230
k   -0.243550
m   -0.276183
dtype: float64
```

```python
In [6]: s2.ix['b':'h']
Out[6]:
c   -0.539890
```
1.36.4 Changes to Series [] operator

As an notational convenience, you can pass a sequence of labels or a label slice to a Series when getting and setting values via [] (i.e. the __getitem__ and __setitem__ methods). The behavior will be the same as passing similar input to ix except in the case of integer indexing:

```
In [8]: s = Series(randn(6), index=list('acegkm'))

In [9]: s
Out[9]:
  a -0.800734
  c -0.229737
  e -0.781940
  g  0.756053
  k  2.613373
  m -0.159310
Length: 6, dtype: float64

In [10]: s[['m', 'a', 'c', 'e']]
→
m -0.159310
 a -0.800734
 c -0.229737
 e -0.781940
Length: 4, dtype: float64

In [11]: s['b':'l']
→
c -0.229737
 e -0.781940
 g  0.756053
 k  2.613373
Length: 4, dtype: float64

In [12]: s['c':'k']
→
c -0.229737
 e -0.781940
 g  0.756053
 k  2.613373
Length: 4, dtype: float64
```

In the case of integer indexes, the behavior will be exactly as before (shadowing ndarray):

```
In [13]: s = Series(randn(6), index=range(0, 12, 2))

In [14]: s[[4, 0, 2]]
Out[14]:
  a -0.800734
  c -0.229737
  e -0.781940
  g  0.756053
  k  2.613373
Length: 5, dtype: float64
```

If you wish to do indexing with sequences and slicing on an integer index with label semantics, use `ix`.

### 1.36.5 Other API Changes

- The deprecated `LongPanel` class has been completely removed.
- If `Series.sort` is called on a column of a DataFrame, an exception will now be raised. Before it was possible to accidentally mutate a DataFrame’s column by doing `df[col].sort()` instead of the side-effect free method `df[col].order()` (GH316).
- Miscellaneous renames and deprecations which will (harmlessly) raise `FutureWarning`.
- `drop` added as an optional parameter to `DataFrame.reset_index` (GH699).

### 1.36.6 Performance improvements

- *Cythonized GroupBy aggregations* no longer presort the data, thus achieving a significant speedup (GH93). GroupBy aggregations with Python functions significantly sped up by clever manipulation of the ndarray data type in Cython (GH496).
- Better error message in DataFrame constructor when passed column labels don’t match data (GH497).
- Substantially improve performance of multi-GroupBy aggregation when a Python function is passed, reuse ndarray object in Cython (GH496).
- Can store objects indexed by tuples and floats in HDFStore (GH492).
- Don’t print length by default in `Series.to_string`, add `length` option (GH489).
- Improve Cython code for multi-groupby to aggregate without having to sort the data (GH93).
- Improve `MultiIndex` reindexing speed by storing tuples in the `MultiIndex`, test for backwards unpickling compatibility.
- Improve column reindexing performance by using specialized Cython take function.
- Further performance tweaking of `Series.__getitem__` for standard use cases.
- Avoid Index dict creation in some cases (i.e. when getting slices, etc.), regression from prior versions.
- Friendlier error message in setup.py if NumPy not installed.
- Use common set of NA-handling operations (sum, mean, etc.) in `Panel` class also (GH536).
- Default name assignment when calling `reset_index` on DataFrame with a regular (non-hierarchical) index (GH476).
• Use Cythonized groupers when possible in Series/DataFrame stat ops with level parameter passed (GH545)
• Ported skiplist data structure to C to speed up rolling_median by about 5-10x in most typical use cases (GH374)

1.37 v.0.6.1 (December 13, 2011)

1.37.1 New features

• Can append single rows (as Series) to a DataFrame
• Add Spearman and Kendall rank correlation options to Series.corr and DataFrame.corr (GH428)
• Added get_value and set_value methods to Series, DataFrame, and Panel for very low-overhead access (>2x faster in many cases) to scalar elements (GH437, GH438). set_value is capable of producing an enlarged object.
• Add PyQt table widget to sandbox (GH435)
• DataFrame.align can accept Series arguments and an axis option (GH461)
• Implement new SparseArray and SparseList data structures. SparseSeries now derives from SparseArray (GH463)
• Better console printing options (GH453)
• Implement fast data ranking for Series and DataFrame, fast versions of scipy.stats.rankdata (GH428)
• Implement DataFrame.from_items alternate constructor (GH444)
• DataFrame.convert_objects method for inferring better dtypes for object columns (GH302)
• Add rolling_corr_pairwise function for computing Panel of correlation matrices (GH189)
• Add margins option to pivot_table for computing subgroup aggregates (GH114)
• Add Series.from_csv function (GH482)
• Can pass DataFrame/DataFrame and DataFrame/Series to rolling_corr/rolling_cov (GH #462)
• MultiIndex.get_level_values can accept the level name

1.37.2 Performance improvements

• Improve memory usage of DataFrame.describe (do not copy data unnecessarily) (PR #425)
• Optimize scalar value lookups in the general case by 25% or more in Series and DataFrame
• Fix performance regression in cross-sectional count in DataFrame, affecting DataFrame.dropna speed
• Column deletion in DataFrame copies no data (computes views on blocks) (GH #158)

1.38 v.0.6.0 (November 25, 2011)

1.38.1 New Features

• Added melt function to pandas.core.reshape
• Added level parameter to group by level in Series and DataFrame descriptive statistics (GH313)
• Added head and tail methods to Series, analogous to to DataFrame (GH296)
• Added Series.isin function which checks if each value is contained in a passed sequence (GH289)
• Added float_format option to Series.to_string
• Added skip_footer (GH291) and converters (GH343) options to read_csv and read_table
• Added drop_duplicates and duplicated functions for removing duplicate DataFrame rows and checking for duplicate rows, respectively (GH319)
• Implemented operators ‘&’, ‘|’, ‘^’, ‘-’ on DataFrame (GH347)
• Added Series.mad, mean absolute deviation
• Added QuarterEnd DateOffset (GH321)
• Added dot to DataFrame (GH65)
• Added orient option to Panel.from_dict (GH359, GH301)
• Added orient option to DataFrame.from_dict
• Added passing list of tuples or list of lists to DataFrame.from_records (GH357)
• Added multiple levels to groupby (GH103)
• Allow multiple columns in by argument of DataFrame.sort_index (GH92, GH362)
• Added fast get_value and put_value methods to DataFrame (GH360)
• Added cov instance methods to Series and DataFrame (GH194, GH362)
• Added kind='bar' option to DataFrame.plot (GH348)
• Added idxmin and idxmax to Series and DataFrame (GH286)
• Added read_clipboard function to parse DataFrame from clipboard (GH300)
• Added nunique function to Series for counting unique elements (GH297)
• Made DataFrame constructor use Series name if no columns passed (GH373)
• Support regular expressions in read_table/read_csv (GH364)
• Added DataFrame.to_html for writing DataFrame to HTML (GH387)
• Added support for MaskedArray data in DataFrame, masked values converted to NaN (GH396)
• Added DataFrame.boxplot function (GH368)
• Can pass extra args, kwds to DataFrame.apply (GH376)
• Implement DataFrame.join with vector on argument (GH312)
• Added legend boolean flag to DataFrame.plot (GH324)
• Can pass multiple levels to stack and unstack (GH370)
• Can pass multiple values columns to pivot_table (GH381)
• Use Series name in GroupBy for result index (GH363)
• Added raw option to DataFrame.apply for performance if only need ndarray (GH309)
• Added proper, tested weighted least squares to standard and panel OLS (GH303)
1.38.2 Performance Enhancements

- VBENCH Cythonized `cache_readonly`, resulting in substantial micro-performance enhancements throughout the codebase (GH361)
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations with 3-5x better performance than `np.apply_along_axis` (GH309)
- VBENCH Improved performance of `MultiIndex.from_tuples`
- VBENCH Special Cython matrix iterator for applying arbitrary reduction operations
- VBENCH + DOCUMENT Add `raw` option to `DataFrame.apply` for getting better performance when
- VBENCH Faster cythonized count by level in Series and DataFrame (GH341)
- VBENCH? Significant GroupBy performance enhancement with multiple keys with many “empty” combinations
- VBENCH New Cython vectorized function `map_infer` speeds up `Series.apply` and `Series.map` significantly when passed elementwise Python function, motivated by (GH355)
- VBENCH Significantly improved performance of `Series.order`, which also makes `np.unique` called on a Series faster (GH327)
- VBENCH Vastly improved performance of GroupBy on axes with a MultiIndex (GH299)

1.39 v.0.5.0 (October 24, 2011)

1.39.1 New Features

- Added `DataFrame.align` method with standard join options
- Added `parse_dates` option to `read_csv` and `read_table` methods to optionally try to parse dates in the index columns
- Added `nrows`, `chunksize`, and `iterator` arguments to `read_csv` and `read_table`. The last two return a new `TextParser` class capable of lazily iterating through chunks of a flat file (GH242)
- Added ability to join on multiple columns in `DataFrame.join` (GH214)
- Added private `_get_duplicates` function to `Index` for identifying duplicate values more easily (ENH5c)
- Added `column` attribute access to `DataFrame`
- Added Python tab completion hook for `DataFrame` columns. (GH233, GH230)
- Implemented `Series.describe` for Series containing objects (GH241)
- Added `inner` join option to `DataFrame.join` when joining on key(s) (GH248)
- Implemented selecting `DataFrame` columns by passing a list to `__getitem__` (GH253)
- Implemented `&` and `|` to intersect / union `Index` objects, respectively (GH261)
- Added `pivot_table` convenience function to pandas namespace (GH234)
- Implemented `Panel.rename_axis` function (GH243)
- `DataFrame` will show index level names in console output (GH334)
- Implemented `Panel.take`
- Added `set_eng_float_format` for alternate `DataFrame` floating point string formatting (ENH61)
• **Added** convenience `set_index` function for creating a DataFrame index from its existing columns

• **Implemented** `groupby` hierarchical index level name (GH223)

• **Added** support for different delimiters in `DataFrame.to_csv` (GH244)

• TODO: DOCS ABOUT TAKE METHODS

### 1.39.2 Performance Enhancements

- VBENCH Major performance improvements in file parsing functions `read_csv` and `read_table`
- VBENCH Added Cython function for converting tuples to ndarray very fast. Speeds up many MultiIndex-related operations
- VBENCH Refactored merging / joining code into a tidy class and disabled unnecessary computations in the float/object case, thus getting about 10% better performance (GH211)
- VBENCH Improved speed of `DataFrame.xs` on mixed-type DataFrame objects by about 5x, regression from 0.3.0 (GH215)
- VBENCH With new `DataFrame.align` method, speeding up binary operations between differently-indexed DataFrame objects by 10-25%.
- VBENCH Significantly sped up conversion of nested dict into DataFrame (GH212)
- VBENCH Significantly speed up DataFrame `__repr__` and `count` on large mixed-type DataFrame objects

### 1.40 v.0.4.3 through v0.4.1 (September 25 - October 9, 2011)

#### 1.40.1 New Features

- Added Python 3 support using 2to3 (GH200)
- *Added* `name` attribute to `Series`, now prints as part of `Series.__repr__`
- *Added* instance methods `isnull` and `notnull` to `Series` (GH209, GH203)
- *Added* `Series.align` method for aligning two series with choice of join method (ENH56)
- *Added* method `get_level_values` to `MultiIndex` (GH188)
- Set values in mixed-type DataFrame objects via `.ix` indexing attribute (GH135)
- Added new `DataFrame` methods `get_dtypes_counts` and property `dtypes` (ENHdc)
- **Added** `ignore_index` option to `DataFrame.append` to stack DataFrames (ENH1b)
- `read_csv` tries to *sniff* delimiters using `csv.Sniffer` (GH146)
- `read_csv` can *read* multiple columns into a MultiIndex; `DataFrame`'s `to_csv` method writes out a corresponding MultiIndex (GH151)
- `DataFrame.rename` has a new `copy` parameter to *rename* a DataFrame in place (ENHed)
- Enable unstacking by name (GH142)
- Enable `sortlevel` to work by level (GH141)
1.40.2 Performance Enhancements

• Altered binary operations on differently-indexed SparseSeries objects to use the integer-based (dense) alignment logic which is faster with a larger number of blocks (GH205)
• Wrote faster Cython data alignment / merging routines resulting in substantial speed increases
• Improved performance of isnull and notnull, a regression from v0.3.0 (GH187)
• Refactored code related to DataFrame.join so that intermediate aligned copies of the data in each DataFrame argument do not need to be created. Substantial performance increases result (GH176)
• Substantially improved performance of generic Index.intersection and Index.union
• Implemented BlockManager.take resulting in significantly faster take performance on mixed-type DataFrame objects (GH104)
• Improved performance of Series.sort_index
• Significant groupby performance enhancement: removed unnecessary integrity checks in DataFrame internals that were slowing down slicing operations to retrieve groups
• Optimized _ensure_index function resulting in performance savings in type-checking Index objects
• Wrote fast time series merging / joining methods in Cython. Will be integrated later into DataFrame.join and related functions
CHAPTER TWO

INSTALLATION

The easiest way to install pandas is to install it as part of the Anaconda distribution, a cross platform distribution for data analysis and scientific computing. This is the recommended installation method for most users.

Instructions for installing from source, PyPI, ActivePython, various Linux distributions, or a development version are also provided.

2.1 Plan for dropping Python 2.7

The Python core team plans to stop supporting Python 2.7 on January 1st, 2020. In line with NumPy’s plans, all pandas releases through December 31, 2018 will support Python 2.

The final release before December 31, 2018 will be the last release to support Python 2. The released package will continue to be available on PyPI and through conda.

Starting January 1, 2019, all releases will be Python 3 only.

If there are people interested in continued support for Python 2.7 past December 31, 2018 (either backporting bugfixes or funding) please reach out to the maintainers on the issue tracker.

For more information, see the Python 3 statement and the Porting to Python 3 guide.

2.2 Python version support

Officially Python 2.7, 3.5, and 3.6.

2.3 Installing pandas

2.3.1 Installing with Anaconda

Installing pandas and the rest of the NumPy and SciPy stack can be a little difficult for inexperienced users.

The simplest way to install not only pandas, but Python and the most popular packages that make up the SciPy stack (IPython, NumPy, Matplotlib, . . . ) is with Anaconda, a cross-platform (Linux, Mac OS X, Windows) Python distribution for data analytics and scientific computing.

After running the installer, the user will have access to pandas and the rest of the SciPy stack without needing to install anything else, and without needing to wait for any software to be compiled.

Installation instructions for Anaconda can be found here.
A full list of the packages available as part of the Anaconda distribution can be found here.

Another advantage to installing Anaconda is that you don’t need admin rights to install it. Anaconda can install in the user’s home directory, which makes it trivial to delete Anaconda if you decide (just delete that folder).

### 2.3.2 Installing with Miniconda

The previous section outlined how to get pandas installed as part of the Anaconda distribution. However this approach means you will install well over one hundred packages and involves downloading the installer which is a few hundred megabytes in size.

If you want to have more control on which packages, or have a limited internet bandwidth, then installing pandas with Miniconda may be a better solution.

**Conda** is the package manager that the Anaconda distribution is built upon. It is a package manager that is both cross-platform and language agnostic (it can play a similar role to a pip and virtualenv combination).

**Miniconda** allows you to create a minimal self contained Python installation, and then use the **Conda** command to install additional packages.

First you will need **Conda** to be installed and downloading and running the **Miniconda** will do this for you. The installer can be found here

The next step is to create a new conda environment. A conda environment is like a virtualenv that allows you to specify a specific version of Python and set of libraries. Run the following commands from a terminal window:

```
conda create -n name_of_my_env python
```

This will create a minimal environment with only Python installed in it. To put your self inside this environment run:

```
source activate name_of_my_env
```

On Windows the command is:

```
activate name_of_my_env
```

The final step required is to install pandas. This can be done with the following command:

```
conda install pandas
```

To install a specific pandas version:

```
conda install pandas=0.20.3
```

To install other packages, IPython for example:

```
conda install ipython
```

To install the full Anaconda distribution:

```
conda install anaconda
```

If you need packages that are available to pip but not conda, then install pip, and then use pip to install those packages:

```
conda install pip
pip install django
```
2.3.3 Installing from PyPI

pandas can be installed via pip from PyPI.

```bash
pip install pandas
```

2.3.4 Installing with ActivePython

Installation instructions for ActivePython can be found here. Versions 2.7 and 3.5 include pandas.

2.3.5 Installing using your Linux distribution’s package manager.

The commands in this table will install pandas for Python 3 from your distribution. To install pandas for Python 2, you may need to use the `python-pandas` package.

<table>
<thead>
<tr>
<th>Distribution</th>
<th>Status</th>
<th>Download / Repository Link</th>
<th>Install method</th>
</tr>
</thead>
<tbody>
<tr>
<td>Debian</td>
<td>stable</td>
<td>official Debian repository</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>Debian &amp; Ubuntu</td>
<td>unstable (latest packages)</td>
<td>NeuroDebian</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>Ubuntu</td>
<td>stable</td>
<td>official Ubuntu repository</td>
<td><code>sudo apt-get install python3-pandas</code></td>
</tr>
<tr>
<td>OpenSuse</td>
<td>stable</td>
<td>OpenSuse Repository</td>
<td><code>zypper in python3-pandas</code></td>
</tr>
<tr>
<td>Fedora</td>
<td>stable</td>
<td>official Fedora repository</td>
<td><code>dnf install python3-pandas</code></td>
</tr>
<tr>
<td>Centos/RHEL</td>
<td>stable</td>
<td>EPEL repository</td>
<td><code>yum install python3-pandas</code></td>
</tr>
</tbody>
</table>

However, the packages in the Linux package managers are often a few versions behind, so to get the newest version of pandas, it’s recommended to install using the `pip` or `conda` methods described above.

2.3.6 Installing from source

See the contributing documentation for complete instructions on building from the git source tree. Further, see creating a development environment if you wish to create a pandas development environment.

2.4 Running the test suite

pandas is equipped with an exhaustive set of unit tests, covering about 97% of the codebase as of this writing. To run it on your machine to verify that everything is working (and that you have all of the dependencies, soft and hard, installed), make sure you have `pytest` and run:

```bash
>>> import pandas as pd
>>> pd.test()
running: pytest --skip-slow --skip-network C:\Users\TP\Anaconda3\envs\py36\lib\site-packages\pandas
=================================================================== test session starts ====================================================================
(continues on next page)
2.5 Dependencies

- **setuptools**: 24.2.0 or higher
- **NumPy**: 1.9.0 or higher
- **python-dateutil**: 2.5.0 or higher
- **pytz**

### 2.5.1 Recommended Dependencies

- **numexpr**: for accelerating certain numerical operations. numexpr uses multiple cores as well as smart chunking and caching to achieve large speedups. If installed, must be Version 2.4.6 or higher.
- **bottleneck**: for accelerating certain types of nan evaluations. bottleneck uses specialized cython routines to achieve large speedups. If installed, must be Version 1.0.0 or higher.

**Note:** You are highly encouraged to install these libraries, as they provide speed improvements, especially when working with large data sets.

### 2.5.2 Optional Dependencies

- **Cython**: Only necessary to build development version. Version 0.24 or higher.
- **SciPy**: miscellaneous statistical functions, Version 0.14.0 or higher
- **xarray**: pandas like handling for > 2 dims, needed for converting Panels to xarray objects. Version 0.7.0 or higher is recommended.
- **PyTables**: necessary for HDF5-based storage. Version 3.0.0 or higher required, Version 3.2.1 or higher highly recommended.
- **Feather Format**: necessary for feather-based storage, version 0.3.1 or higher.
- **Apache Parquet**, either **pyarrow** (>= 0.4.1) or **fastparquet** (>= 0.0.6) for parquet-based storage. The **snappy** and brotli are available for compression support.
- **SQLAlchemy**: for SQL database support. Version 0.8.1 or higher recommended. Besides SQLAlchemy, you also need a database specific driver. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs. Some common drivers are:
  - **psycopg2**: for PostgreSQL
- **pymysql**: for MySQL.
- **SQLite**: for SQLite, this is included in Python’s standard library by default.

**• matplotlib**: for plotting, Version 1.4.3 or higher.

**• For Excel I/O:**
  - **xlrdlxlwt**: Excel reading (xlrd) and writing (xlwt)
  - **openpyxl**: openpyxl version 2.4.0 for writing .xlsx files (xlrd $\geq$ 0.9.0)
  - **XlsxWriter**: Alternative Excel writer

**• Jinja2**: Template engine for conditional HTML formatting.

**• s3fs**: necessary for Amazon S3 access ($\geq$ 0.0.7).

**• blosc**: for msgpack compression using blosc

**• One of qtpy (requires PyQt or PySide), PyQt5, PyQt4, pygtk, xsel, or xclip**: necessary to use `read_clipboard()`.
  - Most package managers on Linux distributions will have `xclip` and/or `xsel` immediately available for installation.

**• pandas-gbq**: for Google BigQuery I/O.

**• Backports.lzma**: Only for Python 2, for writing to and/or reading from an xz compressed DataFrame in CSV; Python 3 support is built into the standard library.

**• One of the following combinations of libraries is needed to use the top-level `read_html()` function:**
  - Changed in version 0.23.0.

  **Note:** If using BeautifulSoup4 a minimum version of 4.2.1 is required

  - BeautifulSoup4 and html5lib (Any recent version of html5lib is okay.)
  - BeautifulSoup4 and lxml
  - BeautifulSoup4 and html5lib and lxml
  - Only lxml, although see *HTML Table Parsing* for reasons as to why you should probably not take this approach.

**Warning:**

- if you install BeautifulSoup4 you must install either lxml or html5lib or both. `read_html()` will not work with only BeautifulSoup4 installed.
- You are highly encouraged to read *HTML Table Parsing gotchas*. It explains issues surrounding the installation and usage of the above three libraries.

**Note:**

- if you’re on a system with apt-get you can do

  ```
sudo apt-get build-dep python-lxml
  ```

  to get the necessary dependencies for installation of lxml. This will prevent further headaches down the line.

2.5. Dependencies
Note: Without the optional dependencies, many useful features will not work. Hence, it is highly recommended that you install these. A packaged distribution like Anaconda, ActivePython (version 2.7 or 3.5), or Enthought Canopy may be worth considering.
CHAPTER THREE

CONTRIBUTING TO PANDAS

Table of contents:

• Where to start?
• Bug reports and enhancement requests
• Working with the code
  – Version control, Git, and GitHub
  – Getting started with Git
  – Forking
  – Creating a development environment
    • Installing a C Compiler
    • Creating a Python Environment
    • Creating a Python Environment (pip)
  – Creating a branch
• Contributing to the documentation
  – About the pandas documentation
  – How to build the pandas documentation
    • Requirements
    • Building the documentation
    • Building master branch documentation
• Contributing to the code base
  – Code standards
    • C (cpplint)
    • Python (PEP8)
    • Backwards Compatibility
  – Testing With Continuous Integration
  – Test-driven development/code writing
    • Writing tests
3.1 Where to start?

All contributions, bug reports, bug fixes, documentation improvements, enhancements, and ideas are welcome.

If you are brand new to pandas or open-source development, we recommend going through the GitHub “issues” tab to find issues that interest you. There are a number of issues listed under Docs and Difficulty Novice where you could start out. Once you’ve found an interesting issue, you can return here to get your development environment setup.

Feel free to ask questions on the mailing list or on Gitter.

3.2 Bug reports and enhancement requests

Bug reports are an important part of making pandas more stable. Having a complete bug report will allow others to reproduce the bug and provide insight into fixing. See this stackoverflow article and this blogpost for tips on writing a good bug report.

Trying the bug-producing code out on the master branch is often a worthwhile exercise to confirm the bug still exists. It is also worth searching existing bug reports and pull requests to see if the issue has already been reported and/or fixed.

Bug reports must:

1. Include a short, self-contained Python snippet reproducing the problem. You can format the code nicely by using GitHub Flavored Markdown:

```python
```python
>>> from pandas import DataFrame
>>> df = DataFrame(...) ...```

2. Include the full version string of pandas and its dependencies. You can use the built in function:
3. Explain why the current behavior is wrong/not desired and what you expect instead.
The issue will then show up to the pandas community and be open to comments/ideas from others.

3.3 Working with the code

Now that you have an issue you want to fix, enhancement to add, or documentation to improve, you need to learn how to work with GitHub and the pandas code base.

3.3.1 Version control, Git, and GitHub

To the new user, working with Git is one of the more daunting aspects of contributing to pandas. It can very quickly become overwhelming, but sticking to the guidelines below will help keep the process straightforward and mostly trouble free. As always, if you are having difficulties please feel free to ask for help.

The code is hosted on GitHub. To contribute you will need to sign up for a free GitHub account. We use Git for version control to allow many people to work together on the project.

Some great resources for learning Git:

- the GitHub help pages.
- the NumPy's documentation.
- Matthew Brett’s Pydagogue.

3.3.2 Getting started with Git

GitHub has instructions for installing git, setting up your SSH key, and configuring git. All these steps need to be completed before you can work seamlessly between your local repository and GitHub.

3.3.3 Forking

You will need your own fork to work on the code. Go to the pandas project page and hit the Fork button. You will want to clone your fork to your machine:

```
git clone https://github.com/your-user-name/pandas.git pandas-yourname
cd pandas-yourname
git remote add upstream https://github.com/pandas-dev/pandas.git
```

This creates the directory pandas-yourname and connects your repository to the upstream (main project) pandas repository.

3.3.4 Creating a development environment

To test out code changes, you’ll need to build pandas from source, which requires a C compiler and Python environment. If you’re making documentation changes, you can skip to Contributing to the documentation but you won’t be able to build the documentation locally before pushing your changes.
3.3.4.1 Installing a C Compiler

Pandas uses C extensions (mostly written using Cython) to speed up certain operations. To install pandas from source, you need to compile these C extensions, which means you need a C compiler. This process depends on which platform you’re using. Follow the CPython contributing guidelines for getting a compiler installed. You don’t need to do any of the .configure or make steps; you only need to install the compiler.

For Windows developers, the following links may be helpful.

- https://cowboyprogrammer.org/building-python-wheels-for-windows/
- https://blog.ionelmc.ro/2014/12/21/compiling-python-extensions-on-windows/

Let us know if you have any difficulties by opening an issue or reaching out on Gitter.

3.3.4.2 Creating a Python Environment

Now that you have a C compiler, create an isolated pandas development environment:

- Install either Anaconda or miniconda
- Make sure your conda is up to date (conda update conda)
- Make sure that you have cloned the repository
- cd to the pandas source directory

We’ll now kick off a three-step process:

1. Install the build dependencies
2. Build and install pandas
3. Install the optional dependencies

```
# Create and activate the build environment
conda env create -f ci/environment-dev.yaml
conda activate pandas-dev

# or with older versions of Anaconda:
source activate pandas-dev

# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .

# Install the rest of the optional dependencies
conda install -c defaults -c conda-forge --file=ci/requirements-optional-conda.txt
```

At this point you should be able to import pandas from your locally built version:

```
$ python  # start an interpreter
>>> import pandas
>>> print(pandas.__version__)
0.22.0.dev0+29.g4ad6d4d74
```
This will create the new environment, and not touch any of your existing environments, nor any existing Python installation.

To view your environments:

```
conda info -e
```

To return to your root environment:

```
conda deactivate
```

See the full conda docs [here](#).

### 3.3.4.3 Creating a Python Environment (pip)

If you aren’t using conda for you development environment, follow these instructions. You’ll need to have at least python3.5 installed on your system.

```bash
# Create a virtual environment
# Use an ENV_DIR of your choice. We’ll use ~/virtualenvs/pandas-dev
# Any parent directories should already exist
python3 -m venv ~/virtualenvs/pandas-dev
# Activate the virtualenv
. ~/virtualenvs/pandas-dev/bin/activate

# Install the build dependencies
python -m pip install -r ci/requirements_dev.txt
# Build and install pandas
python setup.py build_ext --inplace -j 4
python -m pip install -e .
# Install additional dependencies
python -m pip install -r ci/requirements-optional-pip.txt
```

### 3.3.5 Creating a branch

You want your master branch to reflect only production-ready code, so create a feature branch for making your changes. For example:

```
git branch shiny-new-feature
git checkout shiny-new-feature
```

The above can be simplified to:

```
git checkout -b shiny-new-feature
```

This changes your working directory to the shiny-new-feature branch. Keep any changes in this branch specific to one bug or feature so it is clear what the branch brings to `pandas`. You can have many shiny-new-features and switch in between them using the git checkout command.

When creating this branch, make sure your master branch is up to date with the latest upstream master version. To update your local master branch, you can do:

```
git checkout master
git pull upstream master --ff-only
```
When you want to update the feature branch with changes in master after you created the branch, check the section on updating a PR.

3.4 Contributing to the documentation

Contributing to the documentation benefits everyone who uses pandas. We encourage you to help us improve the documentation, and you don’t have to be an expert on pandas to do so! In fact, there are sections of the docs that are worse off after being written by experts. If something in the docs doesn’t make sense to you, updating the relevant section after you figure it out is a great way to ensure it will help the next person.

Documentation:

- About the pandas documentation
- How to build the pandas documentation
  - Requirements
  - Building the documentation
  - Building master branch documentation

3.4.1 About the pandas documentation

The documentation is written in reStructuredText, which is almost like writing in plain English, and built using Sphinx. The Sphinx Documentation has an excellent introduction to reST. Review the Sphinx docs to perform more complex changes to the documentation as well.

Some other important things to know about the docs:

- The pandas documentation consists of two parts: the docstrings in the code itself and the docs in this folder pandas/doc/.
  The docstrings provide a clear explanation of the usage of the individual functions, while the documentation in this folder consists of tutorial-like overviews per topic together with some other information (what’s new, installation, etc).

- The docstrings follow a pandas convention, based on the Numpy Docstring Standard. Follow the pandas docstring guide for detailed instructions on how to write a correct docstring.

3.4.1.1 pandas docstring guide

Note: Video tutorial: Pandas docstring guide by Frank Akogun.

About docstrings and standards

A Python docstring is a string used to document a Python module, class, function or method, so programmers can understand what it does without having to read the details of the implementation.

Also, it is a common practice to generate online (html) documentation automatically from docstrings. Sphinx serves this purpose.
Next example gives an idea on how a docstring looks like:

```python
def add(num1, num2):
    """
    Add up two integer numbers.
    This function simply wraps the `+` operator, and does not
do anything interesting, except for illustrating what is
the docstring of a very simple function.

    Parameters
    ----------
    num1 : int
        First number to add
    num2 : int
        Second number to add

    Returns
    -------
    int
        The sum of `num1` and `num2`

    See Also
    --------
    subtract : Subtract one integer from another

    Examples
    --------
    >>> add(2, 2)
    4
    >>> add(25, 0)
    25
    >>> add(10, -10)
    0
    """
    return num1 + num2
```

Some standards exist about docstrings, so they are easier to read, and they can be exported to other formats such as html or pdf.

The first conventions every Python docstring should follow are defined in PEP-257.

As PEP-257 is quite open, and some other standards exist on top of it. In the case of pandas, the numpy docstring
convention is followed. The conventions is explained in this document:

- numpydoc docstring guide (which is based in the original Guide to NumPy/SciPy documentation)

numpydoc is a Sphinx extension to support the numpy docstring convention.

The standard uses reStructuredText (reST). reStructuredText is a markup language that allows encoding styles
in plain text files. Documentation about reStructuredText can be found in:

- Sphinx reStructuredText primer
- Quick reStructuredText reference
- Full reStructuredText specification

Pandas has some helpers for sharing docstrings between related classes, see Sharing Docstrings.

The rest of this document will summarize all the above guides, and will provide additional convention specific
to the pandas project.
**Writing a docstring**

**General rules**

Docstrings must be defined with three double-quotes. No blank lines should be left before or after the docstring. The text starts in the next line after the opening quotes. The closing quotes have their own line (meaning that they are not at the end of the last sentence).

In rare occasions reST styles like bold text or italics will be used in docstrings, but is it common to have inline code, which is presented between backticks. It is considered inline code:

- The name of a parameter
- Python code, a module, function, built-in, type, literal... (e.g. os, list, numpy.abs, datetime.date,True)
- A pandas class (in the form :class:`pandas.Series`)
- A pandas method (in the form :meth:`pandas.Series.sum`)
- A pandas function (in the form :func:`pandas.to_datetime`)

**Note:** To display only the last component of the linked class, method or function, prefix it with ~. For example, :class:`~pandas.Series` will link to pandas.Series but only display the last part, Series as the link text. See Sphinx cross-referencing syntax for details.

**Good:**

```python
def add_values(arr):
    ""
    Add the values in `arr`.
    This is equivalent to Python `sum` of :meth:`pandas.Series.sum`.
    Some sections are omitted here for simplicity.
    ""
    return sum(arr)
```

**Bad:**

```python
def func():
    """Some function.
    With several mistakes in the docstring.
    It has a blank line after the signature `def func():`.
    The text 'Some function' should go in the line after the opening quotes of the docstring, not in the same line.
    There is a blank line between the docstring and the first line of code `foo = 1`.
    The closing quotes should be in the next line, not in this one.""
    foo = 1
```

(continues on next page)
Section 1: Short summary

The short summary is a single sentence that expresses what the function does in a concise way.

The short summary must start with a capital letter, end with a dot, and fit in a single line. It needs to express what the object does without providing details. For functions and methods, the short summary must start with an infinitive verb.

**Good:**

```python
def astype(dtype):
    """
    Cast Series type.
    
    This section will provide further details.
    """
    pass
```

**Bad:**

```python
def astype(dtype):
    """
    Casts Series type.
    
    Verb in third-person of the present simple, should be infinitive.
    """
    pass
```

```python
def astype(dtype):
    """
    Method to cast Series type.
    
    Does not start with verb.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type
    
    Missing dot at the end.
    """
    pass
```

```python
def astype(dtype):
    """
    Cast Series type from its current type to the new type defined in the parameter dtype.
    
    Summary is too verbose and doesn't fit in a single line.
    """
    pass
```
Section 2: Extended summary

The extended summary provides details on what the function does. It should not go into the details of the parameters, or discuss implementation notes, which go in other sections.

A blank line is left between the short summary and the extended summary. And every paragraph in the extended summary is finished by a dot.

The extended summary should provide details on why the function is useful and their use cases, if it is not too generic.

```python
def unstack():
    """
    Pivot a row index to columns.

    When using a multi-index, a level can be pivoted so each value in the index becomes a column. This is especially useful when a subindex is repeated for the main index, and data is easier to visualize as a pivot table.

    The index level will be automatically removed from the index when added as columns.
    """
    pass
```

Section 3: Parameters

The details of the parameters will be added in this section. This section has the title “Parameters”, followed by a line with a hyphen under each letter of the word “Parameters”. A blank line is left before the section title, but not after, and not between the line with the word “Parameters” and the one with the hyphens.

After the title, each parameter in the signature must be documented, including *args and **kwargs, but not self. The parameters are defined by their name, followed by a space, a colon, another space, and the type (or types). Note that the space between the name and the colon is important. Types are not defined for *args and **kwargs, but must be defined for all other parameters. After the parameter definition, it is required to have a line with the parameter description, which is indented, and can have multiple lines. The description must start with a capital letter, and finish with a dot.

For keyword arguments with a default value, the default will be listed after a comma at the end of the type. The exact form of the type in this case will be “int, default 0”. In some cases it may be useful to explain what the default argument means, which can be added after a comma “int, default -1, meaning all cpus”.

In cases where the default value is None, meaning that the value will not be used. Instead of “str, default None”, it is preferred to write “str, optional”. When None is a value being used, we will keep the form “str, default None”. For example, in df.to_csv(compression=None), None is not a value being used, but means that compression is optional, and no compression is being used if not provided. In this case we will use str, optional. Only in cases like func(value=None) and None is being used in the same way as 0 or foo would be used, then we will specify “str, int or None, default None”.

Good:

```python
class Series:
    def plot(self, kind, color='blue', **kwargs):
        """
        Generate a plot.
        """
```

(continues on next page)
Render the data in the Series as a matplotlib plot of the specified kind.

Parameters
---------
kind : str
    Kind of matplotlib plot.
color : str, default 'blue'
    Color name or rgb code.
**kwargs
    These parameters will be passed to the matplotlib plotting function.

""
pass

Bad:

```python
class Series:
    def plot(self, kind, **kwargs):
        ""
        Generate a plot.
        Render the data in the Series as a matplotlib plot of the specified kind.
        Note the blank line between the parameters title and the first parameter. Also, note that after the name of the parameter 'kind' and before the colon, a space is missing.
        Also, note that the parameter descriptions do not start with a capital letter, and do not finish with a dot.
        Finally, the `**kwargs` parameter is missing.

        Parameters
        ---------

        kind: str
            kind of matplotlib plot
        ""
        pass
```

Parameter types

When specifying the parameter types, Python built-in data types can be used directly (the Python type is preferred to the more verbose string, integer, boolean, etc):

- int
- float
- str
- bool

For complex types, define the subtypes. For `dict` and `tuple`, as more than one type is present, we use the brackets to help read the type (curly brackets for `dict` and normal brackets for `tuple`):
- list of int
- dict of {str : int}
- tuple of (str, int, int)
- tuple of (str,)
- set of str

In case where there are just a set of values allowed, list them in curly brackets and separated by commas (followed by a space). If the values are ordinal and they have an order, list them in this order. Otherwise, list the default value first, if there is one:
- {0, 10, 25}
- {'simple', 'advanced'}
- {'low', 'medium', 'high'}
- {'cat', 'dog', 'bird'}

If the type is defined in a Python module, the module must be specified:
- datetime.date
- datetime.datetime
- decimal.Decimal

If the type is in a package, the module must be also specified:
- numpy.ndarray
- scipy.sparse.coo_matrix

If the type is a pandas type, also specify pandas except for Series and DataFrame:
- Series
- DataFrame
- pandas.Index
- pandas.Categorical
- pandas.SparseArray

If the exact type is not relevant, but must be compatible with a numpy array, array-like can be specified. If Any type that can be iterated is accepted, iterable can be used:
- array-like
- iterable

If more than one type is accepted, separate them by commas, except the last two types, that need to be separated by the word ‘or’:
- int or float
- float, decimal.Decimal or None
- str or list of str

If None is one of the accepted values, it always needs to be the last in the list.

For axis, the convention is to use something like:
- axis : {0 or ‘index’, 1 or ‘columns’, None}, default None
Section 4: Returns or Yields

If the method returns a value, it will be documented in this section. Also if the method yields its output.

The title of the section will be defined in the same way as the “Parameters”. With the names “Returns” or “Yields” followed by a line with as many hyphens as the letters in the preceding word.

The documentation of the return is also similar to the parameters. But in this case, no name will be provided, unless the method returns or yields more than one value (a tuple of values).

The types for “Returns” and “Yields” are the same as the ones for the “Parameters”. Also, the description must finish with a dot.

For example, with a single value:

```python
def sample():
    """
    Generate and return a random number.
    The value is sampled from a continuous uniform distribution between 0 and 1.
    
    Returns
    ------
    float
    Random number generated.
    """
    return random.random()
```

With more than one value:

```python
def random_letters():
    """
    Generate and return a sequence of random letters.
    The length of the returned string is also random, and is also returned.
    
    Returns
    ------
    length : int
        Length of the returned string.
    letters : str
        String of random letters.
    """
    length = random.randint(1, 10)
    letters = ''.join(random.choice(string.ascii_lowercase)
            for i in range(length))
    return length, letters
```

If the method yields its value:

```python
def sample_values():
    """
    Generate an infinite sequence of random numbers.
    The values are sampled from a continuous uniform distribution between 0 and 1.
    """
    yield random.random()
```

(continues on next page)
Section 5: See Also

This section is used to let users know about pandas functionality related to the one being documented. In rare cases, if no related methods or functions can be found at all, this section can be skipped.

An obvious example would be the head() and tail() methods. As tail() does the equivalent as head() but at the end of the Series or DataFrame instead of at the beginning, it is good to let the users know about it.

To give an intuition on what can be considered related, here there are some examples:

- **loc** and **iloc**, as they do the same, but in one case providing indices and in the other positions
- **max** and **min**, as they do the opposite
- **iterrows**, **itertuples** and **iteritems**, as it is easy that a user looking for the method to iterate over columns ends up in the method to iterate over rows, and vice-versa
- **fillna** and **dropna**, as both methods are used to handle missing values
- **read_csv** and **to_csv**, as they are complementary
- **merge** and **join**, as one is a generalization of the other
- **astype** and **pandas.to_datetime**, as users may be reading the documentation of **astype** to know how to cast as a date, and the way to do it is with **pandas.to_datetime**
- **where** is related to **numpy.where**, as its functionality is based on it

When deciding what is related, you should mainly use your common sense and think about what can be useful for the users reading the documentation, especially the less experienced ones.

When relating to other libraries (mainly **numpy**), use the name of the module first (not an alias like **np**). If the function is in a module which is not the main one, like **scipy.sparse**, list the full module (e.g. **scipy.sparse.coo_matrix**).

This section, as the previous, also has a header, “See Also” (note the capital S and A). Also followed by the line with hyphens, and preceded by a blank line.

After the header, we will add a line for each related method or function, followed by a space, a colon, another space, and a short description that illustrated what this method or function does, why is it relevant in this context, and what are the key differences between the documented function and the one referencing. The description must also finish with a dot.

Note that in “Returns” and “Yields”, the description is located in the following line than the type. But in this section it is located in the same line, with a colon in between. If the description does not fit in the same line, it can continue in the next ones, but it has to be indented in them.

For example:
```python
class Series:
    def head(self):
        """
        Return the first 5 elements of the Series.
        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.
        """
        Returns
        -------
        Series
        Subset of the original series with the 5 first values.
        See Also
        --------
        Series.tail : Return the last 5 elements of the Series.
        Series.iloc : Return a slice of the elements in the Series,
                      which can also be used to return the first or last n.
        """
        return self.iloc[:5]
```

Section 6: Notes

This is an optional section used for notes about the implementation of the algorithm. Or to document technical aspects of the function behavior.

Feel free to skip it, unless you are familiar with the implementation of the algorithm, or you discover some counter-intuitive behavior while writing the examples for the function.

This section follows the same format as the extended summary section.

Section 7: Examples

This is one of the most important sections of a docstring, even if it is placed in the last position. As often, people understand concepts better with examples, than with accurate explanations.

Examples in docstrings, besides illustrating the usage of the function or method, must be valid Python code, that in a deterministic way returns the presented output, and that can be copied and run by users.

They are presented as a session in the Python terminal. >>> is used to present code. ... is used for code continuing from the previous line. Output is presented immediately after the last line of code generating the output (no blank lines in between). Comments describing the examples can be added with blank lines before and after them.

The way to present examples is as follows:

1. Import required libraries (except numpy and pandas)
2. Create the data required for the example
3. Show a very basic example that gives an idea of the most common use case
4. Add examples with explanations that illustrate how the parameters can be used for extended functionality

A simple example could be:
class Series:
    def head(self, n=5):
        """
        Return the first elements of the Series.

        This function is mainly useful to preview the values of the
        Series without displaying the whole of it.

        Parameters
        ----------
        n : int
            Number of values to return.

        Return
        ------
        pandas.Series
            Subset of the original series with the n first values.

        See Also
        --------
        tail : Return the last n elements of the Series.

        Examples
        --------
        >>> s = pd.Series(['Ant', 'Bear', 'Cow', 'Dog', 'Falcon',
                         'Lion', 'Monkey', 'Rabbit', 'Zebra'])
        >>> s.head()  
        0   Ant
        1   Bear
        2    Cow
        3    Dog
        4  Falcon
        dtype: object

        With the 'n' parameter, we can change the number of returned rows:

        >>> s.head(n=3)
        0   Ant
        1   Bear
        2    Cow
        dtype: object
        """
        return self.iloc[:n]

The examples should be as concise as possible. In cases where the complexity of the function requires long examples, is recommended to use blocks with headers in bold. Use double star ** to make a text bold, like in **this example**.

Conventions for the examples

Code in examples is assumed to always start with these two lines which are not shown:

```python
import numpy as np
import pandas as pd
```

Any other module used in the examples must be explicitly imported, one per line (as recommended in PEP-8)
and avoiding aliases. Avoid excessive imports, but if needed, imports from the standard library go first, followed by third-party libraries (like matplotlib).

When illustrating examples with a single `Series` use the name `s`, and if illustrating with a single `DataFrame` use the name `df`. For indices, `idx` is the preferred name. If a set of homogeneous `Series` or `DataFrame` is used, name them `s1, s2, s3...` or `df1, df2, df3...` If the data is not homogeneous, and more than one structure is needed, name them with something meaningful, for example `df_main` and `df_to_join`.

Data used in the example should be as compact as possible. The number of rows is recommended to be around 4, but make it a number that makes sense for the specific example. For example in the `head` method, it requires to be higher than 5, to show the example with the default values. If doing the `mean`, we could use something like `[1, 2, 3]`, so it is easy to see that the value returned is the mean.

For more complex examples (grouping for example), avoid using data without interpretation, like a matrix of random numbers with columns A, B, C, D... And instead use a meaningful example, which makes it easier to understand the concept. Unless required by the example, use names of animals, to keep examples consistent. And numerical properties of them.

When calling the method, keywords arguments `head(n=3)` are preferred to positional arguments `head(3)`.

**Good:**

```python
class Series:
    def mean(self):
        """
        Compute the mean of the input.
        Examples
        --------
        >>> s = pd.Series([1, 2, 3])
        >>> s.mean()
        2
        """
        pass

deffillna(self, value):
    """
    Replace missing values by 'value'.
    Examples
    --------
    >>> s = pd.Series([1, np.nan, 3])
    >>> s.fillna(0)
    [1, 0, 3]
    """
    pass

def groupby_mean(self):
    """
    Group by index and return mean.
    Examples
    --------
    >>> s = pd.Series([380., 370., 24., 26],
    ... name='max_speed',
    ... index=['falcon', 'falcon', 'parrot', 'parrot'])
    >>> s.groupby_mean()
    index
```

(continues on next page)
falcon 375.0
parrot 25.0
Name: max_speed, dtype: float64

```python
def contains(self, pattern, case_sensitive=True, na=numpy.nan):
    """
    Return whether each value contains `pattern`.
    
    In this case, we are illustrating how to use sections, even
    if the example is simple enough and does not require them.
    
    Examples
    --------
    >>> s = pd.Series('Antelope', 'Lion', 'Zebra', numpy.nan)
    >>> s.contains(pattern='a')
    0    False
    1    False
    2     True
    3    NaN
    dtype: bool
    **Case sensitivity**
    With `case_sensitive` set to `False` we can match `a` with both
    `a` and `A`:
    >>> s.contains(pattern='a', case_sensitive=False)
    0     True
    1    False
    2     True
    3     NaN
    dtype: bool
    **Missing values**
    We can fill missing values in the output using the `na` parameter:
    >>> s.contains(pattern='a', na=False)
    0    False
    1    False
    2     True
    3    False
    dtype: bool
    """
    pass
```

**Bad:**

```python
def method(foo=None, bar=None):
    """
    A sample DataFrame method.
    
    Do not import numpy and pandas.
    
    Try to use meaningful data, when it makes the example easier
    ```
Try to avoid positional arguments like in `df.method(1)`. They can be all right if previously defined with a meaningful name, like in `present_value(interest_rate)`, but avoid them otherwise.

When presenting the behavior with different parameters, do not place all the calls one next to the other. Instead, add a short sentence explaining what the example shows.

Examples
--------
>>> import numpy as np
>>> import pandas as pd
>>> df = pd.DataFrame(numpy.random.randn(3, 3),
... columns=('a', 'b', 'c'))
>>> df.method(1)
21
>>> df.method(bar=14)
123
***
pass

Tips for getting your examples pass the doctests

Getting the examples pass the doctests in the validation script can sometimes be tricky. Here are some attention points:

- Import all needed libraries (except for pandas and numpy, those are already imported as import pandas as pd and import numpy as np) and define all variables you use in the example.

- Try to avoid using random data. However random data might be OK in some cases, like if the function you are documenting deals with probability distributions, or if the amount of data needed to make the function result meaningful is too much, such that creating it manually is very cumbersome. In those cases, always use a fixed random seed to make the generated examples predictable. Example:

  ```python
  >>> np.random.seed(42)
  >>> df = pd.DataFrame({'normal': np.random.normal(100, 5, 20)})
  ```

- If you have a code snippet that wraps multiple lines, you need to use ‘…’ on the continued lines:

  ```python
  >>> df = pd.DataFrame([[1, 2, 3], [4, 5, 6]], index=['a', 'b', 'c'],
  ... columns=['A', 'B'])
  ```

- If you want to show a case where an exception is raised, you can do:

  ```python
  >>> pd.to_datetime(['712-01-01'])
  Traceback (most recent call last):
  OutOfBoundsDatetime: Out of bounds nanosecond timestamp: 712-01-01 00:00:00
  ```

  It is essential to include the “Traceback (most recent call last):”, but for the actual error only the error name is sufficient.

- If there is a small part of the result that can vary (e.g. a hash in an object represenation), you can use ... to represent this part.
If you want to show that `s.plot()` returns a matplotlib AxesSubplot object, this will fail the doctest

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at 0x7efd0c0b0690>
```

However, you can do (notice the comment that needs to be added)

```python
>>> s.plot()
<matplotlib.axes._subplots.AxesSubplot at ...>
```

## Plots in examples

There are some methods in pandas returning plots. To render the plots generated by the examples in the documentation, the `.plot:` directive exists.

To use it, place the next code after the “Examples” header as shown below. The plot will be generated automatically when building the documentation.

```python
class Series:
    def plot(self):
        """
        Generate a plot with the `Series` data.
        
        Examples
        --------
        .. plot::
            :context: close-figs
            
            >>> s = pd.Series([1, 2, 3])
            >>> s.plot()
        """
        pass
```

## Sharing Docstrings

Pandas has a system for sharing docstrings, with slight variations, between classes. This helps us keep docstrings consistent, while keeping things clear for the user reading. It comes at the cost of some complexity when writing.

Each shared docstring will have a base template with variables, like `%klass`s. The variables filled in later on using the `Substitution` decorator. Finally, docstrings can be appended to with the `Appender` decorator.

In this example, we’ll create a parent docstring normally (this is like `pandas.core.generic.NDFrame`). Then we’ll have two children (like `pandas.core.series.Series` and `pandas.core.frame.DataFrame`). We’ll substitute the children’s class names in this docstring.

```python
class Parent:
    def my_function(self):
        """Apply my function to `%klass`s.""
        ...

class ChildA(Parent):
    @Substitution(klass="ChildA")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
```

(continues on next page)
class ChildB(Parent):
    @Substitution(klass="ChildB")
    @Appender(Parent.my_function.__doc__)
    def my_function(self):
        ...

The resulting docstrings are

```python
>>> print(Parent.my_function.__doc__)
Apply my function to %(klass)s.
>>> print(ChildA.my_function.__doc__)
Apply my function to ChildA.
>>> print(ChildB.my_function.__doc__)
Apply my function to ChildB.
```

Notice two things:

1. We “append” the parent docstring to the children docstrings, which are initially empty.
2. Python decorators are applied inside out. So the order is Append then Substitution, even though Substitution comes first in the file.

Our files will often contain a module-level `_shared_doc_kwargs` with some common substitution values (things like `klass`, `axes`, etc).

You can substitute and append in one shot with something like

```python
@Appender(template % _shared_doc_kwargs)
def my_function(self):
    ...
```

where `template` may come from a module-level `_shared_docs` dictionary mapping function names to docstrings. Wherever possible, we prefer using `Appender` and `Substitution`, since the docstring-writing processes is slightly closer to normal.

See `pandas.core.generic.NDFramefillna` for an example template, and `pandas.core.series.Seriesfillna` and `pandas.core.generic.framefillna` for the filled versions.

- The tutorials make heavy use of the `ipython directive` sphinx extension. This directive lets you put code in the documentation which will be run during the doc build. For example:

```python
.. ipython:: python
    : Glow: False

    x = 2
    x**3
```

will be rendered as:

```
In [1]: x = 2
In [2]: x**3
Out[2]: 8
```

Almost all code examples in the docs are run (and the output saved) during the doc build. This approach means that code examples will always be up to date, but it does make the doc building a bit more complex.
• Our API documentation in doc/source/api.rst houses the auto-generated documentation from the docstrings. For classes, there are a few subtleties around controlling which methods and attributes have pages auto-generated.

We have two autosummary templates for classes.

1. _templates/autosummary/class.rst. Use this when you want to automatically generate a page for every public method and attribute on the class. The Attributes and Methods sections will be automatically added to the class’ rendered documentation by numpydoc. See DataFrame for an example.

2. _templates/autosummary/class_without_autosummary. Use this when you want to pick a subset of methods / attributes to auto-generate pages for. When using this template, you should include an Attributes and Methods section in the class docstring. See CategoricalIndex for an example.

Every method should be included in a toctree in api.rst, else Sphinx will emit a warning.

Note: The .rst files are used to automatically generate Markdown and HTML versions of the docs. For this reason, please do not edit CONTRIBUTING.md directly, but instead make any changes to doc/source/contributing.rst. Then, to generate CONTRIBUTING.md, use pandoc with the following command:

```
pandoc doc/source/contributing.rst -t markdown_github > CONTRIBUTING.md
```

The utility script scripts/validate_docstrings.py can be used to get a csv summary of the API documentation. And also validate common errors in the docstring of a specific class, function or method. The summary also compares the list of methods documented in doc/source/api.rst (which is used to generate the API Reference page) and the actual public methods. This will identify methods documented in doc/source/api.rst that are not actually class methods, and existing methods that are not documented in doc/source/api.rst.

### 3.4.2 How to build the pandas documentation

#### 3.4.2.1 Requirements

First, you need to have a development environment to be able to build pandas (see the docs on creating a development environment above).

#### 3.4.2.2 Building the documentation

So how do you build the docs? Navigate to your local pandas/doc/ directory in the console and run:

```
python make.py html
```

Then you can find the HTML output in the folder pandas/doc/build/html/.

The first time you build the docs, it will take quite a while because it has to run all the code examples and build all the generated docstring pages. In subsequent evocations, sphinx will try to only build the pages that have been modified.

If you want to do a full clean build, do:

```
python make.py clean
python make.py html
```

You can tell make.py to compile only a single section of the docs, greatly reducing the turn-around time for checking your changes.
For comparison, a full documentation build may take 15 minutes, but a single section may take 15 seconds. Subsequent builds, which only process portions you have changed, will be faster.

You can also specify to use multiple cores to speed up the documentation build:

```
python make.py html --num-jobs 4
```

Open the following file in a web browser to see the full documentation you just built:

```
pandas/docs/build/html/index.html
```

And you’ll have the satisfaction of seeing your new and improved documentation!

### 3.4.2.3 Building master branch documentation

When pull requests are merged into the `pandas` master branch, the main parts of the documentation are also built by Travis-CI. These docs are then hosted here, see also the Continuous Integration section.

### 3.5 Contributing to the code base

**Code Base:**

- Code standards
  - C (cpplint)
  - Python (PEP8)
  - Backwards Compatibility
- Testing With Continuous Integration
- Test-driven development/code writing
  - Writing tests
  - Transitioning to pytest
  - Using pytest
- Running the test suite
- Running the performance test suite
3.5.1 Code standards

Writing good code is not just about what you write. It is also about how you write it. During Continuous Integration testing, several tools will be run to check your code for stylistic errors. Generating any warnings will cause the test to fail. Thus, good style is a requirement for submitting code to pandas.

In addition, because a lot of people use our library, it is important that we do not make sudden changes to the code that could have the potential to break a lot of user code as a result, that is, we need it to be as backwards compatible as possible to avoid mass breakages.

Additional standards are outlined on the code style wiki page.

3.5.1.1 C (cpplint)

pandas uses the Google standard. Google provides an open source style checker called cpplint, but we use a fork of it that can be found here. Here are some of the more common cpplint issues:

- we restrict line-length to 80 characters to promote readability
- every header file must include a header guard to avoid name collisions if re-included

Continuous Integration will run the cpplint tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir modified-c-file
```

You can also run this command on an entire directory if necessary:

```
cpplint --extensions=c,h --headers=h --filter=-readability/casting,-runtime/int,-build/include_subdir --recursive modified-c-directory
```

To make your commits compliant with this standard, you can install the ClangFormat tool, which can be downloaded here. To configure, in your home directory, run the following command:

```
clang-format style=google -dump-config > .clang-format
```

Then modify the file to ensure that any indentation width parameters are at least four. Once configured, you can run the tool as follows:

```
clang-format modified-c-file
```

This will output what your file will look like if the changes are made, and to apply them, run the following command:

```
clang-format -i modified-c-file
```

To run the tool on an entire directory, you can run the following analogous commands:

```
clang-format modified-c-directory/*.c modified-c-directory/*.h
clang-format -i modified-c-directory/*.c modified-c-directory/*.h
```

Do note that this tool is best-effort, meaning that it will try to correct as many errors as possible, but it may not correct all of them. Thus, it is recommended that you run cpplint to double check and make any other style fixes manually.
### 3.5.1.2 Python (PEP8)

`pandas` uses the PEP8 standard. There are several tools to ensure you abide by this standard. Here are some of the more common PEP8 issues:

- we restrict line-length to 79 characters to promote readability
- passing arguments should have spaces after commas, e.g. `foo(arg1, arg2, kw1='bar')`

Continuous Integration will run the `flake8` tool and report any stylistic errors in your code. Therefore, it is helpful before submitting code to run the check yourself on the diff:

```
git diff master -u -- "*.py" | flake8 --diff
```

This command will catch any stylistic errors in your changes specifically, but be beware it may not catch all of them. For example, if you delete the only usage of an imported function, it is stylistically incorrect to import an unused function. However, style-checking the diff will not catch this because the actual import is not part of the diff. Thus, for completeness, you should run this command, though it will take longer:

```
git diff master --name-only -- "*.py" | grep "pandas/" | xargs -r flake8
```

Note that on OSX, the `-r` flag is not available, so you have to omit it and run this slightly modified command:

```
git diff master --name-only -- "*.py" | grep "pandas/" | xargs flake8
```

Note that on Windows, these commands are unfortunately not possible because commands like `grep` and `xargs` are not available natively. To imitate the behavior with the commands above, you should run:

```
git diff master --name-only -- "*.py"
```

This will list all of the Python files that have been modified. The only ones that matter during linting are any whose directory filepath begins with “pandas.” For each filepath, copy and paste it after the `flake8` command as shown below:

```
flake8 <python-filepath>
```

Alternatively, you can install the `grep` and `xargs` commands via the MinGW toolchain, and it will allow you to run the commands above.

### 3.5.1.3 Backwards Compatibility

Please try to maintain backward compatibility. `pandas` has lots of users with lots of existing code, so don’t break it if at all possible. If you think breakage is required, clearly state why as part of the pull request. Also, be careful when changing method signatures and add deprecation warnings where needed. Also, add the deprecated sphinx directive to the deprecated functions or methods.

If a function with the same arguments as the one being deprecated exist, you can use the `pandas.util._decorators.deprecate`:

```
from pandas.util._decorators import deprecate

deprecate('old_func', 'new_func', '0.21.0')
```

Otherwise, you need to do it manually:
def old_func():
    """Summary of the function.
    .. deprecated:: 0.21.0
       Use new_func instead.
    """
    warnings.warn('Use new_func instead.', FutureWarning, stacklevel=2)
    new_func()

3.5.2 Testing With Continuous Integration

The pandas test suite will run automatically on Travis-CI, Appveyor, and Circle CI continuous integration services, once your pull request is submitted. However, if you wish to run the test suite on a branch prior to submitting the pull request, then the continuous integration services need to be hooked to your GitHub repository. Instructions are here for Travis-CI, Appveyor, and CircleCI.

A pull-request will be considered for merging when you have an all ‘green’ build. If any tests are failing, then you will get a red ‘X’, where you can click through to see the individual failed tests. This is an example of a green build.

Note: Each time you push to your fork, a new run of the tests will be triggered on the CI. Appveyor will auto-cancel any non-currently-running tests for that same pull-request. You can enable the auto-cancel feature for Travis-CI here and for CircleCI here.

3.5.3 Test-driven development/code writing

pandas is serious about testing and strongly encourages contributors to embrace test-driven development (TDD). This development process “relies on the repetition of a very short development cycle: first the developer writes an (initially failing) automated test case that defines a desired improvement or new function, then produces the minimum amount
of code to pass that test.” So, before actually writing any code, you should write your tests. Often the test can be taken from the original GitHub issue. However, it is always worth considering additional use cases and writing corresponding tests.

Adding tests is one of the most common requests after code is pushed to pandas. Therefore, it is worth getting in the habit of writing tests ahead of time so this is never an issue.

Like many packages, pandas uses pytest and the convenient extensions in numpy.testing.

**Note:** The earliest supported pytest version is 3.1.0.

### 3.5.3.1 Writing tests

All tests should go into the `tests` subdirectory of the specific package. This folder contains many current examples of tests, and we suggest looking to these for inspiration. If your test requires working with files or network connectivity, there is more information on the testing page of the wiki.

The pandas.util.testing module has many special assert functions that make it easier to make statements about whether Series or DataFrame objects are equivalent. The easiest way to verify that your code is correct is to explicitly construct the result you expect, then compare the actual result to the expected correct result:

```python
def test_pivot(self):
    data = {
        'index' : ['A', 'B', 'C', 'C', 'B', 'A'],
        'columns' : ['One', 'One', 'One', 'Two', 'Two', 'Two'],
        'values' : [1., 2., 3., 3., 2., 1.]
    }

    frame = DataFrame(data)
    pivoted = frame.pivot(index='index', columns='columns', values='values')

    expected = DataFrame({
        'One' : {'A' : 1., 'B' : 2., 'C' : 3.},
        'Two' : {'A' : 1., 'B' : 2., 'C' : 3.}
    })

    assert_frame_equal(pivoted, expected)
```

### 3.5.3.2 Transitioning to pytest

pandas existing test structure is mostly class based, meaning that you will typically find tests wrapped in a class.

```python
class TestReallyCoolFeature(object):
    ....
```

Going forward, we are moving to a more functional style using the pytest framework, which offers a richer testing framework that will facilitate testing and developing. Thus, instead of writing test classes, we will write test functions like this:

```python
def test_really_cool_feature():
    ....
```

### 3.5. Contributing to the code base

477
3.5.3.3 Using pytest

Here is an example of a self-contained set of tests that illustrate multiple features that we like to use.

- functional style: tests are like test_* and only take arguments that are either fixtures or parameters
- pytest.mark can be used to set metadata on test functions, e.g. skip or xfail.
- using parametrize: allow testing of multiple cases
- to set a mark on a parameter, pytest.param(..., marks=...) syntax should be used
- fixture, code for object construction, on a per-test basis
- using bare assert for scalars and truth-testing
- tm.assert_series_equal (and its counter part tm.assert_frame_equal), for pandas object comparisons.
- the typical pattern of constructing an expected and comparing versus the result

We would name this file test_cool_feature.py and put in an appropriate place in the pandas/tests/ structure.

```python
import pytest
import numpy as np
import pandas as pd
from pandas.util import testing as tm

@pytest.mark.parametrize('dtype', ['int8', 'int16', 'int32', 'int64'])
def test_dtypes(dtype):
    assert str(np.dtype(dtype)) == dtype

@pytest.mark.parametrize('dtype', ['float32',
                                    pytest.param('int16', marks=pytest.mark.skip),
                                    pytest.param('int32',
                                                 marks=pytest.mark.xfail(reason='to show how it works'))])
def test_mark(dtype):
    assert str(np.dtype(dtype)) == 'float32'

@pytest.fixture
def series():
    return pd.Series([1, 2, 3])

@pytest.fixture(params=['int8', 'int16', 'int32', 'int64'])
def dtype(request):
    return request.param

def test_series(series, dtype):
    result = series.astype(dtype)
    assert result.dtype == dtype

    expected = pd.Series([1, 2, 3], dtype=dtype)
    tm.assert_series_equal(result, expected)
```

A test run of this yields

```
((pandas) bash-3.2$ pytest test_cool_feature.py -v
=========================== test session starts ===========================
platform darwin -- Python 3.6.2, pytest-3.2.1, py-1.4.31, pluggy-0.4.0
collected 11 items

... (output truncated) ...

--->rerun

================================================================================
Collected 11 items

test_dtypes (test_cool_feature) ... xfail(reason='to show how it works'))])

RuntimeError: Check failed:  numpy.int16 vs 'float32'

### Failed tests ###

test_dtypes (test_cool_feature) ... int64'))

... (output truncated) ...

--->rerun

================================================================================
Collected 11 items

... (output truncated) ...

--->rerun

================================================================================
Collected 11 items

... (output truncated) ...
```
Tests that we have parametrized are now accessible via the test name, for example we could run these with -k int8 to sub-select only those tests which match int8.

The tests suite is exhaustive and takes around 20 minutes to run. Often it is worth running only a subset of tests first around your changes before running the entire suite.

The easiest way to do this is with:

```
pytest pandas/path/to/test.py -k regex_matching_test_name
```

Or with one of the following constructs:

```
pytest pandas/tests/[test-module].py
pytest pandas/tests/[test-module].py::[TestClass]
pytest pandas/tests/[test-module].py::[TestClass]::[test_method]
```

Using `pytest-xdist`, one can speed up local testing on multicore machines. To use this feature, you will need to install `pytest-xdist` via:

```
pip install pytest-xdist
```

Two scripts are provided to assist with this. These scripts distribute testing across 4 threads.

On Unix variants, one can type:

```
test_fast.sh
```

On Windows, one can type:

```
test_fast.bat
```
This can significantly reduce the time it takes to locally run tests before submitting a pull request. For more, see the pytest documentation.

Furthermore one can run

```
pd.test()
```

with an imported pandas to run tests similarly.

## 3.5.5 Running the performance test suite

Performance matters and it is worth considering whether your code has introduced performance regressions. pandas is in the process of migrating to asv benchmarks to enable easy monitoring of the performance of critical pandas operations. These benchmarks are all found in the pandas/asv_bench directory. asv supports both python2 and python3.

To use all features of asv, you will need either conda or virtualenv. For more details please check the asv installation webpage.

To install asv:

```
pip install git+https://github.com/spacetelescope/asv
```

If you need to run a benchmark, change your directory to asv_bench/ and run:

```
asv continuous -f 1.1 upstream/master HEAD
```

You can replace HEAD with the name of the branch you are working on, and report benchmarks that changed by more than 10%. The command uses conda by default for creating the benchmark environments. If you want to use virtualenv instead, write:

```
asv continuous -f 1.1 -E virtualenv upstream/master HEAD
```

The -E virtualenv option should be added to all asv commands that run benchmarks. The default value is defined in asv.conf.json.

Running the full test suite can take up to one hour and use up to 3GB of RAM. Usually it is sufficient to paste only a subset of the results into the pull request to show that the committed changes do not cause unexpected performance regressions. You can run specific benchmarks using the -b flag, which takes a regular expression. For example, this will only run tests from a pandas/asv_bench/benchmarks/groupby.py file:

```
asv continuous -f 1.1 upstream/master HEAD -b ^groupby
```

If you want to only run a specific group of tests from a file, you can do it using . as a separator. For example:

```
asv continuous -f 1.1 upstream/master HEAD -b groupby.GroupByMethods
```

will only run the GroupByMethods benchmark defined in groupby.py.

You can also run the benchmark suite using the version of pandas already installed in your current Python environment. This can be useful if you do not have virtualenv or conda, or are using the setup.py develop approach discussed above; for the in-place build you need to set PYTHONPATH, e.g. PYTHONPATH="$PWD/.." asv [remaining arguments]. You can run benchmarks using an existing Python environment by:
```bash
asv run -e -E existing
```

or, to use a specific Python interpreter:

```bash
asv run -e -E existing:python3.5
```

This will display stderr from the benchmarks, and use your local python that comes from your $PATH.

Information on how to write a benchmark and how to use asv can be found in the asv documentation.

### 3.5.6 Documenting your code

Changes should be reflected in the release notes located in `doc/source/whatsnew/vx.y.z.txt`. This file contains an ongoing change log for each release. Add an entry to this file to document your fix, enhancement or (unavoidable) breaking change. Make sure to include the GitHub issue number when adding your entry (using `:issue:`1234` where 1234 is the issue/pull request number).

If your code is an enhancement, it is most likely necessary to add usage examples to the existing documentation. This can be done following the section regarding documentation above. Further, to let users know when this feature was added, the `versionadded` directive is used. The sphinx syntax for that is:

```markdown
.. versionadded:: 0.21.0
```

This will put the text New in version 0.21.0 wherever you put the sphinx directive. This should also be put in the docstring when adding a new function or method (example) or a new keyword argument (example).

### 3.6 Contributing your changes to pandas

#### 3.6.1 Committing your code

Keep style fixes to a separate commit to make your pull request more readable.

Once you’ve made changes, you can see them by typing:

```bash
git status
```

If you have created a new file, it is not being tracked by git. Add it by typing:

```bash
git add path/to/file-to-be-added.py
```

Doing `git status` again should give something like:

```bash
# On branch shiny-new-feature
#
# modified: /relative/path/to/file-you-added.py
```

Finally, commit your changes to your local repository with an explanatory message. Pandas uses a convention for commit message prefixes and layout. Here are some common prefixes along with general guidelines for when to use them:

- ENH: Enhancement, new functionality
- BUG: Bug fix
The following defines how a commit message should be structured. Please reference the relevant GitHub issues in your commit message using GH1234 or #1234. Either style is fine, but the former is generally preferred:

- a subject line with < 80 chars.
- One blank line.
- Optionally, a commit message body.

Now you can commit your changes in your local repository:

```bash
git commit -m
```

### 3.6.2 Pushing your changes

When you want your changes to appear publicly on your GitHub page, push your forked feature branch’s commits:

```bash
git push origin shiny-new-feature
```

Here `origin` is the default name given to your remote repository on GitHub. You can see the remote repositories:

```bash
git remote -v
```

If you added the upstream repository as described above you will see something like:

```
origin  git@github.com:yourname/pandas.git (fetch)
origin  git@github.com:yourname/pandas.git (push)
upstream git://github.com/pandas-dev/pandas.git (fetch)
upstream git://github.com/pandas-dev/pandas.git (push)
```

Now your code is on GitHub, but it is not yet a part of the `pandas` project. For that to happen, a pull request needs to be submitted on GitHub.

### 3.6.3 Review your code

When you’re ready to ask for a code review, file a pull request. Before you do, once again make sure that you have followed all the guidelines outlined in this document regarding code style, tests, performance tests, and documentation. You should also double check your branch changes against the branch it was based on:

1. Navigate to your repository on GitHub – https://github.com/your-user-name/pandas
2. Click on Branches
3. Click on the Compare button for your feature branch
4. Select the base and compare branches, if necessary. This will be master and shiny-new-feature, respectively.
3.6.4 Finally, make the pull request

If everything looks good, you are ready to make a pull request. A pull request is how code from a local repository becomes available to the GitHub community and can be looked at and eventually merged into the master version. This pull request and its associated changes will eventually be committed to the master branch and available in the next release. To submit a pull request:

1. Navigate to your repository on GitHub
2. Click on the **Pull Request** button
3. You can then click on **Commits** and **Files Changed** to make sure everything looks okay one last time
4. Write a description of your changes in the **Preview Discussion** tab
5. Click **Send Pull Request**.

This request then goes to the repository maintainers, and they will review the code.

3.6.5 Updating your pull request

Based on the review you get on your pull request, you will probably need to make some changes to the code. In that case, you can make them in your branch, add a new commit to that branch, push it to GitHub, and the pull request will be automatically updated. Pushing them to GitHub again is done by:

```
git push origin shiny-new-feature
```

This will automatically update your pull request with the latest code and restart the **Continuous Integration** tests.

Another reason you might need to update your pull request is to solve conflicts with changes that have been merged into the master branch since you opened your pull request.

To do this, you need to “merge upstream master” in your branch:

```
git checkout shiny-new-feature
git fetch upstream
git merge upstream/master
```

If there are no conflicts (or they could be fixed automatically), a file with a default commit message will open, and you can simply save and quit this file.

If there are merge conflicts, you need to solve those conflicts. See for example at [https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/](https://help.github.com/articles/resolving-a-merge-conflict-using-the-command-line/) for an explanation on how to do this. Once the conflicts are merged and the files where the conflicts were solved are added, you can run `git commit` to save those fixes.

If you have uncommitted changes at the moment you want to update the branch with master, you will need to **stash** them prior to updating (see the **stash** docs). This will effectively store your changes and they can be reapplied after updating.

After the feature branch has been update locally, you can now update your pull request by pushing to the branch on GitHub:

```
git push origin shiny-new-feature
```

3.6.6 Delete your merged branch (optional)

Once your feature branch is accepted into upstream, you’ll probably want to get rid of the branch. First, merge upstream master into your branch so git knows it is safe to delete your branch:
Then you can do:

git branch -d shiny-new-feature

Make sure you use a lower-case `-d`, or else git won’t warn you if your feature branch has not actually been merged. The branch will still exist on GitHub, so to delete it there do:

git push origin --delete shiny-new-feature
pandas is an open source, BSD-licensed library providing high-performance, easy-to-use data structures and data analysis tools for the Python programming language.

pandas consists of the following elements:

- A set of labeled array data structures, the primary of which are Series and DataFrame.
- Index objects enabling both simple axis indexing and multi-level / hierarchical axis indexing.
- An integrated group by engine for aggregating and transforming data sets.
- Date range generation (date_range) and custom date offsets enabling the implementation of customized frequencies.
- Input/Output tools: loading tabular data from flat files (CSV, delimited, Excel 2003), and saving and loading pandas objects from the fast and efficient PyTables/HDF5 format.
- Memory-efficient “sparse” versions of the standard data structures for storing data that is mostly missing or mostly constant (some fixed value).
- Moving window statistics (rolling mean, rolling standard deviation, etc.).

### 4.1 Data Structures

<table>
<thead>
<tr>
<th>Dimensions</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Series</td>
<td>1D labeled homogeneously-typed array</td>
</tr>
<tr>
<td>2</td>
<td>DataFrame</td>
<td>General 2D labeled, size-mutable tabular structure with potentially heterogeneously-typed column</td>
</tr>
</tbody>
</table>

#### 4.1.1 Why more than one data structure?

The best way to think about the pandas data structures is as flexible containers for lower dimensional data. For example, DataFrame is a container for Series, and Series is a container for scalars. We would like to be able to insert and remove objects from these containers in a dictionary-like fashion.

Also, we would like sensible default behaviors for the common API functions which take into account the typical orientation of time series and cross-sectional data sets. When using ndarrays to store 2- and 3-dimensional data, a burden is placed on the user to consider the orientation of the data set when writing functions; axes are considered more or less equivalent (except when C- or Fortran-contiguousness matters for performance). In pandas, the axes are intended to lend more semantic meaning to the data; i.e., for a particular data set there is likely to be a “right” way to orient the data. The goal, then, is to reduce the amount of mental effort required to code up data transformations in downstream functions.
For example, with tabular data (DataFrame) it is more semantically helpful to think of the index (the rows) and the columns rather than axis 0 and axis 1. Iterating through the columns of the DataFrame thus results in more readable code:

```python
for col in df.columns:
    series = df[col]
    # do something with series
```

### 4.2 Mutability and copying of data

All pandas data structures are value-mutable (the values they contain can be altered) but not always size-mutable. The length of a Series cannot be changed, but, for example, columns can be inserted into a DataFrame. However, the vast majority of methods produce new objects and leave the input data untouched. In general we like to favor immutability where sensible.

### 4.3 Getting Support

The first stop for pandas issues and ideas is the Github Issue Tracker. If you have a general question, pandas community experts can answer through Stack Overflow.

### 4.4 Community

pandas is actively supported today by a community of like-minded individuals around the world who contribute their valuable time and energy to help make open source pandas possible. Thanks to all of our contributors.

If you’re interested in contributing, please visit Contributing to pandas webpage.

pandas is a NumFOCUS sponsored project. This will help ensure the success of development of pandas as a world-class open-source project, and makes it possible to donate to the project.

### 4.5 Project Governance

The governance process that pandas project has used informally since its inception in 2008 is formalized in Project Governance documents. The documents clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

Wes McKinney is the Benevolent Dictator for Life (BDFL).

### 4.6 Development Team

The list of the Core Team members and more detailed information can be found on the people’s page of the governance repo.
4.7 Institutional Partners

The information about current institutional partners can be found on pandas website page.

IN NO EVENT SHALL THE COPYRIGHT HOLDER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
This is a short introduction to pandas, geared mainly for new users. You can see more complex recipes in the *Cookbook*. Customarily, we import as follows:

```
In [1]: import pandas as pd
In [2]: import numpy as np
In [3]: import matplotlib.pyplot as plt
```

### 5.1 Object Creation

See the *Data Structure Intro section*. Creating a *Series* by passing a list of values, letting pandas create a default integer index:

```
In [4]: s = pd.Series([1,3,5,np.nan,6,8])
In [5]: s
Out[5]:
0    1.0
1    3.0
2    5.0
3   NaN
4    6.0
5    8.0
dtype: float64
```

Creating a *DataFrame* by passing a NumPy array, with a datetime index and labeled columns:

```
In [6]: dates = pd.date_range('20130101', periods=6)
In [7]: dates
Out[7]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
              '2013-01-05', '2013-01-06'],
              dtype='datetime64[ns]', freq='D')
In [8]: df = pd.DataFrame(np.random.randn(6,4), index=dates, columns=list('ABCD'))
In [9]: df
```

(continues on next page)
Creating a DataFrame by passing a dict of objects that can be converted to series-like.

```python
In [11]: df2
Out[11]:
     A       B         C         D        E         F
0  1.0 2013-01-02  1.00 3.000000  test     foo
1  1.0 2013-01-02  1.00 3.000000  train    foo
2  1.0 2013-01-02  1.00 3.000000  test     foo
3  1.0 2013-01-02  1.00 3.000000  train    foo
```

The columns of the resulting DataFrame have different dtypes.

```python
In [12]: df2.dtypes
Out[12]:
     A       B         C         D       E       F
float64  datetime64[ns]  float32  int32  category  object
```

If you’re using IPython, tab completion for column names (as well as public attributes) is automatically enabled. Here’s a subset of the attributes that will be completed:

```python
In [13]: df2.<TAB>
df2.A   df2.abs   df2.add   df2.add_prefix   df2.add_suffix   df2.align   df2.all   df2.any   df2.append   df2.apply   df2.applymap   df2.D
       df2.bool   df2.boxplot   df2.C   df2.clip   df2.clip_lower   df2.clip_upper   df2.columns   df2.combine   df2.combine_first   df2.compound   df2.consolidate
```

As you can see, the columns A, B, C, and D are automatically tab completed. E is there as well; the rest of the attributes have been truncated for brevity.
5.2 Viewing Data

See the Basics section.

Here is how to view the top and bottom rows of the frame:

```python
In [14]: df.head()
Out[14]:
     A      B      C      D
2013-01-01  0.47  -0.28  -1.51  -1.135
2013-01-02  1.21  -0.17  0.12  -1.044
2013-01-03  0.86  -2.10  0.49  1.071
2013-01-04  0.72  -0.71  0.12  0.271
2013-01-05  0.42  0.57  0.28  -1.09

In [15]: df.tail(3)
Out[15]:
     A      B      C      D
2013-01-04  0.72  -0.71  -1.04  0.271
2013-01-05  0.42  0.57  0.28  -1.09
2013-01-06  0.67  0.11  -1.48  0.52
```

Display the index, columns, and the underlying NumPy data:

```python
In [16]: df.index
Out[16]:
DatetimeIndex(['2013-01-01', '2013-01-02', '2013-01-03', '2013-01-04',
               '2013-01-05', '2013-01-06'],
               dtype='datetime64[ns]', freq='D')

In [17]: df.columns
Out[17]:
Index(['A', 'B', 'C', 'D'], dtype='object')

In [18]: df.values
Out[18]:
array([[ 0.47,  -0.28,  -1.51,  -1.135],
       [ 1.21,  -0.17,   0.12,  -1.044],
       [ 0.86,  -2.10,   0.49,   1.071],
       [ 0.72,  -0.71,  -1.04,   0.271],
       [ 0.42,   0.57,   0.28,  -1.09],
       [ 0.67,   0.11,  -1.48,   0.52]])
```

describe() shows a quick statistic summary of your data:

```python
In [19]: df.describe()
Out[19]:
     A      B      C      D
count 6.0000 6.0000 6.0000 6.0000
mean  0.0737 -0.4311 -0.6878 -0.2331
std   0.8432  0.9228  0.7799  0.9731
min  -0.8618 -2.1046  0.4949  1.0718
25%  -0.6115 -0.6008 -1.3687 -1.0766
50%   0.0220 -0.2280  0.7799  0.9731
75%   0.6713  0.9603 -0.0343  0.4617
max   1.2121  0.5702  0.2762  1.0718
```
Transposing your data:

```
In [20]: df.T
Out[20]:
A   0.469112   1.212112  -0.861849   0.721555  -0.424972  -0.673690
B  -0.282863  -0.173215  -2.104569  -0.706771   0.567020   0.113648
C  -1.509059   0.119209  -0.494929  -1.039575   0.276232  -1.478427
D  -1.135632  -1.044236   1.071804   0.271860  -1.087401   0.524988
```

Sorting by an axis:

```
In [21]: df.sort_index(axis=1, ascending=False)
Out[21]:
    D  C  B  A
2013-01-01 -1.135632 -1.509059 -0.282863  0.469112
2013-01-02 -1.044236  0.119209 -0.173215  1.212112
2013-01-03   1.071804  -0.494929 -2.104569  -0.861849
2013-01-04   0.271860  -1.039575  -0.706771   0.567020
2013-01-05  -1.087401   0.276232   0.567020  -0.424972
2013-01-06   0.524988  -1.478427   0.113648  -0.673690
```

Sorting by values:

```
In [22]: df.sort_values(by='B')
Out[22]:
    A    B    C    D
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
2013-01-04   0.721555  -0.706771 -1.039575   0.271860
2013-01-01   0.469112  -0.282863 -1.509059  -1.135632
2013-01-02   1.212112  -0.173215  0.119209  -1.044236
2013-01-06  -0.673690   0.113648 -1.478427   0.524988
2013-01-05  -0.424972   0.276232  0.567020  -1.087401
```

5.3 Selection

Note: While standard Python / Numpy expressions for selecting and setting are intuitive and come in handy for interactive work, for production code, we recommend the optimized pandas data access methods, `.at`, `.iat`, `.loc` and `.iloc`.

See the indexing documentation [Indexing and Selecting Data](#) and [MultiIndex / Advanced Indexing](#).

5.3.1 Getting

Selecting a single column, which yields a Series, equivalent to `df.A`:

```
In [23]: df['A']
Out[23]:
2013-01-01    0.469112
2013-01-02    1.212112
2013-01-03   -0.861849
2013-01-04    0.721555
```
Selecting via [], which slices the rows.

```
In [24]: df[0:3]
Out[24]:
A   B     C      D
2013-01-01  0.469112 -0.282863 -1.509059 -1.135632
2013-01-02  1.212112 -0.173215  0.119209 -1.044236
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [25]: df['20130102':'20130104']

In [26]: df.loc[dates[0]]
Out[26]:
A    0.469112
B   -0.282863
C  -1.509059
D  -1.135632
Name: 2013-01-01 00:00:00, dtype: float64
```

5.3.2 Selection by Label

See more in Selection by Label.

For getting a cross section using a label:

```
In [26]: df.loc[dates[0]]
Out[26]:
A    0.469112
B   -0.282863
C  -1.509059
D  -1.135632
Name: 2013-01-01 00:00:00, dtype: float64
```

Selecting on a multi-axis by label:

```
In [27]: df.loc[:,['A','B']]
Out[27]:
      A     B
2013-01-01  0.469112 -0.282863
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
2013-01-05 -0.424972  0.567020
2013-01-06 -0.673690  0.113648
```

Showing label slicing, both endpoints are included:

```
In [28]: df.loc['20130102':'20130104',['A','B']]
Out[28]:
      A     B
2013-01-02  1.212112 -0.173215
2013-01-03 -0.861849 -2.104569
2013-01-04  0.721555 -0.706771
```
Reduction in the dimensions of the returned object:

```
In [29]: df.loc['20130102', ['A', 'B']]
Out[29]:
   A    B
0 1.212112 -0.173215
Name: 2013-01-02 00:00:00, dtype: float64
```

For getting a scalar value:

```
In [30]: df.loc[dates[0], 'A']
Out[30]:
0.46911229990718628
```

For getting fast access to a scalar (equivalent to the prior method):

```
In [31]: df.at[dates[0], 'A']
Out[31]:
0.46911229990718628
```

### 5.3.3 Selection by Position

See more in *Selection by Position*.

Select via the position of the passed integers:

```
In [32]: df.iloc[3]
Out[32]:
   A    B    C    D
0 0.721555 -0.706771 -1.039575 0.271860
Name: 2013-01-04 00:00:00, dtype: float64
```

By integer slices, acting similar to numpy/python:

```
In [33]: df.iloc[3:5,0:2]
Out[33]:
   A    B
0 0.721555 -0.706771
1 -0.424972  0.567020
```

By lists of integer position locations, similar to the numpy/python style:

```
In [34]: df.iloc[[1,2,4], [0,2]]
Out[34]:
   A    C
0 1.212112  0.119209
1 -0.861849 -0.494929
2 -0.424972  0.276232
```

For slicing rows explicitly:

```
In [35]: df.iloc[1:3,:]
Out[35]:
   A    B    C    D
0 1.212112 -0.173215 0.119209 -1.044236
1 -0.861849 -2.104569 -0.494929  1.071804
```
For slicing columns explicitly:

<table>
<thead>
<tr>
<th>In [36]: df.iloc[:,1:3]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out [36]:</td>
</tr>
<tr>
<td>B  C</td>
</tr>
<tr>
<td>2013-01-01 -0.282863 -1.509059</td>
</tr>
<tr>
<td>2013-01-02 -0.173215  0.119209</td>
</tr>
<tr>
<td>2013-01-03 -2.104569 -0.494929</td>
</tr>
<tr>
<td>2013-01-04 -0.706771 -1.039575</td>
</tr>
<tr>
<td>2013-01-05  0.567020  0.276232</td>
</tr>
<tr>
<td>2013-01-06  0.113648 -1.478427</td>
</tr>
</tbody>
</table>

For getting a value explicitly:

<table>
<thead>
<tr>
<th>In [37]: df.iloc[1,1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out [37]:</td>
</tr>
<tr>
<td>-0.17321464905330858</td>
</tr>
</tbody>
</table>

For getting fast access to a scalar (equivalent to the prior method):

<table>
<thead>
<tr>
<th>In [38]: df.iat[1,1]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out [38]:</td>
</tr>
<tr>
<td>-0.17321464905330858</td>
</tr>
</tbody>
</table>

5.3.4 Boolean Indexing

Using a single column’s values to select data.

<table>
<thead>
<tr>
<th>In [39]: df[df.A &gt; 0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out [39]:</td>
</tr>
<tr>
<td>A  B  C  D</td>
</tr>
<tr>
<td>2013-01-01  0.469112  -0.282863 -1.509059 -1.135632</td>
</tr>
<tr>
<td>2013-01-02  1.212112  -0.173215  0.119209  -1.044236</td>
</tr>
<tr>
<td>2013-01-04  0.721555  -0.706771 -1.039575  0.271860</td>
</tr>
</tbody>
</table>

Selecting values from a DataFrame where a boolean condition is met.

<table>
<thead>
<tr>
<th>In [40]: df[df &gt; 0]</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out [40]:</td>
</tr>
<tr>
<td>A  B  C  D</td>
</tr>
<tr>
<td>2013-01-01  0.469112  NaN  NaN  NaN</td>
</tr>
<tr>
<td>2013-01-02  1.212112  NaN  0.119209  NaN</td>
</tr>
<tr>
<td>2013-01-03  NaN  NaN  NaN  1.071804</td>
</tr>
<tr>
<td>2013-01-04  0.721555  NaN  NaN  0.271860</td>
</tr>
<tr>
<td>2013-01-05  NaN  0.567020  0.276232  NaN</td>
</tr>
<tr>
<td>2013-01-06  NaN  0.113648  NaN  0.524988</td>
</tr>
</tbody>
</table>

Using the \texttt{isin()} method for filtering:

<table>
<thead>
<tr>
<th>In [41]: df2 = df.copy()</th>
</tr>
</thead>
<tbody>
<tr>
<td>In [42]: df2['E'] = ['one', 'one','two','three','four','three']</td>
</tr>
<tr>
<td>In [43]: df2</td>
</tr>
<tr>
<td>Out [43]:</td>
</tr>
<tr>
<td>A  B  C  D  E</td>
</tr>
<tr>
<td>2013-01-01  0.469112  -0.282863 -1.509059 -1.135632  one</td>
</tr>
<tr>
<td>2013-01-02  1.212112  -0.173215  0.119209  -1.044236  one</td>
</tr>
</tbody>
</table>

(continues on next page)
2013-01-03 -0.861849 -2.104569 -0.494929 1.071804 two
2013-01-04  0.721555 -0.706771 -1.039575  0.271860 three
2013-01-05 -0.424972  0.567020  0.276232 -1.087401 four
2013-01-06 -0.673690  0.113648 -1.478427  0.524988 three

In [44]: df2[df2['E'].isin(['two','four'])]

Out[44]:
    A    B       C       D       E
2013-01-03 -0.861849 -2.104569 -0.494929  1.071804 two
2013-01-05 -0.424972  0.567020  0.276232 -1.087401 four

5.3.5 Setting

Setting a new column automatically aligns the data by the indexes.

In [45]: s1 = pd.Series([1,2,3,4,5,6], index=pd.date_range('20130102', periods=6))
In [46]: s1
Out[46]:
Freq: D, dtype: int64

In [47]: df['F'] = s1

Setting values by label:

In [48]: df.at[dates[0],'A'] = 0

Setting values by position:

In [49]: df.iat[0,1] = 0

Setting by assigning with a NumPy array:

In [50]: df.loc[:, 'D'] = np.array([5] * len(df))

The result of the prior setting operations.

In [51]: df
Out[51]:
    A    B       C       D       F
2013-01-01 0.000000 0.000000 -1.509059  5.0 NaN
2013-01-02 1.212112 -0.173215  0.119209  5.0  1.0
2013-01-03 -0.861849 -2.104569 -0.494929  5.0  2.0
2013-01-04 0.721555 -0.706771  0.113648 -1.478427  5.0  3.0
2013-01-05 -0.424972  0.567020  0.276232  5.0  4.0
2013-01-06 -0.673690  0.113648 -1.478427  5.0  5.0

A where operation with setting.
In [52]: df2 = df.copy()

In [53]: df2[df2 > 0] = -df2

In [54]: df2

Out[54]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>-1.212112</td>
<td>-0.173215</td>
<td>-0.119209</td>
<td>5</td>
<td>-1.0</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>5</td>
<td>-2.0</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>-0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>5</td>
<td>-3.0</td>
</tr>
<tr>
<td>2013-01-05</td>
<td>-0.424972</td>
<td>-0.567020</td>
<td>-2.762323</td>
<td>5</td>
<td>-4.0</td>
</tr>
<tr>
<td>2013-01-06</td>
<td>-0.673690</td>
<td>-0.113648</td>
<td>-1.478427</td>
<td>5</td>
<td>-5.0</td>
</tr>
</tbody>
</table>

5.4 Missing Data

pandas primarily uses the value np.nan to represent missing data. It is by default not included in computations. See the Missing Data section.

Reindexing allows you to change/add/delete the index on a specified axis. This returns a copy of the data.

In [55]: df1 = df.reindex(index=dates[0:4], columns=list(df.columns) + ['E'])

In [56]: df1.loc[dates[0]:dates[1],'E'] = 1

In [57]: df1

Out[57]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>NaN</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>5</td>
<td>2.0</td>
<td>NaN</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>5</td>
<td>3.0</td>
<td>NaN</td>
</tr>
</tbody>
</table>

To drop any rows that have missing data.

In [58]: df1.dropna(how='any')

Out[58]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
</tbody>
</table>

Filling missing data.

In [59]: df1.fillna(value=5)

Out[59]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-01</td>
<td>0.000000</td>
<td>0.000000</td>
<td>-1.509059</td>
<td>5</td>
<td>5.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-02</td>
<td>1.212112</td>
<td>-0.173215</td>
<td>0.119209</td>
<td>5</td>
<td>1.0</td>
<td>1.0</td>
</tr>
<tr>
<td>2013-01-03</td>
<td>-0.861849</td>
<td>-2.104569</td>
<td>-0.494929</td>
<td>5</td>
<td>2.0</td>
<td>5.0</td>
</tr>
<tr>
<td>2013-01-04</td>
<td>0.721555</td>
<td>-0.706771</td>
<td>-1.039575</td>
<td>5</td>
<td>3.0</td>
<td>5.0</td>
</tr>
</tbody>
</table>

To get the boolean mask where values are nan.

In [60]: pd.isna(df1)

Out[60]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>F</th>
<th>E</th>
</tr>
</thead>
</table>

(continues on next page)
5.5 Operations

See the Basic section on Binary Ops.

5.5.1 Stats

Operations in general exclude missing data.

Performing a descriptive statistic:

```
In [61]: df.mean()
Out[61]:
A   -0.004474
B   -0.383981
C   -0.687758
D    5.000000
F    3.000000
dtype: float64
```

Same operation on the other axis:

```
In [62]: df.mean(1)
Out[62]:
2013-01-01 0.872735
2013-01-02 1.431621
2013-01-03 0.707731
2013-01-04 1.395042
2013-01-05 1.883656
2013-01-06 1.592306
Freq: D, dtype: float64
```

Operating with objects that have different dimensionality and need alignment. In addition, pandas automatically broadcasts along the specified dimension.

```
In [63]: s = pd.Series([1,3,5,np.nan,6,8], index=dates).shift(2)

In [64]: s
Out[64]:
2013-01-01  NaN
2013-01-02  NaN
2013-01-03   1.0
2013-01-04  3.0
2013-01-05   5.0
2013-01-06  NaN
Freq: D, dtype: float64

In [65]: df.sub(s, axis='index')
```
## 5.5.2 Apply

Applying functions to the data:

### In [66]: df.apply(np.cumsum)

```python
# Output
```

```python
A  B  C  D  F
2013-01-01 0.000000 0.000000 -1.509059 5 NaN
2013-01-02 1.212112 -0.173215 -1.389850 10 1.0
2013-01-03 0.350263 -2.277784 -1.884779 15 3.0
2013-01-04 1.071818 -2.984555 -2.924354 20 6.0
2013-01-05 0.646846 -2.417535 -2.648122 25 10.0
2013-01-06 -0.026844 -2.303886 -4.126549 30 15.0
```

### In [67]: df.apply(lambda x: x.max() - x.min())

```python
A 2.073961
B 2.671590
C 1.785291
D 0.000000
F 4.000000
dtype: float64
```

## 5.5.3 Histogramming

See more at *Histogramming and Discretization*.

### In [68]: s = pd.Series(np.random.randint(0, 7, size=10))

### In [69]: s

```python
# Output
```

```
0 4
1 2
2 1
3 2
4 6
5 4
6 4
7 6
8 4
9 4
dtype: int64
```

### In [70]: s.value_counts()

```python
# Output
```

```
0 4
1 2
2 1
3 2
4 6
5 4
6 4
7 6
8 4
9 4
dtype: int64
```

(continues on next page)
5.5.4 String Methods

Series is equipped with a set of string processing methods in the `str` attribute that make it easy to operate on each element of the array, as in the code snippet below. Note that pattern-matching in `str` generally uses regular expressions by default (and in some cases always uses them). See more at Vectorized String Methods.

```python
In [71]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [72]: s.str.lower()
Out[72]:
0    a
1    b
2    c
3   aaba
4    baca
5     NaN
6    caba
7    dog
8    cat
dtype: object
```

5.6 Merge

5.6.1 Concat

pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

See the Merging section.

Concatenating pandas objects together with `concat()`:

```python
In [73]: df = pd.DataFrame(np.random.randn(10, 4))
In [74]: df
Out[74]:
   0         1         2         3
0 -0.548702  1.467327 -1.015962 -0.483075
1  1.637550 -1.217659 -0.291519 -1.745505
2 -0.263952  0.991460 -0.919069  0.266046
3 -0.709661  1.669052  1.037882 -1.705775
4 -0.919854 -0.042379  1.247642 -0.009920
5  0.290213  0.495767  0.362949  1.548106
6 -1.131345 -0.089329  0.337863 -0.945867
```

(continues on next page)
5.6.2 Join

SQL style merges. See the Database style joining section.

```python
In [77]: left = pd.DataFrame({'key': ['foo', 'foo'], 'lval': [1, 2]})
```

```python
In [78]: right = pd.DataFrame({'key': ['foo', 'foo'], 'rval': [4, 5]})
```

```python
In [79]: left
```

```
Out[79]:
key lval
0 foo 1
1 foo 2
```

```python
In [80]: right
```

```
Out[80]:
key rval
0 foo 4
1 foo 5
```

```python
In [81]: pd.merge(left, right, on='key')
```

```
Out[81]:
key lval rval
0 foo 1 4
1 foo 1 5
2 foo 2 4
3 foo 2 5
```

Another example that can be given is:

```python
In [82]: left = pd.DataFrame({'key': ['foo', 'bar'], 'lval': [1, 2]})
```

```python
In [83]: right = pd.DataFrame({'key': ['foo', 'bar'], 'rval': [4, 5]})
```

(continues on next page)
In [84]: left
Out[84]:
   key  lval
0  foo    1
1  bar    2

In [85]: right
   key  rval
0  foo    4
1  bar    5

In [86]: pd.merge(left, right, on='key')
   key  lval  rval
0  foo    1    4
1  bar    2    5

5.6.3 Append

Append rows to a dataframe. See the *Appending* section.

In [87]: df = pd.DataFrame(np.random.randn(8, 4), columns=['A','B','C','D'])

In [88]: df
Out[88]:
   A         B         C         D
0 1.346061  1.511763  1.627081 -0.990582
1 -0.441652  1.211526  0.268520  0.024580
2 -1.577585  0.396823 -0.105381 -0.532532
3  1.453749  1.208843 -0.080952 -0.264610
4 -0.727965 -0.589346  0.339969 -0.693205
5 -0.339355  0.593616  0.884345  1.591431
6  0.141809  0.220390  0.435589  0.192451
7 -0.096701  0.803351  1.715071 -0.708758

In [89]: s = df.iloc[3]

In [90]: df.append(s, ignore_index=True)
Out[90]:
   A         B         C         D
0 1.346061  1.511763  1.627081 -0.990582
1 -0.441652  1.211526  0.268520  0.024580
2 -1.577585  0.396823 -0.105381 -0.532532
3  1.453749  1.208843 -0.080952 -0.264610
4 -0.727965 -0.589346  0.339969 -0.693205
5 -0.339355  0.593616  0.884345  1.591431
6  0.141809  0.220390  0.435589  0.192451
7 -0.096701  0.803351  1.715071 -0.708758
8  1.453749  1.208843 -0.080952 -0.264610
# 5.7 Grouping

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria
- **Applying** a function to each group independently
- **Combining** the results into a data structure

See the [Grouping section](#).

```python
In [91]: df = pd.DataFrame({'A' : ['foo', 'bar', 'foo', 'bar', 'foo', 'bar', 'foo', 'foo'],
                      'B' : ['one', 'one', 'two', 'three', 'two', 'two', 'one', 'three'],
                      'C' : np.random.randn(8), 'D' : np.random.randn(8)})
```

Grouping and then applying the `sum()` function to the resulting groups.

```python
In [92]: df.groupby('A').sum()
Out[92]:
       C     D
A
bar  -2.802588  2.42611
foo   3.146492 -0.63958
```

Grouping by multiple columns forms a hierarchical index, and again we can apply the `sum` function.

```python
In [93]: df.groupby(['A','B']).sum()
Out[93]:
       C     D
A B
bar one -1.814470  2.395985
       three -0.595447  0.166599
two -0.392670 -0.136473
foo one  0.007207 -0.561757
       three  1.928123 -1.623033
two  2.414034  1.600434
```

# 5.8 Reshaping

See the sections on [Hierarchical Indexing](#) and [Reshaping](#).
5.8.1 Stack

```python
In [95]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
...:   'foo', 'foo', 'qux', 'qux'],
...:   ['one', 'two', 'one', 'two',
...:   'one', 'two', 'one', 'two']]))

In [96]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [97]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [98]: df2 = df[:4]

In [99]: df2
Out[99]:
   A   B
bar one 0.029399 -0.542108
two 0.282696 -0.087302
baz one -1.575170 1.771208
two 0.816482 1.100230

The `stack()` method “compresses” a level in the DataFrame’s columns.

```python
In [100]: stacked = df2.stack()

In [101]: stacked
Out[101]:
   first second
bar one  A  0.029399
        B -0.542108
two   A  0.282696
        B -0.087302
baz one A -1.575170
        B  1.771208
two   A  0.816482
        B  1.100230
dtype: float64
```

With a “stacked” DataFrame or Series (having a `MultiIndex` as the index), the inverse operation of `stack()` is `unstack()`, which by default unstacks the last level:

```python
In [102]: stacked.unstack()
Out[102]:
   A   B
bar one 0.029399 -0.542108
two 0.282696 -0.087302
baz one -1.575170 1.771208
two 0.816482 1.100230

In [103]: stacked.unstack(1)
```

(continues on next page)
5.8.2 Pivot Tables

See the section on Pivot Tables.

In [105]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 3, 
                         'B': ['A', 'B', 'C'] * 4, 
                         'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 2, 
                         'D': np.random.randn(12), 
                         'E': np.random.randn(12))

In [106]: df

Out[106]:
     A  B   C        D         E
0  one A  foo  1.418757  -0.179666
1  one B  foo  1.879024  1.291836
2  two C  foo  0.536826  -0.009614
3  three A  bar  1.006160  0.392149
4   one B  bar  0.029716  0.264599
5   one C  bar -1.146178  -0.057409
6   two A  foo  0.100900  1.425638
7   three B  foo  1.035018  1.024098
8    one C  foo  0.314665  -0.106062
9    one A  bar -0.773723  1.824375
10   two B  bar -1.170653  0.595974
11   three C  bar  0.648740  1.167115

We can produce pivot tables from this data very easily:

In [107]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])

Out[107]:
       C
A  B  bar  foo
one A -0.773723  1.418757
     B  0.029716  -1.879024
     C  1.146178  0.314665
three A  1.006160  NaN
       B  NaN  1.035018
       C  0.648740  NaN
two  A  NaN   0.100900

(continues on next page)
5.9 Time Series

pandas has simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications. See the Time Series section.

```python
In [108]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [109]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [110]: ts.resample('5Min').sum()
Out[110]:
2012-01-01  25083
Freq: 5T, dtype: int64
```

Time zone representation:

```python
In [111]: rng = pd.date_range('3/6/2012 00:00', periods=5, freq='D')
In [112]: ts = pd.Series(np.random.randn(len(rng)), rng)
In [113]: ts
Out[113]:
2012-03-06  0.464000
2012-03-07  0.227371
2012-03-08 -0.496922
2012-03-09  0.306389
2012-03-10 -2.290613
Freq: D, dtype: float64
In [114]: ts_utc = ts.tz_localize('UTC')
In [115]: ts_utc
Out[115]:
2012-03-05 19:00:00-05:00  0.464000
2012-03-06 19:00:00-05:00  0.227371
2012-03-07 19:00:00-05:00 -0.496922
2012-03-08 19:00:00-05:00  0.306389
2012-03-09 19:00:00-05:00 -2.290613
Freq: D, dtype: float64
```

Converting to another time zone:

```python
In [116]: ts_utc.tz_convert('US/Eastern')
Out[116]:
2012-03-05  05:00:00+00:00  0.464000
2012-03-06  05:00:00+00:00  0.227371
2012-03-07  05:00:00+00:00 -0.496922
2012-03-08  05:00:00+00:00  0.306389
2012-03-09  05:00:00+00:00 -2.290613
Freq: D, dtype: float64
```
Converting between time span representations:

```python
In [117]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [118]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [119]: ts
Out[119]:
2012-01-31 -1.134623
2012-02-29 -1.561819
2012-03-31 -0.260838
2012-04-30  0.281957
2012-05-31  1.523962
Freq: M, dtype: float64
In [120]: ps = ts.to_period()
In [121]: ps
Out[121]:
2012-01 -1.134623
2012-02 -1.561819
2012-03 -0.260838
2012-04  0.281957
2012-05  1.523962
Freq: M, dtype: float64
In [122]: ps.to_timestamp()
Out[122]:
2012-01-01 -1.134623
2012-02-01 -1.561819
2012-03-01 -0.260838
2012-04-01  0.281957
2012-05-01  1.523962
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```python
In [123]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [124]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [125]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [126]: ts.head()
Out[126]:
1990-03-01 09:00 -0.902937
1990-06-01 09:00  0.068159
1990-09-01 09:00 -0.057873
1990-12-01 09:00 -0.368204
1991-03-01 09:00 -1.144073
Freq: H, dtype: float64
```

5.9. Time Series
5.10 Categoricals

pandas can include categorical data in a DataFrame. For full docs, see the categorical introduction and the API documentation.

```python
In [127]: df = pd.DataFrame({"id":[1,2,3,4,5,6], "raw_grade":["a", 'b', 'b', 'a', 'a', 'e']})

Convert the raw grades to a categorical data type.

```python
In [128]: df["grade"] = df["raw_grade"].astype("category")
```

```python
In [129]: df["grade"]
Out[129]:
0  a
1  b
2  b
3  a
4  a
5  e
Name: grade, dtype: category
Categories (3, object): [a, b, e]
```

Rename the categories to more meaningful names (assigning to `Series.cat.categories` is inplace!).

```python
In [130]: df["grade"].cat.categories = ["very good", "good", "very bad"]
```

Reorder the categories and simultaneously add the missing categories (methods under `Series.cat` return a new `Series` by default).

```python
In [131]: df["grade"] = df["grade"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"], categories=True)
```

```python
In [132]: df["grade"]
Out[132]:
0  very good
1   good
2   good
3  very good
4  very good
5  very bad
Name: grade, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
```

Sorting is per order in the categories, not lexical order.

```python
In [133]: df.sort_values(by="grade")
```

```python
Out[133]:
       id  raw_grade grade
5   6        e     very bad
1   2        b       good
2   3        b       good
0   1        a  very good
3   4        a  very good
4   5        a  very good
```

Grouping by a categorical column also shows empty categories.
5.11 Plotting

See the *Plotting* docs.

In [134]: df.groupby("grade").size()
Out[134]:
grade
very bad 1
bad 0
medium 0
good 2
very good 3
dtype: int64

In [135]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000',
periods=1000))

In [136]: ts = ts.cumsum()

In [137]: ts.plot()
Out[137]: <matplotlib.axes._subplots.AxesSubplot at 0x114cb06d8>

On a DataFrame, the *plot()* method is a convenience to plot all of the columns with labels:
5.12 Getting Data In/Out

5.12.1 CSV

Writing to a csv file.

```
In [141]: df.to_csv('foo.csv')
```

Reading from a csv file.

```
In [142]: pd.read_csv('foo.csv')
Out[142]:
    Unnamed: 0  A  B  C  D
0        NaN  0  0  0  0
1        NaN  0  0  0  0
2        NaN  0  0  0  0
3        NaN  0  0  0  0
4        NaN  0  0  0  0
5        NaN  0  0  0  0
6        NaN  0  0  0  0
7        NaN  0  0  0  0
8        NaN  0  0  0  0
9        NaN  0  0  0  0
```
5.12.2 HDF5

Reading and writing to HDFStores.

Writing to a HDF5 Store.

```python
In [143]: df.to_hdf('foo.h5','df')
```

Reading from a HDF5 Store.

```python
In [144]: pd.read_hdf('foo.h5','df')
Out [144]:
   A         B         C         D

5.12.3 Excel

Reading and writing to MS Excel.

Writing to an excel file.

5.12. Getting Data In/Out
In [145]: df.to_excel('foo.xlsx', sheet_name='Sheet1')

Reading from an excel file.

In [146]: pd.read_excel('foo.xlsx', 'Sheet1', index_col=None, na_values=['NA'])

Out[146]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>

[1000 rows x 4 columns]

5.13 Gotchas

If you are attempting to perform an operation you might see an exception like:

```python
>>> if pd.Series([False, True, False]):
    print("I was true")
Traceback
...
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.all().
```

See *Comparisons* for an explanation and what to do.

See *Gotchas* as well.
This is a guide to many pandas tutorials, geared mainly for new users.

6.1 Internal Guides

pandas’ own 10 Minutes to pandas.
More complex recipes are in the Cookbook.
A handy pandas cheat sheet.

6.2 pandas Cookbook

The goal of this 2015 cookbook (by Julia Evans) is to give you some concrete examples for getting started with pandas. These are examples with real-world data, and all the bugs and weirdness that entails.

Here are links to the v0.2 release. For an up-to-date table of contents, see the pandas-cookbook GitHub repository. To run the examples in this tutorial, you’ll need to clone the GitHub repository and get IPython Notebook running. See How to use this cookbook.

• A quick tour of the IPython Notebook: Shows off IPython’s awesome tab completion and magic functions.
• Chapter 1: Reading your data into pandas is pretty much the easiest thing. Even when the encoding is wrong!
• Chapter 2: It’s not totally obvious how to select data from a pandas dataframe. Here we explain the basics (how to take slices and get columns)
• Chapter 3: Here we get into serious slicing and dicing and learn how to filter dataframes in complicated ways, really fast.
• Chapter 4: Groupby/aggregate is seriously my favorite thing about pandas and I use it all the time. You should probably read this.
• Chapter 5: Here you get to find out if it’s cold in Montreal in the winter (spoiler: yes). Web scraping with pandas is fun! Here we combine dataframes.
• Chapter 6: Strings with pandas are great. It has all these vectorized string operations and they’re the best. We will turn a bunch of strings containing “Snow” into vectors of numbers in a trice.
• Chapter 7: Cleaning up messy data is never a joy, but with pandas it’s easier.
• Chapter 8: Parsing Unix timestamps is confusing at first but it turns out to be really easy.
• Chapter 9: Reading data from SQL databases.
6.3 Lessons for new pandas users

For more resources, please visit the main repository.

- 01 - Lesson: - Importing libraries - Creating data sets - Creating data frames - Reading from CSV - Exporting to CSV - Finding maximums - Plotting data
- 02 - Lesson: - Reading from TXT - Exporting to TXT - Selecting top/bottom records - Descriptive statistics - Grouping/sorting data
- 03 - Lesson: - Creating functions - Reading from EXCEL - Exporting to EXCEL - Outliers - Lambda functions - Slice and dice data
- 04 - Lesson: - Adding/deleting columns - Index operations
- 05 - Lesson: - Stack/Unstack/Transpose functions
- 06 - Lesson: - GroupBy function
- 07 - Lesson: - Ways to calculate outliers
- 08 - Lesson: - Read from Microsoft SQL databases
- 09 - Lesson: - Export to CSV/EXCEL/TXT
- 10 - Lesson: - Converting between different kinds of formats
- 11 - Lesson: - Combining data from various sources

6.4 Practical data analysis with Python

This guide is a comprehensive introduction to the data analysis process using the Python data ecosystem and an interesting open dataset. There are four sections covering selected topics as follows:

- Munging Data
- Aggregating Data
- Visualizing Data
- Time Series

6.5 Exercises for new users

Practice your skills with real data sets and exercises. For more resources, please visit the main repository.

- 01 - Getting & Knowing Your Data
- 02 - Filtering & Sorting
- 03 - Grouping
- 04 - Apply
- 05 - Merge
- 06 - Stats
- 07 - Visualization
- 08 - Creating Series and DataFrames
• 09 - Time Series
• 10 - Deleting

6.6 Modern pandas

Tutorial series written in 2016 by Tom Augspurger. The source may be found in the GitHub repository TomAugspurger/effective-pandas.

- Modern Pandas
- Method Chaining
- Indexes
- Performance
- Tidy Data
- Visualization
- Timeseries

6.7 Excel charts with pandas, vincent and xlsxwriter

- Using Pandas and XlsxWriter to create Excel charts

6.8 Video Tutorials

- Pandas: .head() to .tail() (2016) (1:26) GitHub repo

6.9 Various Tutorials

- Wes McKinney’s (pandas BDFL) blog
- Statistical analysis made easy in Python with SciPy and pandas DataFrames, by Randal Olson
- Statistical Data Analysis in Python, tutorial videos, by Christopher Fonnesbeck from SciPy 2013
- Financial analysis in Python, by Thomas Wiecki
- Intro to pandas data structures, by Greg Reda
- Pandas and Python: Top 10, by Manish Amde
- Pandas Tutorial, by Mikhail Semeniuk
- Pandas DataFrames Tutorial, by Karlijn Willems
- A concise tutorial with real life examples
This is a repository for short and sweet examples and links for useful pandas recipes. We encourage users to add to this documentation.

Adding interesting links and/or inline examples to this section is a great First Pull Request.

Simplified, condensed, new-user friendly, in-line examples have been inserted where possible to augment the Stack-Overflow and GitHub links. Many of the links contain expanded information, above what the in-line examples offer.

Pandas (pd) and Numpy (np) are the only two abbreviated imported modules. The rest are kept explicitly imported for newer users.

These examples are written for Python 3. Minor tweaks might be necessary for earlier python versions.

### 7.1 Idioms

These are some neat pandas idioms

if-then/if-then-else on one column, and assignment to another one or more columns:

```python
In [1]: df = pd.DataFrame(
    ...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40], 'CCC' : [100,50,-30,-50]});

Out[1]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>6</td>
<td>-30</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>-50</td>
</tr>
</tbody>
</table>
```

#### 7.1.1 if-then...

An if-then on one column

```python
In [2]: df.loc[df.AAA >= 5,'BBB'] = -1; df

Out[2]:

<table>
<thead>
<tr>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>4</td>
<td>100</td>
</tr>
<tr>
<td>1</td>
<td>-1</td>
<td>50</td>
</tr>
<tr>
<td>2</td>
<td>-1</td>
<td>-30</td>
</tr>
<tr>
<td>3</td>
<td>-1</td>
<td>-50</td>
</tr>
</tbody>
</table>
```

An if-then with assignment to 2 columns:
In [3]: df.loc[df.AAA >= 5,['BBB','CCC']] = 555; df
Out[3]:
   AAA  BBB  CCC
0   4    10  100
1   5   555  555
2   6   555  555
3   7   555  555

Add another line with different logic, to do the -else

In [4]: df.loc[df.AAA < 5,['BBB','CCC']] = 2000; df
Out[4]:
   AAA  BBB  CCC
0   4  2000  2000
1   5   555  555
2   6   555  555
3   7   555  555

Or use pandas where after you’ve set up a mask

In [6]: df.where(df_mask,-1000)
Out[6]:
   AAA  BBB  CCC
0   4 -1000  2000
1   5 -1000 -1000
2   6 -1000  555
3   7 -1000 -1000

if-then-else using numpy’s where()

In [7]: df = pd.DataFrame(  
...:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
...:
Out[7]:
   AAA  BBB  CCC
0   4    10  100
1   5    20   50
2   6    30  -30
3   7    40  -50

In [8]: df['logic'] = np.where(df['AAA'] > 5,'high','low'); df
Out[8]:
   AAA  BBB  CCC    logic
0   4    10  100  low
1   5    20   50  low
2   6    30  -30  low
3   7    40  -50  high

7.1.2 Splitting

Split a frame with a boolean criterion
In [9]: df = pd.DataFrame(
    ...:    {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
    ...
Out[9]:
    AAA  BBB  CCC
0     4     10    100
1     5     20     50
2     6     30    -30
3     7     40    -50

In [10]: dflow = df[df.AAA <= 5]; dflow
   \\→
   AAA  BBB  CCC
0     4     10    100
1     5     20     50

In [11]: dfhigh = df[df.AAA > 5]; dfhigh
   \\\→
   AAA  BBB  CCC
2     6     30    -30
3     7     40    -50

7.1.3 Building Criteria

Select with multi-column criteria

In [12]: df = pd.DataFrame(
    ...:    {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
    ...
Out[12]:
    AAA  BBB  CCC
0     4     10    100
1     5     20     50
2     6     30    -30
3     7     40    -50

... and (without assignment returns a Series)

In [13]: newseries = df.loc[(df['BBB'] < 25) & (df['CCC'] >= -40), 'AAA']; newseries
Out[13]:
0     4
1     5
Name: AAA, dtype: int64

... or (without assignment returns a Series)

In [14]: newseries = df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA']; newseries;

... or (with assignment modifies the DataFrame.)

In [15]: df.loc[(df['BBB'] > 25) | (df['CCC'] >= 75), 'AAA'] = 0.1; df
Out[15]:
    AAA  BBB  CCC
0  0.1    10    100
(continues on next page)
Select rows with data closest to certain value using argsort

```
In [16]: df = pd.DataFrame(
    ....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
    ....:
Out[16]:
     AAA  BBB  CCC
   0    4    10  100
   1    5    20   50
   2    6    30  -30
   3    7    40  -50

In [17]: aValue = 43.0

In [18]: df.loc[(df.CCC-aValue).abs().argsort()]
Out[18]:
     AAA  BBB  CCC
   0    4    10  100
   1    5    20   50
   2    6    30  -30
   3    7    40  -50
```

Dynamically reduce a list of criteria using a binary operators

```
In [19]: df = pd.DataFrame(
    ....:     {'AAA' : [4,5,6,7], 'BBB' : [10,20,30,40],'CCC' : [100,50,-30,-50]}); df
    ....:
Out[19]:
     AAA  BBB  CCC
   0    4    10  100
   1    5    20   50
   2    6    30  -30
   3    7    40  -50

In [20]: Crit1 = df.AAA <= 5.5
In [21]: Crit2 = df.BBB == 10.0
In [22]: Crit3 = df.CCC > -40.0

One could hard code:

```
In [23]: AllCrit = Crit1 & Crit2 & Crit3

...Or it can be done with a list of dynamically built criteria

```
```
In [24]: CritList = [Crit1,Crit2,Crit3]

In [25]: AllCrit = functools.reduce(lambda x,y: x & y, CritList)

In [26]: df[AllCrit]
Out[26]:
```

(continues on next page)
7.2 Selection

7.2.1 DataFrames

The `indexing` docs.

Using both row labels and value conditionals

```python
In [27]: df = pd.DataFrame(
    ....:     {'AAA': [4,5,6,7], 'BBB': [10,20,30,40], 'CCC': [100,50,-30,-50]}); df
    ....:     Out[27]:
    AAA  BBB  CCC
    0    4    10   100
    1    5    20    50
    2    6    30   -30
    3    7    40   -50

In [28]: df[(df.AAA <= 6) & (df.index.isin([0,2,4]))]
   └───────────────────────────────────────────────────────────────────────────────────────────Out[28]:
    AAA  BBB  CCC
    0    4    10   100
    2    6    30   -30
```

Use `loc` for label-oriented slicing and `iloc` positional slicing

```python
In [29]: data = {'AAA': [4,5,6,7], 'BBB': [10,20,30,40],'CCC': [100,50,-30,-50]}

In [30]: df = pd.DataFrame(data=data,index=['foo','bar','boo','kar']); df
   Out[30]:
     AAA  BBB  CCC
    foo   4   10   100
    bar   5   20    50
    boo   6   30   -30
    kar   7   40   -50
```

There are 2 explicit slicing methods, with a third general case

1. Positional-oriented (Python slicing style : exclusive of end)
2. Label-oriented (Non-Python slicing style : inclusive of end)
3. General (Either slicing style : depends on if the slice contains labels or positions)

```python
In [31]: df.loc['bar':'kar']  #Label
   Out[31]:
     AAA  BBB  CCC
    bar   5   20    50
    boo   6   30   -30
    kar   7   40   -50
```

(continues on next page)
# Generic

In [32]: df.iloc[0:3]

→

<table>
<thead>
<tr>
<th></th>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>foo</td>
<td>4</td>
<td>10</td>
<td>100</td>
</tr>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>30</td>
<td>-30</td>
</tr>
</tbody>
</table>

In [33]: df.loc['bar':'kar']

→

<table>
<thead>
<tr>
<th></th>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>boo</td>
<td>6</td>
<td>30</td>
<td>-30</td>
</tr>
<tr>
<td>kar</td>
<td>7</td>
<td>40</td>
<td>-50</td>
</tr>
</tbody>
</table>

Ambiguity arises when an index consists of integers with a non-zero start or non-unit increment.

In [34]: df2 = pd.DataFrame(data=data,index=[1,2,3,4]); #Note index starts at 1.

In [35]: df2.iloc[1:3] #Position-oriented

Out[35]:

<table>
<thead>
<tr>
<th></th>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>30</td>
<td>-30</td>
</tr>
</tbody>
</table>

In [36]: df2.loc[1:3] #Label-oriented

Out[36]:

<table>
<thead>
<tr>
<th></th>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>4</td>
<td>10</td>
<td>100</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td>6</td>
<td>30</td>
<td>-30</td>
</tr>
</tbody>
</table>

Using inverse operator (~) to take the complement of a mask

In [37]: df = pd.DataFrame(
    ...:   {'AAA': [4,5,6,7], 'BBB': [10,20,30,40], 'CCC': [100,50,-30,-50]});

In [38]: df[~((df.AAA <= 6) & (df.index.isin([0,2,4])))]

→

<table>
<thead>
<tr>
<th></th>
<th>AAA</th>
<th>BBB</th>
<th>CCC</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>5</td>
<td>20</td>
<td>50</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>40</td>
<td>-50</td>
</tr>
</tbody>
</table>
### 7.2.2 Panels

Extend a panel frame by transposing, adding a new dimension, and transposing back to the original dimensions

```python
In [39]: rng = pd.date_range('1/1/2013', periods=100, freq='D')
In [40]: data = np.random.randn(100, 4)
In [41]: cols = ['A', 'B', 'C', 'D']
In [42]: df1, df2, df3 = pd.DataFrame(data, rng, cols), pd.DataFrame(data, rng, cols),
                    pd.DataFrame(data, rng, cols)
In [43]: pf = pd.Panel({'df1':df1,'df2':df2,'df3':df3});pf
Out[43]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 100 (major_axis) x 4 (minor_axis)
Items axis: df1 to df3
Major_axis axis: 2013-01-01 00:00:00 to 2013-04-10 00:00:00
Minor_axis axis: A to D
In [44]: pf.loc[:, :, 'F'] = pd.DataFrame(data, rng, cols);pf
```

Mask a panel by using `np.where` and then reconstructing the panel with the new masked values

### 7.2.3 New Columns

Efficiently and dynamically creating new columns using `applymap`

```python
In [45]: df = pd.DataFrame(
     ....:   {'AAA' : [1,2,1,3], 'BBB' : [1,1,2,2], 'CCC' : [2,1,3,1]}); df
Out[45]:
     AAA  BBB  CCC
    0    1    1    2
    1    2    1    1
    2    1    2    3
    3    3    2    1
In [46]: source_cols = df.columns # or some subset would work too.
In [47]: new_cols = [str(x) + "_cat" for x in source_cols]
In [48]: categories = {1 : 'Alpha', 2 : 'Beta', 3 : 'Charlie'}
In [49]: df[new_cols] = df[source_cols].applymap(categories.get);df
Out[49]:
     AAA  BBB  CCC  AAA_cat  BBB_cat  CCC_cat
    0    1    1    2    Alpha    Alpha    Beta
```

(continues on next page)
Keep other columns when using min() with groupby

```
In [50]: df = pd.DataFrame(
  ....:     {'AAA' : [1,1,1,2,2,2,3,3], 'BBB' : [2,1,3,4,5,1,2,3]}); df
  ....:
Out[50]:
   AAA  BBB
0  1  2
1  1  1
2  2  3
3  2  4
4  2  5
5  2  1
6  3  2
7  3  3
```

Method 1 : idxmin() to get the index of the mins

```
In [51]: df.loc[df.groupby("AAA")["BBB").idxmin()]
Out[51]:
    AAA  BBB
  1  1  1
  5  2  1
  6  3  2
```

Method 2 : sort then take first of each

```
In [52]: df.sort_values(by="BBB").groupby("AAA", as_index=False).first()
Out[52]:
    AAA  BBB
  0  1  1
  1  2  1
  2  3  2
```

Notice the same results, with the exception of the index.

## 7.3 MultilIndexing

The `multindexing` docs.

Creating a multi-index from a labeled frame

```
In [53]: df = pd.DataFrame({'row' : [0,1,2],
  ....:     'One_X' : [1.1,1.1,1.1],
  ....:     'One_Y' : [1.2,1.2,1.2],
  ....:     'Two_X' : [1.11,1.11,1.11],
  ....:     'Two_Y' : [1.22,1.22,1.22]}); df
  ....:
Out[53]:
 row One_X  One_Y  Two_X  Two_Y
0   0  1.1  1.2  1.11  1.22
```
# As Labelled Index

```python
In [54]: df = df.set_index('row'); df
```

```
   One_X  One_Y  Two_X  Two_Y
  row
0  1.1    1.2    1.11   1.22
1  1.1    1.2    1.11   1.22
2  1.1    1.2    1.11   1.22
```

# With Hierarchical Columns

```python
In [55]: df.columns = pd.MultiIndex.from_tuples([tuple(c.split('_')) for c in df.columns]); df
```

```
   One  Two
   X    Y
  row
0  1.1  1.2    1.11  1.22
1  1.1  1.2    1.11  1.22
2  1.1  1.2    1.11  1.22
```

# Now stack & Reset

```python
In [56]: df = df.stack(0).reset_index(1); df
```

```
   level_1    X    Y
  row
0  One  1.10  1.20
0  Two  1.11  1.22
1  One  1.10  1.20
1  Two  1.11  1.22
2  One  1.10  1.20
2  Two  1.11  1.22
```

# And fix the labels (Notice the label 'level_1' got added automatically)

```python
In [57]: df.columns = ['Sample','All_X','All_Y']; df
```

```
   Sample  All_X  All_Y
  row
0  One    1.10   1.20
0  Two    1.11   1.22
1  One    1.10   1.20
1  Two    1.11   1.22
2  One    1.10   1.20
2  Two    1.11   1.22
```

### 7.3.1 Arithmetic

Performing arithmetic with a multi-index that needs broadcasting
In [58]: cols = pd.MultiIndex.from_tuples([(x,y) for x in ['A','B','C'] for y in ['O','I']])

In [59]: df = pd.DataFrame(np.random.randn(2,6),index=['n','m'],columns=cols); df

Out[59]:
A  B  C  
O I  O I  O I
n 1.920906 -0.388231 -2.314394 0.665508 0.402562 0.399555
m -1.765956 0.850423 0.388054 0.992312 0.744086 -0.739776

In [60]: df = df.div(df['C'],level=1); df

Out[60]:
A  B  C  
O I  O I  O I
n 4.771702 -0.971660 -5.749162 1.665625 1.0 1.0
m -2.373321 -1.149568 0.521518 -1.341367 1.0 1.0

7.3.2 Slicing

Slicing a multi-index with xs

In [61]: coords = [('AA','one'),('AA','six'),('BB','one'),('BB','two'),('BB','six')]

In [62]: index = pd.MultiIndex.from_tuples(coords)

In [63]: df = pd.DataFrame([11,22,33,44,55],index,['MyData']); df

Out[63]:
MyData
AA one 11
six 22
BB one 33
two 44
six 55

To take the cross section of the 1st level and 1st axis the index:

In [64]: df.xs('BB',level=0,axis=0)  #Note : level and axis are optional, and default to zero

Out[64]:
MyData
one 33
two 44
six 55

...and now the 2nd level of the 1st axis.

In [65]: df.xs('six',level=1,axis=0)

Out[65]:
MyData
AA 22
BB 55

Slicing a multi-index with xs, method #2
```python
In [66]: index = list(itertools.product(['Ada', 'Quinn', 'Violet'], ['Comp', 'Math', 'Sci']))

In [67]: headr = list(itertools.product(['Exams', 'Labs'], ['I', 'II']))

In [68]: indx = pd.MultiIndex.from_tuples(index, names=['Student', 'Course'])

In [69]: cols = pd.MultiIndex.from_tuples(headr)  # Notice these are un-named

In [70]: data = [[70+x+y+(x*y)%3 for x in range(4)] for y in range(9)]

In [71]: df = pd.DataFrame(data, indx, cols); df

Out[71]:

<table>
<thead>
<tr>
<th></th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
<td>II</td>
</tr>
<tr>
<td>Ada</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>Comp</td>
<td>70</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>71</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
<td>72</td>
</tr>
<tr>
<td>Quinn</td>
<td>Comp</td>
<td>73</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>74</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
<td>75</td>
</tr>
<tr>
<td>Violet</td>
<td>Comp</td>
<td>76</td>
</tr>
<tr>
<td></td>
<td>Math</td>
<td>77</td>
</tr>
<tr>
<td></td>
<td>Sci</td>
<td>78</td>
</tr>
</tbody>
</table>

In [72]: All = slice(None)

In [73]: df.loc['Violet']

Out[73]:

<table>
<thead>
<tr>
<th></th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
<td>II</td>
</tr>
<tr>
<td>Course</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Comp</td>
<td>76</td>
<td>77</td>
</tr>
<tr>
<td>Math</td>
<td>77</td>
<td>79</td>
</tr>
<tr>
<td>Sci</td>
<td>78</td>
<td>81</td>
</tr>
</tbody>
</table>

In [74]: df.loc[(slice('Ada','Quinn'),'Math'),All]

<table>
<thead>
<tr>
<th></th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
<td>II</td>
</tr>
<tr>
<td>Student Course</td>
<td></td>

<tr>
<td>Quinn Math</td>
<td>74</td>
<td>76</td>
</tr>
<tr>
<td>Violet Math</td>
<td>77</td>
<td>79</td>
</tr>
</tbody>
</table>

In [75]: df.loc[(slice('Ada','Quinn'), 'Math'),All]

<table>
<thead>
<tr>
<th></th>
<th>Exams</th>
<th>Labs</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>I</td>
<td>II</td>
</tr>
<tr>
<td>Student Course</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ada Math</td>
<td>71</td>
<td>73</td>
</tr>
<tr>
<td>Quinn Math</td>
<td>74</td>
<td>76</td>
</tr>
</tbody>
</table>

In [76]: df.loc[(All,'Math'), ('Exams')]
```

7.3. MultiIndexing

(continues on next page)
Setting portions of a multi-index with xs

### 7.3.3 Sorting

Sort by specific column or an ordered list of columns, with a multi-index

```python
In [78]: df.sort_values(by=('Labs', 'II'), ascending=False)
```

```
Exams      Labs
          II  II
Student   Course
Violet    Sci   78  81  81  81
          Math  77  79  81  80
          Comp  76  77  78  79
Quinn     Sci   75  78  78  78
          Math  74  76  78  77
          Comp  73  74  75  76
Ada       Sci   72  75  75  75
          Math  71  73  75  74
          Comp  70  71  72  73
```

Partial Selection, the need for sortedness;

### 7.3.4 Levels

Prepending a level to a multiindex

Flatten Hierarchical columns

### 7.4 Missing Data

The missing data docs.

Fill forward a reversed timeseries
In [79]: df = pd.DataFrame(np.random.randn(6,1), index=pd.date_range('2013-08-01', periods=6, freq='B'), columns=list('A'))

In [80]: df.loc[df.index[3], 'A'] = np.nan

In [81]: df
Out[81]:
   A
2013-08-01 -1.054874
2013-08-02 -0.179642
2013-08-05  0.639589
2013-08-06  NaN
2013-08-07  1.906684
2013-08-08  0.104050

In [82]: df.reindex(df.index[::-1]).ffill()

   A
2013-08-08  0.104050
2013-08-07  1.906684
2013-08-06  1.906684
2013-08-05  0.639589
2013-08-02  -0.179642
2013-08-01  -1.054874

cumsum reset at NaN values

7.4.1 Replace

Using replace with backrefs

7.5 Grouping

The grouping docs.

Basic grouping with apply

Unlike agg, apply’s callable is passed a sub-DataFrame which gives you access to all the columns

In [83]: df = pd.DataFrame({'animal': 'cat dog cat fish dog cat cat'.split(),
                       'size': list('SSMMMLL'),
                       'weight': [8, 10, 11, 1, 20, 12, 12],
                       'adult': [False] * 5 + [True] * 2}); df

Out[83]:
   animal size  weight  adult
0    cat     S       8   False
1    dog     S      10   False
2    cat     M      11   False
3    fish    M       1   False
4    dog     M      20   False
5    cat     L      12   True
6    cat     L      12   True

(continues on next page)
# List the size of the animals with the highest weight.

In [84]: df.groupby('animal').apply(lambda subf: subf['size'][subf['weight'].idxmax()])

animal          cat  dog  fish
---              --  --  --
cat             L    M    M
dog             M    M    M
df              cat  dog  fish
   dtype: object

Using `get_group`

In [85]: gb = df.groupby(['animal'])

In [86]: gb.get_group('cat')

Out[86]:
animal size  weight  adult
0     cat   S      8.0 True
2     cat   M      11.0 True
5     cat   L      12.0 True
6     cat   L      12.0 True

Apply to different items in a group

In [87]: def GrowUp(x):
   ....:     avg_weight = sum(x[x['size'] == 'S'].weight * 1.5)
   ....:     avg_weight += sum(x[x['size'] == 'M'].weight * 1.25)
   ....:     avg_weight += sum(x[x['size'] == 'L'].weight)
   ....:     avg_weight /= len(x)
   ....:     return pd.Series(['L', avg_weight, True], index=['size', 'weight', 'adult'])

In [88]: expected_df = gb.apply(GrowUp)

In [89]: expected_df

Out[89]:
size  weight  adult
animal
  cat   L      12.4375   True
  dog   L      20.0000   True
  fish  L      1.25000   True

Expanding Apply

In [90]: S = pd.Series([i / 100.0 for i in range(1,11)])

In [91]: def CumRet(x, y):
   ....:     return x * (1 + y)
   ....:

In [92]: def Red(x):
   ....:     return functools.reduce(CumRet, x, 1.0)
   ....:

In [93]: S.expanding().apply(Red, raw=True)

Out[93]: (continues on next page)
Replacing some values with mean of the rest of a group

```python
In [94]: df = pd.DataFrame({'A' : [1, 1, 2, 2], 'B' : [1, -1, 1, 2]})
In [95]: gb = df.groupby('A')
In [96]: def replace(g):
       ....:     mask = g < 0
       ....:     g.loc[mask] = g[~mask].mean()
       ....:     return g

In [97]: gb.transform(replace)
Out[97]:
     B
0  1.0
1  1.0
2  1.0
3  2.0
```

Sort groups by aggregated data

```python
In [98]: df = pd.DataFrame({'code': ['foo', 'bar', 'baz'] * 2,
       ....:                     'data': [0.16, -0.21, 0.33, 0.45, -0.59, 0.62],
       ....:                     'flag': [False, True] * 3})

In [99]: code_groups = df.groupby('code')

In [100]: agg_n_sort_order = code_groups[['data']].transform(sum).sort_values(by='data')

In [101]: sorted_df = df.loc[agg_n_sort_order.index]

In [102]: sorted_df
Out[102]:
     code   data  flag
0     foo  0.16  False
1     bar -0.21   True
4     bar -0.59  False
0     foo  0.16  False
3     foo  0.45   True
2     baz  0.33  False
5     baz  0.62   True
```

Create multiple aggregated columns
In [103]: rng = pd.date_range(start="2014-10-07", periods=10, freq='2min')

In [104]: ts = pd.Series(data = list(range(10)), index = rng)

In [105]: def MyCust(x):
   .....:     if len(x) > 2:
   .....:         return x[1] * 1.234
   .....:     return pd.NaT
   .....:

In [106]: mhc = {'Mean' : np.mean, 'Max' : np.max, 'Custom' : MyCust}

In [107]: ts.resample("5min").apply(mhc)
Out[107]:
          Custom     Mean     Max
2014-10-07 00:00:00 1.234    1.000    2.000
2014-10-07 00:05:00  NaN      2.000    4.000
2014-10-07 00:10:00 7.404    3.500    7.000
2014-10-07 00:15:00  NaN      9.000    9.000

In [108]: ts

Create a value counts column and reassign back to the DataFrame

In [109]: df = pd.DataFrame({'Color': 'Red Red Red Blue'.split(),
   .....:     'Value': [100, 150, 50, 50]}); df
   ...
Out[109]:
Color Value
0 Red 100
1 Red 150
2 Red 50
3 Blue 50

In [110]: df['Counts'] = df.groupby(['Color']).transform(len)
Shift groups of the values in a column based on the index

```
In [112]: df = pd.DataFrame({
    .....:  'line_race': [10, 10, 8, 10, 10, 8],
    .....:  'beyer': [99, 102, 103, 103, 88, 100],
    .....:  'index':[u'Last Gunfighter', u'Last Gunfighter', u'Last Gunfighter', u'Paynter', u'Paynter', u'Paynter']); df
```

```
In [113]: df['beyer_shifted'] = df.groupby(level=0)['beyer'].shift(1)
```

```
In [114]: df
```

Select row with maximum value from each group

```
In [115]: df = pd.DataFrame({'host': ['other', 'other', 'that', 'this', 'this'],
    .....:  'service': ['mail', 'web', 'mail', 'mail', 'web'],
    .....:  'no': [1, 2, 1, 2, 1]}).set_index(['host', 'service'])
```

```
In [116]: mask = df.groupby(level=0).agg('idxmax')
```

```
In [117]: df_count = df.loc[mask['no']].reset_index()
```

```
In [118]: df_count
```

Grouping like Python's itertools.groupby

7.5. Grouping
7.5.1 Expanding Data

Alignment and to-date

Rolling Computation window based on values instead of counts

Rolling Mean by Time Interval

7.5.2 Splitting

Splitting a frame

Create a list of dataframes, split using a delineation based on logic included in rows.
7.5.3 Pivot

The **Pivot** docs.

Partial sums and subtotals

```
In [127]: df = pd.DataFrame(data={
    ...:     'Province': ['ON','QC','BC','AL','AL','MN','ON'],
    ...:     'City': ['Toronto','Montreal','Vancouver','Calgary'
    ...:                   ,'Edmonton','Winnipeg','Windsor'],
    ...:     'Sales': [13,6,16,8,4,3,1]})
```

```
In [128]: table = pd.pivot_table(df,values=['Sales'],index=['Province'],columns=['City'],aggfunc=np.sum,margins=True)
```

```
In [129]: table.stack('City')
```

```
Out[129]:
                      Sales
               Province City  
             All       12.0
             ...        ...
             AL       Calgary  8.0
                       Edmonton  4.0
             BC       Vancouver  16.0
             MN       Winnipeg  3.0
             ...        ...
             All       Calgary  8.0
                       Edmonton  4.0
                       Montreal  6.0
                        Toronto  13.0
                       Vancouver  16.0
                       Windsor  1.0
                       Winnipeg  3.0

[20 rows x 1 columns]
```

Frequency table like plyr in R

```
In [130]: grades = [48,99,75,80,42,80,72,68,36,78]
```

In [132]: df.groupby('ExamYear').agg({'Participated': lambda x: x.value_counts()['yes'],  'Passed': lambda x: sum(x == 'yes'),  'Employed': lambda x : sum(x),  'Grade' : lambda x : sum(x) / len(x)})

Out[132]:

7.5.4 Apply

Rolling Apply to Organize - Turning embedded lists into a multi-index frame

```python
In [135]: df = pd.DataFrame(data={'A': [[2,4,8,16],[100,200],[10,20,30]], 'B': [['a','b','c'],['jj','kk'],['ccc']]), index=['I','II','III'])

In [136]: def SeriesFromSubList(aList):
       .....:     return pd.Series(aList)
       .....

In [137]: df_orgz = pd.concat(dict((ind,row.apply(SeriesFromSubList)) for ind,row in df.iterrows()))
```

Rolling Apply with a DataFrame returning a Series

Rolling Apply to multiple columns where function calculates a Series before a Scalar from the Series is returned

```python
In [138]: df = pd.DataFrame(data=np.random.randn(2000,2)/10000,
       .....:     index=pd.date_range('2001-01-01',periods=2000),
       .....:     columns=['A','B']); df

Out[138]:
     A         B
2001-01-01  0.000032 -0.000004
2001-01-02 -0.000001  0.000207

7.6 Timeseries

Between times
Using indexer between time
Constructing a datetime range that excludes weekends and includes only certain times

Vectorized Lookup
Aggregation and plotting time series

Turn a matrix with hours in columns and days in rows into a continuous row sequence in the form of a time series. How to rearrange a Python pandas DataFrame?

Dealing with duplicates when reindexing a timeseries to a specified frequency

Calculate the first day of the month for each entry in a DatetimeIndex

```
In [147]: dates = pd.date_range('2000-01-01', periods=5)

In [148]: dates.to_period(freq='M').to_timestamp()
```

```
Out[148]:
```

7.6.1 Resampling

The `Resample` docs.

Using Grouper instead of TimeGrouper for time grouping of values
Time grouping with some missing values
Valid frequency arguments to Grouper
Grouping using a MultiIndex
Using TimeGrouper and another grouping to create subgroups, then apply a custom function
Resampling with custom periods
Resample intraday frame without adding new days
Resample minute data
Resample with groupby
7.7 Merge

The `Concat` docs. The `Join` docs.

Append two dataframes with overlapping index (emulate R `rbind`)

```python
In [149]: rng = pd.date_range('2000-01-01', periods=6)

In [150]: df1 = pd.DataFrame(np.random.randn(6, 3), index=rng, columns=['A', 'B', 'C'])

In [151]: df2 = df1.copy()

Depending on df construction, `ignore_index` may be needed

```python
In [152]: df = df1.append(df2, ignore_index=True); df
```

Self Join of a DataFrame

```python
In [153]: df = pd.DataFrame(data={'Area': ['A'] * 5 + ['C'] * 2,
                      'Bins': [110] * 2 + [160] * 3 + [40] * 2,
                      'Test_0': [0, 1, 0, 1, 2, 0, 1],
                      'Data': np.random.randn(7)}); df

In [154]: df['Test_1'] = df['Test_0'] - 1

In [155]: pd.merge(df, df, left_on=['Bins', 'Area', 'Test_0'], right_on=['Bins', 'Area _', 'Test_1'], suffixes=('_L', '_R'))
```
How to set the index and join
KDB like asof join
Join with a criteria based on the values
Using searchsorted to merge based on values inside a range

7.8 Plotting

The Plotting docs.
Make Matplotlib look like R
Setting x-axis major and minor labels
Plotting multiple charts in an ipython notebook
Creating a multi-line plot
Plotting a heatmap
Annotate a time-series plot
Annotate a time-series plot #2
Generate Embedded plots in excel files using Pandas, Vincent and xlsxwriter
Boxplot for each quartile of a stratifying variable

```
In [156]: df = pd.DataFrame(
       ....:     {u'stratifying_var': np.random.uniform(0, 100, 20),
       ....:      u'price': np.random.normal(100, 5, 20)})
In [157]: df[u'quartiles'] = pd.qcut(
       ....:      df[u'stratifying_var'],
       ....:     4,
       ....:     labels=[u'0-25%', u'25-50%', u'50-75%', u'75-100%'])
In [158]: df.boxplot(column=u'price', by=u'quartiles')
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2110bcc0>
```
7.9 Data In/Out

Performance comparison of SQL vs HDF5

7.9.1 CSV

The CSV docs
read_csv in action
appending to a csv
Reading a csv chunk-by-chunk
Reading only certain rows of a csv chunk-by-chunk
Reading the first few lines of a frame
Reading a file that is compressed but not by gzip/bz2 (the native compressed formats which read_csv understands). This example shows a WinZipped file, but is a general application of opening the file within a context manager and using that handle to read. See here
Inferring dtypes from a file
Dealing with bad lines
Dealing with bad lines II

Reading CSV with Unix timestamps and converting to local timezone

Write a multi-row index CSV without writing duplicates

### 7.9.1.1 Reading multiple files to create a single DataFrame

The best way to combine multiple files into a single DataFrame is to read the individual frames one by one, put all of the individual frames into a list, and then combine the frames in the list using `pd.concat()`:

```python
In [159]: for i in range(3):
    ....:     data = pd.DataFrame(np.random.randn(10, 4))
    ....:     data.to_csv('file_{}.csv'.format(i))
    ....:

In [160]: files = ['file_0.csv', 'file_1.csv', 'file_2.csv']

In [161]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

You can use the same approach to read all files matching a pattern. Here is an example using `glob`:

```python
In [162]: import glob
In [163]: files = glob.glob('file_*.csv')
In [164]: result = pd.concat([pd.read_csv(f) for f in files], ignore_index=True)
```

Finally, this strategy will work with the other `pd.read_*(...)` functions described in the `io docs`.

### 7.9.1.2 Parsing date components in multi-columns

Parsing date components in multi-columns is faster with a format

```python
In [30]: i = pd.date_range('20000101', periods=10000)
In [31]: df = pd.DataFrame(dict(year = i.year, month = i.month, day = i.day))

In [32]: df.head()
Out[32]:
   day  month  year
0     1      1   2000
1     2      1   2000
2     3      1   2000
3     4      1   2000
4     5      1   2000

In [33]: %timeit pd.to_datetime(df.year*10000+df.month*100+df.day, format='%Y%m%d')
   100 loops, best of 3: 7.08 ms per loop

# simulate combinging into a string, then parsing
In [34]: ds = df.apply(lambda x: "%04d%02d%02d" % (x['year'],x['month'],x['day']), axis=1)
In [35]: ds.head()
Out[35]:
   0   1   2   3   4

(continues on next page)
7.9.1.3 Skip row between header and data

Option 1: pass rows explicitly to skiprows

```python
In [166]: pd.read_csv(StringIO(data), sep=';', skiprows=[11,12],
                      index_col=0, parse_dates=True, header=10)
```

```
Out[166]:
          Param1  Param2  Param4  Param5
date
1990-01-01 00:00:00    1     1      2     3
1990-01-01 01:00:00    5     3      4     5
1990-01-01 02:00:00    9     5      6     7
1990-01-01 03:00:00   13     7      8     9
1990-01-01 04:00:00   17     9     10    11
1990-01-01 05:00:00   21    11     12    13
```
Option 2: read column names and then data

```python
In [167]: pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
Out[167]: Index(['date', 'Param1', 'Param2', 'Param4', 'Param5'], dtype='object')
In [168]: columns = pd.read_csv(StringIO(data), sep=';', header=10, nrows=10).columns
In [169]: pd.read_csv(StringIO(data), sep=';', index_col=0,
       ......:       header=12, parse_dates=True, names=columns)
       ......:
Out[169]:
<table>
<thead>
<tr>
<th>date</th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1990-01-01 00:00:00</td>
<td>1</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>1990-01-01 01:00:00</td>
<td>5</td>
<td>3</td>
<td>4</td>
<td>5</td>
</tr>
<tr>
<td>1990-01-01 02:00:00</td>
<td>9</td>
<td>5</td>
<td>6</td>
<td>7</td>
</tr>
<tr>
<td>1990-01-01 03:00:00</td>
<td>13</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
<tr>

<td>17</td>
<td>9</td>
<td>10</td>
<td>11</td>
</tr>
<tr>
<td>1990-01-01 05:00:00</td>
<td>21</td>
<td>11</td>
<td>12</td>
<td>13</td>
</tr>
</tbody>
</table>
```

7.9.2 SQL

The `SQL` docs
Reading from databases with SQL

7.9.3 Excel

The `Excel` docs
Reading from a filelike handle
Modifying formatting in XlsxWriter output

7.9.4 HTML

Reading HTML tables from a server that cannot handle the default request header

7.9.5 HDFStore

The `HDFStores` docs
Simple Queries with a Timestamp Index
Managing heterogeneous data using a linked multiple table hierarchy
Merging on-disk tables with millions of rows
Avoiding inconsistencies when writing to a store from multiple processes/threads
De-duplicating a large store by chunks, essentially a recursive reduction operation. Shows a function for taking in data from csv file and creating a store by chunks, with date parsing as well. See here
Creating a store chunk-by-chunk from a csv file
Appending to a store, while creating a unique index

7.9. Data In/Out 545
Large Data work flows
Reading in a sequence of files, then providing a global unique index to a store while appending
Groupby on a HDFStore with low group density
Groupby on a HDFStore with high group density
Hierarchical queries on a HDFStore
Counting with a HDFStore
Troubleshoot HDFStore exceptions
Setting min_itemsize with strings
Using ptrepack to create a completely-sorted-index on a store
Storing Attributes to a group node

```python
In [170]: df = pd.DataFrame(np.random.randn(8,3))
In [171]: store = pd.HDFStore('test.h5')
In [172]: store.put('df',df)
# you can store an arbitrary Python object via pickle
In [173]: store.get_storer('df').attrs.my_attribute = dict(A = 10)
In [174]: store.get_storer('df').attrs.my_attribute
Out[174]: {'A': 10}
```

### 7.9.6 Binary Files

pandas readily accepts NumPy record arrays, if you need to read in a binary file consisting of array of C structs. For example, given this C program in a file called `main.c` compiled with `gcc main.c -std=gnu99` on a 64-bit machine,

```
#include <stdio.h>
#include <stdint.h>

typedef struct _Data
{
    int32_t count;
    double avg;
    float scale;
} Data;

int main(int argc, const char *argv[])
{
    size_t n = 10;
    Data d[n];

    for (int i = 0; i < n; ++i)
    {
        d[i].count = i;
        d[i].avg = i + 1.0;
        d[i].scale = (float) i + 2.0f;
    }
```
the following Python code will read the binary file `binary.dat` into a pandas DataFrame, where each element of the struct corresponds to a column in the frame:

```python
names = 'count', 'avg', 'scale'

# note that the offsets are larger than the size of the type because of # struct padding
offsets = 0, 8, 16
formats = 'i4', 'f8', 'f4'

dt = np.dtype({'names': names, 'offsets': offsets, 'formats': formats},
               align=True)
df = pd.DataFrame(np.fromfile('binary.dat', dt))
```

**Note:** The offsets of the structure elements may be different depending on the architecture of the machine on which the file was created. Using a raw binary file format like this for general data storage is not recommended, as it is not cross platform. We recommended either HDF5 or msgpack, both of which are supported by pandas’ IO facilities.

### 7.10 Computation

Numerical integration (sample-based) of a time series

#### 7.11 Timedeltas

The Timedeltas docs.

Using timedeltas

```python
In [175]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [176]: s - s.max()
Out[176]:
0   -2 days
1   -1 days
2    0 days
dtype: timedelta64[ns]

In [177]: s.max() - s
Out[177]:
0    2 days
1    1 days
2    0 days
dtype: timedelta64[ns]
```
In [178]: s = datetime.datetime(2011,1,1,3,5)

    →
    0  364 days 20:55:00
    1  365 days 20:55:00
    2  366 days 20:55:00
dtype: timedelta64[ns]

In [179]: s + datetime.timedelta(minutes=5)

    →
    0  2012-01-01 00:05:00
    1  2012-01-02 00:05:00
    2  2012-01-03 00:05:00
dtype: datetime64[ns]

In [180]: datetime.datetime(2011,1,1,3,5) - s

    →
    0  -365 days +03:05:00
    1  -366 days +03:05:00
    2  -367 days +03:05:00
dtype: timedelta64[ns]

In [181]: datetime.timedelta(minutes=5) + s

    →
    0  2012-01-01 00:05:00
    1  2012-01-02 00:05:00
    2  2012-01-03 00:05:00
dtype: datetime64[ns]

Adding and subtracting deltas and dates

In [182]: deltas = pd.Series([datetime.timedelta(days=i) for i in range(3)])

In [183]: df = pd.DataFrame(dict(A = s, B = deltas)); df

Out[183]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2012-01-01 00:00:00</td>
<td>0 days</td>
</tr>
<tr>
<td>1</td>
<td>2012-01-02 00:00:00</td>
<td>1 days</td>
</tr>
<tr>
<td>2</td>
<td>2012-01-03 00:00:00</td>
<td>2 days</td>
</tr>
</tbody>
</table>

In [184]: df['New Dates'] = df['A'] + df['B'];

In [185]: df['Delta'] = df['A'] - df['New Dates']; df

Out[185]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>New Dates</th>
<th>Delta</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2012-01-01 00:00:00</td>
<td>0 days</td>
<td>2012-01-01</td>
<td>0 days</td>
</tr>
<tr>
<td>1</td>
<td>2012-01-02 00:00:00</td>
<td>1 days</td>
<td>2012-01-03</td>
<td>-1 days</td>
</tr>
<tr>
<td>2</td>
<td>2012-01-03 00:00:00</td>
<td>2 days</td>
<td>2012-01-05</td>
<td>-2 days</td>
</tr>
</tbody>
</table>

In [186]: df.dtypes

    →
    A    datetime64[ns]
Another example

Values can be set to NaT using np.nan, similar to datetime

```
In [187]: y = s - s.shift(); y
Out[187]:
0    NaT
1    1 days
2    1 days
dtype: timedelta64[ns]
```

```
In [188]: y[1] = np.nan; y
```

```
In [188]: y[1] = np.nan; y
```

```
Out[188]:
0    NaT
1    NaT
2    1 days
dtype: timedelta64[ns]
```

## 7.12 Aliasing Axis Names

To globally provide aliases for axis names, one can define these 2 functions:

```
In [189]: def set_axis_alias(cls, axis, alias):
    ....:     if axis not in cls._AXIS_NUMBERS:
    ....:         raise Exception("invalid axis \[%s\] for alias \[%s\]" % (axis, alias))
    ....:     cls._AXIS_ALIASES[alias] = axis
    ....:
```

```
In [190]: def clear_axis_alias(cls, axis, alias):
    ....:     if axis not in cls._AXIS_NUMBERS:
    ....:         raise Exception("invalid axis \[%s\] for alias \[%s\]" % (axis, alias))
    ....:     cls._AXIS_ALIASES.pop(alias,None)
    ....:
```

```
In [191]: set_axis_alias(pd.DataFrame,'columns', 'myaxis2')
```

```
In [192]: df2 = pd.DataFrame(np.random.randn(3,2),columns=['c1','c2'],index=['i1','i2 →','i3'])
```

```
In [193]: df2.sum(axis='myaxis2')
Out[193]:
    i1   0.745167
    i2  -0.176251
    i3   0.014354
dtype: float64
```

```
In [194]: clear_axis_alias(pd.DataFrame,'columns', 'myaxis2')
```

7.12. Aliasing Axis Names
7.13 Creating Example Data

To create a dataframe from every combination of some given values, like R’s `expand.grid()` function, we can create a dict where the keys are column names and the values are lists of the data values:

```python
In [195]: def expand_grid(data_dict):
    rows = itertools.product(*data_dict.values())
    return pd.DataFrame.from_records(rows, columns=data_dict.keys())

In [196]: df = expand_grid(
    {'height': [60, 70],
     'weight': [100, 140, 180],
     'sex': ['Male', 'Female']})

In [197]: df
Out[197]:
   height  weight  sex
0      60      100  Male
1      60      100  Female
2      60      140  Male
3      60      140  Female
4      60      180  Male
5      60      180  Female
6      70      100  Male
7      70      100  Female
8      70      140  Male
9      70      140  Female
10     70      180  Male
11     70      180  Female
We’ll start with a quick, non-comprehensive overview of the fundamental data structures in pandas to get you started. The fundamental behavior about data types, indexing, and axis labeling / alignment apply across all of the objects. To get started, import NumPy and load pandas into your namespace:

```
In [1]: import numpy as np
In [2]: import pandas as pd
```

Here is a basic tenet to keep in mind: **data alignment is intrinsic.** The link between labels and data will not be broken unless done so explicitly by you.

We’ll give a brief intro to the data structures, then consider all of the broad categories of functionality and methods in separate sections.

### 8.1 Series

*Series* is a one-dimensional labeled array capable of holding any data type (integers, strings, floating point numbers, Python objects, etc.). The axis labels are collectively referred to as the **index**. The basic method to create a Series is to call:

```
>>> s = pd.Series(data, index=index)
```

Here, *data* can be many different things:

- a Python dict
- an ndarray
- a scalar value (like 5)

The passed **index** is a list of axis labels. Thus, this separates into a few cases depending on what *data* is:

#### From ndarray

If *data* is an ndarray, **index** must be the same length as *data*. If no index is passed, one will be created having values `[0, ..., len(data) - 1]`.

```
In [3]: s = pd.Series(np.random.randn(5), index=["a", "b", "c", "d", "e"])
In [4]: s
Out[4]:
a   0.4691
b  -0.2829
```

(continues on next page)
c  -1.5091
d  -1.1356
e   1.2121
dtype: float64

```
In [5]: s.index
Out[5]:
Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
```

```
In [6]: pd.Series(np.random.randn(5))
Out[6]:
0   -0.1732
1    0.1192
2   -1.0442
3    -0.8618
4   -2.1046
dtype: float64
```

Note: pandas supports non-unique index values. If an operation that does not support duplicate index values is attempted, an exception will be raised at that time. The reason for being lazy is nearly all performance-based (there are many instances in computations, like parts of GroupBy, where the index is not used).

**From dict**

Series can be instantiated from dicts:

```
In [7]: d = {'b' : 1, 'a' : 0, 'c' : 2}
```

```
In [8]: pd.Series(d)
Out[8]:
b  1
a  0
c  2
dtype: int64
```

Note: When the data is a dict, and an index is not passed, the Series index will be ordered by the dict’s insertion order, if you’re using Python version >= 3.6 and Pandas version >= 0.23.

If you’re using Python < 3.6 or Pandas < 0.23, and an index is not passed, the Series index will be the lexically ordered list of dict keys.

In the example above, if you were on a Python version lower than 3.6 or a Pandas version lower than 0.23, the Series would be ordered by the lexical order of the dict keys (i.e. ['a', 'b', 'c'] rather than ['b', 'a', 'c']).

If an index is passed, the values in data corresponding to the labels in the index will be pulled out.

```
In [9]: d = {'a' : 0., 'b' : 1., 'c' : 2.}
```

```
In [10]: pd.Series(d)
Out[10]:
a  0.0
b  1.0
c  2.0
```
**8.1. Series**

**From scalar value**

If `data` is a scalar value, an index must be provided. The value will be repeated to match the length of `index`.

```python
In [12]: pd.Series(5., index=['a', 'b', 'c', 'd', 'e'])
Out[12]:
a 5.0
b 5.0
c 5.0
d 5.0
e 5.0
dtype: float64
```

**Note:** NaN (not a number) is the standard missing data marker used in pandas.

**8.1.1 Series is ndarray-like**

`Series` acts very similarly to an `ndarray`, and is a valid argument to most NumPy functions. However, operations such as slicing will also slice the index.

```python
In [13]: s[0]
Out[13]: 0.46911229990718628

In [14]: s[:3]
Out[14]:
a 0.4691
b -0.2829
c -1.5091
dtype: float64

In [15]: s[s > s.median()]
Out[15]:
a 0.4691
e 1.2121
dtype: float64

In [16]: s[[4, 3, 1]]
```

(continues on next page)
8.1.2 Series is dict-like

A Series is like a fixed-size dict in that you can get and set values by index label:

```python
In [18]: s['a']
Out[18]: 0.46911229990718628

In [19]: s['e'] = 12.

In [20]: s
Out[20]:
a    0.4691
b   -0.2829
c   -1.5091
d   -1.1356
e   12.0000
dtype: float64

In [21]: 'e' in s
Out[21]: True

In [22]: 'f' in s
Out[22]: False
```

If a label is not contained, an exception is raised:

```python
>>> s['f']
KeyError: 'f'
```

Using the `get` method, a missing label will return None or specified default:

```python
In [23]: s.get('f')

In [24]: s.get('f', np.nan)
Out[24]: nan
```

See also the section on attribute access.
8.1.3 Vectorized operations and label alignment with Series

When working with raw NumPy arrays, looping through value-by-value is usually not necessary. The same is true when working with Series in pandas. Series can also be passed into most NumPy methods expecting an ndarray.

```
In [25]: s + s
Out[25]:
      a  0.9382
      b -0.5657
      c -3.0181
      d -2.2713
      e  24.0000
dtype: float64

In [26]: s * 2
       a  0.9382
       b -0.5657
       c -3.0181
       d -2.2713
       e  24.0000
dtype: float64

In [27]: np.exp(s)
       a 1.5986
       b 0.7536
       c 0.2211
       d 0.3212
       e 162754.7914
dtype: float64
```

A key difference between Series and ndarray is that operations between Series automatically align the data based on label. Thus, you can write computations without giving consideration to whether the Series involved have the same labels.

```
In [28]: s[1:] + s[:-1]
Out[28]:
       a  NaN
       b -0.5657
       c -3.0181
       d -2.2713
       e  NaN
dtype: float64
```

The result of an operation between unaligned Series will have the **union** of the indexes involved. If a label is not found in one Series or the other, the result will be marked as missing NaN. Being able to write code without doing any explicit data alignment grants immense freedom and flexibility in interactive data analysis and research. The integrated data alignment features of the pandas data structures set pandas apart from the majority of related tools for working with labeled data.

**Note:** In general, we chose to make the default result of operations between differently indexed objects yield the **union** of the indexes in order to avoid loss of information. Having an index label, though the data is missing, is typically important information as part of a computation. You of course have the option of dropping labels with
missing data via the `dropna` function.

### 8.1.4 Name attribute

Series can also have a `name` attribute:

```python
In [29]: s = pd.Series(np.random.rand(5), name='something')
In [30]: s
Out[30]:
   0  -0.4949
   1   1.0718
   2   0.7216
   3  -0.7068
   4  -1.0396
Name: something, dtype: float64
In [31]: s.name
   → 'something'
```

The Series `name` will be assigned automatically in many cases, in particular when taking 1D slices of DataFrame as you will see below.

New in version 0.18.0.

You can rename a Series with the `pandas.Series.rename()` method.

```python
In [32]: s2 = s.rename("different")
In [33]: s2.name
Out[33]: 'different'
```

Note that `s` and `s2` refer to different objects.

### 8.2 DataFrame

**DataFrame** is a 2-dimensional labeled data structure with columns of potentially different types. You can think of it like a spreadsheet or SQL table, or a dict of Series objects. It is generally the most commonly used pandas object. Like Series, DataFrame accepts many different kinds of input:

- Dict of 1D ndarrays, lists, dicts, or Series
- 2-D `numpy.ndarray`
- **Structured or record numpy.ndarray**
- A Series
- Another DataFrame

Along with the data, you can optionally pass `index` (row labels) and `columns` (column labels) arguments. If you pass an index and / or columns, you are guaranteeing the index and / or columns of the resulting DataFrame. Thus, a dict of Series plus a specific index will discard all data not matching up to the passed index.

If axis labels are not passed, they will be constructed from the input data based on common sense rules.
Note: When the data is a dict, and columns is not specified, the DataFrame columns will be ordered by the dict’s insertion order, if you are using Python version >= 3.6 and Pandas >= 0.23.

If you are using Python < 3.6 or Pandas < 0.23, and columns is not specified, the DataFrame columns will be the lexically ordered list of dict keys.

### 8.2.1 From dict of Series or dicts

The resulting index will be the union of the indexes of the various Series. If there are any nested dicts, these will first be converted to Series. If no columns are passed, the columns will be the ordered list of dict keys.

```
In [34]: d = {'one': pd.Series([1., 2., 3.], index=['a', 'b', 'c']),
       ...:     'two': pd.Series([1., 2., 3., 4.], index=['a', 'b', 'c', 'd'])}
       ...

In [35]: df = pd.DataFrame(d)

In [36]: df
Out[36]:
   one  two
  a  1.0  1.0
  b  2.0  2.0
  c  3.0  3.0
  d  NaN  4.0

In [37]: pd.DataFrame(d, index=['d', 'b', 'a'])
     one  two
    d  NaN  4.0
    b  2.0  2.0
    a  1.0  1.0

In [38]: pd.DataFrame(d, index=['d', 'b', 'a'], columns=['two', 'three'])
    two  three
    d    NaN
    b  2.0    NaN
    a  1.0    NaN
```

The row and column labels can be accessed respectively by accessing the index and columns attributes:

Note: When a particular set of columns is passed along with a dict of data, the passed columns override the keys in the dict.

```
In [39]: df.index
Out[39]: Index([‘a’, ‘b’, ‘c’, ‘d’], dtype=’object’)

In [40]: df.columns
Out[40]: Index([‘one’, ‘two’], dtype=’object’)
```
8.2.2 From dict of ndarrays / lists

The ndarrays must all be the same length. If an index is passed, it must clearly also be the same length as the arrays. If no index is passed, the result will be range(n), where n is the array length.

```python
In [41]: d = {'one' : [1., 2.], 'two' : [4., 3., 2., 1.],
    .....:}
In [42]: pd.DataFrame(d)
Out[42]:
     one two
0   1.0  4.0
1   2.0  3.0
2   3.0  2.0
3   4.0  1.0
```

```python
In [43]: pd.DataFrame(d, index=['a', 'b', 'c', 'd'])
Out[43]:
     one two
a   1.0  4.0
b   2.0  3.0
c   3.0  2.0
d   4.0  1.0
```

8.2.3 From structured or record array

This case is handled identically to a dict of arrays.

```python
In [44]: data = np.zeros((2,), dtype=[('A', 'i4'),('B', 'f4'),('C', 'a10')])
In [45]: data[0] = (1,2.,'Hello')
In [46]: pd.DataFrame(data)
Out[46]:
     A   B      C
0  1.0  2.0 b'Hello'
1  2.0  3.0 b'World'
```

```python
In [47]: pd.DataFrame(data, index=['first', 'second'])
Out[47]:
     A   B      C
first 1.0  2.0 b'Hello'
second 2.0  3.0 b'World'
```

```python
In [48]: pd.DataFrame(data, columns=['C', 'A', 'B'])
```

Note: DataFrame is not intended to work exactly like a 2-dimensional NumPy ndarray.
8.2.4 From a list of dicts

```python
In [49]: data2 = [{'a': 1, 'b': 2}, {'a': 5, 'b': 10, 'c': 20}]

In [50]: pd.DataFrame(data2)
Out[50]:
          a  b  c
0      1  2  NaN
1      5 10 20.0

In [51]: pd.DataFrame(data2, index=['first', 'second'])
          a  b  c
first   1  2  NaN
second  5 10 20.0

In [52]: pd.DataFrame(data2, columns=['a', 'b'])
          a  b
0      1  2
1      5 10
```

8.2.5 From a dict of tuples

You can automatically create a multi-indexed frame by passing a tuples dictionary.

```python
In [53]: pd.DataFrame({('a', 'b'): {('A', 'B'): 1, ('A', 'C'): 2},
                    ('a', 'a'): {('A', 'C'): 3, ('A', 'B'): 4},
                    ('b', 'a'): {('A', 'C'): 5, ('A', 'B'): 6},
                    ('b', 'b'): {('A', 'D'): 7, ('A', 'B'): 8}})
Out[53]:
       a  b
A B 1.0 4.0 5.0 8.0 10.0
C 2.0 3.0 6.0 7.0 NaN
D NaN NaN NaN NaN 9.0
```

8.2.6 From a Series

The result will be a DataFrame with the same index as the input Series, and with one column whose name is the original name of the Series (only if no other column name provided).

Missing Data

Much more will be said on this topic in the Missing data section. To construct a DataFrame with missing data, we use `np.nan` to represent missing values. Alternatively, you may pass a `numpy.MaskedArray` as the data argument to the DataFrame constructor, and its masked entries will be considered missing.

8.2.7 Alternate Constructors

`DataFrame.from_dict`
DataFrame.from_dict takes a dict of dicts or a dict of array-like sequences and returns a DataFrame. It operates like the DataFrame constructor except for the orient parameter which is 'columns' by default, but which can be set to 'index' in order to use the dict keys as row labels.

```
In [54]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]))
Out[54]:
    A  B
0  1  4
1  2  5
2  3  6
```

If you pass orient='index', the keys will be the row labels. In this case, you can also pass the desired column names:

```
In [55]: pd.DataFrame.from_dict(dict([('A', [1, 2, 3]), ('B', [4, 5, 6])]),
                             orient='index', columns=['one', 'two', 'three'])
```

DataFrame.from_records takes a list of tuples or an ndarray with structured dtype. It works analogously to the normal DataFrame constructor, except that the resulting DataFrame index may be a specific field of the structured dtype. For example:

```
In [56]: data
Out[56]:
array([(1, 2., b'Hello'), (2, 3., b'World')],
      dtype=[('A', '<i4'), ('B', '<f4'), ('C', 'S10')])
In [57]: pd.DataFrame.from_records(data, index='C')
```

8.2.8 Column selection, addition, deletion

You can treat a DataFrame semantically like a dict of like-indexed Series objects. Getting, setting, and deleting columns works with the same syntax as the analogous dict operations:

```
In [58]: df['one']
Out[58]:
    a    1.0
    b    2.0
    c    3.0
d  NaN
Name: one, dtype: float64
In [59]: df['three'] = df['one'] * df['two']
```
In [60]: df['flag'] = df['one'] > 2

In [61]: df
Out[61]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
<th>flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>1.0</td>
<td>1.0</td>
<td>False</td>
</tr>
<tr>
<td>b</td>
<td>2.0</td>
<td>2.0</td>
<td>4.0</td>
<td>False</td>
</tr>
<tr>
<td>c</td>
<td>3.0</td>
<td>3.0</td>
<td>9.0</td>
<td>True</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>4.0</td>
<td>NaN</td>
<td>False</td>
</tr>
</tbody>
</table>

Columns can be deleted or popped like with a dict:

In [62]: del df['two']

In [63]: three = df.pop('three')

In [64]: df
Out[64]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>flag</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>False</td>
</tr>
<tr>
<td>b</td>
<td>2.0</td>
<td>False</td>
</tr>
<tr>
<td>c</td>
<td>3.0</td>
<td>True</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>False</td>
</tr>
</tbody>
</table>

When inserting a scalar value, it will naturally be propagated to fill the column:

In [65]: df['foo'] = 'bar'

In [66]: df
Out[66]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>flag</th>
<th>foo</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>False</td>
<td>bar</td>
</tr>
<tr>
<td>b</td>
<td>2.0</td>
<td>False</td>
<td>bar</td>
</tr>
<tr>
<td>c</td>
<td>3.0</td>
<td>True</td>
<td>bar</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>False</td>
<td>bar</td>
</tr>
</tbody>
</table>

When inserting a Series that does not have the same index as the DataFrame, it will be conformed to the DataFrame's index:

In [67]: df['one_trunc'] = df['one'][:2]

In [68]: df
Out[68]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>flag</th>
<th>foo</th>
<th>one_trunc</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>False</td>
<td>bar</td>
<td>1.0</td>
</tr>
<tr>
<td>b</td>
<td>2.0</td>
<td>False</td>
<td>bar</td>
<td>2.0</td>
</tr>
<tr>
<td>c</td>
<td>3.0</td>
<td>True</td>
<td>bar</td>
<td>NaN</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>False</td>
<td>bar</td>
<td>NaN</td>
</tr>
</tbody>
</table>

You can insert raw ndarrays but their length must match the length of the DataFrame’s index.

By default, columns get inserted at the end. The `insert` function is available to insert at a particular location in the columns:

In [69]: df.insert(1, 'bar', df['one'][:2])

In [70]: df
Out[70]:
<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>flag</th>
<th>foo</th>
<th>one_trunc</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1.0</td>
<td>False</td>
<td>bar</td>
<td>1.0</td>
</tr>
<tr>
<td>b</td>
<td>2.0</td>
<td>False</td>
<td>bar</td>
<td>2.0</td>
</tr>
<tr>
<td>c</td>
<td>3.0</td>
<td>True</td>
<td>bar</td>
<td>NaN</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
<td>False</td>
<td>bar</td>
<td>NaN</td>
</tr>
</tbody>
</table>
### 8.2.9 Assigning New Columns in Method Chains

Inspired by dplyr's `mutate` verb, DataFrame has an `assign()` method that allows you to easily create new columns that are potentially derived from existing columns.

```python
In [71]: iris = pd.read_csv('data/iris.data')

In [72]: iris.head()
```

```
Out[72]:
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
</tr>
</tbody>
</table>
```

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

```python
In [73]: (iris.assign(sepal_ratio = iris['SepalWidth'] / iris['SepalLength'])).head()
```

```
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6863</td>
</tr>
<tr>
<td>4.9</td>
<td>3.0</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6122</td>
</tr>
<tr>
<td>4.7</td>
<td>3.2</td>
<td>1.3</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6809</td>
</tr>
<tr>
<td>4.6</td>
<td>3.1</td>
<td>1.5</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6739</td>
</tr>
<tr>
<td>5.0</td>
<td>3.6</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.7200</td>
</tr>
</tbody>
</table>
```

In the example above, we inserted a precomputed value. We can also pass in a function of one argument to be evaluated on the DataFrame being assigned to.

```python
In [74]: iris.assign(sepal_ratio = lambda x: (x['SepalWidth'] / x['SepalLength'])).head()
```

```
<table>
<thead>
<tr>
<th>SepalLength</th>
<th>SepalWidth</th>
<th>PetalLength</th>
<th>PetalWidth</th>
<th>Name</th>
<th>sepal_ratio</th>
</tr>
</thead>
<tbody>
<tr>
<td>5.1</td>
<td>3.5</td>
<td>1.4</td>
<td>0.2</td>
<td>Iris-setosa</td>
<td>0.6863</td>
</tr>
<tr>

```

`assign` **always** returns a copy of the data, leaving the original DataFrame untouched.

Passing a callable, as opposed to an actual value to be inserted, is useful when you don’t have a reference to the DataFrame at hand. This is common when using `assign` in a chain of operations. For example, we can limit the DataFrame to just those observations with a Sepal Length greater than 5, calculate the ratio, and plot:
Since a function is passed in, the function is computed on the DataFrame being assigned to. Importantly, this is the DataFrame that’s been filtered to those rows with sepal length greater than 5. The filtering happens first, and then the ratio calculations. This is an example where we didn’t have a reference to the filtered DataFrame available.

The function signature for assign is simply **kwargs. The keys are the column names for the new fields, and the values are either a value to be inserted (for example, a Series or NumPy array), or a function of one argument to be called on the DataFrame. A copy of the original DataFrame is returned, with the new values inserted.

Changed in version 0.23.0.

Starting with Python 3.6 the order of **kwargs is preserved. This allows for dependent assignment, where an expression later in **kwargs can refer to a column created earlier in the same assign().

8.2. DataFrame

(continues on next page)
In the second expression, `x['C']` will refer to the newly created column, that's equal to `dfa['A'] + dfa['B']`. To write code compatible with all versions of Python, split the assignment in two.

```python
In [78]: dependent = pd.DataFrame({'A': [1, 1, 1]})

In [79]: (dependent.assign(A=lambda x: x['A'] + 1)
   ....: .assign(B=lambda x: x['A'] + 2))
```

```
Out[79]:
     A  B  
0   2   4  
1   2   4  
2   2   4  
```

**Warning:** Dependent assignment maybe subtly change the behavior of your code between Python 3.6 and older versions of Python.

If you wish write code that supports versions of python before and after 3.6, you’ll need to take care when passing `assign` expressions that

- Updating an existing column
- Referring to the newly updated column in the same `assign`

For example, we’ll update column “A” and then refer to it when creating “B”.

```python
>>> dependent = pd.DataFrame({'A': [1, 1, 1]})
>>> dependent.assign(A=lambda x: x['A'] + 1,
...                   B=lambda x: x['A'] + 2)
```

For Python 3.5 and earlier the expression creating B refers to the “old” value of A, [1, 1, 1]. The output is then

```
   A  B  
0   2   3  
1   2   3  
2   2   3  
```

For Python 3.6 and later, the expression creating A refers to the “new” value of A, [2, 2, 2], which results in

```
   A  B  
0   2   4  
1   2   4  
2   2   4  
```

### 8.2.10 Indexing / Selection

The basics of indexing are as follows:
### DataFrame

8.2.11 Data alignment and arithmetic

Data alignment between DataFrame objects automatically align on both the columns and the index (row labels). Again, the resulting object will have the union of the column and row labels.

```
In [82]: df = pd.DataFrame(np.random.randn(10, 4), columns=['A', 'B', 'C', 'D'])
In [83]: df2 = pd.DataFrame(np.random.randn(7, 3), columns=['A', 'B', 'C'])
In [84]: df + df2
Out[84]:
          A     B      C     D
0  0.0457  -0.0141  1.3809  NaN
1 -0.9554  -1.5010  0.0372  NaN
2  0.6627   1.5348 -0.8597  NaN
3  2.4529   1.5348 -0.8597  NaN
4  1.4145  -1.9517 -2.3204  NaN
5  0.4949  -1.6497 -1.0846  NaN
6 -1.0476  -0.7486 -0.8055  NaN
7   NaN     NaN     NaN  NaN
8   NaN     NaN     NaN  NaN
9   NaN     NaN     NaN  NaN
```
When doing an operation between DataFrame and Series, the default behavior is to align the Series index on the DataFrame columns, thus broadcasting row-wise. For example:

```
In [85]: df - df.iloc[0]
Out[85]:
   A    B    C    D
0 0.0000 0.0000 0.0000 0.0000
1 -1.3593 -0.2487 -0.4534 -1.7547
2  0.2531  0.8297  0.0100 -1.9912
3 -1.3111  0.0543 -1.7249 -1.6205
4  0.5730  1.5007 -0.6761  1.3673
5 -1.7412  0.7820 -1.2416 -2.0531
6 -1.2408 -0.8696 -0.1533  0.0004
7 -0.7439  0.4110 -0.9296 -0.2824
8 -1.1949  1.3207  0.2382 -1.4826
9  2.2938  1.8562  0.7733 -1.4465
```

In the special case of working with time series data, and the DataFrame index also contains dates, the broadcasting will be column-wise:

```
In [86]: index = pd.date_range('1/1/2000', periods=8)
In [87]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=list('ABC'))
In [88]: df
Out[88]:
    A    B    C
2000-01-01 -1.2268  0.7698 -1.2812
2000-01-02 -0.7277 -0.1213 -0.0979
2000-01-03  0.6958  0.3417  0.9597
2000-01-04 -1.1103 -0.6200  0.1497
2000-01-05 -0.7323  0.6877  0.1764
2000-01-06  0.4033 -0.1550  0.3016
2000-01-07 -2.1799 -1.3698 -0.9542
2000-01-08  1.4627 -1.7432 -0.8266
```

```
In [89]: type(df['A'])
Out[89]:
<pandas.core.series.Series></p>
```

```
In [90]: df - df['A']
```

(continues on next page)
2000-01-05    NaN ...    NaN    NaN    NaN    NaN    NaN    NaN    NaN
2000-01-06    NaN ...    NaN    NaN    NaN    NaN    NaN    NaN    NaN
2000-01-07    NaN ...    NaN    NaN    NaN    NaN    NaN    NaN    NaN
2000-01-08    NaN ...    NaN    NaN    NaN    NaN    NaN    NaN    NaN

[8 rows x 11 columns]

Warning:
```
df - df['A']
```

is now deprecated and will be removed in a future release. The preferred way to replicate this behavior is
```
df.sub(df['A'], axis=0)
```

For explicit control over the matching and broadcasting behavior, see the section on flexible binary operations.

Operations with scalars are just as you would expect:

```
In [91]: df * 5 + 2
Out [91]:
         A         B         C
2000-01-01 -4.1341  5.8490 -4.4062
2000-01-02 -1.6385  1.3935  1.5106
2000-01-03  5.4789  3.7087  6.7986
2000-01-04 -3.5517 -1.0999  2.7487
2000-01-05 -1.6617  5.4387  2.8822
2000-01-06  4.0165  1.2252  3.5081
2000-01-07 -8.8993 -4.8492 -2.7710
2000-01-08  9.3135 -6.7158 -2.1330

In [92]: 1 / df
Out [92]:
         A         B         C

2000-01-05 -1.3655  1.4540  5.6675
2000-01-06  2.4795 -6.4537  3.3154
2000-01-07 -0.4587 -0.7300 -1.0480
2000-01-08  0.6837 -0.5737 -1.2098

In [93]: df ** 4
Out [93]:
         A         B         C
2000-01-01  2.2653  0.3512  2.6948e+00
2000-01-02  0.2804  0.0002  9.1796e-05
2000-01-03  0.2344  0.0136  8.4838e-01
2000-01-04  1.5199  0.1477  5.0286e-04
2000-01-05  0.2876  0.2237  9.6924e-04
2000-01-06  0.0265  0.0006  8.2769e-03
2000-01-07  22.5795  3.5212  8.2903e-01
2000-01-08  4.5774  9.2332  4.6683e-01
Boolean operators work as well:

```python
In [94]: df1 = pd.DataFrame({'a' : [1, 0, 1], 'b' : [0, 1, 1] }, dtype=bool)
In [95]: df2 = pd.DataFrame({'a' : [0, 1, 1], 'b' : [1, 1, 0] }, dtype=bool)
In [96]: df1 & df2
Out[96]:
   a  b  
0  F  F
1  F  T
2  T  F
In [97]: df1 | df2
Out[97]:
   a  b  
0  T  T
1  T  T
2  T  T
In [98]: df1 ^ df2
   a  b  
0  T  T
1  T  F
2  F  T
In [99]: -df1
   a  b  
0  F  T
1  T  F
2  F  F
```

### 8.2.12 Transposing

To transpose, access the `T` attribute (also the `transpose` function), similar to an `ndarray`:

```python
# only show the first 5 rows
In [100]: df[:5].T
Out[100]:
A  -1.2268   -0.7277    0.6958   -1.1103   -0.7323
B   0.7698   -0.1213    0.3417   -0.6200    0.6877
C  -1.2812   -0.0979    0.9597    0.1497    0.1764
```

### 8.2.13 DataFrame interoperability with NumPy functions

Elementwise NumPy ufuncs (log, exp, sqrt, ...) and various other NumPy functions can be used with no issues on DataFrame, assuming the data within are numeric:

```python
In [101]: np.exp(df)
Out[101]:
(continues on next page)
The dot method on DataFrame implements matrix multiplication:

```
In [103]: df.T.dot(df)
Out[103]:
   A   B   C
A 11.3419 -0.0598 3.0080
B -0.0598 6.5206 2.0833
C  3.0080 2.0833 4.3105
```

Similarly, the dot method on Series implements dot product:

```
In [104]: s1 = pd.Series(np.arange(5,10))
In [105]: s1.dot(s1)
Out[105]: 255
```

DataFrame is not intended to be a drop-in replacement for ndarray as its indexing semantics are quite different in places from a matrix.

### 8.2.14 Console display

Very large DataFrames will be truncated to display them in the console. You can also get a summary using `info()`. (Here I am reading a CSV version of the `baseball` dataset from the `plyr` R package):

```
In [106]: baseball = pd.read_csv('data/baseball.csv')
In [107]: print(baseball)
```

(continues on next page)
In [108]: baseball.info()

→<class 'pandas.core.frame.DataFrame'>
RangeIndex: 100 entries, 0 to 99
Data columns (total 23 columns):
id 100 non-null int64
player 100 non-null object
year 100 non-null int64
stint 100 non-null int64
team 100 non-null object
lg 100 non-null object
g 100 non-null int64
ab 100 non-null int64

sb 100 non-null float64
cs 100 non-null float64
bb 100 non-null int64
so 100 non-null float64
ibb 100 non-null float64
hbp 100 non-null float64
sh 100 non-null float64
sf 100 non-null float64
gidp 100 non-null float64
dtypes: float64(9), int64(11), object(3)
memory usage: 18.0+KB

However, using `to_string` will return a string representation of the DataFrame in tabular form, though it won’t always fit the console width:

In [109]: print(baseball.iloc[-20:, :12].to_string())

<table>

</table>
Wide DataFrames will be printed across multiple rows by default:

```
In [110]: pd.DataFrame(np.random.randn(3, 12))
Out[110]:
     0     1     2     3     4     5     6     7     8     9    10     11
0 -0.345352 1.314232 0.690579 0.995761 2.396780 0.014871 3.357427 -0.317441 ...-236269 0.896171 -0.487602 -0.082240
1 -2.182937 0.380396 0.432390 1.519970 -0.493662 0.600178 0.274230 0.132885 -0.023688 2.410179 1.450520
2  0.206053 -0.251905 -2.213588 1.063327 -0.023688 2.410179 1.450520 -0.025747 -0.988387 0.094055
```

You can change how much to print on a single row by setting the `display.width` option:

```
In [111]: pd.set_option('display.width', 40) # default is 80
In [112]: pd.DataFrame(np.random.randn(3, 12))
Out[112]:
     0     1     2     3     4     5     6     7     8     9    10     11
0 1.262731 1.289997 0.082423 -0.055758 0.536580 -0.489682 0.369374 -0.034571 ...-484478 -0.281461 0.030711 0.109121
1 1.126203 -0.977349 1.474071 -0.064034 -1.282782 0.781836 -1.071357 0.441153 ...-353925 0.583787 0.221471 -0.744471
2 0.758527 1.729689 -0.964980 -0.845696 -1.340896 1.846883 -1.328865 1.682706 ...-717693 0.888782 0.228440 0.901805
```

You can adjust the max width of the individual columns by setting `display.max_colwidth`:

```
In [113]: datafile={'filename': ['filename_01','filename_02'],
                  'path': [
                      "media/user_name/storage/folder_01/filename_01",
                      "media/user_name/storage/folder_02/filename_02"]}
In [114]: pd.set_option('display.max_colwidth',30)
In [115]: pd.DataFrame(datafile)
Out[115]:
     filename path
0  filename_01 media/user_name/storage/fo...
1  filename_02 media/user_name/storage/fo...
```

```
In [116]: pd.set_option('display.max_colwidth',100)
In [117]: pd.DataFrame(datafile)
Out[117]:
     filename path
0  filename_01 media/user_name/storage/folder_01/filename_01
1  filename_02 media/user_name/storage/folder_02/filename_02
```

You can also disable this feature via the `expand_frame_repr` option. This will print the table in one block.
8.2.15 DataFrame column attribute access and IPython completion

If a DataFrame column label is a valid Python variable name, the column can be accessed like an attribute:

```python
In [118]: df = pd.DataFrame({'foo1' : np.random.randn(5),
                         'foo2' : np.random.randn(5)})

In [119]: df
Out[119]:
   foo1   foo2
0   1.17  -0.86
1   0.52  0.31
2  -1.20  0.03
3  -1.07  0.38
4  -0.30  1.57

In [120]: df.foo1
```

The columns are also connected to the IPython completion mechanism so they can be tab-completed:

```python
In [5]: df.fo<TAB>
   df.foo1  df.foo2
```

8.3 Panel

**Warning:** In 0.20.0, Panel is deprecated and will be removed in a future version. See the section *Deprecate Panel*.

Panel is a somewhat less-used, but still important container for 3-dimensional data. The term panel data is derived from econometrics and is partially responsible for the name pandas: pan(el)-da(ta)-s. The names for the 3 axes are intended to give some semantic meaning to describing operations involving panel data and, in particular, econometric analysis of panel data. However, for the strict purposes of slicing and dicing a collection of DataFrame objects, you may find the axis names slightly arbitrary:

- **items**: axis 0, each item corresponds to a DataFrame contained inside
- **major_axis**: axis 1, it is the index (rows) of each of the DataFrames
- **minor_axis**: axis 2, it is the columns of each of the DataFrames

Construction of Panels works about like you would expect:
8.3.1 From 3D ndarray with optional axis labels

In [121]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'],
   ....:     major_axis=pd.date_range('1/1/2000', periods=5),
   ....:     minor_axis=['A', 'B', 'C', 'D'])

In [122]: wp
Out[122]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D

8.3.2 From dict of DataFrame objects

In [123]: data = {'Item1' : pd.DataFrame(np.random.randn(4, 3)),
   ....:   'Item2' : pd.DataFrame(np.random.randn(4, 2))}

In [124]: pd.Panel(data)
Out[124]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 4 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 0 to 3
Minor_axis axis: 0 to 2

Note that the values in the dict need only be convertible to DataFrame. Thus, they can be any of the other valid inputs to DataFrame as per above.

One helpful factory method is `Panel.from_dict`, which takes a dictionary of DataFrames as above, and the following named parameters:

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Default</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>intersect</td>
<td>False</td>
<td>drops elements whose indices do not align</td>
</tr>
<tr>
<td>orient</td>
<td>items</td>
<td>use minor to use DataFrames’ columns as panel items</td>
</tr>
</tbody>
</table>

For example, compare to the construction above:

In [125]: pd.Panel.from_dict(data, orient='minor')
Out[125]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 4 (major_axis) x 2 (minor_axis)
Items axis: 0 to 2
Major_axis axis: 0 to 3
Minor_axis axis: Item1 to Item2

Orient is especially useful for mixed-type DataFrames. If you pass a dict of DataFrame objects with mixed-type columns, all of the data will get upcasted to dtype=object unless you pass orient='minor':

In [126]: df = pd.DataFrame({'a': ['foo', 'bar', 'baz'],
   ......:   'b': np.random.randn(3)})
In [127]: df
Out[127]:
   a     b
0  foo -0.308853
1  bar -0.681087
2  baz  0.377953

In [128]: data = {'item1': df, 'item2': df}
In [129]: panel = pd.Panel.from_dict(data, orient='minor')
In [130]: panel['a']
Out[130]:
   item1  item2
0    foo    foo
1    bar    bar
2    baz    baz

In [131]: panel['b']
   item1  item2
0 -0.308853 -0.308853
1 -0.681087 -0.681087
2  0.377953  0.377953

In [132]: panel['b'].dtypes
   item1  float64
   item2  float64
dtype: object

Note: Panel, being less commonly used than Series and DataFrame, has been slightly neglected feature-wise. A number of methods and options available in DataFrame are not available in Panel.

### 8.3.3 From DataFrame using `to_panel` method

to_panel converts a DataFrame with a two-level index to a Panel.

In [133]: midx = pd.MultiIndex(levels=[['one', 'two'], ['x','y']], labels=[[1,1,0,0], [1,0,1,0]])
In [134]: df = pd.DataFrame({'A' : [1, 2, 3, 4], 'B': [5, 6, 7, 8]}, index=midx)
In [135]: df.to_panel()
Out[135]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 2 (major_axis) x 2 (minor_axis)
Items axis: A to B
Major_axis axis: one to two
Minor_axis axis: x to y
8.3.4 Item selection / addition / deletion

Similar to DataFrame functioning as a dict of Series, Panel is like a dict of DataFrames:

In [136]: wp['Item1']
Out[136]:
A     B     C     D
--- --- --- ----
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02  -0.014805 -0.284319  0.650776  1.461665
2000-01-03  -1.137707  0.891060  0.693921  1.613616
2000-01-04   0.464000  0.227371 -0.496922  0.306389
2000-01-05  -2.290613 -1.134623 -1.561819 -0.260838

In [137]: wp['Item3'] = wp['Item1'] / wp['Item2']

The API for insertion and deletion is the same as for DataFrame. And as with DataFrame, if the item is a valid Python identifier, you can access it as an attribute and tab-complete it in IPython.

8.3.5 Transposing

A Panel can be rearranged using its transpose method (which does not make a copy by default unless the data are heterogeneous):

In [138]: wp.transpose(2, 0, 1)
Out[138]:
<class 'pandas.core.panel.Panel'>
Dimensions: 4 (items) x 3 (major_axis) x 5 (minor_axis)
Items axis: A to D
Major_axis axis: Item1 to Item3
Minor_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00

8.3.6 Indexing / Selection

<table>
<thead>
<tr>
<th>Operation</th>
<th>Syntax</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select item</td>
<td>wp[item]</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Get slice at major_axis label</td>
<td>wp.major_xs(val)</td>
<td>DataFrame</td>
</tr>
<tr>
<td>Get slice at minor_axis label</td>
<td>wp.minor_xs(val)</td>
<td>DataFrame</td>
</tr>
</tbody>
</table>

For example, using the earlier example data, we could do:

In [139]: wp['Item1']
Out[139]:
A     B     C     D
--- --- --- ----
2000-01-01  1.588931  0.476720  0.473424 -0.242861
2000-01-02  -0.014805 -0.284319  0.650776  1.461665
2000-01-03  -1.137707  0.891060  0.693921  1.613616
2000-01-04   0.464000  0.227371 -0.496922  0.306389
2000-01-05  -2.290613 -1.134623 -1.561819 -0.260838

In [140]: wp.major_xs(wp.major_axis[2])

(continues on next page)
A -1.137707 0.800193 -1.421791
B -0.891060 0.782098 -1.139320
C -0.693921 -1.069094 0.649074
D 1.613616 -1.099248 -1.467927

In [141]: wp.minor_axis
Index(['A', 'B', 'C', 'D'], dtype='object')

In [142]: wp.minor_xs('C')

     Item1   Item2   Item3
2000-01-01  0.473424 -0.902937 -0.524316
2000-01-02  0.650776 -1.144073 -0.568824
2000-01-03 -0.693921 -1.069094  0.649074
2000-01-04 -0.496922  0.661084 -0.751678
2000-01-05 -1.561819 -1.056652  1.478083

8.3.7 Squeezing

Another way to change the dimensionality of an object is to **squeeze** a 1-len object, similar to `wp['Item1']`.

In [143]: wp.reindex(items=['Item1']).squeeze()
Out[143]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>1.588931</td>
<td>0.476720</td>
<td>0.473424</td>
<td>-0.242861</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.014805</td>
<td>-0.284319</td>
<td>0.650776</td>
<td>-1.461665</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-1.137707</td>
<td>-0.891060</td>
<td>-0.693921</td>
<td>1.613616</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.464000</td>
<td>0.227371</td>
<td>-0.496922</td>
<td>0.306389</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-2.290613</td>
<td>-1.134623</td>
<td>-1.561819</td>
<td>-0.260838</td>
</tr>
</tbody>
</table>

In [144]: wp.reindex(items=['Item1'], minor=['B']).squeeze()

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>0.476720</td>
<td></td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.284319</td>
<td></td>
</tr>
<tr>
<td>2000-01-03</td>
<td>-0.891060</td>
<td></td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.227371</td>
<td></td>
</tr>
<tr>
<td>2000-01-05</td>
<td>-1.134623</td>
<td></td>
</tr>
</tbody>
</table>
Freq: D, Name: B, dtype: float64

8.3.8 Conversion to DataFrame

A Panel can be represented in 2D form as a hierarchically indexed DataFrame. See the section **hierarchical indexing** for more on this. To convert a Panel to a DataFrame, use the `to_frame` method:

In [145]: panel = pd.Panel(np.random.randn(3, 5, 4), items=['one', 'two', 'three'],
                      major_axis=pd.date_range('1/1/2000', periods=5),
                      minor_axis=['a', 'b', 'c', 'd'])

In [146]: panel.to_frame()
8.4 Deprecate Panel

Over the last few years, pandas has increased in both breadth and depth, with new features, datatype support, and manipulation routines. As a result, supporting efficient indexing and functional routines for Series, DataFrame and Panel has contributed to an increasingly fragmented and difficult-to-understand codebase.

The 3-D structure of a Panel is much less common for many types of data analysis, than the 1-D of the Series or the 2-D of the DataFrame. Going forward it makes sense for pandas to focus on these areas exclusively.

Oftentimes, one can simply use a MultiIndex DataFrame for easily working with higher dimensional data.

In addition, the xarray package was built from the ground up, specifically in order to support the multi-dimensional analysis that is one of Panel’s main usecases. Here is a link to the xarray panel-transition documentation.

```
In [147]: p = tm.makePanel()
In [148]: p
Out[148]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 30 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-02-11 00:00:00
Minor_axis axis: A to D

Convert to a MultiIndex DataFrame.
```

```
In [149]: p.to_frame()
Out[149]:
     ItemA   ItemB    ItemC
major minor
2000-01-03 A         -0.390201 -1.624062 -0.605044
```

(continues on next page)
### Example Data Table

```
<table>
<thead>
<tr>
<th>Date</th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-04</td>

</tr>
</tbody>
</table>
```

(continues on next page)
Alternatively, one can convert to an `xarray` DataArray.

```python
In [150]: p.to_xarray()
Out[150]:
<xarray.DataArray (items: 3, major_axis: 30, minor_axis: 4)>
array([[-0.390201, 1.562443, -1.085663, 0.136235],
       [ 1.207122, 0.763264, -1.114738, 0.886313],
       [ 1.592673, -0.571329, 1.998044, 0.303638],
       [ 1.559318, -0.026671, -0.244548, -0.917368],
       [-1.624062, 0.483103, 0.768159, -0.021763],
       [-0.758514, 0.061495, 0.225441, -0.047152],
       [ 2.137827, -1.761442, 0.292058, 0.388254],
       [ 0.452429, -0.899454, -2.019610, 0.479630],
       [-0.605044, 0.583129, -0.273458, -0.700648],
       [ 0.878404, -0.876690, -0.335117, -1.166607],
       [-0.828784, -0.826439, -0.500569, 0.303638],
       [-1.716981, 0.124808, 0.931536, 0.870690]],

Coordinates:
* items   (items) object 'ItemA' 'ItemB' 'ItemC'
* major_axis (major_axis) datetime64[ns] 2000-01-03 2000-01-04 2000-01-05 ...
* minor_axis (minor_axis) object 'A' 'B' 'C' 'D'
```

You can see the full-documentation for the `xarray` package.

8.4. Deprecate Panel
Here we discuss a lot of the essential functionality common to the pandas data structures. Here’s how to create some of the objects used in the examples from the previous section:

```python
In [1]: index = pd.date_range('1/1/2000', periods=8)
In [2]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [3]: df = pd.DataFrame(np.random.randn(8, 3), index=index, columns=['A', 'B', 'C'])
In [4]: wp = pd.Panel(np.random.randn(2, 5, 4), items=['Item1', 'Item2'], major_axis=pd.date_range('1/1/2000', periods=5), minor_axis=['A', 'B', 'C', 'D'])
```

### 9.1 Head and Tail

To view a small sample of a Series or DataFrame object, use the `head()` and `tail()` methods. The default number of elements to display is five, but you may pass a custom number.

```python
In [5]: long_series = pd.Series(np.random.randn(1000))
In [6]: long_series.head()
Out[6]:
0 0.229453
1 0.304418
2 0.736135
3 -0.859631
4 -0.424100
dtype: float64
In [7]: long_series.tail(3)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[7]:
˓→
997 -0.351587
998 1.136249
999 -0.448789
dtype: float64
```
9.2 Attributes and the raw ndarray(s)

pandas objects have a number of attributes enabling you to access the metadata

- **shape**: gives the axis dimensions of the object, consistent with ndarray

- Axis labels
  - **Series**: *index* (only axis)
  - **DataFrame**: *index* (rows) and *columns*
  - **Panel**: *items*, *major_axis*, and *minor_axis*

Note, these attributes can be safely assigned to!

To get the actual data inside a data structure, one need only access the **values** property:

(continues on next page)
If a DataFrame or Panel contains homogeneously-typed data, the ndarray can actually be modified in-place, and the changes will be reflected in the data structure. For heterogeneous data (e.g. some of the DataFrame’s columns are not all the same dtypes), this will not be the case. The values attribute itself, unlike the axis labels, cannot be assigned to.

**Note:** When working with heterogeneous data, the dtype of the resulting ndarray will be chosen to accommodate all of the data involved. For example, if strings are involved, the result will be of object dtype. If there are only floats and integers, the resulting array will be of float dtype.

### 9.3 Accelerated operations

pandas has support for accelerating certain types of binary numerical and boolean operations using the **numexpr** library and the **bottleneck** libraries.

These libraries are especially useful when dealing with large data sets, and provide large speedups. **numexpr** uses smart chunking, caching, and multiple cores. **bottleneck** is a set of specialized cython routines that are especially fast when dealing with arrays that have **nans**.

Here is a sample (using 100 column x 100,000 row DataFrames):

<table>
<thead>
<tr>
<th>Operation</th>
<th>0.11.0 (ms)</th>
<th>Prior Version (ms)</th>
<th>Ratio to Prior</th>
</tr>
</thead>
<tbody>
<tr>
<td>df1 &gt; df2</td>
<td>13.32</td>
<td>125.35</td>
<td>0.1063</td>
</tr>
<tr>
<td>df1 * df2</td>
<td>21.71</td>
<td>36.63</td>
<td>0.5928</td>
</tr>
<tr>
<td>df1 + df2</td>
<td>22.04</td>
<td>36.50</td>
<td>0.6039</td>
</tr>
</tbody>
</table>

You are highly encouraged to install both libraries. See the section **Recommended Dependencies** for more installation info.

These are both enabled to be used by default, you can control this by setting the options:

New in version 0.20.0.

```python
pd.set_option('compute.use_bottleneck', False)
pd.set_option('compute.use_numexpr', False)
```

### 9.4 Flexible binary operations

With binary operations between pandas data structures, there are two key points of interest:

- Broadcasting behavior between higher- (e.g. DataFrame) and lower-dimensional (e.g. Series) objects.
- Missing data in computations.

We will demonstrate how to manage these issues independently, though they can be handled simultaneously.
9.4.1 Matching / broadcasting behavior

DataFrame has the methods `add()`, `sub()`, `mul()`, `div()` and related functions `radd()`, `rsub()`, ... for carrying out binary operations. For broadcasting behavior, Series input is of primary interest. Using these functions, you can use to either match on the `index` or `columns` via the `axis` keyword:

```python
In [14]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c', 'd']),
                        'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
                        'three' : pd.Series(np.random.randn(3), index=['b', 'c', 'd']))

In [15]: df
Out[15]:
   one   two   three
a -1.1015  1.1245  NaN
b -0.1773  2.4871 -0.6343
c  0.4622 -0.4861  1.9312
d  NaN   -0.4563 -1.2229

In [16]: row = df.iloc[1]
In [17]: column = df['two']
In [18]: df.sub(row, axis='columns')
Out[18]:
   one   two   three
a -0.9243 -1.3626  NaN
b  0.0000  0.0000  0.0000
c  0.6395 -2.9731  2.5655
d  NaN   -2.9434 -0.5886
In [19]: df.sub(row, axis=1)
   one   two   three
→ a -2.2260  0.0   NaN
→ b -2.6644 -3.1214  NaN
→ c  0.9483  2.4172  2.4172
→ d  NaN  -0.7666 -0.7666
In [20]: df.sub(column, axis='index')
   one   two   three
→ a -2.2260  0.0   NaN
→ b -2.6644 -3.1214  NaN
→ c  0.9483  2.4172  2.4172
→ d  NaN  -0.7666 -0.7666
In [21]: df.sub(column, axis=0)
   one   two   three
→ a -2.2260  0.0   NaN
→ b -2.6644 -3.1214  NaN
(continues on next page)
Furthermore you can align a level of a multi-indexed DataFrame with a Series.

```python
In [22]: dfmi = df.copy()
In [23]: dfmi.index = pd.MultiIndex.from_tuples([(1,'a'),(1,'b'),(1,'c'),(2,'a')],
                                            names=['first','second'])
In [24]: dfmi.sub(column, axis=0, level='second')
```

```
Out[24]:
           one   two   three
first second
  1   a  -2.226031  0.00000   NaN
    b  -2.664393  0.00000 -3.121397
    c   0.948280  0.00000  2.417260
  2   a   NaN   -1.58076 -2.347391
```

With Panel, describing the matching behavior is a bit more difficult, so the arithmetic methods instead (and perhaps confusingly?) give you the option to specify the broadcast axis. For example, suppose we wished to demean the data over a particular axis. This can be accomplished by taking the mean over an axis and broadcasting over the same axis:

```python
In [25]: major_mean = wp.mean(axis='major')
In [26]: major_mean
Out[26]:
     Item1     Item2
A -0.878036 -0.092218
B -0.060128  0.529811
C  0.099453 -0.715139
D  0.248599 -0.186535
In [27]: wp.sub(major_mean, axis='major')
```

```
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to D
```

And similarly for axis="items" and axis="minor".

**Note:** I could be convinced to make the axis argument in the DataFrame methods match the broadcasting behavior of Panel. Though it would require a transition period so users can change their code...

Series and Index also support the `divmod()` builtin. This function takes the floor division and modulo operation at the same time returning a two-tuple of the same type as the left hand side. For example:

```python
In [28]: s = pd.Series(np.arange(10))
In [29]: s
Out[29]:
```

(continues on next page)
In [30]: div, rem = divmod(s, 3)

In [31]: div
Out[31]:
\[\begin{array}{l}
0 \\
1 \\
2 \\
3 \\
4 \\
5 \\
6 \\
7 \\
8 \\
9 \\
\end{array} \]
dtype: int64

In [32]: rem
\[\begin{array}{l}
0 \\
1 \\
2 \\
3 \\
4 \\
5 \\
6 \\
7 \\
8 \\
9 \\
\end{array} \]
dtype: int64

In [33]: idx = pd.Index(np.arange(10))

In [34]: idx
Out[34]: Int64Index([0, 1, 2, 3, 4, 5, 6, 7, 8, 9], dtype='int64')

In [35]: div, rem = divmod(idx, 3)

In [36]: div
Out[36]: Int64Index([0, 0, 0, 1, 1, 1, 2, 2, 2, 3], dtype='int64')

In [37]: rem
\[\begin{array}{l}
0 \\
1 \\
2 \\
3 \\
4 \\
5 \\
6 \\
7 \\
8 \\
9 \\
\end{array} \]
dtype: int64
We can also do elementwise \texttt{divmod}()::

\begin{verbatim}
In [38]: div, rem = divmod(s, [2, 2, 3, 4, 4, 5, 6, 6])

In [39]: div
Out[39]:
0 0
1 0
2 0
3 1
4 1
5 1
6 1
7 1
8 1
9 1
dtype: int64

In [40]: rem
Out[40]:
0 0
1 1
2 2
3 0
4 0
5 1
6 1
7 2
8 2
9 3
dtype: int64
\end{verbatim}

\subsection*{9.4.2 Missing data / operations with fill values}

In Series and DataFrame, the arithmetic functions have the option of inputting a \textit{fill_value}, namely a value to substitute when at most one of the values at a location are missing. For example, when adding two DataFrame objects, you may wish to treat NaN as 0 unless both DataFrames are missing that value, in which case the result will be NaN (you can later replace NaN with some other value using \texttt{fillna} if you wish).

\begin{verbatim}
In [41]: df
Out[41]:
   one   two   three
a -1.101558  1.124472  NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d  NaN   -0.456288 -1.222918

In [42]: df2
Out[42]:
   one   two   three
a -1.101558  1.124472  1.000000
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d  NaN   -0.456288 -1.222918
\end{verbatim}

(continues on next page)
9.4.3 Flexible Comparisons

Series and DataFrame have the binary comparison methods `eq`, `ne`, `lt`, `gt`, `le`, and `ge` whose behavior is analogous to the binary arithmetic operations described above:

```python
In [45]: df.gt(df2)
Out[45]:
     one  two  three
a  False False False
b  False False False
c  False False False
d  False False False
```

```python
In [46]: df2.ne(df)
Out[46]:
     one  two  three
a  False False  True
b  False False False
c  False False False
d  True  False False
```

These operations produce a pandas object of the same type as the left-hand-side input that is of dtype `bool`. These boolean objects can be used in indexing operations, see the section on `Boolean indexing`.

9.4.4 Boolean Reductions

You can apply the reductions: `empty`, `any()`, `all()`, and `bool()` to provide a way to summarize a boolean result.

```python
In [47]: (df > 0).all()
Out[47]:
     one  two  three
a  False False False
b  False False False
c  False False False
d  False False False
```

(continues on next page)
You can reduce to a final boolean value.

```python
In [49]: (df > 0).any().any()
Out[49]: True
```

You can test if a pandas object is empty, via the `empty` property.

```python
In [50]: df.empty
Out[50]: False
```

```python
In [51]: pd.DataFrame(columns=list('ABC')).empty
Out[51]: True
```

To evaluate single-element pandas objects in a boolean context, use the method `bool()`:

```python
In [52]: pd.Series([True]).bool()
Out[52]: True
```

```python
In [53]: pd.Series([False]).bool()
Out[53]: False
```

```python
In [54]: pd.DataFrame([[True]]).bool()
Out[54]: True
```

```python
In [55]: pd.DataFrame([[False]]).bool()
Out[55]: False
```

**Warning:** You might be tempted to do the following:

```python
>>> if df:
    ...
```

Or

```python
>>> df and df2
```

These will both raise errors, as you are trying to compare multiple values.

```
ValueError: The truth value of an array is ambiguous. Use a.empty, a.any() or a.
˓→all().
```

See `gotchas` for a more detailed discussion.
9.4.5 Comparing if objects are equivalent

Often you may find that there is more than one way to compute the same result. As a simple example, consider `df+df` and `df*2`. To test that these two computations produce the same result, given the tools shown above, you might imagine using `(df+df == df*2).all()`. But in fact, this expression is False:

```
In [56]: df+df == df*2
Out[56]:
   one  two  three
  a  True  True  False
  b  True  True  True
  c  True  True  True
  d  False  True  True

In [57]: (df+df == df*2).all()
   one   False
two   True
three  False
dtype: bool
```

Notice that the boolean DataFrame `df+df == df*2` contains some False values! This is because NaNs do not compare as equals:

```
In [58]: np.nan == np.nan
Out[58]: False
```

So, NDFrames (such as Series, DataFrames, and Panels) have an `equals()` method for testing equality, with NaNs in corresponding locations treated as equal.

```
In [59]: (df+df).equals(df*2)
Out[59]: True
```

Note that the Series or DataFrame index needs to be in the same order for equality to be True:

```
In [60]: df1 = pd.DataFrame({'col':['foo', 0, np.nan]})
In [61]: df2 = pd.DataFrame({'col':[np.nan, 0, 'foo']}, index=[2,1,0])
In [62]: df1.equals(df2)
Out[62]: False
In [63]: df1.equals(df2.sort_index())
Out[63]: True
```

9.4.6 Comparing array-like objects

You can conveniently perform element-wise comparisons when comparing a pandas data structure with a scalar value:

```
In [64]: pd.Series(['foo', 'bar', 'baz']) == 'foo'
Out[64]:
0   True
1  False
2  False
dtype: bool
```

(continues on next page)
In [65]: pd.Index(['foo', 'bar', 'baz']) == 'foo'
Out[65]: array([ True, False, False], dtype=bool)

Pandas also handles element-wise comparisons between different array-like objects of the same length:

In [66]: pd.Series(['foo', 'bar', 'baz']) == pd.Index(['foo', 'bar', 'qux'])
Out[66]:
0    True
1    True
2    False
dtype: bool

In [67]: pd.Series(['foo', 'bar', 'baz']) == np.array(['foo', 'bar', 'qux'])
Out[67]:
0    True
1    True
2    False
dtype: bool

Trying to compare Index or Series objects of different lengths will raise a ValueError:

In [55]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo', 'bar'])
ValueError: Series lengths must match to compare

In [56]: pd.Series(['foo', 'bar', 'baz']) == pd.Series(['foo'])
ValueError: Series lengths must match to compare

Note that this is different from the NumPy behavior where a comparison can be broadcast:

In [68]: np.array([1, 2, 3]) == np.array([2])
Out[68]:
array([False, True, False], dtype=bool)

or it can return False if broadcasting can not be done:

In [69]: np.array([1, 2, 3]) == np.array([1, 2])
Out[69]: False

### 9.4.7 Combining overlapping data sets

A problem occasionally arising is the combination of two similar data sets where values in one are preferred over the other. An example would be two data series representing a particular economic indicator where one is considered to be of “higher quality”. However, the lower quality series might extend further back in history or have more complete data coverage. As such, we would like to combine two DataFrame objects where missing values in one DataFrame are conditionally filled with like-labeled values from the other DataFrame. The function implementing this operation is `combine_first()`, which we illustrate:

In [70]: df1 = pd.DataFrame({'A': [1., np.nan, 3., 5., np.nan],
                      'B': [np.nan, 2., 3., np.nan, 6.]})

In [71]: df2 = pd.DataFrame({'A': [5., 2., 4., np.nan, 3., 7.],
                      'B': [np.nan, np.nan, 3., 4., 6., 8.]})

9.4.8 General DataFrame Combine

The `combine_first()` method above calls the more general `DataFrame.combine()` method. This method takes another DataFrame and a combiner function, aligns the input DataFrame and then passes the combiner function pairs of Series (i.e., columns whose names are the same).

So, for instance, to reproduce `combine_first()` as above:

```python
In [75]: combiner = lambda x, y: np.where(pd.isna(x), y, x)

In [76]: df1.combine(df2, combiner)
```

```
Out[76]:
   A  B
0  1.0 NaN
1  2.0  2.0
2  3.0  3.0
3  5.0  4.0
4  3.0  6.0
5  7.0  8.0
```
9.5 Descriptive statistics

There exists a large number of methods for computing descriptive statistics and other related operations on Series, DataFrame, and Panel. Most of these are aggregations (hence producing a lower-dimensional result) like sum(), mean(), and quantile(), but some of them, like cumsum() and cumprod(), produce an object of the same size. Generally speaking, these methods take an axis argument, just like ndarray.{sum, std, ...}, but the axis can be specified by name or integer:

- **Series**: no axis argument needed
- **DataFrame**: “index” (axis=0, default), “columns” (axis=1)
- **Panel**: “items” (axis=0), “major” (axis=1, default), “minor” (axis=2)

For example:

```
In [77]: df
Out[77]:
   one    two    three
a -1.101558  1.124472  NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d   NaN    0.456288 -1.222918

In [78]: df.mean(0)
→
   one     two     three
   0.272211  0.667306  0.024661
dtype: float64
```

All such methods have a skipna option signaling whether to exclude missing data (True by default):

```
In [80]: df.sum(0, skipna=False)
Out[80]:
   one     NaN     two     2.669223     three     NaN
dtype: float64
```

```
In [81]: df.sum(axis=1, skipna=True)
→
   a     0.022914     b     1.675522     c     1.907343     d   -1.679206
dtype: float64
```
Combined with the broadcasting / arithmetic behavior, one can describe various statistical procedures, like standardization (rendering data zero mean and standard deviation 1), very concisely:

```python
In [82]: ts_stand = (df - df.mean()) / df.std()
In [83]: ts_stand.std()
Out[83]:
        one  two  three
   a   1.0  1.0   NaN
   b   1.0  1.0 -0.634293
   c -0.816633  3.125511  1.296901
   d   NaN  2.669223  0.073983
```

Note that methods like `cumsum()` and `cumprod()` preserve the location of NaN values. This is somewhat different from `expanding()` and `rolling()`. For more details please see this note.

Here is a quick reference summary table of common functions. Each also takes an optional `level` parameter which applies only if the object has a hierarchical index.
# Descriptive statistics

There is a convenient `describe()` function which computes a variety of summary statistics about a Series or the columns of a DataFrame (excluding NAs of course):

```python
In [93]: series = pd.Series(np.random.randn(1000))
In [94]: series[::2] = np.nan
In [95]: series.describe()
Out[95]:
         count       sum         mean       mad  
barometer 399.5  -1.679400   -0.000917  1.5473
season    399.5  -2.048900   -0.001617  1.5473

       min       max     mode     abs  
barometer       nan  1.299400       nan  2.7580
season          nan  1.299400       nan  2.7580

       prod       std          var  
barometer  4.22e-05  1.547300  2.3918e-03
season      nan  1.547300  2.3918e-03

       sem     skew        kurt  
barometer  0.00000   0.00000   0.00000
season      nan   0.00000   0.00000

       quantile  
barometer  1.299400  
season          nan  
```

Note that by chance some NumPy methods, like `mean`, `std`, and `sum`, will exclude NAs on Series input by default:

```python
In [87]: np.mean(df['one'])
Out[87]: -0.27221094480450114

In [88]: np.mean(df['one'].values)
Out[88]: nan
```

`Series.nunique()` will return the number of unique non-NA values in a Series:

```python
In [89]: series = pd.Series(np.random.randn(500))
In [90]: series[20:500] = np.nan
In [91]: series[10:20] = 5
In [92]: series.nunique()
Out[92]: 11
```
You can select specific percentiles to include in the output:

```python
In [99]: series.describe(percentiles=[.05, .25, .75, .95])
```
```
Out[99]:
   count   a     b     c     d     e
count 500.000000 500.000000 500.000000 500.000000 500.000000
mean -0.045109 -0.052045 0.024520 0.006117 0.001141
std  1.029268  1.002320  1.042793  1.040134  1.005207
min -2.915767 -3.294023 -3.610499 -2.907036 -3.010899
25%  1.735455  1.735455  1.735455  1.735455  1.735455
50% -0.086033 -0.048843  0.006093  0.043191 -0.001651
75%  1.042793  1.042793  1.042793  1.042793  1.042793
max  3.400646  2.925597  3.416896  3.331522  3.007143
dtype: float64
```

By default, the median is always included.

For a non-numerical Series object, `describe()` will give a simple summary of the number of unique values and most frequently occurring values:

```python
In [100]: s = pd.Series(['a', 'a', 'b', 'b', 'a', 'a', np.nan, 'c', 'd', 'a'])

In [101]: s.describe()
```
```
Out[101]:
   count     9
  unique     4
     top     a
      freq     5
dtype: object
```
Note that on a mixed-type DataFrame object, `describe()` will restrict the summary to include only numerical columns or, if none are, only categorical columns:

```python
In [102]: frame = pd.DataFrame({'a': ['Yes', 'Yes', 'No', 'No'], 'b': range(4)})

In [103]: frame.describe()
Out[103]:

   b
count 4.000000
mean 1.500000
std  1.290994
min  0.000000
25%  0.750000
50%  1.500000
75%  2.250000
max  3.000000
```

This behaviour can be controlled by providing a list of types as `include/exclude` arguments. The special value `all` can also be used:

```python
In [104]: frame.describe(include=['object'])
Out[104]:

   a
count 4
unique 2
top   Yes
freq  2

In [105]: frame.describe(include=['number'])

   b
count 4.000000
mean 1.500000
std  1.290994
min  0.000000
25%  0.750000
50%  1.500000
75%  2.250000
max  3.000000

In [106]: frame.describe(include='all')

   →   a   b
count 4  4.000000
unique 2  NaN
top   Yes  NaN
freq  2  NaN
mean  NaN  1.500000
std   NaN  1.290994
min   NaN  0.000000
25%   NaN  0.750000
50%   NaN  1.500000
75%   NaN  2.250000
max   NaN  3.000000
```

That feature relies on `select_dtypes`. Refer to there for details about accepted inputs.
9.5.2 Index of Min/Max Values

The `idxmin()` and `idxmax()` functions on Series and DataFrame compute the index labels with the minimum and maximum corresponding values:

```python
In [107]: s1 = pd.Series(np.random.randn(5))

In [108]: s1
Out[108]:
0  -1.649461
1   0.169660
2   1.246181
3   0.131682
4  -2.001988
dtype: float64

In [109]: s1.idxmin(), s1.idxmax()
Out[109]: (4, 2)

In [110]: df1 = pd.DataFrame(np.random.randn(5,3), columns=['A','B','C'])

In [111]: df1
Out[111]:
   A   B   C
0 -1.273023 0.870502 0.214583
1  0.088452 -0.173364 1.207466
2  0.546121 0.409515 -0.310515
3  0.585014 -0.490528 -0.054639
4 -0.239226 0.701089 0.228656

In [112]: df1.idxmin(axis=0)
Out[112]:
   A  B  C
0  0  3  2

dtype: int64

In [113]: df1.idxmax(axis=1)
Out[113]:
   0  1  2  3  4
A B C A B
dtype: object
```

When there are multiple rows (or columns) matching the minimum or maximum value, `idxmin()` and `idxmax()` return the first matching index:

```python
In [114]: df3 = pd.DataFrame([2, 1, 1, 3, np.nan], columns=['A'], index=list('edcba'))

In [115]: df3
Out[115]:
   A
e  2.0
```

(continues on next page)
In [116]: df3['A'].idxmin()
Out[116]: 'd'

Note: idxmin and idxmax are called argmin and argmax in NumPy.

9.5.3 Value counts (histogramming) / Mode

The value_counts() Series method and top-level function computes a histogram of a 1D array of values. It can also be used as a function on regular arrays:

In [117]: data = np.random.randint(0, 7, size=50)
In [118]: data
Out[118]: array([3, 3, 0, 2, 1, 0, 5, 5, 3, 6, 1, 5, 6, 2, 0, 0, 6, 3, 3, 5, 0, 4, 3, 3, 0, 6, 1, 3, 5, 5, 0, 4, 0, 6, 3, 6, 5, 4, 3, 2, 1, 5, 0, 1, 1, 6, 4, 1, 4])
In [119]: s = pd.Series(data)
In [120]: s.value_counts()
Out[120]:
3    11
0     9
5     8
6     7
1     7
4     5
2     3
dtype: int64
In [121]: pd.value_counts(data)
Out[121]:
3    11
0     9
5     8
6     7
1     7
4     5
2     3
dtype: int64

Similarly, you can get the most frequently occurring value(s) (the mode) of the values in a Series or DataFrame:

In [122]: s5 = pd.Series([1, 1, 3, 3, 3, 5, 5, 7, 7, 7])
In [123]: s5.mode()
### 9.5.4 Discretization and quantiling

Continuous values can be discretized using the `cut()` (bins based on values) and `qcut()` (bins based on sample quantiles) functions:

```python
In [126]: arr = np.random.randn(20)

In [127]: factor = pd.cut(arr, 4)

Out[128]:
[(-2.611, -1.58], (-2.611, -1.58], (-2.611, -1.58], (-1.58, -0.554], ...
Length: 20
Categories (4, interval[float64]): [(-2.611, -1.58] < (-1.58, -0.554] < (-0.554, 0.473) < (0.473, 1.499])

In [129]: factor = pd.cut(arr, [-5, -1, 0, 1, 5])

Out[130]:
[(-5, -1], (0, 1], (-5, -1], (-1, 0], (-1, 0], ..., (1, 5], (1, 5], (-1, 0], (-1, 0], ...
Length: 20
Categories (4, interval[int64]): [(-5, -1] < (-1, 0] < (0, 1] < (1, 5])
```

`qcut()` computes sample quantiles. For example, we could slice up some normally distributed data into equal-size quartiles like so:

```python
In [131]: arr = np.random.randn(30)

In [132]: factor = pd.qcut(arr, [0, .25, .5, .75, 1])

In [133]: factor
```

```python
Out[133]:
[(0.544, 1.976], (0.544, 1.976], (-1.255, -0.375], (0.544, 1.976], (-0.103, 0.544], ...
Length: 30
Categories (4, interval[float64]): [(0.544, 1.976] < (-1.255, -0.375] < (0.544, 1.976] < (-0.103, 0.544] < (-1.255, -0.375)]
```
9.6 Function application

To apply your own or another library’s functions to pandas objects, you should be aware of the three methods below. The appropriate method to use depends on whether your function expects to operate on an entire DataFrame or Series, row- or column-wise, or elementwise.

1. **Tablewise Function Application**: `pipe()`
2. **Row or Column-wise Function Application**: `apply()`
3. **Aggregation API**: `agg()` and `transform()`
4. **Applying Elementwise Functions**: `applymap()`

### 9.6.1 Tablewise Function Application

DataFrames and Series can of course just be passed into functions. However, if the function needs to be called in a chain, consider using the `pipe()` method. Compare the following

```python
# f, g, and h are functions taking and returning `DataFrames`
>>> f(g(h(df), arg1=1), arg2=2, arg3=3)
```

with the equivalent

```python
>>> (df.pipe(h)
    .pipe(g, arg1=1)
    .pipe(f, arg2=2, arg3=3))
```
Pandas encourages the second style, which is known as method chaining. pipe makes it easy to use your own or another library’s functions in method chains, alongside pandas’ methods.

In the example above, the functions f, g, and h each expected the DataFrame as the first positional argument. What if the function you wish to apply takes its data as, say, the second argument? In this case, provide pipe with a tuple of (callable, data_keyword). pipe will route the DataFrame to the argument specified in the tuple.

For example, we can fit a regression using statsmodels. Their API expects a formula first and a DataFrame as the second argument, data. We pass in the function, keyword pair (sm.ols, 'data') to pipe:

```python
In [138]: import statsmodels.formula.api as sm
In [139]: bb = pd.read_csv('data/baseball.csv', index_col='id')
In [140]: (bb.query('h > 0')
....:     .assign(ln_h = lambda df: np.log(df.h))
....:     .pipe((sm.ols, 'data'), 'hr ~ ln_h + year + g + C(lg)')
....:     .fit()
....:     .summary()
....: )
```

```
OLS Regression Results

================================================================================================
OmniBus:              10.875     Durbin-Watson:   1.999
Prob(OmniBus):          0.004     Jarque-Bera (JB): 17.298
Skew:                    0.537     Prob(JB):        0.000175
Kurtosis:                5.225     Cond. No.            1.49e+07
```

The pipe method is inspired by unix pipes and more recently dplyr and magrittr, which have introduced the popular (%>%)(read pipe) operator for R. The implementation of pipe here is quite clean and feels right at home in python.
We encourage you to view the source code of `pipe()`.

### 9.6.2 Row or Column-wise Function Application

Arbitrary functions can be applied along the axes of a DataFrame using the `apply()` method, which, like the descriptive statistics methods, takes an optional `axis` argument:

```python
In [141]: df.apply(np.mean)
Out[141]:
one  -0.272211
two   0.667306
three  0.024661
dtype: float64

In [142]: df.apply(np.mean, axis=1)
Out[142]:
   →
a  0.011457
b  0.558507
c  0.635781
d -0.839603
dtype: float64

In [143]: df.apply(lambda x: x.max() - x.min())
Out[143]:
   →
one   1.563773
two   2.973170
three  3.154112
dtype: float64

In [144]: df.apply(np.cumsum)
Out[144]:
   →
one  two  three
a -1.101558 1.124472 NaN
b -1.278848 3.611576 -0.634293
c -0.816633 3.125511 1.296901
d  NaN  2.669223  0.073983

In [145]: df.apply(np.exp)
Out[145]:
   →
one  two  three
a  0.332353 3.078592 NaN
b  0.837537 12.026397 0.53031
   c  1.587586 0.615041 6.89774
   d  NaN  0.633631 0.29437
```

The `apply()` method will also dispatch on a string method name.

```python
In [146]: df.apply('mean')
Out[146]:
one  -0.272211
two   0.667306
three  0.024661
dtype: float64
```

(continues on next page)
In [147]: df.apply('mean', axis=1)
Out[147]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.011457</td>
<td>b</td>
<td>0.558507</td>
</tr>
<tr>
<td>c</td>
<td>0.635781</td>
<td>d</td>
<td>-0.839603</td>
</tr>
<tr>
<td>dtype: float64</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The return type of the function passed to apply() affects the type of the final output from DataFrame.apply for the default behaviour:

- If the applied function returns a Series, the final output is a DataFrame. The columns match the index of the Series returned by the applied function.
- If the applied function returns any other type, the final output is a Series.

This default behaviour can be overridden using the result_type, which accepts three options: reduce, broadcast, and expand. These will determine how list-likes return values expand (or not) to a DataFrame.

apply() combined with some cleverness can be used to answer many questions about a data set. For example, suppose we wanted to extract the date where the maximum value for each column occurred:

In [148]: tsdf = pd.DataFrame(np.random.randn(1000, 3), columns=['A', 'B', 'C'],
                       index=pd.date_range('1/1/2000', periods=1000))

In [149]: tsdf.apply(lambda x: x.idxmax())
Out[149]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>2001-04-25</td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>2002-05-31</td>
<td></td>
</tr>
<tr>
<td>C</td>
<td>2002-09-25</td>
<td></td>
</tr>
<tr>
<td>dtype: datetime64[ns]</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

You may also pass additional arguments and keyword arguments to the apply() method. For instance, consider the following function you would like to apply:

```python
def subtract_and_divide(x, sub, divide=1):
    return (x - sub) / divide
```

You may then apply this function as follows:

df.apply(subtract_and_divide, args=(5,), divide=3)

Another useful feature is the ability to pass Series methods to carry out some Series operation on each column or row:

In [150]: tsdf
Out[150]:

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.720299</td>
<td>B</td>
</tr>
<tr>
<td>C</td>
<td>0.546303</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-01</td>
<td>-0.720299</td>
<td>0.546303</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>0.200295</td>
<td>-0.577554</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>0.102533</td>
<td>1.653614</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>
Finally, `apply()` takes an argument `raw` which is False by default, which converts each row or column into a Series before applying the function. When set to True, the passed function will instead receive an ndarray object, which has positive performance implications if you do not need the indexing functionality.

### 9.6.3 Aggregation API

New in version 0.20.0.

The aggregation API allows one to express possibly multiple aggregation operations in a single concise way. This API is similar across pandas objects, see [groupby API](#), the [window functions API](#), and the [resample API](#). The entry point for aggregation is `DataFrame.aggregate()`, or the alias `DataFrame.agg()`.

We will use a similar starting frame from above:

```python
In [152]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
                        index=pd.date_range('1/1/2000', periods=10))
In [153]: tsdf.iloc[3:7] = np.nan
In [154]: tsdf
```

```
Out[154]:
          A         B         C
2000-01-01 0.170247 -0.916844  0.835024
2000-01-02 1.259919  0.801111  0.445614
2000-01-03 1.453046  2.430373  0.653093
2000-01-04  NaN       NaN       NaN
2000-01-05  NaN       NaN       NaN
2000-01-06  NaN       NaN       NaN
2000-01-07  NaN       NaN       NaN
2000-01-08 -1.874526  0.569822 -0.609644
2000-01-09 0.812462  0.565894 -1.461363
2000-01-10 -0.985475  1.388154 -0.087847
```

Using a single function is equivalent to `apply()`. You can also pass named methods as strings. These will return a Series of the aggregated output:

```python
In [155]: tsdf.apply(pd.Series.interpolate)
```

```
Out[155]:
          A         B         C
2000-01-01 0.512072  0.565321  0.850145
2000-01-02 0.498242  0.539226  0.557223
2000-01-03 0.484413  0.512674  0.467482
2000-01-04 0.470584  0.486127  0.377802
2000-01-05 0.456754  0.459576  0.288122
2000-01-06 0.442925  0.432497  0.198443
2000-01-07 0.429095  0.405419  0.108764
2000-01-08 0.415265  0.378341  0.019085
2000-01-09 0.401435  0.351313 -0.099306
2000-01-10 0.387605  0.324289 -0.209536
```

```
In [155]: tsdf.agg(np.sum)
Out[155]:
A  0.835673
B  4.838510
C -0.216025
dtype: float64

In [156]: tsdf.agg('sum')
Out[156]:
A  0.835673
B  4.838510
C -0.216025
dtype: float64

# these are equivalent to a `.sum()` because we are aggregating on a single function
In [157]: tsdf.sum()

˓→
A  0.835673
B  4.838510
C -0.216025
dtype: float64

Single aggregations on a Series this will return a scalar value:

In [158]: tsdf.A.agg('sum')
Out[158]: 0.83567297915820504

9.6.3.1 Aggregating with multiple functions

You can pass multiple aggregation arguments as a list. The results of each of the passed functions will be a row in the resulting DataFrame. These are naturally named from the aggregation function.

In [159]: tsdf.agg(['sum'])
Out[159]:
A B C
sum 0.835673 4.83851 -0.216025

Multiple functions yield multiple rows:

In [160]: tsdf.agg(['sum', 'mean'])
Out[160]:
A B C
sum 0.835673 4.838510 -0.216025
mean 0.139279 0.806418 -0.036004

On a Series, multiple functions return a Series, indexed by the function names:

In [161]: tsdf.A.agg(['sum', 'mean'])
Out[161]:
sum 0.835673
mean 0.139279
Name: A, dtype: float64

Passing a lambda function will yield a <lambda> named row:
In [162]: tsdf.A.agg({'sum', lambda x: x.mean()})
Out[162]:
   sum 0.835673
<lambda> 0.139279
Name: A, dtype: float64

Passing a named function will yield that name for the row:

In [163]: def mymean(x):
       ....:     return x.mean()
       ....:
In [164]: tsdf.A.agg({'sum', mymean})
Out[164]:
   sum 0.835673
   mymean 0.139279
Name: A, dtype: float64

9.6.3.2 Aggregating with a dict

Passing a dictionary of column names to a scalar or a list of scalars, to `DataFrame.agg` allows you to customize which functions are applied to which columns. Note that the results are not in any particular order, you can use an OrderedDict instead to guarantee ordering.

In [165]: tsdf.agg({'A': 'mean', 'B': 'sum'})
Out[165]:
A 0.139279
B 4.838510
dtype: float64

Passing a list-like will generate a DataFrame output. You will get a matrix-like output of all of the aggregators. The output will consist of all unique functions. Those that are not noted for a particular column will be NaN:

In [166]: tsdf.agg({'A': ['mean', 'min'], 'B': 'sum'})
Out[166]:
     A   B
mean 0.139279 NaN
min -1.874526 NaN
sum NaN  4.83851

9.6.3.3 Mixed Dtypes

When presented with mixed dtypes that cannot aggregate, `.agg` will only take the valid aggregations. This is similar to how groupby `.agg` works.

In [167]: mdf = pd.DataFrame({'A': [1, 2, 3],
       ....:     'B': [1., 2., 3.],
       ....:     'C': ['foo', 'bar', 'baz'],
       ....:     'D': pd.date_range('20130101', periods=3))
In [168]: mdf.dtypes
Out[168]:
A    int64
B    float64
C    object
D    datetime64[ns]
(continues on next page)
9.6.3.4 Custom describe

With `.agg()` is it possible to easily create a custom describe function, similar to the built in `describe function`.

```python
In [170]: from functools import partial

In [171]: q_25 = partial(pd.Series.quantile, q=0.25)

In [172]: q_25.__name__ = '25%'

In [173]: q_75 = partial(pd.Series.quantile, q=0.75)

In [174]: q_75.__name__ = '75%'

In [175]: tsdf.agg(['count', 'mean', 'std', 'min', q_25, 'median', q_75, 'max'])

Out[175]:
    A     B            C
count 6.000000 6.000000 6.000000
mean 0.139279 0.806418 -0.036004
std 1.323362 1.100830 0.874990
min -1.874526 -0.916844 -1.461363
25% -0.696544 0.566876 -0.476920
median 0.491354 0.685467 0.183433
75% 1.148055 1.241393 0.601223
max 1.453046 2.430373 0.835024
```

9.6.4 Transform API

New in version 0.20.0.

The `transform()` method returns an object that is indexed the same (same size) as the original. This API allows you to provide multiple operations at the same time rather than one-by-one. Its API is quite similar to the `.agg` API.

We create a frame similar to the one used in the above sections.

```python
In [176]: tsdf = pd.DataFrame(np.random.randn(10, 3), columns=['A', 'B', 'C'],
...:                     index=pd.date_range('1/1/2000', periods=10))

In [177]: tsdf.iloc[3:7] = np.nan

In [178]: tsdf

Out[178]:
```
Transform the entire frame. `.transform()` allows input functions as: a NumPy function, a string function name or a user defined function.

```
In [179]: tsdf.transform(np.abs)
```

```
Out[179]:

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>

</tbody>
</table>
```

```
In [180]: tsdf.transform('abs')
```

```
→

```
In [181]: tsdf.transform(lambda x: x.abs())
```

```
→
```

(continues on next page)
Here `transform()` received a single function; this is equivalent to a ufunc application.

```
In [182]: np.abs(tsdf)
Out[182]:
     A     B     C
2000-01-01 0.578465 0.503335 0.987140
2000-01-02 0.767147 0.266046 1.083797
2000-01-03 0.195348 0.722247 0.894537
2000-01-04 NaN    NaN    NaN
2000-01-05 NaN    NaN    NaN
2000-01-06 NaN    NaN    NaN
2000-01-07 NaN    NaN    NaN
2000-01-08 0.556397 0.542165 0.308675
2000-01-09 1.010924 0.672504 1.139222
2000-01-10 0.354653 0.563622 0.365106
```

Passing a single function to `.transform()` with a `Series` will yield a single `Series` in return.

```
In [183]: tsdf.A.transform(np.abs)
Out[183]:
     2000-01-01 0.578465
     2000-01-02 0.767147
     2000-01-03 0.195348
     2000-01-04 NaN
     2000-01-05 NaN
     2000-01-06 NaN
     2000-01-07 NaN
     2000-01-08 0.556397
     2000-01-09 1.010924
     2000-01-10 0.354653
Freq: D, Name: A, dtype: float64
```

### 9.6.4.1 Transform with multiple functions

Passing multiple functions will yield a column multi-indexed DataFrame. The first level will be the original frame column names; the second level will be the names of the transforming functions.

```
In [184]: tsdf.transform([np.abs, lambda x: x+1])
Out[184]:
           A            B            C
        absolute  <lambda>    absolute  <lambda>    absolute  <lambda>
2000-01-01 0.578465  0.421535  0.503335  0.496665  0.987140  0.012860
2000-01-02 0.767147  0.232853  0.266046  0.733954  1.083797  2.083797
2000-01-03 0.195348  1.195348  0.722247  1.722247  0.894537  0.105463
2000-01-04 NaN    NaN    NaN    NaN    NaN    NaN
2000-01-05 NaN    NaN    NaN    NaN    NaN    NaN
2000-01-06 NaN    NaN    NaN    NaN    NaN    NaN
2000-01-07 NaN    NaN    NaN    NaN    NaN    NaN
2000-01-08 0.556397  0.542165  0.308675  0.542165  0.308675  0.691325
2000-01-09 1.010924  0.327496  1.139222  0.327496  1.139222  0.691325
2000-01-10 0.354653  1.354653  0.365106  1.354653  0.365106  0.634894
```

610 Chapter 9. Essential Basic Functionality
Passing multiple functions to a Series will yield a DataFrame. The resulting column names will be the transforming functions.

```python
In [185]: tsdf.A.transform([np.abs, lambda x: x+1])
Out[185]:
           absolute     <lambda>
2000-01-01  0.578465   0.421535
2000-01-02  0.767147   0.232853
2000-01-03  0.195348   1.195348
2000-01-04   NaN        NaN
2000-01-05   NaN        NaN
2000-01-06   NaN        NaN
2000-01-07   NaN        NaN
2000-01-08  0.556397   0.443603
2000-01-09  1.010924  -0.010924
2000-01-10  0.354653   1.354653
```

### 9.6.4.2 Transforming with a dict

Passing a dict of functions will allow selective transforming per column.

```python
In [186]: tsdf.transform({'A': np.abs, 'B': lambda x: x+1})
Out[186]:
    A     B
2000-01-01 0.578465 0.496665
2000-01-02 0.767147 0.733954
2000-01-03 0.195348 1.722247
2000-01-04  NaN   NaN
2000-01-05  NaN   NaN
2000-01-06  NaN   NaN
2000-01-07  NaN   NaN
2000-01-08 0.556397 1.542165
2000-01-09 1.010924 0.327496
2000-01-10 0.354653 1.563622
```

Passing a dict of lists will generate a multi-indexed DataFrame with these selective transforms.

```python
In [187]: tsdf.transform({'A': np.abs, 'B': [lambda x: x+1, 'sqrt']})
Out[187]:
           absolute        sqrt
2000-01-01  0.578465   0.496665   NaN
2000-01-02  0.767147   0.733954   NaN
2000-01-03  0.195348   1.722247  0.849851
2000-01-04   NaN        NaN        NaN
2000-01-05   NaN        NaN        NaN
2000-01-06   NaN        NaN        NaN
2000-01-07   NaN        NaN        NaN
2000-01-08  0.556397   1.542165  0.736318
2000-01-09  1.010924   0.327496   NaN
2000-01-10  0.354653   1.563622  0.750748
```

### 9.6.5 Applying Elementwise Functions

Since not all functions can be vectorized (accept NumPy arrays and return another array or value), the methods `applymap()` on DataFrame and analogously `map()` on Series accept any Python function taking a single value and...
returning a single value. For example:

```
In [188]: df4
Out[188]:
   one  two  three
  a -1.101558  1.124472   NaN
  b -0.177289  2.487104 -0.634293
  c  0.462215 -0.486066  1.931194
  d   NaN   -0.456288 -1.222918

In [189]: f = lambda x: len(str(x))
In [190]: df4['one'].map(f)
Out[190]:
   a    19
   b    20
   c    18
   d     3
Name: one, dtype: int64

In [191]: df4.applymap(f)
Out[191]:
   one  two  three
  a    19   18    3
  b    20   18   19
  c    18   20   18
  d     3   19   19

Series.map() has an additional feature; it can be used to easily “link” or “map” values defined by a secondary series. This is closely related to merging/joining functionality:

```
In [192]: s = pd.Series(['six', 'seven', 'six', 'seven', 'six'],
   index=['a', 'b', 'c', 'd', 'e'])
   ....:
In [193]: t = pd.Series({'six' : 6., 'seven' : 7.})
In [194]: s
Out[194]:
   a   six
   b  seven
   c   six
   d  seven
   e   six
dtype: object

In [195]: s.map(t)
Out[195]:
   a    6.0
   b    7.0
   c    6.0
   d    7.0
   e    6.0
dtype: float64
```
9.6.6 Applying with a Panel

Applying with a Panel will pass a Series to the applied function. If the applied function returns a Series, the result of the application will be a Panel. If the applied function reduces to a scalar, the result of the application will be a DataFrame.

```
In [196]: import pandas.util.testing as tm

In [197]: panel = tm.makePanel(5)

In [198]: panel
Out[198]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [199]: panel['ItemA']

A transformational apply.

In [200]: result = panel.apply(
   ...:     lambda x: x*2, axis='items')

In [201]: result
Out[201]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D

In [202]: result['ItemA']

A reduction operation.

In [203]: panel.apply(
   ...:     lambda x: x.dtype, axis='items')
Out[203]:
```

(continues on next page)
A similar reduction type operation.

```
In [204]: panel.apply(lambda x: x.sum(), axis='major_axis')
Out[204]:
    ItemA  ItemB  ItemC
A  1.841893  0.918017 -1.160547
B  3.488158 -2.629773  0.603397
C -3.164692  0.805970  0.806501
D  0.653349 -0.152299  0.252577
```

This last reduction is equivalent to:

```
In [205]: panel.sum('major_axis')
Out[205]:
    ItemA  ItemB  ItemC
A  1.841893  0.918017 -1.160547
B  3.488158 -2.629773  0.603397
C -3.164692  0.805970  0.806501
D  0.653349 -0.152299  0.252577
```

A transformation operation that returns a Panel, but is computing the z-score across the major_axis.

```
In [206]: result = panel.apply(lambda x: (x-x.mean())/x.std(), axis='major_axis')
```

```
In [207]: result
Out[207]: <class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 5 (major_axis) x 4 (minor_axis)
Items axis: ItemA to ItemC
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: A to D
```

```
In [208]: result['ItemA']
```

```
ItemA  0.585813 -1.496089  1.142642 -0.323445  0.091079
```

Apply can also accept multiple axes in the axis argument. This will pass a DataFrame of the cross-section to the applied function.

```
In [209]: f = lambda x: ((x.T-x.mean(1))/x.std(1)).T

In [210]: result = panel.apply(f, axis = ['items','major_axis'])
In [211]: result
```

(continues on next page)
Out[211]:
<pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
</pandas.core.panel.Panel'>
In [212]: result.loc[:,:,'ItemA']

This is equivalent to the following:

In [213]: result = pd.Panel(dict([ (ax, f(panel.loc[:,:ax])
.....: for ax in panel.minor_axis ]))
In [214]: result
Out[214]:
<pandas.core.panel.Panel'>
Dimensions: 4 (items) x 5 (major_axis) x 3 (minor_axis)
Items axis: A to D
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-07 00:00:00
Minor_axis axis: ItemA to ItemC
</pandas.core.panel.Panel'>
In [215]: result.loc[:,:,'ItemA']

9.7 Reindexing and altering labels

reindex() is the fundamental data alignment method in pandas. It is used to implement nearly all other features relying on label-alignment functionality. To reindex means to conform the data to match a given set of labels along a particular axis. This accomplishes several things:

- Reorders the existing data to match a new set of labels
- Inserts missing value (NA) markers in label locations where no data for that label existed
- If specified, fill data for missing labels using logic (highly relevant to working with time series data)

Here is a simple example:
Here, the \( f \) label was not contained in the Series and hence appears as \( \text{NaN} \) in the result.

With a DataFrame, you can simultaneously reindex the index and columns:

```python
In [219]: df
Out[219]:
     one   two   three
a -1.10156  1.12447  NaN
b -0.17729  2.48710  -0.63429
 0.462215 -0.486066  1.931194
d  NaN -0.456288  -1.222918

In [220]: df.reindex(index=['c', 'f', 'b'], columns=['three', 'two', 'one'])
```

```
→ three   two   one
  c  1.931194 -0.486066  0.462215
  f   NaN       NaN      NaN
  b -0.634293  2.487104  -0.177292
```

You may also use `reindex` with an `axis` keyword:

```python
In [221]: df.reindex(['c', 'f', 'b'], axis='index')
```

```
→ one   two   three
  c  0.462215 -0.486066  1.931194
  f   NaN       NaN      NaN
  b -0.177292  2.487104  -0.634293
```

Note that the Index objects containing the actual axis labels can be shared between objects. So if we have a Series and a DataFrame, the following can be done:

```python
In [222]: rs = s.reindex(df.index)
```

```
In [223]: rs
Out[223]:
     a   b
  0.454087 -0.360309
```

(continues on next page)
This means that the reindexed Series’s index is the same Python object as the DataFrame’s index.

New in version 0.21.0.

`DataFrame.reindex()` also supports an “axis-style” calling convention, where you specify a single `labels` argument and the `axis` it applies to.

```python
In [225]: df.reindex(['c', 'f', 'b'], axis='index')
Out[225]:
   one two three
  c  0.462215 -0.486066  1.931194
  f   NaN       NaN       NaN
  b -0.177289  2.487104 -0.634293
```

```python
In [226]: df.reindex(['three', 'two', 'one'], axis='columns')
```

See also:

MultiIndex / Advanced Indexing is an even more concise way of doing reindexing.

Note: When writing performance-sensitive code, there is a good reason to spend some time becoming a reindexing ninja: many operations are faster on pre-aligned data. Adding two unaligned DataFrames internally triggers a reindexing step. For exploratory analysis you will hardly notice the difference (because `reindex` has been heavily optimized), but when CPU cycles matter sprinkling a few explicit `reindex` calls here and there can have an impact.

9.7.1 Reindexing to align with another object

You may wish to take an object and reindex its axes to be labeled the same as another object. While the syntax for this is straightforward albeit verbose, it is a common enough operation that the `reindex_like()` method is available to make this simpler:

```python
In [227]: df
Out[227]:
   one two
  a  1.124472 -1.101558
  b -0.177289  2.487104
  c  0.462215 -0.486066
  d -1.222918 -0.456288
```

```python
In [228]: df3
```

(continues on next page)
9.7.2 Aligning objects with each other with `align`

The `align()` method is the fastest way to simultaneously align two objects. It supports a `join` argument (related to joining and merging):

- `join='outer'`: take the union of the indexes (default)
- `join='left'`: use the calling object's index
- `join='right'`: use the passed object’s index
- `join='inner'`: intersect the indexes

It returns a tuple with both of the reindexed Series:

```python
In [230]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [231]: s1 = s[:4]
In [232]: s2 = s[1:]
In [233]: s1.align(s2)
Out[233]:
(a 0.505453
 b 1.788110
c -0.405908
d -0.801912
e NaN
dtype: float64, a NaN
 b 1.788110
c -0.405908
d -0.801912
e 0.768460
dtype: float64)

In [234]: s1.align(s2, join='inner')
```

(continues on next page)
c  -0.405908
d  -0.801912
dtype: float64)

In [235]: s1.align(s2, join='left')

→
(a  0.505453
b  1.788110
c -0.405908
d -0.801912
dtype: float64, a NaN
b  1.788110
c -0.405908
d -0.801912
dtype: float64)

For DataFrames, the join method will be applied to both the index and the columns by default:

In [236]: df.align(df2, join='inner')

Out[236]:
(one  two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215  -0.486066, one  two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215  -0.486066)

You can also pass an axis option to only align on the specified axis:

In [237]: df.align(df2, join='inner', axis=0)

Out[237]:
(one  two  three
a -1.101558  1.124472  NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194, one  two
a -1.101558  1.124472
b -0.177289  2.487104
c  0.462215 -0.486066)

If you pass a Series to DataFrame.align(), you can choose to align both objects either on the DataFrame's index or columns using the axis argument:

In [238]: df.align(df2.iloc[0], axis=1)

Out[238]:
(one  three  two
a -1.101558  NaN  1.124472
b -0.177289 -0.634293  2.487104
c  0.462215  1.931194 -0.486066, one  two
 Name: a, dtype: float64)

9.7. Reindexing and altering labels
9.7.3 Filling while reindexing

`reindex()` takes an optional parameter `method` which is a filling method chosen from the following table:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
<tr>
<td>nearest</td>
<td>Fill from the nearest index value</td>
</tr>
</tbody>
</table>

We illustrate these fill methods on a simple Series:

```python
In [239]: rng = pd.date_range('1/3/2000', periods=8)
In [240]: ts = pd.Series(np.random.randn(8), index=rng)
In [241]: ts2 = ts[[0, 3, 6]]
In [242]: ts
Out[242]:
          2000-01-03    0.466284
          2000-01-04    0.457411
          2000-01-05   -0.364060
          2000-01-06    0.785367
          2000-01-07   -1.463093
          2000-01-08    1.187315
          2000-01-09   -0.493153
          2000-01-10   -1.323445
Freq: D, dtype: float64
```

```python
In [243]: ts2
Out[243]:
2000-01-03  0.466284
2000-01-06  0.785367
2000-01-09 -0.493153
dtype: float64
```

```python
In [244]: ts2.reindex(ts.index)
Out[244]:
          2000-01-03    0.466284
          2000-01-04   NaN
          2000-01-05   NaN
          2000-01-06    0.785367
          2000-01-07   NaN
          2000-01-08   NaN
          2000-01-09   NaN
          2000-01-10   NaN
Freq: D, dtype: float64
```

```python
In [245]: ts2.reindex(ts.index, method='ffill')
Out[245]:
          2000-01-03    0.466284
          2000-01-04    0.466284
          2000-01-05    0.466284
          2000-01-06    0.785367
(continues on next page)
```
These methods require that the indexes are ordered increasing or decreasing.

Note that the same result could have been achieved using **fillna** (except for method='nearest') or **interpolate**:  

<table>
<thead>
<tr>
<th>Date</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-03</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-09</td>
<td>0.466284</td>
</tr>
<tr>
<td>2000-01-10</td>
<td>0.466284</td>
</tr>
</tbody>
</table>

**reindex()** will raise a ValueError if the index is not monotonically increasing or decreasing. **fillna()** and **interpolate()** will not perform any checks on the order of the index.

### 9.7.4 Limits on filling while reindexing

The limit and tolerance arguments provide additional control over filling while reindexing. Limit specifies the maximum count of consecutive matches:
In [249]: ts2.reindex(ts.index, method='ffill', limit=1)
Out[249]:
2000-01-03  0.466284
2000-01-04  0.466284
2000-01-05  NaN
2000-01-06  0.785367
2000-01-07  0.785367
2000-01-08  NaN
2000-01-09  -0.493153
2000-01-10  -0.493153
Freq: D, dtype: float64

In contrast, tolerance specifies the maximum distance between the index and indexer values:

In [250]: ts2.reindex(ts.index, method='ffill', tolerance='1 day')
Out[250]:
2000-01-03  0.466284
2000-01-04  0.466284
2000-01-05  NaN
2000-01-06  0.785367
2000-01-07  0.785367
2000-01-08  NaN
2000-01-09  -0.493153
2000-01-10  -0.493153
Freq: D, dtype: float64

Notice that when used on a DatetimeIndex, TimedeltaIndex or PeriodIndex, tolerance will coerced into a Timedelta if possible. This allows you to specify tolerance with appropriate strings.

9.7.5 Dropping labels from an axis

A method closely related to reindex is the drop() function. It removes a set of labels from an axis:

In [251]: df
Out[251]:
   one    two    three
a -1.101558  1.124472  NaN
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
d  NaN -0.456288 -1.222918

In [252]: df.drop(['a', 'd'], axis=0)
   one    two    three
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194

In [253]: df.drop(['one'], axis=1)
   two    three
a  1.124472  NaN
b  2.487104 -0.634293
c -0.486066  1.931194
d -0.456288 -1.222918
Note that the following also works, but is a bit less obvious / clean:

```
In [254]: df.reindex(df.index.difference(['a', 'd']))
Out[254]:
    one  two  three
b -0.177289  2.487104 -0.634293
c  0.462215 -0.486066  1.931194
```

### 9.7.6 Renaming / mapping labels

The `rename()` method allows you to relabel an axis based on some mapping (a dict or Series) or an arbitrary function.

```
In [255]: s
Out[255]:
a  0.505453
b  1.788110
c -0.405908
d -0.801912
e  0.768460
dtype: float64

In [256]: s.rename(str.upper)
Out[256]:
    A   0.505453
    B   1.788110
    C  -0.405908
    D  -0.801912
    E   0.768460
dtype: float64
```

If you pass a function, it must return a value when called with any of the labels (and must produce a set of unique values). A dict or Series can also be used:

```
In [257]: df.rename(columns={'one': 'foo', 'two': 'bar'},
                   index={'a': 'apple', 'b': 'banana', 'd': 'durian'})
Out[257]:
       foo  bar  three
apple -1.101558 1.124472  NaN
banana -0.177289 2.487104 -0.634293
c  0.462215 -0.486066  1.931194
durian  NaN  -0.456288 -1.222918
```

If the mapping doesn’t include a column/index label, it isn’t renamed. Note that extra labels in the mapping don’t throw an error.

New in version 0.21.0.

`DataFrame.rename()` also supports an “axis-style” calling convention, where you specify a single mapper and the axis to apply that mapping to.

```
In [258]: df.rename({'one': 'foo', 'two': 'bar'}, axis='columns')
Out[258]:
       foo  bar  three
a  -1.101558 1.124472  NaN
b -0.177289  2.487104 -0.634293
```

(continues on next page)
In [259]: df.rename({'a': 'apple', 'b': 'banana', 'd': 'durian'}, axis='index')

                one  two  three
apple -1.101558  1.124472  NaN
banana -0.177289  2.487104 -0.634293
c    0.462215 -0.486066  1.931194
durian NaN -0.456288 -1.222918

The rename() method also provides an inplace named parameter that is by default False and copies the underlying data. Pass inplace=True to rename the data in place.

New in version 0.18.0.

Finally, rename() also accepts a scalar or list-like for altering the Series.name attribute.

In [260]: s.rename("scalar-name")

Out[260]:
   a    0.505453
   b    1.788110
   c   -0.405908
   d   -0.801912
   e    0.768460
Name: scalar-name, dtype: float64

The Panel class has a related rename_axis() class which can rename any of its three axes.

9.8 Iteration

The behavior of basic iteration over pandas objects depends on the type. When iterating over a Series, it is regarded as array-like, and basic iteration produces the values. Other data structures, like DataFrame and Panel, follow the dict-like convention of iterating over the “keys” of the objects.

In short, basic iteration (for i in object) produces:

- **Series**: values
- **DataFrame**: column labels
- **Panel**: item labels

Thus, for example, iterating over a DataFrame gives you the column names:

In [261]: df = pd.DataFrame({'col1' : np.random.randn(3), 'col2' : np.random.randn(3)})

In [262]: for col in df:
    ......:    print(col)
    ......:  col1
    ......:  col2
Pandas objects also have the dict-like `iteritems()` method to iterate over the (key, value) pairs.

To iterate over the rows of a DataFrame, you can use the following methods:

- `iterrows()`: Iterate over the rows of a DataFrame as (index, Series) pairs. This converts the rows to Series objects, which can change the dtypes and has some performance implications.
- `itertuples()`: Iterate over the rows of a DataFrame as namedtuples of the values. This is a lot faster than `iterrows()`, and is in most cases preferable to use to iterate over the values of a DataFrame.

**Warning:** Iterating through pandas objects is generally slow. In many cases, iterating manually over the rows is not needed and can be avoided with one of the following approaches:

- Look for a vectorized solution: many operations can be performed using built-in methods or NumPy functions, (boolean) indexing,...
- When you have a function that cannot work on the full DataFrame/Series at once, it is better to use `apply()` instead of iterating over the values. See the docs on `function application`.
- If you need to do iterative manipulations on the values but performance is important, consider writing the inner loop with cython or numba. See the `enhancing performance` section for some examples of this approach.

**Warning:** You should never modify something you are iterating over. This is not guaranteed to work in all cases. Depending on the data types, the iterator returns a copy and not a view, and writing to it will have no effect!

For example, in the following case setting the value has no effect:

```python
In [263]: df = pd.DataFrame({'a': [1, 2, 3], 'b': ['a', 'b', 'c']})
In [264]: for index, row in df.iterrows():
    ....:     row['a'] = 10
    ....:
In [265]: df
Out[265]:
   a   b
0  1   a
1  2   b
2  3   c
```

### 9.8.1 `iteritems`

Consistent with the dict-like interface, `iteritems()` iterates through key-value pairs:

- **Series**: (index, scalar value) pairs
- **DataFrame**: (column, Series) pairs
- **Panel**: (item, DataFrame) pairs

For example:

```python
In [266]: for item, frame in wp.iteritems():
    ....:     print(item)
    ....:     print(frame)
    ....:
```
Item1

</tr>
</tbody>
</table>

9.8.2 iterrows

`iterrows()` allows you to iterate through the rows of a DataFrame as Series objects. It returns an iterator yielding each index value along with a Series containing the data in each row:

```
In [267]: for row_index, row in df.iterrows():
   .....:     print('%s
       %s' % (row_index, row))
   .....:
0    a 1
   b a
Name: 0, dtype: object
1    a 2
   b b
Name: 1, dtype: object
2    a 3
   b c
Name: 2, dtype: object
```

**Note:** Because `iterrows()` returns a Series for each row, it does **not** preserve dtypes across the rows (dtypes are preserved across columns for DataFrames). For example,

```
In [268]: df_orig = pd.DataFrame([[1, 1.5]], columns=['int', 'float'])

In [269]: df_orig.dtypes
Out[269]:
int     int64
float  float64
dtype: object

In [270]: row = next(df_orig.iterrows())[1]

In [271]: row
Out[271]:
int     1.0
float   1.5
Name: 0, dtype: float64
```
All values in `row`, returned as a Series, are now upcasted to floats, also the original integer value in column `x`:

```
In [272]: row['int'].dtype
Out[272]: dtype('float64')
```

```
In [273]: df_orig['int'].dtype
Out[273]: dtype('int64')
```

To preserve dtypes while iterating over the rows, it is better to use `itertuples()` which returns namedtuples of the values and which is generally much faster than `iterrows()`.

For instance, a contrived way to transpose the DataFrame would be:

```
In [274]: df2 = pd.DataFrame({'x': [1, 2, 3], 'y': [4, 5, 6]})
In [275]: print(df2)
x y
0 1 4
1 2 5
2 3 6
In [276]: print(df2.T)
 x  y
0 1 4
1 2 5
2 3 6
In [277]: df2_t = pd.DataFrame(dict((idx,values) for idx, values in df2.iterrows()))
In [278]: print(df2_t)
   0   1   2
   x   y
0 1 2 4
1 2 5 5
2 3 6 6
```

**9.8.3 itertuples**

The `itertuples()` method will return an iterator yielding a namedtuple for each row in the DataFrame. The first element of the tuple will be the row’s corresponding index value, while the remaining values are the row values.

For instance:

```
In [279]: for row in df.itertuples():
   ....:     print(row)
   ....:
Pandas(Index=0, a=1, b='a')
Pandas(Index=1, a=2, b='b')
Pandas(Index=2, a=3, b='c')
```

This method does not convert the row to a Series object; it merely returns the values inside a namedtuple. Therefore, `itertuples()` preserves the data type of the values and is generally faster as `iterrows()`.

**Note:** The column names will be renamed to positional names if they are invalid Python identifiers, repeated, or start with an underscore. With a large number of columns (>255), regular tuples are returned.
9.9 .dt accessor

Series has an accessor to succinctly return datetime like properties for the values of the Series, if it is a date-
time/period like Series. This will return a Series, indexed like the existing Series.

```
# datetime
In [280]: s = pd.Series(pd.date_range('20130101 09:10:12', periods=4))

In [281]: s
Out[281]:
0 2013-01-01 09:10:12
1 2013-01-02 09:10:12
2 2013-01-03 09:10:12
3 2013-01-04 09:10:12
dtype: datetime64[ns]

In [282]: s.dt.hour
Out[282]:
0 9
1 9
2 9
3 9
dtype: int64

In [283]: s.dt.second
Out[283]:
0 12
1 12
2 12
3 12
dtype: int64

In [284]: s.dt.day
Out[284]:
0 1
1 2
2 3
3 4
dtype: int64
```

This enables nice expressions like this:

```
In [285]: s[s.dt.day==2]
Out[285]:
1 2013-01-02 09:10:12
dtype: datetime64[ns]
```

You can easily produces tz aware transformations:

```
In [286]: stz = s.dt.tz_localize('US/Eastern')

In [287]: stz
Out[287]:
0 2013-01-01 09:10:12-05:00
```

(continues on next page)
You can also chain these types of operations:

```python
In [289]: s.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[289]:
0 2013-01-01 04:10:12-05:00
1 2013-01-02 04:10:12-05:00
2 2013-01-03 04:10:12-05:00
3 2013-01-04 04:10:12-05:00
dtype: datetime64[ns, US/Eastern]
```

You can also format datetime values as strings with `Series.dt.strftime()` which supports the same format as the standard `strftime()`.

```
# DatetimeIndex
In [290]: s = pd.Series(pd.date_range('20130101', periods=4))

In [291]: s
Out[291]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: datetime64[ns]

In [292]: s.dt.strftime('%Y/%m/%d')
     →
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

```
# PeriodIndex
In [293]: s = pd.Series(pd.period_range('20130101', periods=4))

In [294]: s
Out[294]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: object

In [295]: s.dt.strftime('%Y/%m/%d')
     →
0 2013/01/01
1 2013/01/02
2 2013/01/03
3 2013/01/04
dtype: object
```

(continues on next page)
The `.dt` accessor works for period and timedelta dtypes.

```python
# period
In [296]: s = pd.Series(pd.period_range('20130101', periods=4, freq='D'))

In [297]: s
Out[297]:
0 2013-01-01
1 2013-01-02
2 2013-01-03
3 2013-01-04
dtype: object

In [298]: s.dt.year
Out[298]:
0 2013
1 2013
2 2013
3 2013
dtype: int64

In [299]: s.dt.day
Out[299]:
0 1
1 2
2 3
3 4
dtype: int64
```

```python
# timedelta
In [300]: s = pd.Series(pd.timedelta_range('1 day 00:00:05', periods=4, freq='s'))

In [301]: s
Out[301]:
0  1 days 00:00:05
1  1 days 00:00:06
2  1 days 00:00:07
3  1 days 00:00:08
dtype: timedelta64[ns]

In [302]: s.dt.days
Out[302]:
0 1
1 1
2 1
3 1
dtype: int64
```
In [303]: s.dt.seconds

→
0  5
1  6
2  7
3  8
dtype: int64

In [304]: s.dt.components

→
   days  hours  minutes  seconds  milliseconds  microseconds  nanoseconds
0   1      0        0       5          0             0             0
1   1      0        0       6          0             0             0
2   1      0        0       7          0             0             0
3   1      0        0       8          0             0             0

Note: Series.dt will raise a TypeError if you access with a non-datetime-like values.

9.10 Vectorized string methods

Series is equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the Series’s str attribute and generally have names matching the equivalent (scalar) built-in string methods. For example:

In [305]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog
→', 'cat'])

In [306]: s.str.lower()

Out[306]:
0    a
1    b
2    c
3   aaba
4   baca
5   NaN
6    caba
7    dog
8    cat
dtype: object

Powerful pattern-matching methods are provided as well, but note that pattern-matching generally uses regular expressions by default (and in some cases always uses them).

Please see Vectorized String Methods for a complete description.
## 9.11 Sorting

Pandas supports three kinds of sorting: sorting by index labels, sorting by column values, and sorting by a combination of both.

### 9.11.1 By Index

The `Series.sort_index()` and `DataFrame.sort_index()` methods are used to sort a pandas object by its index levels.

```python
In [307]: df = pd.DataFrame({'one' : pd.Series(np.random.randn(3), index=['a', 'b', 'c', 'd']),
        'two' : pd.Series(np.random.randn(4), index=['a', 'b', 'c', 'd']),
        'three' : pd.Series(np.random.randn(3), index=['b', 'c', 'd']))

In [308]: unsorted_df = df.reindex(index=['a', 'b', 'c', 'd'],
                             columns=['three', 'two', 'one'])

In [309]: unsorted_df
Out[309]:
            three  two  one
      a  NaN   0.708543  0.036274
      b -0.540166  0.586626   NaN
      c  0.410238  1.121731  1.044630
      d -0.282532 -2.038777 -0.490032

# DataFrame
In [310]: unsorted_df.sort_index()
Out[310]:
            three  two  one
      a  NaN   0.708543  0.036274
      b -0.540166  0.586626   NaN
      c  0.410238  1.121731  1.044630
      d -0.282532 -2.038777 -0.490032

In [311]: unsorted_df.sort_index(ascending=False)
Out[311]:
            three  two  one
      d -0.540166  0.586626   NaN
      c  0.410238  1.121731  1.044630
      b -0.282532 -2.038777 -0.490032
      a  NaN   0.708543  0.036274

In [312]: unsorted_df.sort_index(axis=1)
Out[312]:
         one  three  two
      a  0.036274   NaN  0.708543
      d  NaN -0.540166  0.586626
      c  1.044630  0.410238  1.121731
```

(continues on next page)
9.11.2 By Values

The `Series.sort_values()` method is used to sort a `Series` by its values. The `DataFrame.sort_values()` method is used to sort a `DataFrame` by its column or row values. The optional `by` parameter to `DataFrame.sort_values()` may used to specify one or more columns to use to determine the sorted order.

```python
In [314]: df1 = pd.DataFrame({'one':[2,1,1,1],'two':[1,3,2,4],'three':[5,4,3,2]})
In [315]: df1.sort_values(by='two')
Out[315]:
   one two three
0   2   1    5
2   1   2    3
1   1   3    4
3   1   4    2
```

The `by` parameter can take a list of column names, e.g.:

```python
In [316]: df1[['one', 'two', 'three']].sort_values(by=['one','two'])
Out[316]:
   one two three
2   1   2    3
1   1   3    4
3   1   4    2
0   2   1    5
```

These methods have special treatment of NA values via the `na_position` argument:

```python
In [317]: s[2] = np.nan
In [318]: s.sort_values()
Out[318]:
   0  A
   3  Aaba
   1  B
   4  Baca
   6  CABA
   8  cat
   7  dog
   2  NaN
   5  NaN
dtype: object
```

(continues on next page)
9.11.3 By Indexes and Values

New in version 0.23.0.

Strings passed as the by parameter to DataFrame.sort_values() may refer to either columns or index level names.

```
# Build MultiIndex
In [320]: idx = pd.MultiIndex.from_tuples([('a', 1), ('a', 2), ('a', 2),
                                       ('b', 2), ('b', 1), ('b', 1)])

# Build DataFrame
In [321]: df_multi = pd.DataFrame({'A': np.arange(6, 0, -1)},
                               index=idx)

In [323]: df_multi
```

```
Out[323]:
           A
first second
a  1  6
  2  5
  2  4
b  2  3
  1  2
  1  1
```

Sort by ‘second’ (index) and ‘A’ (column)

```
In [324]: df_multi.sort_values(by=['second', 'A'])
```

```
Out[324]:
           A
first second
b  1  1
  1  2
a  1  6
b  2  3
a  2  4
  2  5
```
Note: If a string matches both a column name and an index level name then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

9.11.4 searchsorted

Series has the `searchsorted()` method, which works similarly to `numpy.ndarray.searchsorted()`.

```
In [325]: ser = pd.Series([1, 2, 3])
In [326]: ser.searchsorted([0, 3])
Out[326]: array([0, 2])
In [327]: ser.searchsorted([0, 4])
Out[327]: array([0, 3])
In [328]: ser.searchsorted([1, 3], side='right')
Out[328]: array([1, 3])
In [329]: ser.searchsorted([1, 3], side='left')
Out[329]: array([0, 2])
In [330]: ser = pd.Series([3, 1, 2])
In [331]: ser.searchsorted([0, 3], sorter=np.argsort(ser))
Out[331]: array([0, 2])
```

9.11.5 smallest / largest values

Series has the `nsmallest()` and `nlargest()` methods which return the smallest or largest \(n\) values. For a large Series this can be much faster than sorting the entire Series and calling `head(n)` on the result.

```
In [332]: s = pd.Series(np.random.permutation(10))
In [333]: s
Out[333]:
0     8
1     2
2     9
3     5
4     6
5     0
6     1
7     7
8     4
9     3
dtype: int64
In [334]: s.sort_values()
Out[334]:
5  0
6  1
```

(continues on next page)
1 2
3 4
5 6
7 8
9 0
dtype: int64

In [335]: s.nsmallest(3)

5 0
6 1
1 2
dtype: int64

In [336]: s.nlargest(3)

2 9
0 8
7 7
dtype: int64

DataFrame also has the nlargest and nsmallest methods.

In [337]: df = pd.DataFrame({'a': [-2, -1, 1, 10, 8, 11, -1],
                           'b': list('abdceff'),
                           'c': [1.0, 2.0, 4.0, 3.2, np.nan, 3.0, 4.0]})

In [338]: df.nlargest(3, 'a')

Out[338]:
   a  b  c
0 -2 a  1.0
1 -1 b  2.0
3 11 f  3.0

In [339]: df.nlargest(5, ['a', 'c'])

Out[339]:
   a  b  c
2 -1 d  4.0
5 11 f  3.0
3 10 c  3.2
4  8 e  NaN
0  1 d  4.0

In [340]: df.nsmallest(3, 'a')

Out[340]:
   a  b  c
0 -2 a  1.0
1 -1 b  2.0
3 10 c  3.2
In [341]: df.nsmallest(5, ['a', 'c'])

    →
  a  b  c
 0 -2  a 1.0
 2  1  d 4.0
 4  8  e  NaN
 1 -1  b 2.0
 6 -1  f 4.0

9.11.6 Sorting by a multi-index column

You must be explicit about sorting when the column is a multi-index, and fully specify all levels to by.

In [342]: df1.columns = pd.MultiIndex.from_tuples([('a','one'),('a','two'),('b','three')])

In [343]: df1.sort_values(by=('a','two'))

Out[343]:
   a  b
   one two three
0  2 1 5
1  1 2 3
2  1 3 4
3  1 4 2

9.12 Copying

The copy() method on pandas objects copies the underlying data (though not the axis indexes, since they are immutable) and returns a new object. Note that it is seldom necessary to copy objects. For example, there are only a handful of ways to alter a DataFrame in-place:

- Inserting, deleting, or modifying a column.
- Assigning to the index or columns attributes.
- For homogeneous data, directly modifying the values via the values attribute or advanced indexing.

To be clear, no pandas method has the side effect of modifying your data; almost every method returns a new object, leaving the original object untouched. If the data is modified, it is because you did so explicitly.

9.13 dtypes

The main types stored in pandas objects are float, int, bool, datetime64[ns] and datetime64[ns, tz], timedelta[ns], category and object. In addition these dtypes have item sizes, e.g. int64 and int32. See Series with TZ for more detail on datetime64[ns, tz] dtypes.

A convenient dtypes attribute for DataFrame returns a Series with the data type of each column.

In [344]: dft = pd.DataFrame(dict(A = np.random.rand(3), B = 1))

(continues on next page)
C = 'foo',
D = pd.Timestamp('20010102'),
E = pd.Series([1.0]*3).astype('float32'),
F = False,
G = pd.Series([1]*3,dtype='int8'))

In [345]: dft
Out[345]:
      A     B   C         D       E     F     G
0  0.809585  1  foo 2001-01-02  1.0  False  1
1  0.128238  1  foo 2001-01-02  1.0  False  1
2  0.775752  1  foo 2001-01-02  1.0  False  1

In [346]: dft.dtypes
Out[346]:
A    float64
B    int64
C    object
D  datetime64[ns]
E  float32
F     bool
G    int8
dtype: object

On a Series object, use the dtype attribute.

In [347]: dft['A'].dtype
Out[347]: dtype('float64')

If a pandas object contains data with multiple dtypes in a single column, the dtype of the column will be chosen to accommodate all of the data types (object is the most general).

# these ints are coerced to floats
In [348]: pd.Series([1, 2, 3, 4, 5, 6.])
Out[348]:
0     1.0
1     2.0
2     3.0
3     4.0
4     5.0
5     6.0
dtype: float64

# string data forces an 'object' dtype
In [349]: pd.Series([1, 2, 3, 6., 'foo'])
Out[349]:
0     1
1     2
2     3
3     6
4    foo
dtype: object

The number of columns of each type in a DataFrame can be found by calling get_dtype_counts().
In [350]: dft.get_dtype_counts()

Out[350]:
float64 1
float32 1
int64 1
int8 1
datetime64[ns] 1
bool 1
object 1
dtype: int64

Numeric dtypes will propagate and can coexist in DataFrames. If a dtype is passed (either directly via the dtype keyword, a passed ndarray, or a passed Series, then it will be preserved in DataFrame operations. Furthermore, different numeric dtypes will NOT be combined. The following example will give you a taste.

In [351]: df1 = pd.DataFrame(np.random.randn(8, 1), columns=['A'], dtype='float32')

In [352]: df1
Out[352]:
   A
0  0.890400
1  0.283331
2 -0.303613
3 -1.192210
4  0.065420
5  0.455918
6  2.008328
7  0.188942

In [353]: df1.dtypes
Out[353]:
A float32
dtype: object

In [354]: df2 = pd.DataFrame(dict( A = pd.Series(np.random.randn(8), dtype='float16'),
.....: B = pd.Series(np.random.randn(8)),
.....: C = pd.Series(np.array(np.random.randn(8), dtype='uint8') )))

In [355]: df2
Out[355]:
   A     B      C
0 -0.454346  0.200071  255
1 -0.916504 -0.557756  255
2  0.640625 -0.141988    0
3  2.675781 -0.174060    0
4 -0.007866  0.258626    0
5 -0.204224  0.941688    0
6 -1.000980 -1.849045    0
7 -0.402100 -0.949458    0

(continues on next page)
9.13.1 defaults

By default integer types are int64 and float types are float64, regardless of platform (32-bit or 64-bit). The following will all result in int64 dtypes.

```
In [357]: pd.DataFrame([1, 2], columns=['a']).dtypes
Out[357]:
a    int64
dtype: object

In [358]: pd.DataFrame({'a': [1, 2]}).dtypes
Out[358]:
a    int64
dtype: object

In [359]: pd.DataFrame({'a': 1}, index=list(range(2))).dtypes
Out[359]:
a    int64
dtype: object
```

Note that Numpy will choose platform-dependent types when creating arrays. The following WILL result in int32 on 32-bit platform.

```
In [360]: frame = pd.DataFrame(np.array([1, 2]))
```

9.13.2 upcasting

Types can potentially be upcasted when combined with other types, meaning they are promoted from the current type (e.g. int to float).

```
In [361]: df3 = df1.reindex_like(df2).fillna(value=0.0) + df2

In [362]: df3
Out[362]:
       A         B         C
0  0.436054  0.200071  255.0
1 -0.633173 -0.557756  255.0
2  0.337012 -0.141988   0.0
3  1.483571 -0.174060   0.0
4  0.057555  0.258626   0.0
5  0.251695  0.941688   0.0
6  1.908231 -1.849045   0.0
7 -0.213158 -0.949458   0.0

In [363]: df3.dtypes
```

(continues on next page)
The values attribute on a DataFrame return the lower-common-denominator of the dtypes, meaning the dtype that can accommodate ALL of the types in the resulting homogeneous dtyped NumPy array. This can force some upcasting:

```python
In [364]: df3.values.dtype
Out[364]: dtype('float64')
```

### 9.13.3 astype

You can use the astype() method to explicitly convert dtypes from one to another. These will by default return a copy, even if the dtype was unchanged (pass copy=False to change this behavior). In addition, they will raise an exception if the astype operation is invalid.

Upcasting is always according to the numpy rules. If two different dtypes are involved in an operation, then the more general one will be used as the result of the operation:

```python
In [365]: df3
Out[365]:
   A       B       C
0  0.436054  0.200071  255.0
1 -0.633173 -0.557756  255.0
2  0.337012 -0.141988   0.0
3  1.483571 -0.174060   0.0
4  0.057555  0.258626   0.0
5  0.251695  0.941688   0.0
6  1.908231 -1.849045   0.0
7 -0.213158 -0.949458   0.0
In [366]: df3.dtypes
Out[366]:
A float32
B float64
C float64
dtype: object
```

```
# conversion of dtypes
In [367]: df3.astype('float32').dtypes
Out[367]:
A float32
B float32
C float32
dtype: object
```

Convert a subset of columns to a specified type using astype().

```python
In [368]: dft = pd.DataFrame({'a': [1,2,3], 'b': [4,5,6], 'c': [7, 8, 9]})
In [369]: dft[['a','b']] = dft[['a','b']].astype(np.uint8)
In [370]: dft
```
New in version 0.19.0.

Convert certain columns to a specific dtype by passing a dict to `astype()`.

```
In [372]: df1 = pd.DataFrame({'a': [1, 0, 1], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [373]: df1 = df1.astype({'a': np.bool, 'c': np.float64})
```

```
In [374]: df1
```

```
0   True 4 7.0
1  False 5 8.0
2   True 6 9.0
```

```
In [375]: df1.dtypes
```

```
˓→
a   bool
b  int64
c  float64
dtype: object
```

**Note:** When trying to convert a subset of columns to a specified type using `astype()` and `loc()`, upcasting occurs. `loc()` tries to fit in what we are assigning to the current dtypes, while [] will overwrite them taking the dtype from the right hand side. Therefore the following piece of code produces the unintended result.

```
In [376]: df = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6], 'c': [7, 8, 9]})
```

```
In [377]: df.loc[:, ['a', 'b']].astype(np.uint8).dtypes
```

```
Out[377]:
a    uint8
b    uint8
dtype: object
```

```
In [378]: df.loc[:, ['a', 'b']] = df.loc[:, ['a', 'b']].astype(np.uint8)
```

```
In [379]: df.dtypes
```

```
Out[379]:
a    int64
b    int64
c    int64
```

(continues on next page)
9.13.4 object conversion

pandas offers various functions to try to force conversion of types from the object dtype to other types. In cases where the data is already of the correct type, but stored in an object array, the \texttt{DataFrame.infer_objects()} and \texttt{Series.infer_objects()} methods can be used to soft convert to the correct type.

```python
In [380]: import datetime
In [381]: df = pd.DataFrame([[1, 2], ['a', 'b'], [datetime.datetime(2016, 3, 2), datetime.datetime(2016, 3, 2)]])
In [382]: df = df.T
In [383]: df
Out[383]:
   0 1 2
0 1 a 2016-03-02 00:00:00
1 2 b 2016-03-02 00:00:00
```

Because the data was transposed the original inference stored all columns as object, which \texttt{infer_objects} will correct.

```python
In [384]: df.dtypes
Out[384]:
0  object
1  object
2  object
dtype: object
```

The following functions are available for one dimensional object arrays or scalars to perform hard conversion of objects to a specified type:

- \texttt{to_numeric()} (conversion to numeric dtypes)

```python
In [385]: m = ['1.1', 2, 3]
In [386]: pd.to_numeric(m)
Out[386]: array([ 1.1,  2. ,  3. ])
```

- \texttt{to_datetime()} (conversion to datetime objects)
In [388]: import datetime

In [389]: m = ['2016-07-09', datetime.datetime(2016, 3, 2)]

In [390]: pd.to_datetime(m)
Out[390]: DatetimeIndex(['2016-07-09', '2016-03-02'], dtype='datetime64[ns]', freq=None)

• to_timedelta() (conversion to timedelta objects)

In [391]: m = ['5us', pd.Timedelta('1day')]

In [392]: pd.to_timedelta(m)
Out[392]: TimedeltaIndex(['0 days 00:00:00.000005', '1 days 00:00:00'], dtype='timedelta64[ns]', freq=None)

To force a conversion, we can pass in an errors argument, which specifies how pandas should deal with elements that cannot be converted to desired dtype or object. By default, errors='raise', meaning that any errors encountered will be raised during the conversion process. However, if errors='coerce', these errors will be ignored and pandas will convert problematic elements to pd.NaT (for datetime and timedelta) or np.nan (for numeric). This might be useful if you are reading in data which is mostly of the desired dtype (e.g. numeric, datetime), but occasionally has non-conforming elements intermixed that you want to represent as missing:

In [393]: import datetime

In [394]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [395]: pd.to_datetime(m, errors='coerce')
Out[395]: DatetimeIndex(['NaT', '2016-03-02'], dtype='datetime64[ns]', freq=None)

In [396]: m = ['apple', 2, 3]

In [397]: pd.to_numeric(m, errors='coerce')
Out[397]: array(['apple', 2, 3], dtype=object)

In [398]: m = ['apple', pd.Timedelta('1day')]

In [399]: pd.to_timedelta(m, errors='coerce')
Out[399]: TimedeltaIndex([NaT, '1 days'], dtype='timedelta64[ns]', freq=None)

The errors parameter has a third option of errors='ignore', which will simply return the passed in data if it encounters any errors with the conversion to a desired data type:

In [400]: import datetime

In [401]: m = ['apple', datetime.datetime(2016, 3, 2)]

In [402]: pd.to_datetime(m, errors='ignore')
Out[402]: array([ 'apple', datetime.datetime(2016, 3, 2, 0, 0)], dtype=object)

In [403]: m = ['apple', 2, 3]

In [404]: pd.to_numeric(m, errors='ignore')
Out[404]: array(['apple', 2, 3], dtype=object)

In [405]: m = ['apple', pd.Timedelta('1day')]

(continues on next page)
In addition to object conversion, `to_numeric()` provides another argument `downcast`, which gives the option of downcasting the newly (or already) numeric data to a smaller dtype, which can conserve memory:

In [407]: m = ['1', 2, 3]

In [408]: pd.to_numeric(m, downcast='integer')  # smallest signed int dtype
Out[408]: array([1, 2, 3], dtype=int8)

In [409]: pd.to_numeric(m, downcast='signed')  # same as 'integer'
Out[409]: array([1, 2, 3], dtype=int8)

In [410]: pd.to_numeric(m, downcast='unsigned')  # smallest unsigned int dtype
Out[410]: array([1, 2, 3], dtype=uint8)

In [411]: pd.to_numeric(m, downcast='float')  # smallest float dtype
Out[411]: array([ 1., 2., 3.], dtype=float32)

As these methods apply only to one-dimensional arrays, lists or scalars; they cannot be used directly on multi-dimensional objects such as DataFrames. However, with `apply()`, we can “apply” the function over each column efficiently:

In [412]: import datetime

In [413]: df = pd.DataFrame([[2016-07-09, datetime.datetime(2016, 3, 2)]] * 2, dtype='O')

In [414]: df
Out[414]:
   0    1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [415]: df.apply(pd.to_datetime)
   
   0    1
0 2016-07-09 2016-03-02
1 2016-07-09 2016-03-02

In [416]: df = pd.DataFrame([[1.1, 2, 3]] * 2, dtype='O')

In [417]: df
Out[417]:
   0  1  2
0  1.1 2  3
1  1.1 2  3

In [418]: df.apply(pd.to_numeric)
   
   0  1  2
0  1.1 2  3
1  1.1 2  3
In [419]: df = pd.DataFrame([['5us', pd.Timedelta('1day')]] * 2, dtype='O')

In [420]: df
Out[420]:
   0  1
 0 5us 1 days 00:00:00
 1 5us 1 days 00:00:00

In [421]: df.apply(pd.to_timedelta)
Out[421]:
          
   0  1
 0  0  0 00:00:00.000005 1 days
 1  0  0 00:00:00.000005 1 days

9.13.5 gotchas

Performing selection operations on integer type data can easily upcast the data to floating. The dtype of the input data will be preserved in cases where nans are not introduced. See also Support for integer NA.

In [422]: dfi = df3.astype('int32')

In [423]: dfi['E'] = 1

In [424]: dfi
Out[424]:
   A  B  C  E
0 0  0 255 1
1 0  0 255 1
2 0  0  0 1
3 1  0  0 1
4 0  0  0 1
5 0  0  0 1
6 1 -1  0 1
7 0  0  0 1

In [425]: dfi.dtypes

In [426]: casted = dfi[dfi>0]

In [427]: casted
Out[427]:
   A  B  C  E
0  NaN NaN 255.0 1
1  NaN NaN 255.0 1
2  NaN NaN   NaN 1
While float dtypes are unchanged.

9.14 Selecting columns based on `dtype`

The `select_dtypes()` method implements subsetting of columns based on their `dtype`.

First, let’s create a `DataFrame` with a slew of different dtypes:
In [435]: df = pd.DataFrame({'string': list('abc'),
......:   'int64': list(range(1, 4)),
......:   'uint8': np.arange(3, 6).astype('u1'),
......:   'float64': np.arange(4.0, 7.0),
......:   'bool1': [True, False, True],
......:   'bool2': [False, True, False],
......:   'dates': pd.date_range('now', periods=3).values,
......:   'category': pd.Series(list('ABC')).astype('category')})

In [436]: df['tdeltas'] = df.dates.diff()

In [437]: df['uint64'] = np.arange(3, 6).astype('u8')

In [438]: df['other_dates'] = pd.date_range('20130101', periods=3).values

In [439]: df['tz_aware_dates'] = pd.date_range('20130101', periods=3, tz='US/Eastern')

In [440]: df

Out[440]:
<table>
<thead>
<tr>
<th>0</th>
<th>a</th>
<th>1</th>
<th>3</th>
<th>4.0</th>
<th>True</th>
<th></th>
<th>A</th>
<th>NaT</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>b</td>
<td>2</td>
<td>4</td>
<td>5.0</td>
<td>False</td>
<td></td>
<td>B</td>
<td>1 days</td>
</tr>
<tr>
<td>2</td>
<td>c</td>
<td>3</td>
<td>5</td>
<td>6.0</td>
<td>True</td>
<td></td>
<td>C</td>
<td>1 days</td>
</tr>
<tr>
<td>3</td>
<td>d</td>
<td>4</td>
<td>6</td>
<td>7.0</td>
<td>True</td>
<td></td>
<td>D</td>
<td>1 days</td>
</tr>
</tbody>
</table>

[3 rows x 12 columns]

And the dtypes:

In [441]: df.dtypes

Out[441]:
<table>
<thead>
<tr>
<th>0</th>
<th>string</th>
<th>object</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>int64</td>
<td>int64</td>
</tr>
<tr>
<td>2</td>
<td>uint8</td>
<td>uint8</td>
</tr>
<tr>
<td>3</td>
<td>float64</td>
<td>float64</td>
</tr>
<tr>
<td>4</td>
<td>bool1</td>
<td>bool</td>
</tr>
<tr>
<td>5</td>
<td>bool2</td>
<td>bool</td>
</tr>
<tr>
<td>6</td>
<td>dates</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>7</td>
<td>category</td>
<td>category</td>
</tr>
<tr>
<td>8</td>
<td>tdeltas</td>
<td>timedelta64[ns]</td>
</tr>
<tr>
<td>9</td>
<td>uint64</td>
<td>uint64</td>
</tr>
<tr>
<td>10</td>
<td>other_dates</td>
<td>datetime64[ns]</td>
</tr>
<tr>
<td>11</td>
<td>tz_aware_dates</td>
<td>datetime64[ns, US/Eastern]</td>
</tr>
</tbody>
</table>

`select_dtypes()` has two parameters `include` and `exclude` that allow you to say “give me the columns with these dtypes” (include) and/or “give the columns without these dtypes” (exclude).

For example, to select bool columns:

In [442]: df.select_dtypes(include=[bool])

Out[442]:
<table>
<thead>
<tr>
<th>0</th>
<th>bool1</th>
<th>bool2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>True</td>
<td>False</td>
</tr>
</tbody>
</table>
You can also pass the name of a dtype in the NumPy dtype hierarchy:

```python
In [443]: df.select_dtypes(include=['bool'])
Out[443]:
bool1  bool2
0   True  False
1  False   True
2   True  False
```

`select_dtypes()` also works with generic dtypes as well.

For example, to select all numeric and boolean columns while excluding unsigned integers:

```python
In [444]: df.select_dtypes(include=['number', 'bool'], exclude=['unsignedinteger'])
Out[444]:
int64  float64  bool1  bool2  tdeltas
0    1       4.0    True   False   NaT
1    2        5.0   False   True   1 days
2    2       5.0    True   False   1 days
```

To select string columns you must use the `object` dtype:

```python
In [445]: df.select_dtypes(include=['object'])
Out[445]:
string
0  a
1  b
2  c
```

To see all the child dtypes of a generic dtype like `numpy.number` you can define a function that returns a tree of child dtypes:

```python
In [446]: def subdtypes(dtype):
   ...:     subs = dtype.__subclasses__()
   ...:     if not subs:
   ...:         return dtype
   ...:     return [dtype, [subdtypes(dt) for dt in subs]]
   ...
```

All NumPy dtypes are subclasses of `numpy.generic`:

```python
In [447]: subdtypes(np.generic)
Out[447]:
[numpy.generic,
[numpy.number,
[[numpy.integer,
[[numpy.signedinteger,
[numpy.int8,
numpy.int16,
numpy.int32,
numpy.int64,
numpy.int64,
numpy.timedelta64]],
[numpy.unsignedinteger,
```
Note: Pandas also defines the types `category` and `datetime64[ns, tz]`, which are not integrated into the normal NumPy hierarchy and won’t show up with the above function.
Series and Index are equipped with a set of string processing methods that make it easy to operate on each element of the array. Perhaps most importantly, these methods exclude missing/NA values automatically. These are accessed via the `str` attribute and generally have names matching the equivalent (scalar) built-in string methods:

```python
In [1]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
```

```python
In [2]: s.str.lower()
Out[2]:
0    a
1    b
2    c
3   aaba
4   baca
5      NaN
6    caba
7      dog
8      cat
dtype: object
```

```python
In [3]: s.str.upper()
```

```python
→
0    A
1    B
2    C
3   AABA
4   BACA
5      NaN
6   CABA
7     DOG
8     CAT
dtype: object
```

```python
In [4]: s.str.len()
```

```python
→
0   1.0
1   1.0
2   1.0
3   4.0
4   4.0
5   NaN
6   4.0
7   3.0
```
The string methods on Index are especially useful for cleaning up or transforming DataFrame columns. For instance, you may have columns with leading or trailing whitespace:

```
In [9]: df = pd.DataFrame(randn(3, 2), columns=[' Column A ', ' Column B '],
                           index=range(3))
In [10]: df
Out[10]:
        Column A     Column B
0   -1.425575  -1.336299
1   0.740933   1.032121
2  -1.585660   0.913812
```

Since `df.columns` is an Index object, we can use the `.str` accessor:

```
In [11]: df.columns.str.strip()
Out[11]: Index(['Column A', 'Column B'], dtype='object')
```

```
In [12]: df.columns.str.lower()
Out[12]: Index([' column a ', ' column b '], dtype='object')
```

These string methods can then be used to clean up the columns as needed. Here we are removing leading and trailing whitespaces, lowercasing all names, and replacing any remaining whitespaces with underscores:

```
In [13]: df.columns = df.columns.str.strip().str.lower().str.replace(' ', '_')
In [14]: df
Out[14]:
          column_a      column_b
0  -1.425575   -1.336299
1   0.740933    1.032121
2  -1.585660    0.913812
```

**Note:** If you have a Series where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series), it can be faster to convert the original Series to one of type `category` and then use `.str.<method>` or `.dt.<property>` on that. The performance difference comes from the fact that, for Series of type `category`, the string operations are done on the `.categories` and not on
each element of the *Series*.

Please note that a *Series* of type *category* with string .categories has some limitations in comparison of *Series* of type string (e.g. you can’t add strings to each other: s + " " + s won’t work if s is a *Series* of type category). Also, .str methods which operate on elements of type list are not available on such a *Series*.

### 10.1 Splitting and Replacing Strings

Methods like *split* return a *Series* of lists:

```python
In [15]: s2 = pd.Series(['a_b_c', 'c_d_e', np.nan, 'f_g_h'])
In [16]: s2.str.split('_')
Out[16]:
0    [a, b, c]
1    [c, d, e]
2      NaN
3    [f, g, h]
dtype: object
```

Elements in the split lists can be accessed using *get* or [*] notation:

```python
In [17]: s2.str.split('_').str.get(1)
Out[17]:
0     b
1     d
2   NaN
3     g
dtype: object

In [18]: s2.str.split('_').str[1]
```

It is easy to expand this to return a *DataFrame* using *expand*.

```python
In [19]: s2.str.split('_', expand=True)
Out[19]:
   0  1  2
0 a b c
1 c d e
2 NaN NaN NaN
3 f g h
```

It is also possible to limit the number of splits:

```python
In [20]: s2.str.split('_', expand=True, n=1)
Out[20]:
   0  1
0 a b_c
1 c d_e
```

(continues on next page)
rsplit is similar to split except it works in the reverse direction, i.e., from the end of the string to the beginning of the string:

```python
In [21]: s2.str.rsplit('_', expand=True, n=1)
Out[21]:
   0     1
0  a_b  c
1  c_d  e
2  NaN  NaN
3  f_g  h
```

replace by default replaces regular expressions:

```python
In [22]: s3 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca',
.....: ', np.nan, 'CABA', 'dog', 'cat'])
.....:
In [23]: s3
Out[23]:
0   A
1   B
2   C
3  Aaba
4  Baca
5   
6  NaN
7  CABA
8   dog
9   cat
dtype: object
In [24]: s3.str.replace('^.*dog', 'XX-XX ', case=False)
```

Some caution must be taken to keep regular expressions in mind! For example, the following code will cause trouble because of the regular expression meaning of $:

```python
# Consider the following badly formatted financial data
In [25]: dollars = pd.Series(['12', '-$10', '$10,000'])

# This does what you'd naively expect:
```
In [26]: dollars.str.replace('\$\\', '')
Out[26]:
0   12
1  -10
2  10,000
dtype: object

# But this doesn't:
In [27]: dollars.str.replace('-\$\\', '-')
Out[27]:
0   12
1  -$10
2  $10,000
dtype: object

# We need to escape the special character (for >1 len patterns)
In [28]: dollars.str.replace(r'-\$\\', '-')
Out[28]:
0   12
1  -10
2  $10,000
dtype: object

New in version 0.23.0.

If you do want literal replacement of a string (equivalent to \texttt{str.replace()}), you can set the optional \texttt{regex} parameter to \texttt{False}, rather than escaping each character. In this case both \texttt{pat} and \texttt{repl} must be strings:

# These lines are equivalent
In [29]: dollars.str.replace(r'\$\\', ' -')
Out[29]:
0   12
1  -10
2  $10,000
dtype: object

In [30]: dollars.str.replace('\$\\', ' -', regex=False)
Out[30]:
0   12
1  -10
2  $10,000
dtype: object

New in version 0.20.0.

The \texttt{replace} method can also take a callable as replacement. It is called on every \texttt{pat} using \texttt{re.sub()}. The callable should expect one positional argument (a regex object) and return a string.

# Reverse every lowercase alphabetic word
In [31]: pat = r'[a-z]+'
In [32]: repl = lambda m: m.group(0)[::-1]
In [33]: pd.Series(['foo 123', 'bar baz', np.nan]).str.replace(pat, repl)
Out[33]:
0  oof 123
(continues on next page)
1 rab zab
2 NaN
dtype: object

# Using regex groups
In [34]: pat = r"(?P<one>\w+) (?P<two>\w+) (?P<three>\w+)"

In [35]: repl = lambda m: m.group('two').swapcase()

In [36]: pd.Series(['Foo Bar Baz', np.nan]).str.replace(pat, repl)
Out[36]:
0  bAR
1  NaN
dtype: object

New in version 0.20.0.

The replace method also accepts a compiled regular expression object from `re.compile()` as a pattern. All flags should be included in the compiled regular expression object.

In [37]: import re

In [38]: regex_pat = re.compile(r'^.a|dog', flags=re.IGNORECASE)

In [39]: s3.str.replace(regex_pat, 'XX-XX ')
Out[39]:
0   A
1   B
2   C
3  XX-XX ba
4  XX-XX ca
5   NaN
6  XX-XX BA
7  XX-XX
8   XX-XX t
9  XX-XX t
dtype: object

Including a flags argument when calling replace with a compiled regular expression object will raise a `ValueError`.

In [40]: s3.str.replace(regex_pat, 'XX-XX ', flags=re.IGNORECASE)
---------------------------------------------------------------------------
ValueError: case and flags cannot be set when pat is a compiled regex

10.2 Concatenation

There are several ways to concatenate a `Series` or `Index`, either with itself or others, all based on `cat()`, resp. `Index.str.cat`.

10.2.1 Concatenating a single Series into a string

The content of a `Series` (or `Index`) can be concatenated:
In [41]: s = pd.Series(['a', 'b', 'c', 'd'])

In [42]: s.str.cat(sep=',')
Out[42]: 'a,b,c,d'

If not specified, the keyword sep for the separator defaults to the empty string, sep='':

In [43]: s.str.cat()
Out[43]: 'abcd'

By default, missing values are ignored. Using na_rep, they can be given a representation:

In [44]: t = pd.Series(['a', 'b', np.nan, 'd'])

In [45]: t.str.cat(sep=',')
Out[45]: 'a,b,d'

In [46]: t.str.cat(sep=',', na_rep='-')
Out[46]: 'a,b,-,d'

10.2.2 Concatenating a Series and something list-like into a Series

The first argument to cat() can be a list-like object, provided that it matches the length of the calling Series (or Index).

In [47]: s.str.cat(['A', 'B', 'C', 'D'])
Out[47]:
0  aA
1  bB
2  cC
3  dD
dtype: object

Missing values on either side will result in missing values in the result as well, unless na_rep is specified:

In [48]: s.str.cat(t)
Out[48]:
0  aa
1  bb
2  NaN
3  dd
dtype: object

In [49]: s.str.cat(t, na_rep='-')
Out[49]:
0  aa
1  bb
2  c-
3  dd
dtype: object

10.2.3 Concatenating a Series and something array-like into a Series

New in version 0.23.0.
The parameter `others` can also be two-dimensional. In this case, the number or rows must match the lengths of the calling `Series` (or `Index`).

```
In [50]: d = pd.concat([t, s], axis=1)
In [51]: s
Out[51]:
0    a
1    b
2    c
3    d
dtype: object
In [52]: d
Out[52]:
     0 1
0   a a
1   b b
2   NaN c
3    d d
In [53]: s.str.cat(d, na_rep='--')
->
   0   aaa
   1  cbb
   2 c-c
   3  ddd
dtype: object
```

### 10.2.4 Concatenating a Series and an indexed object into a Series, with alignment

New in version 0.23.0.

For concatenation with a `Series` or `DataFrame`, it is possible to align the indexes before concatenation by setting the `join`-keyword.

```
In [54]: u = pd.Series(['b', 'd', 'a', 'c'], index=[1, 3, 0, 2])
In [55]: s
Out[55]:
0    a
1    b
2    c
3    d
dtype: object
In [56]: u
Out[56]:
1    b
3    d
0    a
2    c
dtype: object
In [57]: s.str.cat(u)
-> (continues on next page)
```
Warning: If the join keyword is not passed, the method `cat()` will currently fall back to the behavior before version 0.23.0 (i.e. no alignment), but a `FutureWarning` will be raised if any of the involved indexes differ, since this default will change to `join='left'` in a future version.

The usual options are available for `join` (one of 'left', 'outer', 'inner', 'right'). In particular, alignment also means that the different lengths do not need to coincide anymore.
The same alignment can be used when `others` is a DataFrame:

```
In [64]: f = d.loc[[3, 2, 1, 0], :]
```

```
In [65]: s
Out[65]:
0  a
1  b
2  c
3  d
dtype: object
```

```
In [66]: f
Out[66]:
0  NaN  c
1  b     b
2  c     c
3  d     d
```

```
In [67]: s.str.cat(f, join='left', na_rep='-')
```

```
0  aaa
1  bbb
2  c-c
3  ddd
```

**10.2.5 Concatenating a Series and many objects into a Series**

All one-dimensional list-likes can be arbitrarily combined in a list-like container (including iterators, `dict`-views, etc.):

```
In [68]: s
Out[68]:
0  a
1  b
2  c
3  d
```

```
In [69]: u
Out[69]:
0  a
1  b
2  c
```
In [70]: s.str.cat([u, pd.Index(u.values), ['A', 'B', 'C', 'D'], map(int, u.index)],
na_rep='--')

------------------------------------------------------------------------
TypeError Traceback (most recent call last)
<ipython-input-70-8326d4c98be5> in <module>()
----> 1 s.str.cat([u, pd.Index(u.values), ['A', 'B', 'C', 'D'], map(int, u.index)],
                   na_rep='--')

~/sandbox/pandas-docs/pandas/core/strings.py in cat(self, others, sep, na_rep, join)
    2189     # turn anything in "others" into lists of Series
    2190     others, fu_wrn = self._get_series_list(others,
--> 2191         ignore_index=(join is None))
    2192     except ValueError: # do not catch TypeError raised by _get_series_list
    2193         ignore_index=(join is None))

    2018

TypeError: others must be Series, Index, DataFrame, np.ndarray or list-like (either containing only strings or containing only objects of type Series/Index/list-like/Ndarray)

All elements must match in length to the calling Series (or Index), except those having an index if join is not None:

In [72]: s.str.cat([u, v, ['A', 'B', 'C', 'D']], join='outer', na_rep='--')

Out[72]:
-1 --z--
 0 aaaA
 1 bbbB
 2 cc-C
 3 dddD
 4 --e--
dtype: object

If using join='right' on a list of others that contains different indexes, the union of these indexes will be used as the basis for the final concatenation:
10.3 Indexing with `.str`

You can use `[]` notation to directly index by position locations. If you index past the end of the string, the result will be a NaN.

```
In [76]: s = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat'])
In [77]: s.str[0]
Out[77]:
0    A
1    B
2    C
3    A
4    B
5  NaN
6    C
7    d
8    c
dtype: object

In [78]: s.str[1]

0  NaN
1  NaN
2  NaN
3    a
4    a
5  NaN
6    A
7    o
8    a
dtype: object
```
10.4 Extracting Substrings

10.4.1 Extract first match in each subject (extract)

**Warning:** In version 0.18.0, `extract` gained the `expand` argument. When `expand=False` it returns a `Series`, `Index`, or `DataFrame`, depending on the subject and regular expression pattern (same behavior as pre-0.18.0). When `expand=True` it always returns a `DataFrame`, which is more consistent and less confusing from the perspective of a user. `expand=True` is the default since version 0.23.0.

The `extract` method accepts a regular expression with at least one capture group.

Extracting a regular expression with more than one group returns a `DataFrame` with one column per group.

```
In [79]: pd.Series(["a1", "b2", "c3"]).str.extract("([ab])\d", expand=False)
Out[79]:
   0   1
0  a  1
1  b  2
2  NaN NaN
```

Elements that do not match return a row filled with `NaN`. Thus, a Series of messy strings can be “converted” into a like-indexed Series or DataFrame of cleaned-up or more useful strings, without necessitating `get()` to access tuples or `re.match` objects. The dtype of the result is always object, even if no match is found and the result only contains `NaN`.

Named groups like

```
In [80]: pd.Series(["a1", "b2", "c3"]).str.extract("(?P<letter>\[ab\])(?P<digit>\d)\", expand=False)
Out[80]:
   letter  digit
0      a       1
1      b       2
2  NaN   NaN
```

and optional groups like

```
In [81]: pd.Series(["a1", "b2", "3"]).str.extract("([ab])?\d\", expand=False)
Out[81]:
   0  1
0  a  1
1  b  2
2  NaN 3
```

can also be used. Note that any capture group names in the regular expression will be used for column names; otherwise capture group numbers will be used.

Extracting a regular expression with one group returns a `DataFrame` with one column if `expand=True`.

```
In [82]: pd.Series(["a1", "b2", "c3"]).str.extract("[ab]\d\", expand=True)
Out[82]:
   0
0  1
1  2
2  NaN
```
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

It returns a Series if expand=False.
In [83]: pd.Series(['a1', 'b2', 'c3']).str.extract('[ab](\d)', expand=False)
Out[83]:
0
1
1
2
2
NaN
dtype: object

Calling on an Index with a regex with exactly one capture group returns a DataFrame with one column if
expand=True.
In [84]: s = pd.Series(["a1", "b2", "c3"], ["A11", "B22", "C33"])
In [85]: s
Out[85]:
A11
a1
B22
b2
C33
c3
dtype: object
In [86]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=True)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[86]:
letter
0
A
1
B
2
C

It returns an Index if expand=False.
In [87]: s.index.str.extract("(?P<letter>[a-zA-Z])", expand=False)
Out[87]: Index(['A', 'B', 'C'], dtype='object', name='letter')

Calling on an Index with a regex with more than one capture group returns a DataFrame if expand=True.
In [88]: s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=True)
Out[88]:
letter
1
0
A 11
1
B 22
2
C 33

It raises ValueError if expand=False.
>>> s.index.str.extract("(?P<letter>[a-zA-Z])([0-9]+)", expand=False)
ValueError: only one regex group is supported with Index

The table below summarizes the behavior of extract(expand=False) (input subject in first column, number of
groups in regex in first row)

Index
Series

664

1 group
Index
Series

>1 group
ValueError
DataFrame

Chapter 10. Working with Text Data


10.4.2 Extract all matches in each subject (extractall)

New in version 0.18.0.

Unlike `extract` (which returns only the first match),

```python
In [89]: s = pd.Series(["a1a2", "b1", "c1"], index=["A", "B", "C"])
In [90]: s
Out [90]:
     letter
dtype: object
     digit
A   a  1
    b  1
   C   c  1
```

the `extractall` method returns every match. The result of `extractall` is always a DataFrame with a MultiIndex on its rows. The last level of the MultiIndex is named `match` and indicates the order in the subject.

```python
In [91]: two_groups = '(?P<letter>[a-z])(?P<digit>[0-9])'
In [92]: s.str.extract(two_groups, expand=True)
Out [92]:
     letter
dtype: object
     digit
A   a  1
    b  1
   C   c  1
```

When each subject string in the Series has exactly one match,

```python
In [93]: s = pd.Series(['a3', 'b3', 'c2'])
In [94]: s
Out [94]:
     letter
dtype: object
     digit
  0   a  3
   1   b  3
   2   c  2
```

then `extractall(pat).xs(0, level='match')` gives the same result as `extract(pat)`.

```python
In [95]: extract_result = s.str.extract(two_groups, expand=True)
In [96]: extract_result
Out [96]:
     letter
dtype: object
     digit
  0   a  3
   1   b  3
   2   c  2
```

(continues on next page)
Index also supports `str.extractall`. It returns a DataFrame which has the same result as a `Series.str.extractall` with a default index (starts from 0).

New in version 0.19.0.

You can check whether elements contain a pattern:

**10.5 Testing for Strings that Match or Contain a Pattern**
Or whether elements match a pattern:

```python
In [105]: pd.Series(['1', '2', '3a', '3b', '03c']).str.match(pattern)
Out[105]:
0    False
1    False
2     True
3     True
4    False
dtype: bool
```

The distinction between `match` and `contains` is strictness: `match` relies on strict `re.match`, while `contains` relies on `re.search`.

Methods like `match`, `contains`, `startswith`, and `endswith` take an extra `na` argument so missing values can be considered True or False:

```python
In [106]: s4 = pd.Series(['A', 'B', 'C', 'Aaba', 'Baca', np.nan, 'CABA', 'dog', 'cat
   →'])

In [107]: s4.str.contains('A', na=False)
Out[107]:
0   True
1   False
2   False
3   True
4   False
5   False
6   True
7   False
8   False
dtype: bool
```

### 10.6 Creating Indicator Variables

You can extract dummy variables from string columns. For example if they are separated by a `'|'`:

```python
In [108]: s = pd.Series(['a', 'a|b', np.nan, 'a|c'])

In [109]: s.str.get_dummies(sep='|')
Out[109]:
     a  b  c
0 1 0 0
1 1 1 0
2 0 0 0
3 1 0 1
```

String Index also supports `get_dummies` which returns a MultiIndex.

New in version 0.18.1.
```python
In [110]: idx = pd.Index(['a', 'a|b', np.nan, 'a|c'])

In [111]: idx.str.get_dummies(sep='|')
```

```
Out[111]:
MultiIndex(levels=[[0, 1], [0, 1], [0, 1]],
labels=[[1, 1, 0, 1], [0, 1, 0, 0], [0, 0, 0, 1]],
names=['a', 'b', 'c'])
```

See also `get_dummies()`.

### 10.7 Method Summary

<table>

11.1 Overview

pandas has an options system that lets you customize some aspects of its behaviour, display-related options being those the user is most likely to adjust.

Options have a full “dotted-style”, case-insensitive name (e.g. \texttt{display.max_rows}). You can get/set options directly as attributes of the top-level \texttt{options} attribute:

\begin{Verbatim}
In [1]: import pandas as pd
In [2]: pd.options.display.max_rows
Out[2]: 15
In [3]: pd.options.display.max_rows = 999
In [4]: pd.options.display.max_rows
Out[4]: 999
\end{Verbatim}

The API is composed of 5 relevant functions, available directly from the \texttt{pandas} namespace:

\begin{itemize}
  \item \texttt{get_option() \slash set_option()} - get/set the value of a single option.
  \item \texttt{reset_option()} - reset one or more options to their default value.
  \item \texttt{describe_option()} - print the descriptions of one or more options.
  \item \texttt{option_context()} - execute a codeblock with a set of options that revert to prior settings after execution.
\end{itemize}

\textbf{Note:} Developers can check out \texttt{pandas/core/config.py} for more information.

All of the functions above accept a regexp pattern (\texttt{re.search} style) as an argument, and so passing in a substring will work - as long as it is unambiguous:

\begin{Verbatim}
In [5]: pd.get_option("display.max_rows")
Out[5]: 999
In [6]: pd.set_option("display.max_rows",101)
In [7]: pd.get_option("display.max_rows")
Out[7]: 101
In [8]: pd.set_option("max_r",102)
In [9]: pd.get_option("display.max_rows")
Out[9]: 102
\end{Verbatim}
The following will not work because it matches multiple option names, e.g. display.max_colwidth, display.max_rows, display.max_columns:

```
In [10]: try:
    ....:     pd.get_option("column")
    ....:     except KeyError as e:
    ....:         print(e)
    ....:  'Pattern matched multiple keys'
```

Note: Using this form of shorthand may cause your code to break if new options with similar names are added in future versions.

You can get a list of available options and their descriptions with describe_option. When called with no argument describe_option will print out the descriptions for all available options.

### 11.2 Getting and Setting Options

As described above, get_option() and set_option() are available from the pandas namespace. To change an option, call set_option('option regex', new_value).

```
In [11]: pd.get_option('mode.sim_interactive')
Out[11]: False

In [12]: pd.set_option('mode.sim_interactive', True)

In [13]: pd.get_option('mode.sim_interactive')
Out[13]: True
```

Note: The option ‘mode.sim_interactive’ is mostly used for debugging purposes.

All options also have a default value, and you can use reset_option to do just that:

```
In [14]: pd.get_option("display.max_rows")
Out[14]: 60

In [15]: pd.set_option("display.max_rows", 999)

In [16]: pd.get_option("display.max_rows")
Out[16]: 999

In [17]: pd.reset_option("display.max_rows")

In [18]: pd.get_option("display.max_rows")
Out[18]: 60
```

It’s also possible to reset multiple options at once (using a regex):

```
In [19]: pd.reset_option("^display")
```

option_context context manager has been exposed through the top-level API, allowing you to execute code with given option values. Option values are restored automatically when you exit the with block:

```
In [20]: with pd.option_context("display.max_rows", 10, "display.max_columns", 5):
    ....:     print(pd.get_option("display.max_rows"))
    ....:     print(pd.get_option("display.max_columns"))
```

(continues on next page)
11.3 Setting Startup Options in python/ipython Environment

Using startup scripts for the python/ipython environment to import pandas and set options makes working with pandas more efficient. To do this, create a .py or .ipy script in the startup directory of the desired profile. An example where the startup folder is in a default ipython profile can be found at:

```
$IPYTHONDIR/profile_default/startup
```

More information can be found in the ipython documentation. An example startup script for pandas is displayed below:

```python
import pandas as pd
pd.set_option('display.max_rows', 999)
pd.set_option('precision', 5)
```

11.4 Frequently Used Options

The following is a walkthrough of the more frequently used display options.

display.max_rows and display.max_columns sets the maximum number of rows and columns displayed when a frame is pretty-printed. Truncated lines are replaced by an ellipsis.

```
In [23]: df = pd.DataFrame(np.random.randn(7,2))
In [24]: pd.set_option('max_rows', 7)
In [25]: df
Out[25]:
   0          1
0  0.469112  -0.282863
1 -1.509059  -1.135632
2  1.212112  -0.173215
3  0.119209  -1.044236
4 -0.861849  -2.104569
5 -0.494929   1.071804
6  0.721555  -0.706771
In [26]: pd.set_option('max_rows', 5)
In [27]: df
Out[27]:
```

(continues on next page)
In [28]: pd.reset_option('max_rows')

display.expand_frame_repr allows for the representation of dataframes to stretch across pages, wrapped over the full column vs row-wise.

In [29]: df = pd.DataFrame(np.random.randn(5,10))

In [30]: pd.set_option('expand_frame_repr', True)

In [31]: df
Out[31]:
   0     1     2     3     4     5     6     7
0 -1.039575 0.271860 -0.424972 0.567020 0.276232 -1.087401 -0.673690 0.113648
   478427 0.524988
1  0.404705 0.577046 -1.715002 -1.039268 -0.370647 -1.157892 -1.344312 0.844885
   0.75770 -1.09050
2  1.643563 -1.469388 0.357021 -0.674600 -1.776904 -0.968914 -1.294524 0.413738

In [54]: pd.reset_option('max_info_columns')
display.max_info_rows: df.info() will usually show null-counts for each column. For large frames this
   can be quite slow. max_info_rows and max_info_cols limit this null check only to frames with smaller
dimensions then specified. Note that you can specify the option df.info(null_counts=True) to override on
   showing a particular frame.

In [55]: df = pd.DataFrame(np.random.choice([0,1,np.nan], size=(10,10)))

display.precision sets the output display precision in terms of decimal places. This is only a suggestion.

11.4. Frequently Used Options
display.chop_threshold sets at what level pandas rounds to zero when it displays a Series of DataFrame. This setting does not change the precision at which the number is stored.

display.colheader_justify controls the justification of the headers. The options are ‘right’, and ‘left’.
In [73]: df = pd.DataFrame(np.array([np.random.randn(6), np.random.randint(1,9,6)*.1, -np.zeros(6)]).T, columns=['A', 'B', 'C'], dtype='float')

In [74]: pd.set_option('colheader_justify', 'right')

In [75]: df
Out[75]:

<td>Combines columns when using a MultiIndex.</td>
</tr>
<tr>
<td>display.latex.multicolumn_format</td>
<td>'l'</td>
<td>Alignment of multicolumn labels.</td>
</tr>
<tr>
<td>display.latex.multirow</td>
<td>False</td>
<td>Combines rows when using a MultiIndex. Centered instead of top-aligned, separate rows.</td>
</tr>
<tr>
<td>display.max_columns</td>
<td>0 or 20</td>
<td>max_rows and max_columns are used in <strong>repr</strong>() methods to decide if to_string() should be used.</td>
</tr>
<tr>
<td>display.max_colwidth</td>
<td>50</td>
<td>The maximum width in characters of a column in the repr of a pandas data structure.</td>
</tr>
</tbody>
</table>

11.5. Available Options 679
### 11.6 Number Formatting

Pandas also allows you to set how numbers are displayed in the console. This option is not set through the `set_options` API.

Use the `set_eng_float_format` function to alter the floating-point formatting of pandas objects to produce a particular format.

For instance:

```python
In [79]: import numpy as np
In [80]: pd.set_eng_float_format(accuracy=3, use_eng_prefix=True)
In [81]: s = pd.Series(np.random.randn(5), index=['a', 'b', 'c', 'd', 'e'])
In [82]: s/1.e3
Out[82]:
     a    236.866u
     b    846.974u
     c    685.597u
     d    609.099u
     e   -303.961u
dtype: float64
```

(continues on next page)
To round floats on a case-by-case basis, you can also use `round()` and `round()`.  

### 11.7 Unicode Formatting

**Warning:** Enabling this option will affect the performance for printing of DataFrame and Series (about 2 times slower). Use only when it is actually required.

Some East Asian countries use Unicode characters whose width corresponds to two Latin characters. If a DataFrame or Series contains these characters, the default output mode may not align them properly.

**Note:** Screen captures are attached for each output to show the actual results.

```python
In [84]: df = pd.DataFrame({u'': ['UK', u''], u'': ['Alice', u'']})
In [85]: df;

Enabling `display.unicode.east_asian_width` allows pandas to check each character’s “East Asian Width” property. These characters can be aligned properly by setting this option to `True`. However, this will result in longer render times than the standard `len` function.

```python
In [86]: pd.set_option('display.unicode.east_asian_width', True)
In [87]: df;

In addition, Unicode characters whose width is “Ambiguous” can either be 1 or 2 characters wide depending on the terminal setting or encoding. The option `display.unicode.ambiguous_as_wide` can be used to handle the ambiguity.
By default, an “Ambiguous” character’s width, such as “¡” (inverted exclamation) in the example below, is taken to be 1.

```python
In [88]: df = pd.DataFrame({'a': ['xxx', u'¡¡'], 'b': ['yyy', u'¡¡']})
In [89]: df;
```

Enabling `display.unicode.ambiguous_as_wide` makes pandas interpret these characters’ widths to be 2. (Note that this option will only be effective when `display.unicode.east_asian_width` is enabled.) However, setting this option incorrectly for your terminal will cause these characters to be aligned incorrectly:

```python
In [90]: pd.set_option('display.unicode.ambiguous_as_wide', True)
In [91]: df;
```

### 11.8 Table Schema Display

New in version 0.20.0.

DataFrame and Series will publish a Table Schema representation by default. False by default, this can be enabled globally with the `display.html.table_schema` option:

```python
In [92]: pd.set_option('display.html.table_schema', True)
```

Only `display.max_rows` are serialized and published.
INDEXING AND SELECTING DATA

The axis labeling information in pandas objects serves many purposes:

- Identifies data (i.e., provides metadata) using known indicators, important for analysis, visualization, and interactive console display.
- Enables automatic and explicit data alignment.
- Allows intuitive getting and setting of subsets of the data set.

In this section, we will focus on the final point: namely, how to slice, dice, and generally get and set subsets of pandas objects. The primary focus will be on Series and DataFrame as they have received more development attention in this area.

**Note:** The Python and NumPy indexing operators `[]` and attribute operator `.` provide quick and easy access to pandas data structures across a wide range of use cases. This makes interactive work intuitive, as there’s little new to learn if you already know how to deal with Python dictionaries and NumPy arrays. However, since the type of the data to be accessed isn’t known in advance, directly using standard operators has some optimization limits. For production code, we recommended that you take advantage of the optimized pandas data access methods exposed in this chapter.

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see *here*.

See the *MultiIndex / Advanced Indexing* for *MultiIndex* and more advanced indexing documentation. See the *cookbook* for some advanced strategies.

### 12.1 Different Choices for Indexing

Object selection has had a number of user-requested additions in order to support more explicit location based indexing. Pandas now supports three types of multi-axis indexing.

- `.loc` is primarily label based, but may also be used with a boolean array. `.loc` will raise `KeyError` when the items are not found. Allowed inputs are:
A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index).

- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See Slicing with labels).

- A boolean array
- A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at Selection by Label.

- .iloc is primarily integer position based (from 0 to length-1 of the axis), but may also be used with a boolean array. .iloc will raise IndexError if a requested indexer is out-of-bounds, except slice indexers which allow out-of-bounds indexing. (this conforms with Python/NumPy slice semantics). Allowed inputs are:
  - An integer e.g. 5.
  - A list or array of integers [4, 3, 0].
  - A slice object with ints 1:7.
  - A boolean array.
  - A callable function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing (one of the above).

New in version 0.18.1.

See more at Selection by Position, Advanced Indexing and Advanced Hierarchical.

- .loc, .iloc, and also [] indexing can accept a callable as indexer. See more at Selection By Callable.

Getting values from an object with multi-axes selection uses the following notation (using .loc as an example, but the following applies to .iloc as well). Any of the axes accessors may be the null slice . Axes left out of the specification are assumed to be :, e.g. p.loc['a'] is equivalent to p.loc['a', :, :].

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Indexers</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>s.loc[indexer]</td>
</tr>
<tr>
<td>DataFrame</td>
<td>df.loc[row_indexer, column_indexer]</td>
</tr>
<tr>
<td>Panel</td>
<td>p.loc[item_indexer, major_indexer, minor_indexer]</td>
</tr>
</tbody>
</table>

### 12.2 Basics

As mentioned when introducing the data structures in the last section, the primary function of indexing with [] (a.k.a. __getitem__ for those familiar with implementing class behavior in Python) is selecting out lower-dimensional slices. The following table shows return type values when indexing pandas objects with []:

<table>
<thead>
<tr>
<th>Object Type</th>
<th>Selection</th>
<th>Return Value Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series</td>
<td>series[label]</td>
<td>scalar value</td>
</tr>
<tr>
<td>DataFrame</td>
<td>frame[colname]</td>
<td>Series corresponding to colname</td>
</tr>
<tr>
<td>Panel</td>
<td>panel[itemname]</td>
<td>DataFrame corresponding to the itemname</td>
</tr>
</tbody>
</table>
Here we construct a simple time series data set to use for illustrating the indexing functionality:

```python
In [1]: dates = pd.date_range('1/1/2000', periods=8)
In [2]: df = pd.DataFrame(np.random.randn(8, 4), index=dates, columns=['A', 'B', 'C', 'D'])
In [3]: df
Out[3]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-08 -0.370647 -1.157892 -1.344312  0.844885

In [4]: panel = pd.Panel({'one' : df, 'two' : df - df.mean()})
In [5]: panel
Out[5]:
<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 8 (major_axis) x 4 (minor_axis)
Items axis: one to two
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-08 00:00:00
Minor_axis axis: A to D
```

**Note:** None of the indexing functionality is time series specific unless specifically stated.

Thus, as per above, we have the most basic indexing using []:

```python
In [6]: s = df['A']
In [7]: s[dates[5]]
Out[7]: -0.67368970808837059

In [8]: panel['two']
```

You can pass a list of columns to [] to select columns in that order. If a column is not contained in the DataFrame, an exception will be raised. Multiple columns can also be set in this manner:

```python
In [9]: df
Out[9]:
          A         B         C         D
```

(continues on next page)
You may find this useful for applying a transform (in-place) to a subset of the columns.

**Warning:** pandas aligns all AXES when setting `Series` and `DataFrame` from `.loc`, and `.iloc`.

This will **not** modify `df` because the column alignment is before value assignment.

The correct way to swap column values is by using raw values:
12.3 Attribute Access

You may access an index on a `Series`, column on a `DataFrame`, and an item on a `Panel` directly as an attribute:

```python
In [17]: sa = pd.Series([1,2,3],index=list('abc'))
In [18]: dfa = df.copy()
In [19]: sa.b
Out[19]: 2
```

```python
In [20]: dfa.A
Out[20]:
          A         B
2000-01-01 0.469112 -0.282863
2000-01-02 1.212112 -0.173215
2000-01-03 -0.861849 -2.104569
2000-01-04 0.721555 -0.706771
2000-01-05 -0.424972  0.567020
2000-01-06 -0.673690  0.113648
2000-01-07  0.404705  0.577046
2000-01-08 -0.370647 -1.157892
Freq: D, Name: A, dtype: float64
```

```python
In [21]: panel.one
```

```python
In [22]: sa.a = 5
In [23]: sa
```

(continues on next page)
Warning:

- You can use this access only if the index element is a valid Python identifier, e.g. s.1 is not allowed. See here for an explanation of valid identifiers.

- The attribute will not be available if it conflicts with an existing method name, e.g. s.min is not allowed.

- Similarly, the attribute will not be available if it conflicts with any of the following list: index, major_axis, minor_axis, items, labels.

- In any of these cases, standard indexing will still work, e.g. s['1'], s['min'], and s['index'] will access the corresponding element or column.

If you are using the IPython environment, you may also use tab-completion to see these accessible attributes.

You can also assign a dict to a row of a DataFrame:

In [28]: x = pd.DataFrame({'x': [1, 2, 3], 'y': [3, 4, 5]})

In [29]: x.iloc[1] = dict(x=9, y=99)
You can use attribute access to modify an existing element of a Series or column of a DataFrame, but be careful; if you try to use attribute access to create a new column, it creates a new attribute rather than a new column. In 0.21.0 and later, this will raise a `UserWarning`:

```python
In[1]: df = pd.DataFrame({'one': [1., 2., 3.]})
In[2]: df.two = [4, 5, 6]
UserWarning: Pandas doesn't allow Series to be assigned into nonexistent columns - see https://pandas.pydata.org/pandas-docs/stable/indexing.html#attribute_access
In[3]: df
Out[3]:
   one
0  1.0
1  2.0
2  3.0
```

### 12.4 Slicing ranges

The most robust and consistent way of slicing ranges along arbitrary axes is described in the *Selection by Position* section detailing the `.iloc` method. For now, we explain the semantics of slicing using the `[]` operator.

With Series, the syntax works exactly as with an `ndarray`, returning a slice of the values and the corresponding labels:

```python
In[31]: s[:5]
Out[31]:
2000-01-01  0.469112
2000-01-02  1.212112
2000-01-03  -0.861849
2000-01-04   0.721555
2000-01-05  -0.424972
Freq: D, Name: A, dtype: float64
```

```python
In[32]: s[::2]
Out[32]:
2000-01-01  0.469112
2000-01-03  -0.861849
2000-01-05  -0.424972
2000-01-07   0.404705
Freq: 2D, Name: A, dtype: float64
```

```python
In[33]: s[::-1]
Out[33]:
2000-01-08  -0.370647
2000-01-07   0.404705
2000-01-06  -0.673690
2000-01-05  -0.424972
```

(continues on next page)
Note that setting works as well:

```
In [34]: s2 = s.copy()
In [35]: s2[:5] = 0
In [36]: s2
Out[36]:
2000-01-01  0.000000
2000-01-02  0.000000
2000-01-03  0.000000
2000-01-04  0.000000
2000-01-05  0.000000
Freq: D, Name: A, dtype: float64
```

With DataFrame, slicing inside of `[]` slices the rows. This is provided largely as a convenience since it is such a common operation.

```
In [37]: df[:3]
Out[37]:
          A         B         C         D
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
```

```
In [38]: df[::-1]
```

```
          A         B         C         D
2000-01-08 -0.370647  0.113648 -1.478427  0.524988
2000-01-07  0.404705  0.577046 -1.715002 -1.039268
2000-01-06 -0.673690  0.113648 -1.478427  0.524988
2000-01-05 -0.424972  0.567020  0.276232 -1.087401
2000-01-04  0.721555 -0.706771 -1.039575  0.271860
2000-01-03 -0.861849 -2.104569 -0.494929  1.071804
2000-01-02  1.212112 -0.173215  0.119209 -1.044236
2000-01-01  0.469112 -0.282863 -1.509059 -1.135632
```

### 12.5 Selection By Label

**Warning:** Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*. 

690 Chapter 12. Indexing and Selecting Data
Warning: 

.loc is strict when you present slicers that are not compatible (or convertible) with the index type. For example using integers in a DatetimeIndex. These will raise a TypeError.

```python
In [39]: dfl = pd.DataFrame(np.random.randn(5,4), columns=list('ABCD'), index=pd.date_range('20130101',periods=5))
In [40]: dfl.loc[2:3]
```

```
TypeError: cannot do slice indexing on <class 'pandas.tseries.index.DatetimeIndex'> with these indexers [2] of <type 'int'>
```

String likes in slicing can be convertible to the type of the index and lead to natural slicing.

```python
In [41]: dfl.loc['20130102':'20130104']
```

```python
Out[41]:
A    B    C     D
2013-01-02 -0.362543 0.276662 -0.472035
2013-01-03 -0.013960 0.413738 0.276662
2013-01-04  0.895717 0.805244 -1.206412
```

Warning: Starting in 0.21.0, pandas will show a FutureWarning if indexing with a list with missing labels. In the future this will raise a KeyError. See list-like Using loc with missing keys in a list is Deprecated.

Pandas provides a suite of methods in order to have purely label based indexing. This is a strict inclusion based protocol. Every label asked for must be in the index, or a KeyError will be raised. When slicing, both the start bound AND the stop bound are included, if present in the index. Integers are valid labels, but they refer to the label and not the position.

The .loc attribute is the primary access method. The following are valid inputs:

- A single label, e.g. 5 or 'a' (Note that 5 is interpreted as a label of the index. This use is not an integer position along the index.).
- A list or array of labels ['a', 'b', 'c'].
- A slice object with labels 'a':'f' (Note that contrary to usual python slices, both the start and the stop are included, when present in the index! See Slicing with labels.).
- A boolean array.
- A callable, see Selection By Callable.

```python
In [42]: sl = pd.Series(np.random.randn(6),index=list('abcdef'))
In [43]: sl
```

```
Out[43]:
s
    1.431256
```

(continues on next page)
In [44]: s1.loc['c':]

Out[44]:
\[\]
<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>c</td>
<td>-1.170299</td>
</tr>
<tr>
<td>d</td>
<td>-0.226169</td>
</tr>
<tr>
<td>e</td>
<td>0.410835</td>
</tr>
<tr>
<td>f</td>
<td>0.813850</td>
</tr>
<tr>

<td>-0.410001</td>
<td>0.769804</td>
</tr>
<tr>
<td>e</td>
<td>0.545952</td>
<td>1.219217</td>
<td>-1.226825</td>
<td>0.769804</td>
</tr>
<tr>
<td>f</td>
<td>-1.281247</td>
<td>-0.727707</td>
<td>-0.121306</td>
<td>-0.097883</td>
</tr>
</tbody>
</table>

In [50]: df1.loc[['a', 'b', 'd'], :]

Out[50]:
\[\]
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>0.132003</td>
<td>-0.827317</td>
<td>-0.076467</td>
<td>-1.187678</td>
</tr>
<tr>
<td>b</td>
<td>1.130127</td>
<td>-1.436737</td>
<td>-1.413681</td>
<td>1.607920</td>
</tr>
</tbody>
</table>

(continues on next page)
d 0.974466 -2.006747 -0.410001 -0.078638

Accessing via label slices:

| In [51]: df1.loc['d':, 'A':'C'] |
| Out[51]: |
| A | B | C |
| d | 0.974466 | -2.006747 | -0.410001 |
| e | 0.545952 | -1.219217 | -1.226825 |
| f | -1.281247 | -0.727707 | -0.121306 |

For getting a crossection using a label (equivalent to df.xs('a')):

| In [52]: df1.loc['a'] |
| Out[52]: |
| A | 0.132003 |
| B | -0.827317 |
| C | -0.076467 |
| D | -1.187678 |
| Name: a, dtype: float64 |

For getting values with a boolean array:

| In [53]: df1.loc['a'] > 0 |
| Out[53]: |
| A | True |
| B | False |
| C | False |
| D | False |
| Name: a, dtype: bool |

| In [54]: df1.loc[:, df1.loc['a'] > 0] |
| Out[54]: |
| A | a | b | c | d | e | f |
| a | 0.132003 |
| b | 1.130127 |
| c | 1.024180 |
| d | 0.974466 |
| e | 0.545952 |
| f | -1.281247 |

For getting a value explicitly (equivalent to deprecated df.get_value('a','A')):

```python
# this is also equivalent to `df1.at['a','A']`
In [55]: df1.loc['a', 'A']
Out[55]: 0.13200317033032932
```

### 12.5.1 Slicing with labels

When using `.loc` with slices, if both the start and the stop labels are present in the index, then elements located between the two (including them) are returned:

| In [56]: s = pd.Series(list('abcde'), index=[0,3,2,5,4]) |
| In [57]: s.loc[3:5] |

(continues on next page)
If at least one of the two is absent, but the index is sorted, and can be compared against start and stop labels, then slicing will still work as expected, by selecting labels which rank between the two:

```python
In [58]: s.sort_index()
Out[58]:
0  a
2  c
3  b
4  e
5  d
dtype: object
```

```python
In [59]: s.sort_index().loc[1:6]
```

```
Out[59]:
2  c
3  b
4  e
5  d
dtype: object
```

However, if at least one of the two is absent and the index is not sorted, an error will be raised (since doing otherwise would be computationally expensive, as well as potentially ambiguous for mixed type indexes). For instance, in the above example, `s.loc[1:6]` would raise `KeyError`.

### 12.6 Selection By Position

**Warning**: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See *Returning a View versus Copy*.

Pandas provides a suite of methods in order to get purely integer based indexing. The semantics follow closely Python and NumPy slicing. These are 0-based indexing. When slicing, the start bounds is included, while the upper bound is excluded. Trying to use a non-integer, even a valid label will raise an `IndexError`.

The `.iloc` attribute is the primary access method. The following are valid inputs:

- An integer e.g. 5.
- A list or array of integers `[4, 3, 0]`.
- A slice object with ints `1:7`.
- A boolean array.
- A callable, see *Selection By Callable*.

```python
In [60]: sl = pd.Series(np.random.randn(5), index=list(range(0,10,2)))
In [61]: sl
```

(continues on next page)
Out[61]:
0   0.695775
2   0.341734
4   0.959726
6  -1.110336
8  -0.619976
dtype: float64

In [62]: s1.iloc[:3]
Out[62]:
0   0.695775
2   0.341734
4   0.959726
dtype: float64

In [63]: s1.iloc[3]
Out[63]:
0   -1.1103361028911669

Note that setting works as well:

In [64]: s1.iloc[:3] = 0

In [65]: s1
Out[65]:
0   0.000000
2   0.000000
4   0.000000
6  -1.110336
8  -0.619976
dtype: float64

With a DataFrame:

In [66]: df1 = pd.DataFrame(np.random.randn(6,4),
                        index=list(range(0,12,2)),
                        columns=list(range(0,8,2)))

In [67]: df1
Out[67]:
          0  2  4  6
0  0.149748 -0.732339 0.687738 0.176444
2  0.403310 -0.154951 0.301624 -2.179861
4 -1.369849 -0.954208 1.462696 -1.743161
6 -0.826591 -0.345352 1.314232 0.690579
8  0.995761  2.396780 0.014871 3.357427
10 -0.317441 -1.236269 0.896171 -0.487602

Select via integer slicing:

In [68]: df1.iloc[:3]
Out[68]:
          0  2  4  6
0  0.149748 -0.732339 0.687738 0.176444
2  0.403310 -0.154951 0.301624 -2.179861
4 -1.369849 -0.954208 1.462696 -1.743161
(continues on next page)
Select via integer list:

```python
In [70]: df1.iloc[[1, 3, 5], [1, 3]]
Out[70]:
   1    3
2 -0.154951 -2.179861
6 -0.345352  0.690579
10 -1.236269  0.487602
```

For getting a cross section using an integer position (equiv to `df.xs(1)`):

```python
In [73]: df1.iloc[1]
Out[73]:
   0   2   4   6
2  0.403310 -0.154951  0.301624 -2.179861
4 -1.369849 -0.954208  1.462696 -1.743161
```

Out of range slice indexes are handled gracefully just as in Python/Numpy.

```python
In [75]: x = list('abcdef')
```
In [76]: x
Out[76]: ['a', 'b', 'c', 'd', 'e', 'f']

In [77]: x[4:10]
Out[77]: ['e', 'f']

In [78]: x[8:10]
Out[78]: []

In [79]: s = pd.Series(x)

In [80]: s
Out[80]:
0  a
1  b
2  c
3  d
4  e
5  f
dtype: object

In [81]: s.iloc[4:10]
Out[81]:
4  e
5  f
dtype: object

In [82]: s.iloc[8:10]
→Series([], dtype: object)

Note that using slices that go out of bounds can result in an empty axis (e.g. an empty DataFrame being returned).

In [83]: df1 = pd.DataFrame(np.random.randn(5,2), columns=list('AB'))

In [84]: df1
Out[84]:
    A         B
0 -0.082240  2.182937
1  0.380396  0.084844
2  0.432390  1.519970
3 -0.493662  0.600178
4  0.274230  0.132885

In [85]: df1.iloc[:, 2:3]
→ Empty DataFrame
Columns: []
Index: [0, 1, 2, 3, 4]

In [86]: df1.iloc[:, 1:3]
→          B
    A         B
0 -2.182937
1  0.084844
A single indexer that is out of bounds will raise an `IndexError`. A list of indexers where any element is out of bounds will raise an `IndexError`.

dfl.iloc[[4, 5, 6]]
`IndexError: positional indexers are out-of-bounds`

dfl.iloc[:, 4]
`IndexError: single positional indexer is out-of-bounds`

## 12.7 Selection By Callable

New in version 0.18.1.

`.loc`, `.iloc`, and also `[]` indexing can accept a **callable** as indexer. The **callable** must be a function with one argument (the calling Series, DataFrame or Panel) and that returns valid output for indexing.

**In [88]:**

```python
df1 = pd.DataFrame(np.random.randn(6, 4),
                   index=list('abcdef'),
                   columns=list('ABCD'))
```

**Out [89]:**

```
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>

In [93]: df1[lambda df: df.columns[0]]

\→
a -0.023688
b -0.251905
c  0.299368
d -0.025747
e  1.289997
f -0.489682
Name: A, dtype: float64

You can use callable indexing in Series.

In [94]: df1.A.loc[lambda s: s > 0]

Out[94]:
c  0.299368
e  1.289997
Name: A, dtype: float64

Using these methods / indexers, you can chain data selection operations without using temporary variable.

In [95]: bb = pd.read_csv('data/baseball.csv', index_col='id')

In [96]: (bb.groupby(['year', 'team']).sum()
    ....:   .loc[lambda df: df.r > 100])

Out[96]:

(continues on next page)
### 12.8 IX Indexer is Deprecated

**Warning:** Starting in 0.20.0, the `.ix` indexer is deprecated, in favor of the more strict `.iloc` and `.loc` indexers.

`.ix` offers a lot of magic on the inference of what the user wants to do. To wit, `.ix` can decide to index *positionally* OR via *labels* depending on the data type of the index. This has caused quite a bit of user confusion over the years.

The recommended methods of indexing are:

- `.loc` if you want to label index.
- `.iloc` if you want to positionally index.

```python
In [97]: dfd = pd.DataFrame({'A': [1, 2, 3],
                       'B': [4, 5, 6],
                       index=list('abc'))

In [98]: dfd
Out[98]:
   A  B
  a 1  4
  b 2  5
  c 3  6
```

Previous behavior, where you wish to get the 0th and the 2nd elements from the index in the ‘A’ column.

```python
In [3]: dfd.ix[[0, 2], 'A']
Out[3]:
   Name: A, dtype: int64
```

Using `.loc`. Here we will select the appropriate indexes from the index, then use label indexing.

```python
In [99]: dfd.loc[dfd.index[[0, 2]], 'A']
Out[99]:
   Name: A, dtype: int64
```

This can also be expressed using `.iloc`, by explicitly getting locations on the indexers, and using position indexing to select things.

```python
In [100]: dfd.iloc[[0, 2], dfd.columns.get_loc('A')]
Out[100]:
```

(continues on next page)
For getting multiple indexers, using .get_indexer:

In [101]: dfd.iloc[[0, 2], dfd.columns.get_indexer(['A', 'B'])]
Out[101]:
   A  B
a  1  4
c  3  6

### 12.9 Indexing with list with missing labels is Deprecated

**Warning:** Starting in 0.21.0, using .loc or [] with a list with one or more missing labels, is deprecated, in favor of .reindex.

In prior versions, using .loc[list-of-labels] would work as long as at least 1 of the keys was found (otherwise it would raise a KeyError). This behavior is deprecated and will show a warning message pointing to this section. The recommended alternative is to use .reindex().

For example.

In [102]: s = pd.Series([1, 2, 3])
In [103]: s
Out[103]:
   0  1
   1  2
   2  3
   dtype: int64

Selection with all keys found is unchanged.

In [104]: s.loc[[1, 2]]
Out[104]:
   1  2
   2  3
dtype: int64

Previous Behavior

In [4]: s.loc[[1, 2, 3]]
Out[4]:
   1  2.0
   2  3.0
   3  NaN
dtype: float64

Current Behavior
In [4]: s.loc[[1, 2, 3]]
Passing list-likes to .loc with any non-matching elements will raise
KeyError in the future, you can use .reindex() as an alternative.

See the documentation here:
http://pandas.pydata.org/pandas-docs/stable/indexing.html#deprecate-loc-reindex-
˓→listlike

Out[4]:
1  2.0
2  3.0
3  NaN
dtype: float64

12.9.1 Reindexing

The idiomatic way to achieve selecting potentially not-found elmenents is via .reindex(). See also the section on reindexing.

In [105]: s.reindex([1, 2, 3])
Out[105]:
1  2.0
2  3.0
3  NaN
dtype: float64

Alternatively, if you want to select only valid keys, the following is idiomatic and efficient; it is guaranteed to preserve
the dtype of the selection.

In [106]: labels = [1, 2, 3]
In [107]: s.loc[s.index.intersection(labels)]
Out[107]:
1  2
2  3
dtype: int64

Having a duplicated index will raise for a .reindex():

In [108]: s = pd.Series(np.arange(4), index=['a', 'a', 'b', 'c'])
In [109]: labels = ['c', 'd']
In [17]: s.reindex(labels)
ValueError: cannot reindex from a duplicate axis

Generally, you can intersect the desired labels with the current axis, and then reindex.

In [110]: s.loc[s.index.intersection(labels)].reindex(labels)
Out[110]:
c  3.0
d  NaN
dtype: float64

However, this would still raise if your resulting index is duplicated.
In [41]: labels = ['a', 'd']

In [42]: s.loc[s.index.intersection(labels)].reindex(labels)

ValueError: cannot reindex from a duplicate axis

12.10 Selecting Random Samples

A random selection of rows or columns from a Series, DataFrame, or Panel with the `sample()` method. The method will sample rows by default, and accepts a specific number of rows/columns to return, or a fraction of rows.

```
In [111]: s = pd.Series([0,1,2,3,4,5])

# When no arguments are passed, returns 1 row.
In [112]: s.sample()
Out[112]:
4 4
dtype: int64

# One may specify either a number of rows:
In [113]: s.sample(n=3)
Out[113]:
0 0
1 1
4 4
dtype: int64

# Or a fraction of the rows:
In [114]: s.sample(frac=0.5)
Out[114]:
1 1
3 3
5 5
dtype: int64
```

By default, `sample` will return each row at most once, but one can also sample with replacement using the `replace` option:

```
In [115]: s = pd.Series([0,1,2,3,4,5])

# Without replacement (default):
In [116]: s.sample(n=6, replace=False)
Out[116]:
0 0
1 1
5 5
3 3
2 2
4 4
dtype: int64

# With replacement:
In [117]: s.sample(n=6, replace=True)
Out[117]:
0 0
4 4
```

(continues on next page)
By default, each row has an equal probability of being selected, but if you want rows to have different probabilities, you can pass the `sample` function sampling weights as `weights`. These weights can be a list, a NumPy array, or a Series, but they must be of the same length as the object you are sampling. Missing values will be treated as a weight of zero, and inf values are not allowed. If weights do not sum to 1, they will be re-normalized by dividing all weights by the sum of the weights. For example:

```python
In [118]: s = pd.Series([0, 1, 2, 3, 4, 5])

In [119]: example_weights = [0, 0, 0.2, 0.2, 0.2, 0.4]

In [120]: s.sample(n=3, weights=example_weights)
Out[120]:
      5
     4
     3
dtype: int64

# Weights will be re-normalized automatically
In [121]: example_weights2 = [0.5, 0, 0, 0, 0, 0]

In [122]: s.sample(n=1, weights=example_weights2)
Out[122]:
     0
dtype: int64
```

When applied to a DataFrame, you can use a column of the DataFrame as sampling weights (provided you are sampling rows and not columns) by simply passing the name of the column as a string.

```python
In [123]: df2 = pd.DataFrame({'col1':[9, 8, 7, 6], 'weight_column':[0.5, 0.4, 0.1, 0]})

In [124]: df2.sample(n=3, weights='weight_column')
Out[124]:
   col1  weight_column
0   8       0.4
1   9       0.5
2   7       0.1
```

`sample` also allows users to sample columns instead of rows using the `axis` argument.

```python
In [125]: df3 = pd.DataFrame({'col1':[1, 2, 3], 'col2':[2, 3, 4]})

In [126]: df3.sample(n=1, axis=1)
Out[126]:
   col
0   1
1   2
2   3
```

Finally, one can also set a seed for `sample`'s random number generator using the `random_state` argument, which will accept either an integer (as a seed) or a NumPy RandomState object.
In [127]: df4 = pd.DataFrame({'col1':[1,2,3], 'col2':[2,3,4]})

# With a given seed, the sample will always draw the same rows.
In [128]: df4.sample(n=2, random_state=2)
Out[128]:
   col1 col2
0    2    3
1    1    2

In [129]: df4.sample(n=2, random_state=2)
Out[129]:
   col1 col2
0    2    3
1    1    2

12.11 Setting With Enlargement

The .loc[] operations can perform enlargement when setting a non-existent key for that axis.
In the Series case this is effectively an appending operation.

In [130]: se = pd.Series([1,2,3])

In [131]: se
Out[131]:
0 1
1 2
2 3
dtype: int64

In [133]: se
Out[133]:
0 1.0
1 2.0
2 3.0
5 5.0
dtype: float64

A DataFrame can be enlarged on either axis via .loc.

In [134]: dfi = pd.DataFrame(np.arange(6).reshape(3,2),
    columns=['A','B'])

In [135]: dfi
Out[135]:
   A  B
0 0 1
1 2 3
2 4 5

In [136]: dfi.loc[:, 'C'] = dfi.loc[:, 'A']

(continues on next page)
This is like an append operation on the DataFrame.

```
In [138]: dfi.loc[3] = 5
In [139]: dfi
Out[139]:
   A  B  C
0  0  1  0
1  2  3  2
2  4  5  4
3  5  5  5
```

12.12 Fast scalar value getting and setting

Since indexing with [] must handle a lot of cases (single-label access, slicing, boolean indexing, etc.), it has a bit of overhead in order to figure out what you’re asking for. If you only want to access a scalar value, the fastest way is to use the at and iat methods, which are implemented on all of the data structures.

Similarly to loc, at provides label based scalar lookups, while, iat provides integer based lookups analogously to iloc

```
In [140]: s.iat[5]
Out[140]: 5

In [141]: df.at[dates[5], 'A']
Out[141]: -0.67368970808837059

In [142]: df.iat[3, 0]
Out[142]: 0.72155516224436689
```

You can also set using these same indexers.

```
In [143]: df.at[dates[5], 'E'] = 7
In [144]: df.iat[3, 0] = 7
```

at may enlarge the object in-place as above if the indexer is missing.

```
In [145]: df.at[dates[-1]+1, 0] = 7
In [146]: df
Out[146]:
   A   B   C   D   E   O
0  0  0.469112 -0.282863 -1.509059 -1.135632 NaN NaN
1  1  1.212112 -0.173215  0.119209 -1.044236 NaN NaN
2  2 -0.861849 -2.104569 -0.494929  1.071804 NaN NaN
3  3  7.000000 -0.706771 -1.039575  0.271860 NaN NaN
```

(continues on next page)
12.13 Boolean indexing

Another common operation is the use of boolean vectors to filter the data. The operators are: | for or, & for and, and ~ for not. These must be grouped by using parentheses, since by default Python will evaluate an expression such as \( \text{df.A} > 2 \ & \ \text{df.B} < 3 \) as \( \text{df.A} > (2 \ & \ \text{df.B}) < 3 \), while the desired evaluation order is \( (\text{df.A} > 2) \ & \ (\text{df.B} < 3) \).

Using a boolean vector to index a Series works exactly as in a NumPy ndarray:

```python
In [147]: s = pd.Series(range(-3, 4))

In [148]: s
Out[148]:
0   -3
1   -2
2   -1
3    0
4    1
5    2
6    3
dtype: int64

In [149]: s[s > 0]
Out[149]:
       4
0    1
1    2
2    3
dtype: int64

In [150]: s[(s < -1) | (s > 0.5)]
       →
0   -3
1   -2
4    1
5    2
6    3
dtype: int64

In [151]: s[~(s < 0)]
       →
3    0
4    1
5    2
6    3
dtype: int64
```

You may select rows from a DataFrame using a boolean vector the same length as the DataFrame’s index (for example,
something derived from one of the columns of the DataFrame):

```
In [152]: df[df['A'] > 0]
Out[152]:
   A      B      C      D      E
0 2000-01-01  0.469112 -0.282863 -1.509059 -1.135632 NaN
1 2000-01-02  1.212112 -0.173215  0.119209 -1.044236 NaN
2 2000-01-04  7.000000 -0.706771 -1.039575  0.271860 NaN
3 2000-01-07  0.404705  0.577046 -1.715002 -1.039268 NaN
```

List comprehensions and map method of Series can also be used to produce more complex criteria:

```
In [153]: df2 = pd.DataFrame({'a' : ['one', 'one', 'two', 'three', 'two', 'one', 'six'], .....:
'.....: 'b' : ['x', 'y', 'y', 'x', 'y', 'x', 'x'],
'.....: 'c' : np.random.randn(7)})

# only want 'two' or 'three'
In [154]: criterion = df2['a'].map(lambda x: x.startswith('t'))
In [155]: df2[criterion]
Out[155]:
a       b       c
2  two    y  0.041290
3  three  x  0.361719
4  two    y -0.238075

# equivalent but slower
In [156]: df2[[x.startswith('t') for x in df2['a']]]
```

With the choice methods Selection by Label, Selection by Position, and Advanced Indexing you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [157]: df2.loc[criterion & (df2['b'] == 'x')]
```

With the choice methods Selection by Label, Selection by Position, and Advanced Indexing you may select along more than one axis using boolean vectors combined with other indexing expressions.

```
In [158]: df2.loc[criterion & (df2['b'] == 'x')]
```

### 12.14 Indexing with isin

Consider the `isin()` method of Series, which returns a boolean vector that is true wherever the Series elements exist in the passed list. This allows you to select rows where one or more columns have values you want:
In [159]: s = pd.Series(np.arange(5), index=np.arange(5)[::-1], dtype='int64')

In [160]: s
Out[160]:
4  0
3  1
2  2
1  3
0  4
dtype: int64

In [161]: s.isin([2, 4, 6])
Out[161]:
4  False
3  False
2  True
1  False
0  True
dtype: bool

In [162]: s[s.isin([2, 4, 6])]
Out[162]:
2  2
0  4
dtype: int64

The same method is available for Index objects and is useful for the cases when you don’t know which of the sought labels are in fact present:

In [163]: s[s.index.isin([2, 4, 6])]
Out[163]:
  2  2
  0  4
dtype: int64

# compare it to the following
In [164]: s.reindex([2, 4, 6])
Out[164]:
2  2.0
4  0.0
6  NaN
dtype: float64

In addition to that, MultiIndex allows selecting a separate level to use in the membership check:

In [165]: s_mi = pd.Series(np.arange(6),
                   index=pd.MultiIndex.from_product([[0, 1], ['a', 'b', 'c']]))

In [166]: s_mi
Out[166]:
    0  a  0
    b  1
c  2
1  a  3

(continues on next page)
DataFrame also has an `isin()` method. When calling `isin`, pass a set of values as either an array or dict. If values is an array, `isin` returns a DataFrame of booleans that is the same shape as the original DataFrame, with True wherever the element is in the sequence of values.

```python
In [169]: df = pd.DataFrame({'vals': [1, 2, 3, 4], 'ids': ['a', 'b', 'f', 'n'],
                         'ids2': ['a', 'n', 'c', 'n']})

In [170]: values = ['a', 'b', 1, 3]

In [171]: df.isin(values)
```

```
Out[171]:
   vals  ids  ids2
0   True  True  True
1   False  True  True
2   True  False  False
3   False  False  False
```

Oftentimes you’ll want to match certain values with certain columns. Just make values a `dict` where the key is the column, and the value is a list of items you want to check for.

```python
In [172]: values = {'ids': ['a', 'b'], 'vals': [1, 3]}

In [173]: df.isin(values)
```

```
Out[173]:
   vals  ids  ids2
0   True  True  False
1   False  True  False
2   True  False  False
3   False  False  False
```

Combine DataFrame’s `isin` with the `any()` and `all()` methods to quickly select subsets of your data that meet a given criteria. To select a row where each column meets its own criterion:

```python
In [174]: values = {'ids': ['a', 'b'], 'ids2': ['a', 'c'], 'vals': [1, 3]}
```

(continues on next page)
In [175]: row_mask = df.isin(values).all(1)

In [176]: df[row_mask]
Out[176]:
   vals  ids  ids2
0    1    a    a

12.15 The \texttt{where()} Method and Masking

Selecting values from a Series with a boolean vector generally returns a subset of the data. To guarantee that selection output has the same shape as the original data, you can use the \texttt{where} method in \texttt{Series} and \texttt{DataFrame}.

To return only the selected rows:

In [177]: s[s > 0]
Out[177]:
   3    1
   2    2
   1    3
   0    4
dtype: int64

To return a Series of the same shape as the original:

In [178]: s.where(s > 0)
Out[178]:
   4  NaN
   3  1.0
   2  2.0
   1  3.0
   0  4.0
dtype: float64

Selecting values from a DataFrame with a boolean criterion now also preserves input data shape. \texttt{where} is used under the hood as the implementation. The code below is equivalent to \texttt{df.where(df < 0)}.

In [179]: df[df < 0]
Out[179]:
   A       B       C       D
0 2000-01-01 -2.104139 -1.309525  NaN  NaN
1 2000-01-02 -0.352480  NaN -1.192319  NaN
2 2000-01-03 -0.864883  NaN  0.227870  NaN
3 2000-01-04  NaN -1.222082  NaN  1.233203
4 2000-01-05  NaN -0.605656 -1.169184  NaN
5 2000-01-06  NaN  0.948458  NaN  0.684718
6 2000-01-07 -2.670153 -0.114722  NaN  0.048048
7 2000-01-08  NaN  NaN -0.048788 -0.808838

In addition, \texttt{where} takes an optional \texttt{other} argument for replacement of values where the condition is False, in the returned copy.

In [180]: df.where(df < 0, -df)
Out[180]:
   A       B       C       D
0 2000-01-01 -2.104139 -1.309525  NaN  NaN
1 2000-01-02 -0.352480  NaN -1.192319  NaN
2 2000-01-03 -0.864883  NaN  0.227870  NaN
3 2000-01-04  NaN -1.222082  NaN -1.233203
4 2000-01-05  NaN -0.605656 -1.169184  NaN
5 2000-01-06  NaN  0.948458  NaN -0.684718
6 2000-01-07 -2.670153 -0.114722  NaN  0.048048
7 2000-01-08  NaN  NaN -0.048788 -0.808838

(continues on next page)
You may wish to set values based on some boolean criteria. This can be done intuitively like so:

```
In [181]: s2 = s.copy()

In [182]: s2[s2 < 0] = 0

In [183]: s2
Out[183]:
4  0
3  1
2  2
1  3
0  4
dtype: int64

In [184]: df2 = df.copy()

In [185]: df2[df2 < 0] = 0

In [186]: df2
Out[186]:
   A          B          C          D
0 2.104139  1.309525  0.485855  0.245166
1 0.352480  0.390389  1.192319  1.655824
2 0.864883  0.299674  0.227870  0.281059
3 0.846958  1.222082  0.600705  1.233203
4 0.669692  0.605656  1.169184  0.342416
5 0.868584  0.948458  2.297780  0.684718
6 2.670153  0.114722  0.168904  0.048048
7 0.801196  1.392071  0.048788  0.808838
```

By default, `where` returns a modified copy of the data. There is an optional parameter `inplace` so that the original data can be modified without creating a copy:

```
In [187]: df_orig = df.copy()

In [188]: df_orig.where(df > 0, -df, inplace=True);

In [189]: df_orig
Out[189]:
   A          B          C          D
0 2.104139  1.309525  0.485855  0.245166
1 0.352480  0.390389  1.192319  1.655824
2 0.864883  0.299674  0.227870  0.281059
3 0.846958  1.222082  0.600705  1.233203
4 0.669692  0.605656  1.169184  0.342416
5 0.868584  0.948458  2.297780  0.684718
6 2.670153  0.114722  0.168904  0.048048
7 0.801196  1.392071  0.048788  0.808838
```
Note: The signature for `DataFrame.where()` differs from `numpy.where()`. Roughly `df1.where(m, df2)` is equivalent to `np.where(m, df1, df2)

In [190]: df.where(df < 0, -df) == np.where(df < 0, df, -df)
Out[190]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
<tr>

<td>True</td>
<td>True</td>
</tr>
<tr>
<td>2000-01-08</td>
<td>True</td>
<td>True</td>
<td>True</td>
<td>True</td>
</tr>
</tbody>
</table>

Furthermore, where aligns the input boolean condition (ndarray or DataFrame), such that partial selection with setting is possible. This is analogous to partial setting via `loc` (but on the contents rather than the axis labels).

In [191]: df2 = df.copy()
In [192]: df2[ df2[1:4] > 0] = 3
In [193]: df2
Out[193]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-2.104139</td>

</tbody>
</table>

12.15. The `where()` Method and Masking
This is equivalent to (but faster than) the following.

In [196]: df2 = df.copy()

In [197]: df.apply(lambda x, y: x.where(x>0, y), y=df['A'])

Out[197]:
          A         B         C         D
2000-01-01  2.104139  2.104139  0.485855  0.245166
2000-01-02 -0.352480  0.390389 -0.352480  1.655824
2000-01-03 -0.864883  0.299674 -0.864883  0.281059
2000-01-04  0.846958  0.846958  0.600705  0.846958
2000-01-05  0.669692  0.669692  0.669692  0.342416
2000-01-06  0.868584  0.868584  2.297780  0.868584
2000-01-07 -2.670153 -2.670153  0.168904 -2.670153
2000-01-08  0.801196  1.392071  0.801196  0.801196

New in version 0.18.1.

Where can accept a callable as condition and other arguments. The function must be with one argument (the calling Series or DataFrame) and that returns valid output as condition and other argument.

In [198]: df3 = pd.DataFrame({'A': [1, 2, 3],
                           'B': [4, 5, 6],
                           'C': [7, 8, 9]})

In [199]: df3.where(lambda x: x > 4, lambda x: x + 10)

Out[199]:
     A   B   C
0   11  14  7
1   12  5  8
2   13  6  9

12.15.1 Mask

_mask_ is the inverse boolean operation of where.

In [200]: s.mask(s >= 0)

Out[200]:
0  NaN
1  NaN
2  NaN
1  NaN
0  NaN
dtype: float64

In [201]: df.mask(df >= 0)

Out[201]:
          A         B         C         D
2000-01-01  2.104139 -1.309525  NaN  NaN
2000-01-02 -0.352480 NaN -1.192319  NaN
2000-01-03 -0.864883 NaN -0.227870  NaN
2000-01-04  NaN -1.222082 NaN -1.233203
2000-01-05  NaN -0.605656 -1.169184  NaN
2000-01-06  NaN -0.948458 NaN -0.684718
2000-01-07 -2.670153 -0.114722 NaN -0.048788
2000-01-08  NaN  NaN -0.048788 -0.808838

Chapter 12. Indexing and Selecting Data
12.16 The query() Method

*DataFrame* objects have a `query()` method that allows selection using an expression.

You can get the value of the frame where column `b` has values between the values of columns `a` and `c`. For example:

```python
In [202]: n = 10
In [203]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [204]: df
Out[204]:
   a        b        c
0  0.438921  0.118680  0.863670
1  0.138138  0.577363  0.686602
2  0.595307  0.564592  0.520630
3  0.913052  0.926075  0.616184
4  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
6  0.792342  0.216974  0.564056
7  0.397890  0.454131  0.915716
8  0.074315  0.437913  0.019794
9  0.559209  0.502065  0.026437
```

# pure python
```python
In [205]: df[(df.a < df.b) & (df.b < df.c)]
```

```
   a        b        c
0  0.138138  0.577363  0.686602
1  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716
```

# query
```python
In [206]: df.query('(a < b) & (b < c)')
```

```
   a        b        c
0  0.138138  0.577363  0.686602
1  0.078718  0.854477  0.898725
5  0.076404  0.523211  0.591538
7  0.397890  0.454131  0.915716
```

Do the same thing but fall back on a named index if there is no column with the name `a`.

```python
In [207]: df = pd.DataFrame(np.random.randint(n / 2, size=(n, 2)), columns=list('bc'))
In [208]: df.index.name = 'a'
In [209]: df
Out[209]:
   b  c
0  4
1  1
2  4
(continues on next page)
In [210]: df.query('a < b and b < c')

Out[210]:

<table>
<thead>
<tr>
<th></th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>3</td>
<td>4</td>
</tr>
</tbody>
</table>

If instead you don’t want to or cannot name your index, you can use the name `index` in your query expression:

In [211]: df = pd.DataFrame(np.random.randint(n, size=(n, 2)), columns=list('bc'))

In [212]: df

Out[212]:

<table>
<thead>
<tr>
<th></th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>3</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>3</td>
<td>0</td>
</tr>
<tr>
<td>2</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>5</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>7</td>
<td>4</td>
</tr>
<tr>
<td>5</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>6</td>
<td>2</td>
<td>5</td>
</tr>
<tr>
<td>7</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>8</td>
<td>6</td>
<td>0</td>
</tr>
<tr>
<td>9</td>
<td>7</td>
<td>9</td>
</tr>
</tbody>
</table>

In [213]: df.query('index < b < c')

Out[213]:

<table>
<thead>
<tr>
<th></th>
<th>b</th>
<th>c</th>
</tr>
</thead>
<tbody>
<tr>
<td>2</td>
<td>5</td>
<td>6</td>
</tr>
</tbody>
</table>

Note: If the name of your index overlaps with a column name, the column name is given precedence. For example,

In [214]: df = pd.DataFrame({'a': np.random.randint(5, size=5)})

In [215]: df.index.name = 'a'

In [216]: df.query('a > 2') # uses the column 'a', not the index

Out[216]:

<p>| |</p>
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

You can still use the index in a query expression by using the special identifier ‘index’:

In [217]: df.query('index > 2')

(continues on next page)
Out[217]:
    a
    a
    3  3
    4  2

If for some reason you have a column named `index`, then you can refer to the index as `ilevel_0` as well, but at this point you should consider renaming your columns to something less ambiguous.

### 12.16.1 MultiIndex query() Syntax

You can also use the levels of a DataFrame with a `MultiIndex` as if they were columns in the frame:

```
In [218]: n = 10
In [219]: colors = np.random.choice(['red', 'green'], size=n)
In [220]: foods = np.random.choice(['eggs', 'ham'], size=n)
In [221]: colors
Out[221]:
array(['red', 'red', 'red', 'green', 'green', 'green', 'green', 'green', 'green', 'green'],
     dtype='<U5')
In [222]: foods
Out[222]:
array(['ham', 'ham', 'eggs', 'eggs', 'eggs', 'ham', 'ham', 'eggs', 'eggs', 'eggs'],
     dtype='<U4')
In [223]: index = pd.MultiIndex.from_arrays([colors, foods], names=['color', 'food'])
In [224]: df = pd.DataFrame(np.random.randn(n, 2), index=index)
In [225]: df
Out[225]:
       0         1
color food
red  ham  0.194889 -0.381994
     ham  0.318587  2.089075
     eggs -0.728293 -0.090255
green eggs -0.748199  1.318931
     eggs -2.029766  0.792652
     ham  0.461007 -0.542749
     ham -0.305384 -0.479195
     eggs  0.095031 -0.270099
     eggs -0.707140 -0.773882
     eggs  0.229453  0.304418
```

In [226]: df.query('color == "red"')
```
(continues on next page)
If the levels of the MultiIndex are unnamed, you can refer to them using special names:

```python
In [227]: df.index.names = [None, None]

In [228]: df
Out[228]:
   0   1
red ham  0.194889 -0.381994
   ham  0.318587  2.089075
   eggs -0.728293 -0.090255
   green eggs -0.748199  1.318931
   eggs -2.029766  0.792652
   ham  0.461007 -0.542749
   ham -0.305384 -0.479195
   eggs  0.095031 -0.270099
   eggs -0.707140 -0.773882
   eggs  0.229453  0.304418
```

The convention is `ilevel_0`, which means “index level 0” for the 0th level of the index.

### 12.16.2 `query()` Use Cases

A use case for `query()` is when you have a collection of `DataFrame` objects that have a subset of column names (or index levels/names) in common. You can pass the same query to both frames without having to specify which frame you’re interested in querying.

```python
In [230]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))

In [231]: df
Out[231]:
   a   b   c
0  0.224283  0.736107  0.139168
1  0.302827  0.657803  0.713897
2  0.611185  0.136624  0.984960
3  0.195246  0.123436  0.627712
4  0.618673  0.371660  0.047902
5  0.480088  0.062993  0.185760
6  0.568018  0.483467  0.445289
7  0.309040  0.274580  0.587101
8  0.258993  0.477769  0.370255
9  0.550459  0.840870  0.304611
```

(continues on next page)
In [232]: df2 = pd.DataFrame(np.random.rand(n + 2, 3), columns=df.columns)

In [233]: df2
Out[233]:
   a     b     c
0  0.357579  0.229800  0.596001
1  0.309059  0.957923  0.965663
2  0.123102  0.336914  0.318616
3  0.526506  0.323321  0.860813
4  0.518736  0.486514  0.384724
5  0.190804  0.505723  0.614533
6  0.891939  0.623977  0.676639
7  0.480559  0.378528  0.460858
8  0.420223  0.136404  0.141295
9  0.732206  0.419540  0.604675
10 0.604466  0.848974  0.896165
11 0.589168  0.920046  0.732716

In [234]: expr = '0.0 <= a <= c <= 0.5'

In [235]: map(lambda frame: frame.query(expr), [df, df2])
Out[235]: <map at 0x1c26bf8588>

12.16.3 query() Python versus pandas Syntax Comparison

Full numpy-like syntax:

In [236]: df = pd.DataFrame(np.random.randint(n, size=(n, 3)), columns=list('abc'))

In [237]: df
Out[237]:
   a  b  c
0  7  8  9
1  1  0  7
2  2  7  2
3  6  2  2
4  2  6  3
5  3  8  2
6  1  7  2
7  5  1  5
8  9  8  0
9  1  5  0

In [238]: df.query('(a < b) & (b < c)')
Out[238]:
   a  b  c
0  7  8  9

In [239]: df[(df.a < df.b) & (df.b < df.c)]
Out[239]:
   a  b  c
0  7  8  9
Slightly nicer by removing the parentheses (by binding making comparison operators bind tighter than `&` and `|`).

```
In [240]: df.query('a < b & b < c')
Out[240]:
  a  b  c
0  7  8  9
```

Use English instead of symbols:

```
In [241]: df.query('a < b and b < c')
Out[241]:
  a  b  c
0  7  8  9
```

Pretty close to how you might write it on paper:

```
In [242]: df.query('a < b < c')
Out[242]:
  a  b  c
0  7  8  9
```

### 12.16.4 The in and not in operators

`query()` also supports special use of Python's `in` and `not in` comparison operators, providing a succinct syntax for calling the `isin` method of a `Series` or `DataFrame`.

```
# get all rows where columns "a" and "b" have overlapping values
In [243]: df = pd.DataFrame({'a': list('aabbccddeeff'), 'b': list('aaaabbbbcccc'),
        'c': np.random.randint(5, size=12),
        'd': np.random.randint(9, size=12))

In [244]: df
Out[244]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

In [245]: df.query('a in b')
```

(continues on next page)
# How you’d do it in pure Python

```python
In [246]: df[df.a.isin(df.b)]
```

```
→
a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
3 b a 2 1
4 c b 3 6
5 c b 0 2
```

```python
In [247]: df.query('a not in b')
```

```
→
a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2
```

# pure Python

```python
In [248]: df[~df.a.isin(df.b)]
```

```
→
a b c d
6 d b 3 3
7 d b 2 1
8 e c 4 3
9 e c 2 0
10 f c 0 6
11 f c 1 2
```

You can combine this with other expressions for very succinct queries:

```
# rows where cols a and b have overlapping values and col c's values are less than, col d's
In [249]: df.query('a in b and c < d')
```

```
Out[249]:
a b c d
0 a a 2 6
1 a a 4 7
2 b a 1 6
4 c b 3 6
5 c b 0 2
```

# pure Python

```python
In [250]: df[df.b.isin(df.a) & (df.c < df.d)]
```

```
→
a b c d
0 a a 2 6
```

(continues on next page)
Note: Note that \texttt{in} and \texttt{not in} are evaluated in Python, since \texttt{numexpr} has no equivalent of this operation. However, only the \texttt{in/not in} expression itself is evaluated in vanilla Python. For example, in the expression \begin{verbatim}
df.query('a in b + c + d')
\end{verbatim}
(b + c + d) is evaluated by \texttt{numexpr} and then the \texttt{in} operation is evaluated in plain Python. In general, any operations that can be evaluated using \texttt{numexpr} will be.

### 12.16.5 Special use of the $==$ operator with \texttt{list} objects

Comparing a list of values to a column using $==$/$!=$ works similarly to \texttt{in/not in}.

\begin{verbatim}
In [251]: df.query('b == ["a", "b", "c"]')
Out[251]:
   a  b  c  d
0  a  a  2  6
1  a  a  4  7
2  b  a  1  6
3  b  a  2  1
4  c  b  3  6
5  c  b  0  2
6  d  b  3  3
7  d  b  2  1
8  e  c  4  3
9  e  c  2  0
10 f  c  0  6
11 f  c  1  2

# pure Python
In [252]: df[df.b.isin(["a", "b", "c"])]  
\end{verbatim}
In [253]: df.query('c == [1, 2]

   →  
   0  a  a  2  6
   2  b  a  1  6
   3  b  a  2  1
   7  d  b  2  1
   9  e  c  2  0
  11  f  c  1  2

In [254]: df.query('c != [1, 2]

   →  
   1  a  a  4  7
   4  c  b  3  6
   5  c  b  0  2
   6  d  b  3  3
   8  e  c  4  3
  10  f  c  0  6

# using in/not in
In [255]: df.query('[1, 2] in c'

   →  
   0  a  a  2  6
   2  b  a  1  6
   3  b  a  2  1
   7  d  b  2  1
   9  e  c  2  0
  11  f  c  1  2

In [256]: df.query('[1, 2] not in c'

   →  
   1  a  a  4  7
   4  c  b  3  6
   5  c  b  0  2
   6  d  b  3  3
   8  e  c  4  3
  10  f  c  0  6

# pure Python
In [257]: df[df.c.isin([1, 2])]

   →  
   0  a  a  2  6
   2  b  a  1  6
   3  b  a  2  1
   7  d  b  2  1
   9  e  c  2  0
  11  f  c  1  2
12.16.6 Boolean Operators

You can negate boolean expressions with the word `not` or the `~` operator.

```python
In [258]: df = pd.DataFrame(np.random.rand(n, 3), columns=list('abc'))
In [259]: df['bools'] = np.random.rand(len(df)) > 0.5
In [260]: df.query('~bools')
Out[260]:
   a    b    c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

In [261]: df.query('not bools')
    
---
   a    b    c  bools
2  0.697753  0.212799  0.329209  False
7  0.275396  0.691034  0.826619  False
8  0.190649  0.558748  0.262467  False

In [262]: df.query('not bools') == df[~df.bools]
    
---
   a    b    c  bools
2  True  True  True  True
7  True  True  True  True
8  True  True  True  True

Of course, expressions can be arbitrarily complex too:

```python
# short query syntax
In [263]: shorter = df.query('a < b < c and (not bools) or bools > 2')

# equivalent in pure Python
In [264]: longer = df[(df.a < df.b) & (df.b < df.c) & (~df.bools) | (df.bools > 2)]

In [265]: shorter
Out[265]:
   a    b    c  bools
7  0.275396  0.691034  0.826619  False

In [266]: longer
    
---
   a    b    c  bools
7  0.275396  0.691034  0.826619  False

In [267]: shorter == longer
    
---
   a    b    c  bools
7  True  True  True  True
```
12.16.7 Performance of \texttt{query()}\\

\texttt{DataFrame.query()} using \texttt{numexpr} is slightly faster than Python for large frames.

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure}
\caption{Graph showing performance comparison between \texttt{python} and \texttt{numexpr} for \texttt{DataFrame.query()}.}
\end{figure}

\textbf{Note:} You will only see the performance benefits of using the \texttt{numexpr} engine with \texttt{DataFrame.query()} if your frame has more than approximately 200,000 rows.

\begin{figure}
\centering
\includegraphics[width=0.5\textwidth]{figure}
\caption{Graph showing performance comparison between \texttt{python} and \texttt{numexpr} for \texttt{DataFrame.query()}.}
\end{figure}

This plot was created using a \texttt{DataFrame} with 3 columns each containing floating point values generated using \texttt{numpy.random.randn()}.

12.17 Duplicate Data

If you want to identify and remove duplicate rows in a DataFrame, there are two methods that will help: \texttt{duplicated} and \texttt{drop_duplicates}. Each takes as an argument the columns to use to identify duplicated rows.
• `duplicated` returns a boolean vector whose length is the number of rows, and which indicates whether a row is duplicated.
• `drop_duplicates` removes duplicate rows.

By default, the first observed row of a duplicate set is considered unique, but each method has a `keep` parameter to specify targets to be kept.

• `keep='first'` (default): mark / drop duplicates except for the first occurrence.
• `keep='last'`: mark / drop duplicates except for the last occurrence.
• `keep=False`: mark / drop all duplicates.

```
In [268]: df2 = pd.DataFrame({'a': ['one', 'one', 'two', 'two', 'two', 'three', 'four'],
                        'b': ['x', 'y', 'x', 'y', 'x', 'x', 'x'],
                        'c': np.random.randn(7))

In [269]: df2
Out[269]:
   a    b         c
0   one  x  -1.067137
1   one  y   0.309500
2   two  x  -0.211056
3   two  y  -1.842023
4   two  x  -0.390820
5   three x  -1.964475
6    four x   1.298329

In [270]: df2.duplicated('a')
Out[270]:
0   False
1   True
2  False
3   True
4   True
5  False
6  False
dtype: bool

In [271]: df2.duplicated('a', keep='last')
Out[271]:
0    True
1   False
2    True
3    True
4   False
5   False
6  False
dtype: bool

In [272]: df2.duplicated('a', keep=False)
Out[272]:
0    True
1    True
(continues on next page)
Also, you can pass a list of columns to identify duplications.

In [276]: df2.duplicated(['a', 'b'])
Out[276]:
0  False
1  False
2   True
3  False
4   True
5  False
6   True
dtype: bool

In [277]: df2.drop_duplicates(['a', 'b'])

To drop duplicates by index value, use Index.duplicated then perform slicing. The same set of options are
available for the keep parameter.

```python
In [278]: df3 = pd.DataFrame({'a': np.arange(6),
                      'b': np.random.randn(6),
                      index=['a', 'a', 'b', 'c', 'b', 'a'])

In [279]: df3
Out[279]:
a  b
a 0 1.440455
  1 2.456086
b 2 1.038402
c 3 -0.894409
b 4 0.683536
a 5 3.082764

In [280]: df3.index.duplicated()
Out[280]:
array([False, True, False, False, True, True], dtype=bool)

In [281]: df3[~df3.index.duplicated(keep='last')]
Out[281]:
a  b
  c 3 -0.894409
  b 4 0.683536
  a 5 3.082764

In [282]: df3[~df3.index.duplicated(keep=False)]
Out[282]:
a  b
  c 3 -0.894409

12.18 Dictionary-like get() method

Each of Series, DataFrame, and Panel have a `get()` method which can return a default value.

```python
In [284]: s = pd.Series([1,2,3], index=['a','b','c'])

In [285]: s.get('a')  # equivalent to s['a']
Out[285]: 1

In [286]: s.get('x', default=-1)
Out[286]: -1
```
12.19 The `lookup()` Method

Sometimes you want to extract a set of values given a sequence of row labels and column labels, and the `lookup` method allows for this and returns a NumPy array. For instance:

```
In [287]: dflookup = pd.DataFrame(np.random.rand(20,4), columns=['A','B','C','D'])
In [288]: dflookup.lookup(list(range(0,10,2)), ['B','C','A','B','D'])
Out[288]: array([ 0.3506, 0.4779, 0.4825, 0.9197, 0.5019])
```

12.20 Index objects

The pandas `Index` class and its subclasses can be viewed as implementing an ordered multiset. Duplicates are allowed. However, if you try to convert an `Index` object with duplicate entries into a set, an exception will be raised.

`Index` also provides the infrastructure necessary for lookups, data alignment, and reindexing. The easiest way to create an `Index` directly is to pass a list or other sequence to `Index`:

```
In [289]: index = pd.Index(['e', 'd', 'a', 'b'])
In [290]: index
Out[290]: Index(['e', 'd', 'a', 'b'], dtype='object')
In [291]: 'd' in index
Out[291]: True
```

You can also pass a name to be stored in the index:

```
In [292]: index = pd.Index(['e', 'd', 'a', 'b'], name='something')
In [293]: index.name
Out[293]: 'something'
```

The name, if set, will be shown in the console display:

```
In [294]: index = pd.Index(list(range(5)), name='rows')
In [295]: columns = pd.Index(['A', 'B', 'C'], name='cols')
In [296]: df = pd.DataFrame(np.random.randn(5, 3), index=index, columns=columns)
In [297]: df
Out[297]:
   A      B      C
0 1.29599  0.18578  0.43626
1 0.67810  0.31137 -0.52838
2 -0.67481 -1.10353 -0.65616
3 1.88996  2.07665 -1.10219
4 -1.21179 -0.79175  0.63472
```

(continues on next page)
12.20.1 Setting metadata

Indexes are “mostly immutable”, but it is possible to set and change their metadata, like the index name (or, for MultiIndex, levels and labels).

You can use the rename, set_names, set_levels, and set_labels to set these attributes directly. They default to returning a copy; however, you can specify inplace=True to have the data change in place.

See Advanced Indexing for usage of MultiIndexes.

```
In [299]: ind = pd.Index([1, 2, 3])

In [300]: ind.rename("apple")
Out[300]: Int64Index([1, 2, 3], dtype='int64', name='apple')

In [301]: ind
Out[301]: Int64Index([1, 2, 3], dtype='int64')

In [302]: ind.set_names(['apple'], inplace=True)

In [303]: ind.name = "bob"

In [304]: ind
Out[304]: Int64Index([1, 2, 3], dtype='int64', name='bob')
```

set_names, set_levels, and set_labels also take an optional level’ argument

```
In [305]: index = pd.MultiIndex.from_product([range(3), ['one', 'two']], names=['first', 'second'])

In [306]: index
Out[306]: MultiIndex(levels=[[0, 1, 2], ['one', 'two']],
                    labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
                    names=['first', 'second'])

In [307]: index.levels[1]
Out[307]: Index(['one', 'two'], dtype='object', name='second')

In [308]: index.set_levels(['a', 'b'], level=1)
Out[308]: MultiIndex(levels=[[0, 1, 2], ['a', 'b']],
                    labels=[[0, 0, 1, 1, 2, 2], [0, 1, 0, 1, 0, 1]],
                    names=['first', 'second'])
```
12.20.2 Set operations on Index objects

The two main operations are union (|) and intersection (&). These can be directly called as instance methods or used via overloaded operators. Difference is provided via the .difference() method.

```
In [309]: a = pd.Index(['c', 'b', 'a'])
In [310]: b = pd.Index(['c', 'e', 'd'])
In [311]: a | b
Out[311]: Index(['a', 'b', 'c', 'd', 'e'], dtype='object')
In [312]: a & b
Out[312]: Index(['c'], dtype='object')
In [313]: a.difference(b)
Out[313]: Index(['a', 'b'], dtype='object')
```

Also available is the symmetric_difference (^) operation, which returns elements that appear in either `idx1` or `idx2`, but not in both. This is equivalent to the Index created by `idx1.difference(idx2).union(idx2.difference(idx1))`, with duplicates dropped.

```
In [314]: idx1 = pd.Index([1, 2, 3, 4])
In [315]: idx2 = pd.Index([2, 3, 4, 5])
In [316]: idx1.symmetric_difference(idx2)
Out[316]: Int64Index([1, 5], dtype='int64')
In [317]: idx1 ^ idx2
Out[317]: Int64Index([1, 5], dtype='int64')
```

Note: The resulting index from a set operation will be sorted in ascending order.

12.20.3 Missing values

**Important:** Even though Index can hold missing values (NaN), it should be avoided if you do not want any unexpected results. For example, some operations exclude missing values implicitly.

Index.fillna fills missing values with specified scalar value.

```
In [318]: idx1 = pd.Index([1, np.nan, 3, 4])
In [319]: idx1
Out[319]: Float64Index([1.0, nan, 3.0, 4.0], dtype='float64')
In [320]: idx1.fillna(2)
Out[320]: Float64Index([1.0, 2.0, 3.0, 4.0], dtype='float64')
```
12.21 Set / Reset Index

Occasionally you will load or create a data set into a DataFrame and want to add an index after you’ve already done so. There are a couple of different ways.

12.21.1 Set an index

DataFrame has a `set_index()` method which takes a column name (for a regular Index) or a list of column names (for a MultiIndex). To create a new, re-indexed DataFrame:

```
In [324]: data
Out[324]:
   a   b   c   d
0  bar  one  z  1.0
1  bar  two  y  2.0
2  foo  one  x  3.0
3  foo  two  w  4.0

In [325]: indexed1 = data.set_index('c')

In [326]: indexed1
Out[326]:
   a   b   d
c  
  bar  one  1.0
  y  bar  two  2.0
  x  foo  one  3.0
  w  foo  two  4.0

In [327]: indexed2 = data.set_index(['a', 'b'])

In [328]: indexed2
Out[328]:
   c   d
a  
  bar  one  1.0
  y  two  2.0
  x  foo  one  3.0
  w  two  4.0
```
The `append` keyword option allow you to keep the existing index and append the given columns to a MultiIndex:

```python
In [329]: frame = data.set_index('c', drop=False)
In [330]: frame = frame.set_index(['a', 'b'], append=True)
In [331]: frame
```

```
c d
a b
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>z</td>
<td>1.0</td>
</tr>
<tr>
<td>y</td>
<td>2.0</td>
</tr>
<tr>
<td>x</td>
<td>3.0</td>
</tr>
<tr>
<td>w</td>
<td>4.0</td>
</tr>
</tbody>
</table>
```

Other options in `set_index` allow you not drop the index columns or to add the index in-place (without creating a new object):

```python
In [332]: data.set_index('c', drop=False)
Out[332]:

```
c d
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>z</td>
<td>1.0</td>
</tr>
<tr>
<td>y</td>
<td>2.0</td>
</tr>
<tr>
<td>x</td>
<td>3.0</td>
</tr>
<tr>
<td>w</td>
<td>4.0</td>
</tr>
</tbody>
</table>
```

```python
In [333]: data.set_index(['a', 'b'], inplace=True)
In [334]: data
```

```
c d
```

```
a b
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
```

### 12.21.2 Reset the index

As a convenience, there is a new function on DataFrame called `reset_index()` which transfers the index values into the DataFrame’s columns and sets a simple integer index. This is the inverse operation of `set_index()`.

```python
In [335]: data
Out[335]:

```
c d
```

```
a b
```

```
<table>
<thead>
<tr>
<th>c</th>
<th>d</th>
</tr>
</thead>
<tbody>
<tr>
<td>z</td>
<td>1.0</td>
</tr>
<tr>
<td>y</td>
<td>2.0</td>
</tr>
<tr>
<td>x</td>
<td>3.0</td>
</tr>
<tr>
<td>w</td>
<td>4.0</td>
</tr>
</tbody>
</table>
```

```python
In [336]: data.reset_index()
```

```
[continues on next page]```
The output is more similar to a SQL table or a record array. The names for the columns derived from the index are the ones stored in the names attribute.

You can use the level keyword to remove only a portion of the index:

```python
In [337]: frame
Out[337]:
   c  d
   a  b
   z bar one z 1.0
   y bar two y 2.0
   x foo one x 3.0
   w foo two w 4.0
```

```python
In [338]: frame.reset_index(level=1)
```

reset_index takes an optional parameter drop which if true simply discards the index, instead of putting index values in the DataFrame’s columns.

### 12.21.3 Adding an ad hoc index

If you create an index yourself, you can just assign it to the index field:

```python
data.index = index
```

### 12.22 Returning a view versus a copy

When setting values in a pandas object, care must be taken to avoid what is called chained indexing. Here is an example.

```python
In [339]: dfmi = pd.DataFrame([list('abcd'),
                     list('efgh'),
                     list('ijkl'),
                     list('mnop')],
                      columns=pd.MultiIndex.from_product([['one','two'],
                                                        ['first','second']))
```

```python
In [340]: dfmi
```

(continues on next page)
Compare these two access methods:

```
In [341]: dfmi['one']['second']
Out[341]:
0   b
1   f
2   j
3   n
Name: second, dtype: object
```

```
In [342]: dfmi.loc[:,('one','second')]
Out[342]:
0   b
1   f
2   j
3   n
Name: (one, second), dtype: object
```

These both yield the same results, so which should you use? It is instructive to understand the order of operations on these and why method 2 (.loc) is much preferred over method 1 (chained []).

dfmi['one'] selects the first level of the columns and returns a DataFrame that is singly-indexed. Then another Python operation dfmi_with_one['second'] selects the series indexed by 'second'. This is indicated by the variable dfmi_with_one because pandas sees these operations as separate events. e.g. separate calls to __getitem__, so it has to treat them as linear operations, they happen one after another.

Contrast this to df.loc[:,('one','second')] which passes a nested tuple of (slice(None), ('one', 'second')) to a single call to __getitem__. This allows pandas to deal with this as a single entity. Furthermore this order of operations can be significantly faster, and allows one to index both axes if so desired.

12.22.1 Why does assignment fail when using chained indexing?

The problem in the previous section is just a performance issue. What’s up with the SettingWithCopy warning? We don’t usually throw warnings around when you do something that might cost a few extra milliseconds!

But it turns out that assigning to the product of chained indexing has inherently unpredictable results. To see this, think about how the Python interpreter executes this code:

```
dfmi.loc[:,('one','second')] = value
# becomes
dfmi.loc.__setitem__((slice(None), ('one', 'second')), value)
```

But this code is handled differently:

```
dfmi['one']['second'] = value
# becomes
dfmi.__getitem__('one').__setitem__('second', value)
```
See that \_getitem\_ in there? Outside of simple cases, it’s very hard to predict whether it will return a view or a copy (it depends on the memory layout of the array, about which pandas makes no guarantees), and therefore whether the \_setitem\_ will modify \texttt{dfmi} or a temporary object that gets thrown out immediately afterward. \textbf{That’s what \texttt{SettingWithCopy} is warning you about!}

\textbf{Note:} You may be wondering whether we should be concerned about the \texttt{loc} property in the first example. But \texttt{dfmi.loc} is guaranteed to be \texttt{dfmi} itself with modified indexing behavior, so \texttt{dfmi.loc.\_getitem\_/dfmi.\_setitem\_} operate on \texttt{dfmi} directly. Of course, \texttt{dfmi.loc.\_getitem\_} may be a view or a copy of \texttt{dfmi}.

Sometimes a \texttt{SettingWithCopy} warning will arise at times when there’s no obvious chained indexing going on. \textbf{These} are the bugs that \texttt{SettingWithCopy} is designed to catch! Pandas is probably trying to warn you that you’ve done this:

\begin{verbatim}
def do_something(df):
    foo = df[['bar', 'baz']]  # Is foo a view? A copy? Nobody knows!
    # ... many lines here ...
    foo['quux'] = value      # We don't know whether this will modify df or not!
    return foo
\end{verbatim}

Yikes!

\subsection*{12.22.2 Evaluation order matters}

When you use chained indexing, the order and type of the indexing operation partially determine whether the result is a slice into the original object, or a copy of the slice.

Pandas has the \texttt{SettingWithCopyWarning} because assigning to a copy of a slice is frequently not intentional, but a mistake caused by chained indexing returning a copy where a slice was expected.

If you would like pandas to be more or less trusting about assignment to a chained indexing expression, you can set the \texttt{option mode.chained_assignment} to one of these values:

- 'warn', the default, means a \texttt{SettingWithCopyWarning} is printed.
- 'raise' means pandas will raise a \texttt{SettingWithCopyException} you have to deal with.
- None will suppress the warnings entirely.

\begin{verbatim}
In [343]: dfb = pd.DataFrame({'a' : ['one', 'one', 'two',
                             'three', 'two', 'one', 'six'],
                             'c' : np.arange(7))

# This will show the SettingWithCopyWarning
# but the frame values will be set
In [344]: dfb['c'][dfb.a.str.startswith('o')] = 42
\end{verbatim}

This however is operating on a copy and will not work.

\begin{verbatim}
>>> pd.set_option('mode.chained_assignment', 'warn')
>>> dfb[dfb.a.str.startswith('o')]['c'] = 42
Traceback (most recent call last)
 ... SettingWithCopyWarning:
\end{verbatim}

(continues on next page)
A value is trying to be set on a copy of a slice from a DataFrame. 
Try using .loc[row_index,col_indexer] = value instead

A chained assignment can also crop up in setting in a mixed dtype frame.

**Note:** These setting rules apply to all of `.loc`/.`iloc`.

This is the correct access method:

```
In [345]: dfc = pd.DataFrame({'A': ['aaa', 'bbb', 'ccc'], 'B': [1, 2, 3]})
In [346]: dfc.loc[0, 'A'] = 11
In [347]: dfc
Out[347]:
   A   B
0  11   1
1  bbb  2
2  ccc  3
```

This *can* work at times, but it is not guaranteed to, and therefore should be avoided:

```
In [348]: dfc = dfc.copy()
In [349]: dfc['A'][0] = 111
In [350]: dfc
Out[350]:
   A   B
0  111   1
1  bbb  2
2  ccc  3
```

This will **not** work at all, and so should be avoided:

```
>>> pd.set_option('mode.chained_assignment', 'raise')
>>> dfc.loc[0]['A'] = 1111
Traceback (most recent call last)
  ... SettingWithCopyException:
    A value is trying to be set on a copy of a slice from a DataFrame.
    Try using .loc[row_index,col_indexer] = value instead
```

**Warning:** The chained assignment warnings / exceptions are aiming to inform the user of a possibly invalid assignment. There may be false positives; situations where a chained assignment is inadvertently reported.
This section covers indexing with a MultiIndex and more advanced indexing features.
See the Indexing and Selecting Data for general indexing documentation.

Warning: Whether a copy or a reference is returned for a setting operation, may depend on the context. This is sometimes called chained assignment and should be avoided. See Returning a View versus Copy.

See the cookbook for some advanced strategies.

13.1 Hierarchical indexing (MultiIndex)

Hierarchical / Multi-level indexing is very exciting as it opens the door to some quite sophisticated data analysis and manipulation, especially for working with higher dimensional data. In essence, it enables you to store and manipulate data with an arbitrary number of dimensions in lower dimensional data structures like Series (1d) and DataFrame (2d).

In this section, we will show what exactly we mean by “hierarchical” indexing and how it integrates with all of the pandas indexing functionality described above and in prior sections. Later, when discussing group by and pivoting and reshaping data, we’ll show non-trivial applications to illustrate how it aids in structuring data for analysis.

See the cookbook for some advanced strategies.

13.1.1 Creating a MultiIndex (hierarchical index) object

The MultiIndex object is the hierarchical analogue of the standard Index object which typically stores the axis labels in pandas objects. You can think of MultiIndex as an array of tuples where each tuple is unique. A MultiIndex can be created from a list of arrays (using MultiIndex.from_arrays), an array of tuples (using MultiIndex.from_tuples), or a crossed set of iterables (using MultiIndex.from_product). The Index constructor will attempt to return a MultiIndex when it is passed a list of tuples. The following examples demonstrate different ways to initialize MultiIndexes.

```
In [1]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
   ...:  ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']
   ...:
   ...
In [2]: tuples = list(zip(*arrays))
In [3]: tuples
Out [3]:
[['bar', 'one'],
 ['bar', 'two'],
 ['baz', 'one'],
 ['baz', 'two'],
 ['foo', 'one'],
 ['foo', 'two'],
 ['qux', 'one'],
 ['qux', 'two']]
```

(continues on next page)
In [4]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [5]: index
Out[5]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

In [6]: s = pd.Series(np.random.randn(8), index=index)

In [7]: s
Out[7]:
first  second
bar  one  0.469112
      two -0.282863
baz  one -1.509059
      two -1.135632
foo  one  1.212112
      two -0.173215
qux  one  0.119209
      two -1.044236
dtype: float64

When you want every pairing of the elements in two iterables, it can be easier to use the MultiIndex. from_product function:

In [8]: iterables = [['bar', 'baz', 'foo', 'qux'], ['one', 'two']]

In [9]: pd.MultiIndex.from_product(iterables, names=['first', 'second'])
Out[9]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
names=['first', 'second'])

As a convenience, you can pass a list of arrays directly into Series or DataFrame to construct a MultiIndex automatically:

In [10]: arrays = [np.array(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux']),
np.array(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'])]

In [11]: s = pd.Series(np.random.randn(8), index=arrays)

In [12]: s
Out[12]:
bar  one  -0.861849
      two  -2.104569
baz  one  -0.494929
(continues on next page)
two  1.071804
foo one  0.721555
two  -0.706771
qux one  -1.039575
two  0.271860
dtype: float64

In [13]: df = pd.DataFrame(np.random.randn(8, 4), index=arrays)

In [14]: df
Out[14]:
   0    1    2    3
bar one -0.424972  0.567020  0.276232 -1.087401
two  -0.673690  0.113648 -1.478427  0.524988
baz one  0.404705  0.577046 -1.715002 -1.039268
two  -0.370647  0.740916 -0.344312  0.844885
foo one  1.075770 -0.109050  1.643563 -1.469388
two   0.357021 -0.674600 -1.776904 -0.968914
qux one -1.294524  0.413738  0.276662 -0.472035
two   -0.013960  0.362543 -0.006154  0.923061

All of the MultiIndex constructors accept a names argument which stores string names for the levels themselves. If no names are provided, None will be assigned:

In [15]: df.index.names
Out[15]: FrozenList([None, None])

This index can back any axis of a pandas object, and the number of levels of the index is up to you:

In [16]: df = pd.DataFrame(np.random.randn(3, 8), index=['A', 'B', 'C'],
                     columns=index)

In [17]: df
Out[17]:
     first  bar  baz  foo  qux
second one  two  two  two  two
A  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299  1.702299 -0.226169
B  0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466  0.206747

In [18]: pd.DataFrame(np.random.randn(6, 6), index=index[:6], columns=index[:6])

first  bar  baz  foo
second one  two  two  two
A  0.895717  0.805244 -1.206412  2.565646  1.431256  1.340309 -1.170299  1.702299 -0.226169
B  0.410835  0.813850  0.132003 -0.827317 -0.076467 -1.187678  1.130127 -1.436737
C -1.413681  1.607920  1.024180  0.569605  0.875906 -2.211372  0.974466  0.206747
D -0.954208  1.462696 -1.743161 -0.826591 -0.345352  1.314232
E  0.690579  0.995761  2.396780  0.014871  3.357427 -0.317441
F -0.410001 -0.078638  0.545952 -1.219217 -1.226825  0.769804

We’ve “sparsified” the higher levels of the indexes to make the console output a bit easier on the eyes. Note that how the index is displayed can be controlled using the multi_sparse option in pandas.set_options():

13.1. Hierarchical indexing (MultiIndex) 741
It’s worth keeping in mind that there’s nothing preventing you from using tuples as atomic labels on an axis:

```
In [20]: pd.Series(np.random.randn(8), index=tuples)
Out[20]:
   (bar, one)  -1.236269
   (bar, two)   0.896171
   (baz, one)  -0.487602
   (baz, two)  -0.082240
   (foo, one)  -2.182937
   (foo, two)   0.380396
   (qux, one)   0.084844
   (qux, two)   0.432390
```

dtype: float64

The reason that the `MultiIndex` matters is that it can allow you to do grouping, selection, and reshaping operations as we will describe below and in subsequent areas of the documentation. As you will see in later sections, you can find yourself working with hierarchically-indexed data without creating a `MultiIndex` explicitly yourself. However, when loading data from a file, you may wish to generate your own `MultiIndex` when preparing the data set.

### 13.1.2 Reconstructing the level labels

The method `get_level_values` will return a vector of the labels for each location at a particular level:

```
In [21]: index.get_level_values(0)
Out[21]:
Index(['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
dtype='object', name='first')

In [22]: index.get_level_values('second')
```

```
Index(['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two'],
dtype='object', name='second')
```

### 13.1.3 Basic indexing on axis with MultiIndex

One of the important features of hierarchical indexing is that you can select data by a “partial” label identifying a subgroup in the data. Partial selection “drops” levels of the hierarchical index in the result in a completely analogous way to selecting a column in a regular DataFrame:

```
In [23]: df['bar']
Out[23]:
 second   one   two
   A   0.895717  0.805244
   B   0.410835  0.813850
   C  -1.413681  1.607920

In [24]: df['bar', 'one']
```

(continues on next page)
C -1.413681
Name: (bar, one), dtype: float64

In [25]: df['bar']['one']

→
A 0.895717
B 0.410835
C -1.413681
Name: one, dtype: float64

In [26]: s['qux']

→
one -1.039575
two 0.271860
dtype: float64

See `Cross-section with hierarchical index` for how to select on a deeper level.

### 13.1.4 Defined Levels

The repr of a `MultiIndex` shows all the defined levels of an index, even if the they are not actually used. When slicing an index, you may notice this. For example:

```python
In [27]: df.columns  # original MultiIndex
Out[27]:
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
                           labels=[[0, 0, 1, 1, 2, 2, 3, 3], [0, 1, 0, 1, 0, 1, 0, 1]],
                           names=['first', 'second'])

In [28]: df[['foo','qux']].columns  # sliced

→
MultiIndex(levels=[['bar', 'baz', 'foo', 'qux'], ['one', 'two']],
                           labels=[[2, 2, 3, 3], [0, 1, 0, 1]],
                           names=['first', 'second'])
```

This is done to avoid a recomputation of the levels in order to make slicing highly performant. If you want to see only the used levels, you can use the `MultiIndex.get_level_values()` method.

```python
In [29]: df[['foo','qux']].columns.values
Out[29]: array([('foo', 'one'), ('foo', 'two'), ('qux', 'one'), ('qux', 'two')],
                 dtype=object)

# for a specific level
In [30]: df[['foo','qux']].columns.get_level_values(0)
Index([('foo', 'foo', 'qux', 'qux'), dtype=object', name='first')]
```

To reconstruct the `MultiIndex` with only the used levels, the `remove_unused_levels` method may be used. New in version 0.20.0.
13.1.5 Data alignment and using reindex

Operations between differently-indexed objects having MultiIndex on the axes will work as you expect; data alignment will work the same as an Index of tuples:

```
In [32]: s + s[:-2]
```

```
bar    one  -1.723698
     two  -4.209138
baz    one  -0.989859
     two   2.143608
foo    one   1.443110
     two  -1.413542
qux    one    NaN
     two    NaN
```

```
In [33]: s + s[::2]
```

```
bar    one  -1.723698
     two    NaN
baz    one  -0.989859
     two    NaN
foo    one   1.443110
     two    NaN
qux    one  -2.079150
     two    NaN
```

reindex can be called with another MultiIndex, or even a list or array of tuples:

```
In [34]: s.reindex(index[:3])
```

```
first  second
bar    one  -0.861849
     two  -2.104569
baz    one  -0.494929
```

```
In [35]: s.reindex([('foo', 'two'), ('bar', 'one'), ('qux', 'one'), ('baz', 'one')])
```

```
foo    two  -0.706771
bar    one  -0.861849
qux    one  -1.039575
baz    one  -0.494929
```

```
13.2 Advanced indexing with hierarchical index

Syntactically integrating MultiIndex in advanced indexing with .loc is a bit challenging, but we’ve made every effort to do so. In general, MultiIndex keys take the form of tuples. For example, the following works as you would expect:

```
In [36]: df = df.T

In [37]: df
Out[37]:
   A   B   C
first second
bar one  0.895717  0.410835 -1.413681
two  0.805244  0.813850  1.607920
baz one  1.206412  0.132003  1.024180
two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
two  1.340309 -1.187678 -2.211372
qux one  1.170299  1.130127  0.974466
two  2.565646 -0.827317  0.569605
```

```
In [38]: df.loc[('bar', 'two'),]
   → A       0.805244
       B       0.813850
       C       1.607920
Name: (bar, two), dtype: float64
```

Note that df.loc[‘bar’, ‘two’] would also work in this example, but this shorthand notation can lead to ambiguity in general.

If you also want to index a specific column with .loc, you must use a tuple like this:

```
In [39]: df.loc[('bar', 'two'), 'A']
Out[39]: 0.8052440253863785
```

You don’t have to specify all levels of the MultiIndex by passing only the first elements of the tuple. For example, you can use “partial” indexing to get all elements with bar in the first level as follows:

df.loc[‘bar’]

This is a shortcut for the slightly more verbose notation df.loc[('bar',),] (equivalent to df.loc[‘bar’,] in this example).

“Partial” slicing also works quite nicely.

```
In [40]: df.loc[('baz':'foo')]
Out[40]:
   A   B   C
first second
baz one  1.206412  0.132003  1.024180
two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
two  1.340309 -1.187678 -2.211372
```

You can slice with a ‘range’ of values, by providing a slice of tuples.
In [41]: df.loc[['baz', 'two']:('qux', 'one')]

Out[41]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>baz</td>
<td>two</td>
<td></td>
<td></td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td></td>
<td></td>
</tr>
<tr>
<td>two</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>qux</td>
<td>one</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

In [42]: df.loc[['baz', 'two']: 'foo']

Out[42]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Passing a list of labels or tuples works similar to reindexing:

In [43]: df.loc[['bar', 'two'], ('qux', 'one')]

Out[43]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>first</td>
<td>second</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>two</td>
<td></td>
<td></td>
</tr>
<tr>
<td>qux</td>
<td>one</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Note: It is important to note that tuples and lists are not treated identically in pandas when it comes to indexing. Whereas a tuple is interpreted as one multi-level key, a list is used to specify several keys. Or in other words, tuples go horizontally (traversing levels), lists go vertically (scanning levels).

Importantly, a list of tuples indexes several complete MultiIndex keys, whereas a tuple of lists refer to several values within a level:

In [44]: s = pd.Series([1, 2, 3, 4, 5, 6],
                   index=pd.MultiIndex.from_product([["A", "B"], ["c", "d", "e"]]))

In [45]: s.loc[('A', 'c'), ('B', 'd')]  # list of tuples

Out[45]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>c</th>
<th>1</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>d</th>
<th>5</th>
</tr>
</thead>
</table>

In [46]: s.loc[('A', 'B'), ('c', 'd')]  # tuple of lists

Out[46]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>c</th>
<th>1</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th></th>
<th>d</th>
<th>2</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th></th>
<th>B</th>
<th>c</th>
<th>4</th>
</tr>
</thead>
</table>

|     | d | 5 |
|-----|---|---|---|
13.2.1 Using slicers

You can slice a MultiIndex by providing multiple indexers.

You can provide any of the selectors as if you are indexing by label, see Selection by Label, including slices, lists of labels, labels, and boolean indexers.

You can use `slice(None)` to select all the contents of that level. You do not need to specify all the deeper levels, they will be implied as `slice(None)`.

As usual, both sides of the slicers are included as this is label indexing.

**Warning:** You should specify all axes in the `.loc` specifier, meaning the indexer for the index and for the columns. There are some ambiguous cases where the passed indexer could be mis-interpreted as indexing both axes, rather than into say the MultiIndex for the rows.

You should do this:

```python
df.loc[('A1','A3'),.....], :]
```

You should not do this:

```python
df.loc[('A1','A3'),.....]
```

```
In [47]: def mklbl(prefix,n):
   ....:     return ['%s%s' % (prefix,i) for i in range(n)]
   ....:

In [48]: miindex = pd.MultiIndex.from_product([mklbl('A',4),
   ....:     mklbl('B',2),
   ....:     mklbl('C',4),
   ....:     mklbl('D',2)])

In [49]: micolumns = pd.MultiIndex.from_tuples([('a','foo'),('a','bar'),
   ....:     ('b','foo'),('b','bah')],
   ....:     names=['lvl0', 'lvl1'])

In [50]: dfmi = pd.DataFrame(np.arange(len(miindex)*len(micolumns)).
   ....:     reshape((len(miindex),len(micolumns))),
   ....:     index=miindex,
   ....:     columns=micolumns).sort_index().sort_index(axis=1)

In [51]: dfmi
```

Out[51]:

<table>
<thead>
<tr>
<th></th>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>lvl0</td>
<td>lvl1</td>
<td></td>
<td></td>
</tr>
<tr>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>D1</td>
<td>5</td>
<td>4</td>
<td>7</td>
</tr>
<tr>
<td>C1</td>
<td>D0</td>
<td>9</td>
<td>8</td>
</tr>
<tr>
<td>D1</td>
<td>13</td>
<td>12</td>
<td>15</td>
</tr>
<tr>
<td>C2</td>
<td>D0</td>
<td>17</td>
<td>16</td>
</tr>
<tr>
<td>D1</td>
<td>21</td>
<td>20</td>
<td>23</td>
</tr>
<tr>
<td>C3</td>
<td>D0</td>
<td>25</td>
<td>24</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>A3</td>
<td>B1</td>
<td>C0</td>
<td>D1</td>
</tr>
</tbody>
</table>

(continues on next page)
Basic multi-index slicing using slices, lists, and labels.

```
In [52]: dfmi.loc[(slice('A1', 'A3'), slice(None), ['C1', 'C3']), :]
Out[52]:
        a   b
lvl0 bar foo bah foo
A0 B0 C1 D0  73  72  75  74
     D1  77  76  79  78
     C3 D0  89  88  91  90
     D1  93  92  95  94
     B1 C1 D0 105 104 107 106
     D1 109 108 111 110
     C3 D0 121 120 123 122
... ... ... ... ...
A3 B0 C1 D1 205 204 207 206
     C3 D0 217 216 219 218
     D1 221 220 223 222
     B1 C1 D0 233 232 235 234
     D1 237 236 239 238
     C3 D0 249 248 251 250
     D1 253 252 255 254
```

[24 rows x 4 columns]

You can use `pandas.IndexSlice` to facilitate a more natural syntax using :, rather than using `slice(0)`.

```
In [53]: idx = pd.IndexSlice
In [54]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]
Out[54]:
        a   b
lvl0 foo foo
A0 B0 C1 D0  8  10
     D1  12  14
     C3 D0 24  26
     D1  28  30
     B1 C1 D0 40  42
     D1  44  46
     C3 D0 56  58
... ... ... ...
A3 B0 C1 D1 204 206
     C3 D0 216 218
     D1 220 222
     B1 C1 D0 232 234
     D1 236 238
     C3 D0 248 250
     D1 252 254
```

(continues on next page)
It is possible to perform quite complicated selections using this method on multiple axes at the same time.

In [55]: dfmi.loc['A1', (slice(None), 'foo')]
Out[55]:
lvl0 a b
lvl1 foo foo
B0 C0 D0 64 66
  D1 68 70
  C1 D0 72 74
  D1 76 78
C2 D0 80 82
  D1 84 86
  C3 D0 88 90
  ...
B1 C0 D1 100 102
  C1 D0 104 106
  D1 108 110
C2 D0 112 114
  D1 116 118
  C3 D0 120 122
  D1 124 126
... ...
A3 B0 C1 D1 204 206
  C3 D0 216 218
  D1 220 222
B1 C1 D0 232 234
  D1 236 238
  C3 D0 248 250
  D1 252 254
[32 rows x 2 columns]

In [56]: dfmi.loc[idx[:, :, ['C1', 'C3']], idx[:, 'foo']]

lvl0 a b
lvl1 foo foo
A0 B0 C1 D0 8 10
  D1 12 14
  C3 D0 24 26
  D1 28 30
B1 C1 D0 40 42
  D1 44 46
  C3 D0 56 58
  ...
A3 B0 C1 D1 204 206
  C3 D0 216 218
  D1 220 222
B1 C1 D0 232 234
  D1 236 238
  C3 D0 248 250
  D1 252 254
[32 rows x 2 columns]

Using a boolean indexer you can provide selection related to the values.

In [57]: mask = dfmi[('a', 'foo')] > 200
    
In [58]: dfmi.loc[idx[mask, :, ['C1', 'C3']], idx[:, 'foo']]
You can also specify the `axis` argument to `.loc` to interpret the passed slicers on a single axis.

```python
In [59]: dfmi.loc(axis=0)[[:, :, ['C1', 'C3']]
Out[59]:
   lvl0  a  b
     lvl1    bar  foo  bah  foo
  A0  B0  C1  D0  9  8  11  10
      D1  13  12  15  14
  C3  D0  25  24  27  26
      D1  29  28  31  30
  B1  C1  D0  41  40  43  42
      D1  45  44  47  46
  C3  D0  57  56  59  58
   ...  ...  ...  ...  ...  ...
  lvl0  a  b
     lvl1    bar  foo  bah  foo
   A3  B0  C1  D1  205 204 207 206
      C3  D0  217 216 219 218
      D1  221 220 223 222
  B1  C1  D0  233 232 235 234
      D1  237 236 239 238
  C3  D0  249 248 251 250
      D1  253 252 255 254
[32 rows x 4 columns]
```

Furthermore you can set the values using the following methods.

```python
In [60]: df2 = dfmi.copy()

In [61]: df2.loc(axis=0)[[:, :, ['C1', 'C3']]] = -10

In [62]: df2
Out[62]:
   lvl0  a  b
     lvl1    bar  foo  bah  foo
  A0  B0  C1  D0  1  0  3  2
      D1  5  4  7  6
  C3  D0 -10 -10 -10 -10
      D1 -10 -10 -10 -10
  B1  C1  D0 -10 -10 -10 -10
      D1 -10 -10 -10 -10
  C3  D0 -10 -10 -10 -10
   ...  ...  ...  ...  ...  ...
  A3  B1  C0  D1  229 228 231 230
      C1  D0 -10 -10 -10 -10
      D1 -10 -10 -10 -10
  C2  D0  241 240 243 242
      D1  245 244 247 246
  C3  D0 -10 -10 -10 -10
      D1 -10 -10 -10 -10
```

(continues on next page)
You can use a right-hand-side of an alignable object as well.

```python
In [63]: df2 = dfmi.copy()

In [64]: df2.loc[idx[:, :, ['C1', 'C3']], :] = df2 * 1000

In [65]: df2
```

```python
Out[65]:
   lvl0  a  b  
  lvl1  
   bar  foo bah foo
A0 B0 C0 D0 1  0  3  2
   5  4  7  6
   9000 8000 11000 10000
   13000 12000 15000 14000
C1 D0 17  16 19  18
   21  20 23  22
   25000 24000 27000 26000
   ... ... ... ... ...
D1 21 20 23 22
   241 240 243 242
   245 244 247 246
   249000 248000 251000 250000
   253000 252000 255000 254000
[64 rows x 4 columns]
```

### 13.2.2 Cross-section

The `xs` method of `DataFrame` additionally takes a level argument to make selecting data at a particular level of a `MultiIndex` easier.

```python
In [66]: df
```

```python
Out[66]:
   A  B  C
  first second
bar one  0.895717  0.410835 -1.413681
    two  0.805244  0.813850  1.607920
baz one  1.206412  0.132003  1.024180
    two  2.565646 -0.827317  0.569605
foo one  1.431256 -0.076467  0.875906
    two  1.340309 -1.187678 -2.211372
qux one  1.170299  1.130127  0.974466
    two -0.226169 -1.436737 -2.006747
```

```python
In [67]: df.xs('one', level='second')
```

```python
Out[67]:
   A  B  C
  first
bar one  0.895717  0.410835 -1.413681
```
# using the slicers

```python
In [68]: df.loc[(slice(None),'one'),:]
Out[68]:
   A    B    C
first second
bar one  0.895717 0.410835 -1.413681
baz one  -1.206412 0.132003  1.024180
foo one  1.431256 -0.076467  0.875906
qux one  -1.170299 1.130127  0.974466
```

You can also select on the columns with `xs()`, by providing the axis argument.

```python
In [69]: df = df.T

In [70]: df.xs('one', level='second', axis=1)
Out[70]:
   A    B    C
first bar baz foo qux
   0.895717 -1.206412 1.431256 -1.170299
   0.410835  0.132003 -0.076467  1.130127
   -1.413681 1.024180  0.875906  0.974466
```

`xs()` also allows selection with multiple keys.

```python
In [71]: df.xs(('one', 'bar'), level=('second', 'first'), axis=1)
Out[71]:
   first bar
second one
   A   0.895717
   B   0.410835
   C  -1.413681
```

You can pass `drop_level=False` to `xs()` to retain the level that was selected.
In [74]: df.xs('one', level='second', axis=1, drop_level=False)
Out[74]:
     first  bar  baz  foo  qux
second one  one  one  one
   A  0.895717 -1.206412 1.431256 -1.170299
   B  0.410835  0.132003 -0.076467 1.130127
   C -1.413681  1.024180  0.875906  0.974466

Compare the above with the result using drop_level=True (the default value).

In [75]: df.xs('one', level='second', axis=1, drop_level=True)
Out[75]:
     first  bar  baz  foo  qux
   A  0.895717 -1.206412 1.431256 -1.170299
   B  0.410835  0.132003 -0.076467 1.130127
   C -1.413681  1.024180  0.875906  0.974466

13.2.3 Advanced reindexing and alignment

The parameter level has been added to the reindex and align methods of pandas objects. This is useful to broadcast values across a level. For instance:

In [76]: midx = pd.MultiIndex(levels=[['zero', 'one'], ['x','y']],
                        labels=[[1,1,0,0],[1,0,1,0]])
In [77]: df = pd.DataFrame(np.random.randn(4,2), index=midx)
In [78]: df
Out[78]:
     0  1
  one y  1.519970  -0.493662
      x  0.600178   0.274230
  zero y  0.132885  -0.023688
      x  2.410179   1.450520

In [79]: df2 = df.mean(level=0)
In [80]: df2
Out[80]:
     0  1
  one  1.060074  -0.109716
  zero  1.271532   0.713416

In [81]: df2.reindex(df.index, level=0)

In [82]: df_aligned, df2_aligned = df.align(df2, level=0)

# aligning
In [83]: df_aligned, df2_aligned = df.align(df2, level=0)

(continues on next page)
In [83]: df_aligned
Out[83]:
    0  1
one y  1.519970 -0.493662
  x  0.600178  0.274230
zero y  0.132885 -0.023688
   x  2.410179  1.450520

In [84]: df2_aligned
   →
    0  1
one y  1.060074 -0.109716
  x  1.060074 -0.109716
zero y  1.271532  0.713416
   x  1.271532  0.713416

13.2.4 Swapping levels with swaplevel()

The swaplevel function can switch the order of two levels:

In [85]: df[:5]
Out[85]:
    0  1
one y  1.519970 -0.493662
  x  0.600178  0.274230
zero y  0.132885 -0.023688
   x  2.410179  1.450520

In [86]: df[:5].swaplevel(0, 1, axis=0)
   →
    0  1
  y one  1.519970 -0.493662
    x one  0.600178  0.274230
  y zero  0.132885 -0.023688
    x zero  2.410179  1.450520

13.2.5 Reordering levels with reorder_levels()

The reorder_levels function generalizes the swaplevel function, allowing you to permute the hierarchical index levels in one step:

In [87]: df[:5].reorder_levels([1,0], axis=0)
Out[87]:
    0  1
  y one  1.519970 -0.493662
    x one  0.600178  0.274230
  y zero  0.132885 -0.023688
    x zero  2.410179  1.450520

Chapter 13. MutiIndex / Advanced Indexing
13.3 Sorting a MultiIndex

For MultiIndex-ed objects to be indexed and sliced effectively, they need to be sorted. As with any index, you can use `sort_index`.

```python
In [88]: import random; random.shuffle(tuples)
In [89]: s = pd.Series(np.random.randn(8), index=pd.MultiIndex.from_tuples(tuples))
In [90]: s
Out[90]:
bar two  0.206053
  qux one -0.251905
  bar one -2.213588
  baz two  1.063327
  foo two  1.266143
  one  0.299368
  baz one -0.863838
  qux two  0.408204
dtype: float64
In [91]: s.sort_index()
   →
  bar one -2.213588
    two  0.206053
  baz one -0.863838
    two  1.063327
  foo one  0.299368
    two  1.266143
  qux one -0.251905
    two  0.408204
dtype: float64
In [92]: s.sort_index(level=0)
   →
  bar one -2.213588
    two  0.206053
  baz one -0.863838
    two  1.063327
  foo one  0.299368
    two  1.266143
  qux one -0.251905
    two  0.408204
dtype: float64
In [93]: s.sort_index(level=1)
   →
  bar one -2.213588
  baz one -0.863838
  foo one  0.299368
  qux one -0.251905
  bar two  0.206053
  baz two  1.063327
  foo two  1.266143
```

(continues on next page)
You may also pass a level name to `sort_index` if the MultiIndex levels are named.

```python
In [94]: s.index.set_names(['L1', 'L2'], inplace=True)

In [95]: s.sort_index(level='L1')
Out[95]:
   L1  L2
bar one -2.213588
    two  0.206053
baz one -0.863838
    two  1.063327
foo one  0.299368
    two  1.266143
qux one -0.251905
    two  0.408204
dtype: float64

In [96]: s.sort_index(level='L2')
```

On higher dimensional objects, you can sort any of the other axes by level if they have a MultiIndex:

```python
In [97]: df.T.sort_index(level=1, axis=1)
Out[97]:
   zero one zero one
        x   x   y   y
0   2.410179  0.600178  0.132885  1.519970
1   1.450520  0.274230 -0.023688 -0.493662
```

Indexing will work even if the data are not sorted, but will be rather inefficient (and show a `PerformanceWarning`). It will also return a copy of the data rather than a view:

```python
In [98]: dfm = pd.DataFrame({'jim': [0, 0, 1, 1],
                      'joe': ['x', 'x', 'z', 'y'],
                      'jolie': np.random.rand(4)});

In [99]: dfm = dfm.set_index(['jim', 'joe'])

In [100]: dfm
Out[100]:
   jolie
```

(continues on next page)
In [4]: dfm.loc[(1, 'z')]
PerformanceWarning: indexing past lexsort depth may impact performance.

Out[4]:
    jolie
    jim joe
1    z    0.64094

Furthermore if you try to index something that is not fully lexsorted, this can raise:

In [5]: dfm.loc[[0,'y']:(1, 'z')]

UnsortedIndexError: 'Key length (2) was greater than MultiIndex lexsort depth (1)'

The `is_lexsorted()` method on an Index show if the index is sorted, and the `lexsort_depth` property returns the sort depth:

In [101]: dfm.index.is_lexsorted()
Out[101]: False

In [102]: dfm.index.lexsort_depth
Out[102]: 1

In [103]: dfm = dfm.sort_index()

In [104]: dfm

Out[104]:
    jolie
    jim joe
0    x    0.490671
     x    0.120248
1    y    0.110968
     z    0.537020

In [105]: dfm.index.is_lexsorted()
Out[105]: True

In [106]: dfm.index.lexsort_depth
Out[106]: 2

And now selection works as expected.

In [107]: dfm.loc[[0,'y']:(1, 'z')]

Out[107]:
    jolie
    jim joe
1    y    0.110968
     z    0.537020

13.3. Sorting a MultiIndex
13.4 Take Methods

Similar to NumPy ndarrays, pandas Index, Series, and DataFrame also provides the `take` method that retrieves elements along a given axis at the given indices. The given indices must be either a list or an ndarray of integer index positions. `take` will also accept negative integers as relative positions to the end of the object.

```
In [108]: index = pd.Index(np.random.randint(0, 1000, 10))
In [109]: index
Out[109]: Int64Index([214, 502, 712, 567, 786, 175, 993, 133, 758, 329], dtype='int64')
In [110]: positions = [0, 9, 3]
In [111]: index[positions]
Out[111]: Int64Index([214, 329, 567], dtype='int64')
In [112]: index.take(positions)
Out[112]: Int64Index([214, 329, 567], dtype='int64')
In [113]: ser = pd.Series(np.random.randn(10))
In [114]: ser.iloc[positions]
Out[114]:
0  -0.179666
9   1.824375
3   0.392149
dtype: float64
In [115]: ser.take(positions)
Out[115]:
0   -0.179666
9    1.824375
3    0.392149
dtype: float64
```

For DataFrames, the given indices should be a 1d list or ndarray that specifies row or column positions.

```
In [116]: frm = pd.DataFrame(np.random.randn(5, 3))
In [117]: frm.take([1, 4, 3])
Out[117]:
      0  1  2
0 -1.237881 0.106854 -1.276829
1  0.629675 -1.425966  1.857704
2 -0.767101  1.499591  0.615855
3  0.979542 -1.633678  0.615855
4  0.629675  1.857704
In [118]: frm.take([0, 2], axis=1)
Out[118]:
      0  2
0  0.595974 0.601544
1 -1.237881 -1.276829
2  0.767101  1.499591
3  0.979542  0.615855
4  0.629675  1.857704
```
It is important to note that the `take` method on pandas objects are not intended to work on boolean indices and may return unexpected results.

```python
In [119]: arr = np.random.randn(10)
In [120]: arr.take([False, False, True, True])
Out[120]: array([-1.1935, -1.1935,  0.6775,  0.6775])
In [121]: arr[[0, 1]]
Out[121]: array([-1.1935, 0.6775])
In [122]: ser = pd.Series(np.random.randn(10))
In [123]: ser.take([False, False, True, True])
Out[123]:
  0   0.233141
  1   -0.223540
      dtype: float64
In [124]: ser.iloc[[0, 1]]
Out[124]:
  0   0.233141
  1  -0.223540
      dtype: float64
```

Finally, as a small note on performance, because the `take` method handles a narrower range of inputs, it can offer performance that is a good deal faster than fancy indexing.

## 13.5 Index Types

We have discussed `MultiIndex` in the previous sections pretty extensively. `DatetimeIndex` and `PeriodIndex` are shown [here](#), and information about `TimedeltaIndex` is found [here](#).

In the following sub-sections we will highlight some other index types.

### 13.5.1 CategoricalIndex

`CategoricalIndex` is a type of index that is useful for supporting indexing with duplicates. This is a container around a `Categorical` and allows efficient indexing and storage of an index with a large number of duplicated elements.

```python
In [125]: from pandas.api.types import CategoricalDtype
In [126]: df = pd.DataFrame({'A': np.arange(6),
                           'B': list('aabbca')})
In [127]: df['B'] = df['B'].astype(CategoricalDtype(list('cab')))  
In [128]: df
```

(continues on next page)
Out[128]:
    A  B
0  0  a
1  1  a
2  2  b
3  3  b
4  4  c
5  5  a

In [129]: df.dtypes

Out[129]:
A  int64
B  category
dtype: object

In [130]: df.B.cat.categories

Index(['c', 'a', 'b'], dtype='object')

Setting the index will create a CategoricalIndex.

In [131]: df2 = df.set_index('B')

In [132]: df2.index

Out[132]: CategoricalIndex(['a', 'a', 'b', 'b', 'c', 'a'], categories=['c', 'a', 'b'],
                            ordered=False, name='B', dtype='category')

Indexing with __getitem__/.iloc/.loc works similarly to an Index with duplicates. The indexers must be in the category or the operation will raise a KeyError.

In [133]: df2.loc['a']

Out[133]:
    A  B
    a  0
    a  1
    a  5

The CategoricalIndex is preserved after indexing:

In [134]: df2.loc['a'].index

Out[134]: CategoricalIndex(['a', 'a', 'a'], categories=['c', 'a', 'b'], ordered=False,
                          name='B', dtype='category')

Sorting the index will sort by the order of the categories (recall that we created the index with CategoricalDtype(list('cab')), so the sorted order is cab).

In [135]: df2.sort_index()

Out[135]:
    A  B
    c  4
    a  0
    a  1
    a  5
    b  2
    b  3
Groupby operations on the index will preserve the index nature as well.

```python
In [136]: df2.groupby(level=0).sum()
Out[136]:
   A  B
a 6  0
b 5  0
c 0  0
```

Reindexing operations will return a resulting index based on the type of the passed indexer. Passing a list will return a plain-old Index; indexing with a Categorical will return a CategoricalIndex, indexed according to the categories of the passed Categorical dtype. This allows one to arbitrarily index these even with values not in the categories, similarly to how you can reindex any pandas index.

```python
In [138]: df2.reindex(['a', 'e'])
Out[138]:
   A  B
a 0  0
a 1  0
a 5  0
e NaN
```

```
In [140]: df2.reindex(pd.Categorical(['a', 'e'], categories=list('abcde')))
```

```
Warning: Reshaping and Comparison operations on a CategoricalIndex must have the same categories or a TypeError will be raised.
```

```python
In [9]: df3 = pd.DataFrame({'A': np.arange(6),
                     'B': pd.Series(list('aabbca')).astype('category')})
In [11]: df3 = df3.set_index('B')
```

```
In [11]: pd.concat([df2, df3])
```
13.5.2 Int64Index and RangeIndex

**Warning:** Indexing on an integer-based Index with floats has been clarified in 0.18.0, for a summary of the changes, see [here](#).

Int64Index is a fundamental basic index in pandas. This is an Immutable array implementing an ordered, sliceable set. Prior to 0.18.0, the Int64Index would provide the default index for all NDFrame objects.

RangeIndex is a sub-class of Int64Index added in version 0.18.0, now providing the default index for all NDFrame objects. RangeIndex is an optimized version of Int64Index that can represent a monotonic ordered set. These are analogous to Python range types.

13.5.3 Float64Index

By default a Float64Index will be automatically created when passing floating, or mixed-integer-floating values in index creation. This enables a pure label-based slicing paradigm that makes [],ix,loc for scalar indexing and slicing work exactly the same.

```
In [142]: indexf = pd.Index([1.5, 2, 3, 4.5, 5])
In [143]: indexf
Out[143]: Float64Index([1.5, 2.0, 3.0, 4.5, 5.0], dtype='float64')
In [144]: sf = pd.Series(range(5), index=indexf)
In [145]: sf
Out[145]:
1.5 0
2.0 1
3.0 2
4.5 3
5.0 4
dtype: int64
```

Scalar selection for [],.loc will always be label based. An integer will match an equal float index (e.g. 3 is equivalent to 3.0).

```
In [146]: sf[3]
Out[146]: 2
In [147]: sf[3.0]
Out[147]: 2
In [148]: sf.loc[3]
Out[148]: 2
In [149]: sf.loc[3.0]
Out[149]: 2
```

The only positional indexing is via iloc.
A scalar index that is not found will raise a `KeyError`. Slicing is primarily on the values of the index when using `[]`, `ix`, `loc`, and `always` positional when using `iloc`. The exception is when the slice is boolean, in which case it will always be positional.

In float indexes, slicing using floats is allowed.

In non-float indexes, slicing using floats will raise a `TypeError`.

**Warning:** Using a scalar float indexer for `.iloc` has been removed in 0.18.0, so the following will raise a `TypeError`:
Here is a typical use-case for using this type of indexing. Imagine that you have a somewhat irregular timedelta-like indexing scheme, but the data is recorded as floats. This could for example be millisecond offsets.

```
In [156]: dfir = pd.concat([pd.DataFrame(np.random.randn(5,2),
                        index=np.arange(5) * 250.0,
                        columns=list('AB')),
                        pd.DataFrame(np.random.randn(6,2),
                        index=np.arange(4,10) * 250.1,
                        columns=list('AB'))])
```

```
In [157]: dfir
Out[157]:
       A       B
0   0.997289  -1.693316
250  0.310610  -0.108002
500  0.936914   0.912560
750  0.936914   0.912560
1000  2.495362  -0.432771
1250  0.310610  -0.108002
1500 -2.281374   0.760010
1750 -0.742532  -1.147708
2000  2.495362  -0.432771
2250 -0.068954   0.043520
```

Selection operations then will always work on a value basis, for all selection operators.

```
In [158]: dfir[0:1000.4]
Out[158]:
       A       B
0   0.997289  -1.693316
250  0.310610  -0.108002
500  0.936914   0.912560
750  0.936914   0.912560
1000  2.495362  -0.432771
1250  0.310610  -0.108002
1500  2.495362  -0.432771
1750  0.310610  -0.108002
```

```
In [159]: dfir.loc[0:1001,'A']
       A
0   0.997289
250 -0.179129
500  0.936914
750 -1.003401
1000 -0.724626
1250 -0.974226
1500 -2.281374
1750 -0.742532
2000 -2.495362
2250 -0.068954
Name: A, dtype: float64
```

```
In [160]: dfir.loc[1000.4]
       A       B
0   0.310610  -0.108002
```

You could retrieve the first 1 second (1000 ms) of data as such:

```
In [161]: dfir[0:1000.4]
Out[161]:
       A       B
0   0.997289  -1.693316
250  0.310610  -0.108002
500  0.936914   0.912560
750  0.936914   0.912560
1000  2.495362  -0.432771
1250  0.310610  -0.108002
1500  2.495362  -0.432771
1750  0.310610  -0.108002
```

You could retrieve the first 1 second (1000 ms) of data as such:
If you need integer based selection, you should use **iloc**:

```
In [162]: dfir.iloc[0:5]
Out[162]:
          A   B
0     0.997289 -1.693316
250.0 -0.179129 -1.598062
500.0  0.936914  0.912560
750.0 -1.003401  1.632781
1000.0 -0.724626  0.178219
```

### 13.5.4 IntervalIndex

New in version 0.20.0.

*IntervalIndex* together with its own dtype, *interval* as well as the *Interval* scalar type, allow first-class support in pandas for interval notation.

The *IntervalIndex* allows some unique indexing and is also used as a return type for the categories in *cut()* and *qcut()*.

**Warning:** These indexing behaviors are provisional and may change in a future version of pandas.

An *IntervalIndex* can be used in Series and in DataFrame as the index.

```
In [163]: df = pd.DataFrame({'A': [1, 2, 3, 4]},
                        index=pd.IntervalIndex.from_breaks([0, 1, 2, 3, 4]))
In [164]: df
Out[164]:

          A
(0, 1]  1
(1, 2]  2
(2, 3]  3
(3, 4]  4
```

Label based indexing via **.loc** along the edges of an interval works as you would expect, selecting that particular interval.

```
In [165]: df.loc[2]
Out[165]:
          A
Name: (1, 2], dtype: int64
```

(continues on next page)
In [166]: df.loc[[2, 3]]
Out[166]:
     A
(1, 2]  2
(2, 3]  3

If you select a label contained within an interval, this will also select the interval.

In [167]: df.loc[2.5]
Out[167]:
     A
Name: (2, 3], dtype: int64

In [168]: df.loc[[2.5, 3.5]]
Out[168]:
     A
(2, 3]  3
(3, 4]  4

Interval and IntervalIndex are used by cut and qcut:

In [169]: c = pd.cut(range(4), bins=2)
In [170]: c
Out[170]:
[(-0.003, 1.5], (-0.003, 1.5], (1.5, 3.0], (1.5, 3.0]]
Categories (2, interval[float64]): 

In [171]: c.categories
IntervalIndex([(-0.003, 1.5], (1.5, 3.0]]
closed='right',
dtype='interval[float64]'

Furthermore, IntervalIndex allows one to bin other data with these same bins, with NaN representing a missing value similar to other dtypes.

In [172]: pd.cut([0, 3, 5, 1], bins=c.categories)
Out[172]:
[(-0.003, 1.5], (1.5, 3.0], NaN, (-0.003, 1.5]]
Categories (2, interval[float64]): 

13.6 Miscellaneous indexing FAQ

13.6.1 Integer indexing

Label-based indexing with integer axis labels is a thorny topic. It has been discussed heavily on mailing lists and among various members of the scientific Python community. In pandas, our general viewpoint is that labels matter more than integer locations. Therefore, with an integer axis index only label-based indexing is possible with the standard tools like .loc. The following code will generate exceptions:
This deliberate decision was made to prevent ambiguities and subtle bugs (many users reported finding bugs when the API change was made to stop “falling back” on position-based indexing).

### 13.6.2 Non-monotonic indexes require exact matches

If the index of a `Series` or `DataFrame` is monotonically increasing or decreasing, then the bounds of a label-based slice can be outside the range of the index, much like slice indexing a normal Python `list`. Monotonicity of an index can be tested with the `is_monotonic_increasing` and `is_monotonic_decreasing` attributes.

```
In [173]: df = pd.DataFrame(index=[2,3,3,4,5], columns=['data'], data=list(range(5)))
In [174]: df.index.is_monotonic_increasing
Out[174]: True

# no rows 0 or 1, but still returns rows 2, 3 (both of them), and 4:
In [175]: df.loc[0:4, :]
Out[175]:
   data
2   0
3   1
3   2
4   3

# slice is outside the index, so empty DataFrame is returned
In [176]: df.loc[13:15, :]
Out[176]:
Empty DataFrame
Columns: [data]
Index: []
```

On the other hand, if the index is not monotonic, then both slice bounds must be *unique* members of the index.

```
In [177]: df = pd.DataFrame(index=[2,3,1,4,3,5], columns=['data'],
                     data=list(range(6)))
In [178]: df.index.is_monotonic_increasing
Out[178]: False

# OK because 2 and 4 are in the index
In [179]: df.loc[2:4, :]
Out[179]:
   data
2   0
3   1
1   2
4   3

# 0 is not in the index
In [9]: df.loc[0:4, :]
```

(continues on next page)
KeyError: 0

# 3 is not a unique label
In [11]: df.loc[2:3, :]
KeyError: 'Cannot get right slice bound for non-unique label: 3'

Index.is_monotonic_increasing() and Index.is_monotonic_decreasing() only check that an index is weakly monotonic. To check for strict monotonicity, you can combine one of those with Index.is_unique()

In [180]: weakly_monotonic = pd.Index(['a', 'b', 'c', 'c'])

In [181]: weakly_monotonic
Out[181]: Index(['a', 'b', 'c', 'c'], dtype='object')

In [182]: weakly_monotonic.is_monotonic_increasing
Out[182]: True

In [183]: weakly_monotonic.is_monotonic_increasing & weakly_monotonic.is_unique
Out[183]: False

13.6.3 Endpoints are inclusive

Compared with standard Python sequence slicing in which the slice endpoint is not inclusive, label-based slicing in pandas is inclusive. The primary reason for this is that it is often not possible to easily determine the “successor” or next element after a particular label in an index. For example, consider the following Series:

In [184]: s = pd.Series(np.random.randn(6), index=list('abcdef'))

In [185]: s
Out[185]:
da 0.112246
db 0.871721
c -0.816064
d -0.784880
e 1.030659
f 0.187483
dtype: float64

Suppose we wished to slice from c to e, using integers this would be accomplished as such:

In [186]: s[2:5]
Out[186]:
c -0.816064
d -0.784880
e 1.030659
dtype: float64

However, if you only had c and e, determining the next element in the index can be somewhat complicated. For example, the following does not work:

s.loc['c':'e'+1]

A very common use case is to limit a time series to start and end at two specific dates. To enable this, we made the design to make label-based slicing include both endpoints:
This is most definitely a “practicality beats purity” sort of thing, but it is something to watch out for if you expect label-based slicing to behave exactly in the way that standard Python integer slicing works.

### 13.6.4 Indexing potentially changes underlying Series dtype

The different indexing operation can potentially change the dtype of a Series.

```
In [188]: series1 = pd.Series([1, 2, 3])
In [189]: series1.dtype
Out[189]: dtype('int64')
In [190]: res = series1.reindex([0, 4])
In [191]: res.dtype
Out[191]: dtype('float64')
In [192]: res
Out[192]:
0     1.0
4    NaN
```

```
In [193]: series2 = pd.Series([True])
In [194]: series2.dtype
Out[194]: dtype('bool')
In [195]: res = series2.reindex_like(series1)
In [196]: res.dtype
Out[196]: dtype('O')
In [197]: res
Out[197]:
0    True
1    NaN
2    NaN
```

This is because the (re)indexing operations above silently inserts NaNs and the dtype changes accordingly. This can cause some issues when using numpy ufuncs such as `numpy.logical_and`.

See the [this old issue](https://github.com/pandas-dev/pandas/issues/2942) for a more detailed discussion.
14.1 Statistical Functions

14.1.1 Percent Change

Series, DataFrame, and Panel all have a method `pct_change()` to compute the percent change over a given number of periods (using `fill_method` to fill NA/null values before computing the percent change).

```
In [1]: ser = pd.Series(np.random.randn(8))

In [2]: ser.pct_change()
Out[2]:
0    NaN
1 -1.602976
2   4.334938
3  -0.247456
4  -2.067345
5  -1.142903
6  -1.688214
7  -9.759729
dtype: float64
```

```
In [3]: df = pd.DataFrame(np.random.randn(10, 4))

In [4]: df.pct_change(periods=3)
Out[4]:
    0       1       2       3
0  NaN  NaN  NaN   NaN
1  NaN  NaN  NaN   NaN
2  NaN  NaN  NaN   NaN
3 -0.218320 -1.054001 1.987147 -0.510183
4 -0.439121 -1.816454 0.649715 -4.822809
5 -0.127833 -3.042065 -5.866604 -1.776977
6 -2.596833 -1.959538 -2.111697 -3.798900
7 -0.117826 -2.169058 0.036094 -0.067696
8  2.492606 -1.357320 -1.205802 -1.558697
9 -1.012977  2.324558 -1.003744 -0.371806
```

14.1.2 Covariance

`Series.cov()` can be used to compute covariance between series (excluding missing values).
In 

```
In [5]: s1 = pd.Series(np.random.randn(1000))
In [6]: s2 = pd.Series(np.random.randn(1000))
In [7]: s1.cov(s2)
Out[7]: 0.00068010881743110871
```

Analogously, `DataFrame.cov()` to compute pairwise covariances among the series in the DataFrame, also excluding NA/null values.

**Note:** Assuming the missing data are missing at random this results in an estimate for the covariance matrix which is unbiased. However, for many applications this estimate may not be acceptable because the estimated covariance matrix is not guaranteed to be positive semi-definite. This could lead to estimated correlations having absolute values which are greater than one, and/or a non-invertible covariance matrix. See Estimation of covariance matrices for more details.

```
In [8]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])
In [9]: frame.cov()
Out[9]:
   a          b         c          d          e
a  1.000882 -0.003177 -0.002698 -0.006889  0.031912
b -0.003177  1.024721  0.000191  0.009212  0.000857
c -0.002698  0.000191  0.950735 -0.031743 -0.005087
d -0.006889  0.009212 -0.031743  1.002983 -0.047952
e  0.031912  0.000857 -0.005087 -0.047952  1.042487
```

DataFrame.cov also supports an optional `min_periods` keyword that specifies the required minimum number of observations for each column pair in order to have a valid result.

```
In [10]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [11]: frame.loc[frame.index[:5], 'a'] = np.nan
In [12]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [13]: frame.cov()
Out[13]:
   a          b          c
a  1.123670 -0.412851  0.018169
b -0.412851  1.154141  0.305260
c  0.018169  0.305260  1.301149
In [14]: frame.cov(min_periods=12)
```

```
   a          b          c
a  1.123670  NaN        0.018169
b  NaN       1.154141  0.305260
c  0.018169  0.305260  1.301149
```
14.1.3 Correlation

Correlation may be computed using the `corr()` method. Using the `method` parameter, several methods for computing correlations are provided:

<table>
<thead>
<tr>
<th>Method name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>pearson</td>
<td>Standard correlation coefficient</td>
</tr>
<tr>
<td>kendall</td>
<td>Kendall Tau correlation coefficient</td>
</tr>
<tr>
<td>spearman</td>
<td>Spearman rank correlation coefficient</td>
</tr>
</tbody>
</table>

All of these are currently computed using pairwise complete observations. Wikipedia has articles covering the above correlation coefficients:

- Pearson correlation coefficient
- Kendall rank correlation coefficient
- Spearman’s rank correlation coefficient

Note: Please see the caveats associated with this method of calculating correlation matrices in the covariance section.

```
In [15]: frame = pd.DataFrame(np.random.randn(1000, 5), columns=['a', 'b', 'c', 'd', 'e'])
In [16]: frame.iloc[::2] = np.nan

# Series with Series
In [17]: frame['a'].corr(frame['b'])
Out[17]: 0.013479040400098794

In [18]: frame['a'].corr(frame['b'], method='spearman')
Out[18]: -0.0072898851595406371

# Pairwise correlation of DataFrame columns
In [19]: frame.corr()
Out[19]:
     a     b     c     d     e
a  1.000000 0.013479 -0.049269 -0.042239 -0.028525
b  0.013479 1.000000 -0.020433 -0.011139 0.005654
c -0.049269 -0.020433 1.000000 0.018587 -0.054269
d -0.042239 -0.011139 0.018587 1.000000 -0.017060
e -0.028525 0.005654 -0.054269 -0.017060 1.000000
```

Note that non-numeric columns will be automatically excluded from the correlation calculation.

Like `cov`, `corr` also supports the optional `min_periods` keyword:

```
In [20]: frame = pd.DataFrame(np.random.randn(20, 3), columns=['a', 'b', 'c'])
In [21]: frame.loc[frame.index[:5], 'a'] = np.nan
In [22]: frame.loc[frame.index[5:10], 'b'] = np.nan
In [23]: frame.corr()
Out[23]:
```

(continues on next page)
A related method `corrwith()` is implemented on DataFrame to compute the correlation between like-labeled Series contained in different DataFrame objects.

```python
In [25]: index = ['a', 'b', 'c', 'd', 'e']
In [26]: columns = ['one', 'two', 'three', 'four']
In [27]: df1 = pd.DataFrame(np.random.randn(5, 4), index=index, columns=columns)
In [28]: df2 = pd.DataFrame(np.random.randn(4, 4), index=index[:4], columns=columns)
In [29]: df1.corrwith(df2)
Out[29]:
\n\n| one   | two   | three  | four  |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>-0.125501</td>
<td>-0.493244</td>
<td>0.344056</td>
<td>0.004183</td>
</tr>
</tbody>
</table>

dtype: float64
```

14.1.4 Data ranking

The `rank()` method produces a data ranking with ties being assigned the mean of the ranks (by default) for the group:

```python
In [31]: s = pd.Series(np.random.randn(5), index=list('abcde'))
In [32]: s['d'] = s['b']  # so there's a tie
In [33]: s.rank()
Out[33]:
\n\n| a   | b   | c   |
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>5.0</td>
<td>2.5</td>
<td>1.0</td>
</tr>
</tbody>
</table>
```
rank() is also a DataFrame method and can rank either the rows (axis=0) or the columns (axis=1). NaN values are excluded from the ranking.

```python
In [34]: df = pd.DataFrame(np.random.randn(10, 6))
In [36]: df
Out[36]:
       0         1         2         3         4         5
0 -0.904948 -1.163537 -1.457187  0.135463 -1.457187  0.294650
1 -0.976288 -0.244652 -0.748406 -0.999601 -0.748406 -0.800809
2  0.401965  1.460840  1.256057  1.308127  1.256057  0.876004
3  0.205954  0.369552 -0.669304  0.038378 -0.669304  1.140296
4 -0.477586 -0.730705 -1.129149 -0.601463 -1.129149 -0.211196
5 -1.092970 -0.689246  0.908114  0.204848    NaN  0.463347
6  0.376892  0.959292  0.095572 -0.593740 -0.593740 -0.691801
7 -1.002601  1.957794 -0.120708  0.094214    NaN -1.467422
8 -0.547231  0.664402 -0.519424 -0.073254 -0.073254  1.263544
9 -0.250277 -0.237428 -1.056443  0.419477    NaN  1.375064
```

rank optionally takes a parameter ascending which by default is true; when false, data is reverse-ranked, with larger values assigned a smaller rank.

rank supports different tie-breaking methods, specified with the method parameter:

- **average**: average rank of tied group
- **min**: lowest rank in the group
- **max**: highest rank in the group
- **first**: ranks assigned in the order they appear in the array

### 14.2 Window Functions

For working with data, a number of window functions are provided for computing common window or rolling statistics. Among these are count, sum, mean, median, correlation, variance, covariance, standard deviation, skewness, and
The rolling() and expanding() functions can be used directly from DataFrameGroupBy objects, see the groupby docs.

**Note:** The API for window statistics is quite similar to the way one works with GroupBy objects, see the documentation here.

We work with rolling, expanding and exponentially weighted data through the corresponding objects, Rolling, Expanding and EWM.

```
In [38]: s = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', periods=1000))
In [39]: s = s.cumsum()
In [40]: s
Out[40]:
2000-01-01 -0.268824
2000-01-02 -1.771855
2000-01-03 -0.818003
2000-01-04 -0.659244
2000-01-05 -1.942133
2000-01-06 -1.869391
2000-01-07 0.563674
...  
2002-09-20 -68.233054
2002-09-21 -66.765687
2002-09-22 -67.457323
2002-09-23 -69.253182
2002-09-24 -70.296818
2002-09-25 -70.844674
2002-09-26 -72.475016
Freq: D, Length: 1000, dtype: float64
```

These are created from methods on Series and DataFrame.

```
In [41]: r = s.rolling(window=60)
In [42]: r
Out[42]: Rolling [window=60,center=False,axis=0]
```

These object provide tab-completion of the available methods and properties.

```
In [14]: r
    r.agg r.apply r.count r.exclusions r.max r.median r.
    r.name r.skew r.sum
    r.aggregate r.corr r.cov r.kurt r.mean r.min r.
    r.quantile r.std r.var
```

Generally these methods all have the same interface. They all accept the following arguments:

- **window**: size of moving window
- **min_periods**: threshold of non-null data points to require (otherwise result is NA)
- **center**: boolean, whether to set the labels at the center (default is False)

We can then call methods on these rolling objects. These return like-indexed objects:
In [43]: r.mean()
Out[43]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05    NaN
2000-01-06    NaN
2000-01-07    NaN
... 
2002-09-20  -62.694135
2002-09-21  -62.812190
2002-09-22  -62.914971
2002-09-23  -63.061867
2002-09-24  -63.213876
2002-09-25  -63.375074
2002-09-26  -63.539734
Freq: D, Length: 1000, dtype: float64

In [44]: s.plot(style='k--')
Out[44]: <matplotlib.axes._subplots.AxesSubplot at 0x1a20046898>

In [45]: r.mean().plot(style='k')
Out[45]: <matplotlib.axes._subplots.AxesSubplot at 0x1a20046898>

14.2. Window Functions
They can also be applied to DataFrame objects. This is really just syntactic sugar for applying the moving window operator to all of the DataFrame’s columns:

```python
In [46]: df = pd.DataFrame(np.random.randn(1000, 4),
                      index=pd.date_range('1/1/2000', periods=1000),
                      columns=['A', 'B', 'C', 'D'])

In [47]: df = df.cumsum()

In [48]: df.rolling(window=60).sum().plot(subplots=True)
```

14.2.1 Method Summary

We provide a number of common statistical functions:
<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>count()</code></td>
<td>Number of non-null observations</td>
</tr>
<tr>
<td><code>sum()</code></td>
<td>Sum of values</td>
</tr>
<tr>
<td><code>mean()</code></td>
<td>Mean of values</td>
</tr>
<tr>
<td><code>median()</code></td>
<td>Arithmetic median of values</td>
</tr>
<tr>
<td><code>min()</code></td>
<td>Minimum</td>
</tr>
<tr>
<td><code>max()</code></td>
<td>Maximum</td>
</tr>
<tr>
<td><code>std()</code></td>
<td>Bessel-corrected sample standard deviation</td>
</tr>
<tr>
<td><code>var()</code></td>
<td>Unbiased variance</td>
</tr>
<tr>
<td><code>skew()</code></td>
<td>Sample skewness (3rd moment)</td>
</tr>
<tr>
<td><code>kurt()</code></td>
<td>Sample kurtosis (4th moment)</td>
</tr>
<tr>
<td><code>quantile()</code></td>
<td>Sample quantile (value at %)</td>
</tr>
<tr>
<td><code>apply()</code></td>
<td>Generic apply</td>
</tr>
<tr>
<td><code>cov()</code></td>
<td>Unbiased covariance (binary)</td>
</tr>
<tr>
<td><code>corr()</code></td>
<td>Correlation (binary)</td>
</tr>
</tbody>
</table>

The `apply()` function takes an extra `func` argument and performs generic rolling computations. The `func` argument should be a single function that produces a single value from an ndarray input. Suppose we wanted to compute the mean absolute deviation on a rolling basis:

```
In [49]: mad = lambda x: np.fabs(x - x.mean()).mean()
In [50]: s.rolling(window=60).apply(mad, raw=True).plot(style='k')
Out[50]: <matplotlib.axes._subplots.AxesSubplot at 0x1a20376f98>
```
14.2.2 Rolling Windows

Passing `win_type` to `.rolling` generates a generic rolling window computation, that is weighted according the `win_type`. The following methods are available:

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sum()</code></td>
<td>Sum of values</td>
</tr>
<tr>
<td><code>mean()</code></td>
<td>Mean of values</td>
</tr>
</tbody>
</table>

The weights used in the window are specified by the `win_type` keyword. The list of recognized types are the `scipy.signal` window functions:

- `boxcar`
- `triang`
- `blackman`
- `hamming`
- `bartlett`
- `parzen`
- `bohman`
• blackmanharris
• nuttall
• barthann
• kaiser (needs beta)
• gaussian (needs std)
• general_gaussian (needs power, width)
• slepian (needs width).

In [51]: ser = pd.Series(np.random.randn(10), index=pd.date_range('1/1/2000', periods=10))

In [52]: ser.rolling(window=5, win_type='triang').mean()
Out[52]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -1.037870
2000-01-06  -0.767705
2000-01-07  -0.383197
2000-01-08  -0.395513
2000-01-09  -0.558440
2000-01-10  -0.672416
Freq: D, dtype: float64

Note that the boxcar window is equivalent to mean().

In [53]: ser.rolling(window=5, win_type='boxcar').mean()
Out[53]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -0.841164
2000-01-06  -0.779948
2000-01-07  -0.565487
2000-01-08  -0.502815
2000-01-09  -0.553755
2000-01-10  -0.472211
Freq: D, dtype: float64

In [54]: ser.rolling(window=5).mean()
For some windowing functions, additional parameters must be specified:

```
In [55]: ser.rolling(window=5, win_type='gaussian').mean(std=0.1)
Out[55]:
2000-01-01    NaN
2000-01-02    NaN
2000-01-03    NaN
2000-01-04    NaN
2000-01-05  -1.309989
2000-01-06  -1.153000
2000-01-07   0.606382
2000-01-08  -0.681101
2000-01-09  -0.289724
2000-01-10  -0.996632
Freq: D, dtype: float64
```

Note: For `.sum()` with a `win_type`, there is no normalization done to the weights for the window. Passing custom weights of `[1, 1, 1]` will yield a different result than passing weights of `[2, 2, 2]`, for example. When passing a `win_type` instead of explicitly specifying the weights, the weights are already normalized so that the largest weight is 1.

In contrast, the nature of the `.mean()` calculation is such that the weights are normalized with respect to each other. Weights of `[1, 1, 1]` and `[2, 2, 2]` yield the same result.

### 14.2.3 Time-aware Rolling

New in version 0.19.0.

New in version 0.19.0 are the ability to pass an offset (or convertible) to a `.rolling()` method and have it produce variable sized windows based on the passed time window. For each time point, this includes all preceding values occurring within the indicated time delta.

This can be particularly useful for a non-regular time frequency index.

```
In [56]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                          index=pd.date_range('20130101 09:00:00', periods=5, freq='s'))

In [57]: dft
Out[57]:
   B
2013-01-01 09:00:00  0.0
2013-01-01 09:00:01  1.0
2013-01-01 09:00:02  2.0
2013-01-01 09:00:03 NaN
2013-01-01 09:00:04  4.0
```

This is a regular frequency index. Using an integer window parameter works to roll along the window frequency.

```
In [58]: dft.rolling(2).sum()
Out[58]:
   B
2013-01-01 09:00:00  NaN
2013-01-01 09:00:01  1.0
(continues on next page)
```
Specifying an offset allows a more intuitive specification of the rolling frequency.

```python
In [60]: dft.rolling('2s').sum()
Out[60]:

   B
2013-01-01 09:00:00 0.0
2013-01-01 09:00:01 1.0
2013-01-01 09:00:02 3.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:04 4.0
```

Using a non-regular, but still monotonic index, rolling with an integer window does not impart any special calculation.

```python
In [61]: dft = pd.DataFrame({'B': [0, 1, 2, np.nan, 4]},
                        index = pd.Index([pd.Timestamp('20130101 09:00:00'),
                                          pd.Timestamp('20130101 09:00:02'),
                                          pd.Timestamp('20130101 09:00:03'),
                                          pd.Timestamp('20130101 09:00:05'),
                                          pd.Timestamp('20130101 09:00:06')],
                        name='foo'))
In [62]: dft
Out[62]:

   B
foo
2013-01-01 09:00:00 0.0
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 2.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 4.0
```

```python
In [63]: dft.rolling(2).sum()
```

```text
Out[63]:

   B
foo
2013-01-01 09:00:00 NaN
2013-01-01 09:00:02 1.0
2013-01-01 09:00:03 3.0
2013-01-01 09:00:05 NaN
2013-01-01 09:00:06 NaN
```
Using the time-specification generates variable windows for this sparse data.

```python
In [64]: dft.rolling('2s').sum()
Out[64]:
        B
    foo
2013-01-01 09:00:00  0.0
2013-01-01 09:00:02  1.0
2013-01-01 09:00:03  3.0
2013-01-01 09:00:05  NaN
2013-01-01 09:00:06  4.0
```

Furthermore, we now allow an optional `on` parameter to specify a column (rather than the default of the index) in a DataFrame.

```python
In [65]: dft = dft.reset_index()
In [66]: dft
Out[66]:
        foo  B
0  2013-01-01 09:00:00  0.0
1  2013-01-01 09:00:02  1.0
2  2013-01-01 09:00:03  2.0
3  2013-01-01 09:00:05  NaN
4  2013-01-01 09:00:06  4.0
In [67]: dft.rolling('2s', on='foo').sum()
```

### 14.2.4 Rolling Window Endpoints

New in version 0.20.0.

The inclusion of the interval endpoints in rolling window calculations can be specified with the `closed` parameter:

<table>
<thead>
<tr>
<th>closed</th>
<th>Description</th>
<th>Default for</th>
</tr>
</thead>
<tbody>
<tr>
<td>right</td>
<td>close right endpoint</td>
<td>time-based windows</td>
</tr>
<tr>
<td>left</td>
<td>close left endpoint</td>
<td></td>
</tr>
<tr>
<td>both</td>
<td>close both endpoints</td>
<td>fixed windows</td>
</tr>
<tr>
<td>neither</td>
<td>open endpoints</td>
<td></td>
</tr>
</tbody>
</table>

For example, having the right endpoint open is useful in many problems that require that there is no contamination from present information back to past information. This allows the rolling window to compute statistics “up to that point in time”, but not including that point in time.

```python
In [68]: df = pd.DataFrame({'x': 1},
                      index = [pd.Timestamp('20130101 09:00:01'),
                                pd.Timestamp('20130101 09:00:02')},
                      (continues on next page)
Currently, this feature is only implemented for time-based windows. For fixed windows, the closed parameter cannot be set and the rolling window will always have both endpoints closed.

### 14.2.5 Time-aware Rolling vs. Resampling

Using `.rolling()` with a time-based index is quite similar to `resampling`. They both operate and perform reductive operations on time-indexed pandas objects.

When using `.rolling()` with an offset. The offset is a time-delta. Take a backwards-in-time looking window, and aggregate all of the values in that window (including the end-point, but not the start-point). This is the new value at that point in the result. These are variable sized windows in time-space for each point of the input. You will get a same sized result as the input.

When using `.resample()` with an offset. Construct a new index that is the frequency of the offset. For each frequency bin, aggregate points from the input within a backwards-in-time looking window that fall in that bin. The result of this aggregation is the output for that frequency point. The windows are fixed size in the frequency space. Your result will have the shape of a regular frequency between the min and the max of the original input object.

To summarize, `.rolling()` is a time-based window operation, while `.resample()` is a frequency-based window operation.

### 14.2.6 Centering Windows

By default the labels are set to the right edge of the window, but a `center` keyword is available so the labels can be set at the center.

```python
In [74]: ser.rolling(window=5).mean()
Out[74]:
2000-01-01  NaN
2000-01-02  NaN
2000-01-03  NaN
2000-01-04  NaN
```

(continues on next page)
### 14.2.7 Binary Window Functions

`cov()` and `corr()` can compute moving window statistics about two `Series` or any combination of `DataFrame`, `Series` or `DataFrame/`Series. Here is the behavior in each case:

- **two `Series`**: compute the statistic for the pairing.
- **`DataFrame/Series`**: compute the statistics for each column of the `DataFrame` with the passed `Series`, thus returning a `DataFrame`.
- **`DataFrame/DataFrame`**: by default compute the statistic for matching column names, returning a `DataFrame`. If the keyword argument `pairwise=True` is passed then computes the statistic for each pair of columns, returning a MultiIndexed `DataFrame` whose index are the dates in question (see the next section).

For example:

```python
In [76]: df = pd.DataFrame(np.random.randn(1000, 4),
                      index=pd.date_range('1/1/2000', periods=1000),
                      columns=['A', 'B', 'C', 'D'])

In [77]: df = df.cumsum()

In [78]: df2 = df[:20]

In [79]: df2.rolling(window=5).corr(df2['B'])
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
</tbody>
</table>

(continues on next page)
14.2.8 Computing rolling pairwise covariances and correlations

**Warning:** Prior to version 0.20.0 if `pairwise=True` was passed, a `Panel` would be returned. This will now return a 2-level MultiIndexed DataFrame, see the what's new here.

In financial data analysis and other fields it’s common to compute covariance and correlation matrices for a collection of time series. Often one is also interested in moving-window covariance and correlation matrices. This can be done by passing the `pairwise` keyword argument, which in the case of DataFrame inputs will yield a MultiIndexed DataFrame whose index are the dates in question. In the case of a single DataFrame argument the `pairwise` argument can even be omitted:

**Note:** Missing values are ignored and each entry is computed using the pairwise complete observations. Please see the covariance section for caveats associated with this method of calculating covariance and correlation matrices.

```
In [80]: covs = df[['B','C','D']].rolling(window=50).cov(df[['A','B','C']], pairwise=True)
In [81]: covs.loc['2002-09-22':]
Out[81]:
         B     C     D
2002-09-22 A 1.367467 8.676734 -8.047366
       B  3.067315 0.865946 -1.052533
       C  0.865946 7.739761 -4.943924
2002-09-23 A 0.910343 8.669065 -8.443062
       B  2.625456 0.565152 -0.907654
       C  0.565152 7.825521 -5.367526
2002-09-24 A 0.463332 8.514509 -8.776514
       B  2.306695 0.267746 -0.732186
       C  0.267746 7.771425 -5.696962
2002-09-25 A 0.467976 8.198236 -9.162599
       B  2.307129 0.267287 -0.754080
       C  0.267287 7.466559 -5.822650
2002-09-26 A 0.545781 7.899084 -9.326238
       B  2.311058 0.322295 -0.844451
       C  0.322295 7.038237 -5.684445
```

14.2. Window Functions
You can efficiently retrieve the time series of correlations between two columns by reshaping and indexing:

```python
In [84]: correls.unstack(1)[('A', 'C')].plot()
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c20c55908>
```
14.3 Aggregation

Once the Rolling, Expanding or EWM objects have been created, several methods are available to perform multiple computations on the data. These operations are similar to the aggregating API, groupby API, and resample API.

In [85]: dfa = pd.DataFrame(np.random.randn(1000, 3),
       ...: index=pd.date_range('1/1/2000', periods=1000),
       ...: columns=['A', 'B', 'C'])
       ...

In [86]: r = dfa.rolling(window=60, min_periods=1)

In [87]: r.aggregate(np.sum)

Out[87]:

A       B       C
2000-01-01 -0.289838 -0.370545 -1.284206
2000-01-02 -0.216612 -1.675528 -1.169415

We can aggregate by passing a function to the entire DataFrame, or select a Series (or multiple Series) via standard __getitem__.

In [88]: r.aggregate(np.sum)
Out[88]:

     A       B       C
2000-01-01 -0.289838 -0.370545 -1.284206
2000-01-02 -0.216612 -1.675528 -1.169415

(continues on next page)
In [89]: r['A'].aggregate(np.sum)

2000-01-01 -0.289838
2000-01-02 -0.216612
2000-01-03  1.546610
2000-01-04  2.969393
2000-01-05  4.690630
2000-01-06  3.880630
2000-01-07  4.001957
...       ...       ...
2002-09-20  2.652493 -10.528875  9.867805
2002-09-21  0.844497  -9.280944  9.522649
2002-09-22  2.860036  -9.270337  6.415245
2002-09-23  3.510163  -8.151439  5.177219
2002-09-24  6.524983  -10.168078  5.792639
2002-09-25  6.409626  -9.956226  5.704050
2002-09-26  5.093787  -7.074515  6.905823
Freq: D, Name: A, Length: 1000, dtype: float64

In [90]: r[['A', 'B']].aggregate(np.sum)

     A       B
2000-01-01 -0.289838 -0.370545
2000-01-02 -0.216612 -1.675528
2000-01-03  1.546610 -1.634017
2000-01-04  2.969393 -4.003274
2000-01-05  4.690630 -4.682017
2000-01-06  3.880630 -4.447700
2000-01-07  4.001957 -2.884072
...       ...       ...
2002-09-20  2.652493 -10.528875
2002-09-21  0.844497  -9.280944
2002-09-22  2.860036  -9.270337
2002-09-23  3.510163  -8.151439
2002-09-24  6.524983  -10.168078
2002-09-25  6.409626  -9.956226
2002-09-26  5.093787  -7.074515
[1000 rows x 2 columns]
As you can see, the result of the aggregation will have the selected columns, or all columns if none are selected.

### 14.3.1 Applying multiple functions

With windowed `Series` you can also pass a list of functions to do aggregation with, outputting a DataFrame:

```python
In [91]: r["A"].agg([np.sum, np.mean, np.std])
Out[91]:
     sum   mean    std
2000-01-01 -0.289838 -0.289838  NaN
2000-01-02 -0.216612 -0.108306  0.256725
2000-01-03  1.154661  0.384887  0.873311
2000-01-04  2.969393  0.742348  1.009734
2000-01-05  4.690630  0.938126  0.977914
2000-01-06  3.880630  0.646772  1.128883
2000-01-07  4.001957  0.571708  1.049487
          ...   ...    ...
2002-09-20  2.652493  0.044208  1.164919
2002-09-21  0.844497  0.014075  1.148231
2002-09-22  2.860036  0.047667  1.132051
2002-09-23  3.510163  0.058503  1.134296
2002-09-24  6.524983  0.108750  1.144204
2002-09-25  6.409626  0.106827  1.142913
2002-09-26  5.093787  0.084896  1.151416
[1000 rows x 3 columns]
```

On a windowed DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```python
In [92]: r.agg([np.sum, np.mean])
Out[92]:
          A              B              C
        sum   mean         sum   mean         sum   mean
2000-01-01 -0.289838 -0.289838   -0.370545 -0.370545   -1.284206 -1.284206
2000-01-02 -0.216612 -0.108306   -1.675528 -0.837764   -1.169415 -0.584708
2000-01-03  1.154661  0.384887   -1.634017 -0.544672   -1.566620 -0.522207
2000-01-04  2.969393  0.742348   -4.003274 -1.000819   -1.816179 -0.454045
2000-01-05  4.690630  0.938126   -4.682017 -0.936403   -2.717209 -0.543442
2000-01-06  3.880630  0.646772   -4.477700 -0.741283   -1.078947 -0.179285
2000-01-07  4.001957  0.571708   -2.884072 -0.412010   -3.116903 -0.445272
          ...   ...              ...   ...              ...   ...
2002-09-20  2.652493  0.044208   -10.528875 -0.175481   9.867805  0.164463
2002-09-21  0.844497  0.014075   -9.280944 -0.154682   9.522649  0.158711
2002-09-22  2.860036  0.047667   -9.270337 -0.154506   6.415245  0.106921
2002-09-23  3.510163  0.058503   -8.151439 -0.135857   5.177219  0.086287
2002-09-24  6.524983  0.108750   -10.168078 -0.169468   5.792639  0.096544
2002-09-25  6.409626  0.106827   -9.956226 -0.165937   5.704050  0.095068
2002-09-26  5.093787  0.084896   -7.074515 -0.117909   6.905823  0.115097
[1000 rows x 6 columns]
```

Passing a dict of functions has different behavior by default, see the next section.
14.3.2 Applying different functions to DataFrame columns

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```python
In [93]: r.agg({'A' : np.sum,
        ....:   'B' : lambda x: np.std(x, ddof=1)})
```

```python
Out[93]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.289838</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.216612</td>
<td>0.660747</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.154661</td>
<td>0.689929</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>2.969393</td>
<td>1.072199</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>4.690630</td>
<td>0.939657</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>3.880630</td>
<td>0.966848</td>
</tr>
<tr>
<td>2000-01-07</td>
<td>4.001957</td>
<td>1.240137</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>2002-09-20</td>
<td>2.652493</td>
<td>1.114814</td>
</tr>
<tr>
<td>2002-09-21</td>
<td>0.844497</td>
<td>1.113220</td>
</tr>
<tr>
<td>2002-09-22</td>
<td>2.860036</td>
<td>1.113208</td>
</tr>
<tr>
<td>2002-09-23</td>
<td>3.510163</td>
<td>1.132381</td>
</tr>
<tr>
<td>2002-09-24</td>
<td>6.524983</td>
<td>1.080963</td>
</tr>
<tr>
<td>2002-09-25</td>
<td>6.409626</td>
<td>1.082911</td>
</tr>
<tr>
<td>2002-09-26</td>
<td>5.093787</td>
<td>1.136199</td>
</tr>
</tbody>
</table>
```

[1000 rows x 2 columns]

The function names can also be strings. In order for a string to be valid it must be implemented on the windowed object:

```python
In [94]: r.agg({'A' : 'sum', 'B' : 'std'})
```

```python
Out[94]:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>2000-01-01</td>
<td>-0.289838</td>
<td>NaN</td>
</tr>
<tr>
<td>2000-01-02</td>
<td>-0.216612</td>
<td>0.660747</td>
</tr>
<tr>
<td>2000-01-03</td>
<td>1.154661</td>
<td>0.689929</td>
</tr>
<tr>
<td>2000-01-04</td>
<td>2.969393</td>
<td>1.072199</td>
</tr>
<tr>
<td>2000-01-05</td>
<td>4.690630</td>
<td>0.939657</td>
</tr>
<tr>
<td>2000-01-06</td>
<td>3.880630</td>
<td>0.966848</td>
</tr>
<tr>

<td>-0.289838</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>std</td>
<td>std</td>
</tr>
</tbody>
</table>

(continues on next page)
A common alternative to rolling statistics is to use an expanding window, which yields the value of the statistic with all the data available up to that point in time.

These follow a similar interface to `.rolling`, with the `.expanding` method returning an `Expanding` object.

As these calculations are a special case of rolling statistics, they are implemented in pandas such that the following two calls are equivalent:

```python
In [96]: df.rolling(window=len(df), min_periods=1).mean()[:5]
Out[96]:
               A         B         C         D
2000-01-01  0.314226 -0.001675  0.071823  0.892566
2000-01-02  0.654522 -0.171495  0.179278  0.853361
2000-01-03  0.708733 -0.064489 -0.238271  1.371111
2000-01-04  0.987613  0.163472 -0.919693  1.566485
2000-01-05  1.426971  0.288267 -1.358877  1.808650

In [97]: df.expanding(min_periods=1).mean()[:5]
```

These have a similar set of methods to `.rolling` methods.
14.4.1 Method Summary

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>

</tr>
</tbody>
</table>

Aside from not having a window parameter, these functions have the same interfaces as their .rolling counterparts. Like above, the parameters they all accept are:

- **min_periods**: threshold of non-null data points to require. Defaults to minimum needed to compute statistic. No NaNs will be output once min_periods non-null data points have been seen.
- **center**: boolean, whether to set the labels at the center (default is False).

**Note:** The output of the .rolling and .expanding methods do not return a NaN if there are at least min_periods non-null values in the current window. For example:

```
In [98]: sn = pd.Series([1, 2, np.nan, 3, np.nan, 4])

In [99]: sn
Out[99]:
0    1.0
1    2.0
2    NaN
3    3.0
4    NaN
5    4.0
dtype: float64

In [100]: sn.rolling(2).max()
Out[100]:
0    NaN
1    2.0
2    NaN
3    NaN
4    NaN
5    NaN
dtype: float64

In [101]: sn.rolling(2, min_periods=1).max()
```

(continues on next page)
In case of expanding functions, this differs from \texttt{cumsum()}, \texttt{cumprod()}, \texttt{cummax()}, and \texttt{cummin()}, which return NaN in the output wherever a NaN is encountered in the input. In order to match the output of \texttt{cumsum} with expanding, use \texttt{fillna}:

\begin{verbatim}
In [102]: sn.expanding().sum()
Out[102]:
  0   1.0
  1   3.0
  2   3.0
  3   6.0
  4   6.0
  5  10.0
dtype: float64

In [103]: sn.cumsum()

Out[103]:
  0   1.0
  1   3.0
  2  NaN
  3   6.0
  4  NaN
  5  10.0
dtype: float64

In [104]: sn.cumsum().fillna(method='ffill')

Out[104]:
  0   1.0
  1   3.0
  2   3.0
  3   6.0
  4   6.0
  5  10.0
dtype: float64
\end{verbatim}

An expanding window statistic will be more stable (and less responsive) than its rolling window counterpart as the increasing window size decreases the relative impact of an individual data point. As an example, here is the \texttt{mean()} output for the previous time series dataset:

\begin{verbatim}
In [105]: s.plot(style='k--')
Out[105]: <matplotlib.axes._subplots.AxesSubplot at 0x1c20ecf6a0>

In [106]: s.expanding().mean().plot(style='k')
Out[106]: <matplotlib.axes._subplots.AxesSubplot at 0x1c20ecf6a0>
\end{verbatim}

14.4. Expanding Windows
14.5 Exponentially Weighted Windows

A related set of functions are exponentially weighted versions of several of the above statistics. A similar interface to `.rolling` and `.expanding` is accessed through the `.ewm` method to receive an EWM object. A number of expanding EW (exponentially weighted) methods are provided:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>mean()</code></td>
<td>EW moving average</td>
</tr>
<tr>
<td><code>var()</code></td>
<td>EW moving variance</td>
</tr>
<tr>
<td><code>std()</code></td>
<td>EW moving standard deviation</td>
</tr>
<tr>
<td><code>corr()</code></td>
<td>EW moving correlation</td>
</tr>
<tr>
<td><code>cov()</code></td>
<td>EW moving covariance</td>
</tr>
</tbody>
</table>

In general, a weighted moving average is calculated as

\[ y_t = \frac{\sum_{i=0}^{t} w_i x_{t-i}}{\sum_{i=0}^{t} w_i}, \]

where \( x_t \) is the input, \( y_t \) is the result and the \( w_i \) are the weights.

The EW functions support two variants of exponential weights. The default, `adjust=True`, uses the weights \( w_i = \)
\[(1 - \alpha)^i\] which gives
\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots + (1 - \alpha)^ix_0}{1 + (1 - \alpha) + (1 - \alpha)^2 + \ldots + (1 - \alpha)^t}
\]

When `adjust=False` is specified, moving averages are calculated as
\[
y_0 = x_0
y_t = (1 - \alpha)y_{t-1} + \alpha x_t,
\]
which is equivalent to using weights
\[
w_i = \begin{cases} 
\alpha(1 - \alpha)^i & \text{if } i < t \\
(1 - \alpha)^i & \text{if } i = t.
\end{cases}
\]

**Note:** These equations are sometimes written in terms of \(\alpha' = 1 - \alpha\), e.g.
\[
y_t = \alpha' y_{t-1} + (1 - \alpha')x_t.
\]

The difference between the above two variants arises because we are dealing with series which have finite history. Consider a series of infinite history:
\[
y_t = \frac{x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots}{1 - (1 - \alpha)}
\]
\[
= [x_t + (1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots] \alpha
\]
\[
= \alpha x_t + [(1 - \alpha)x_{t-1} + (1 - \alpha)^2x_{t-2} + \ldots] \alpha
\]
\[
= \alpha x_t + (1 - \alpha)[x_{t-1} + (1 - \alpha)x_{t-2} + \ldots] \alpha
\]
\[
= \alpha x_t + (1 - \alpha)y_{t-1}
\]
which shows the equivalence of the above two variants for infinite series. When `adjust=True` we have \(y_0 = x_0\) and from the last representation above we have \(y_t = \alpha x_t + (1 - \alpha)y_{t-1}\), therefore there is an assumption that \(x_0\) is not an ordinary value but rather an exponentially weighted moment of the infinite series up to that point.

One must have \(0 < \alpha \leq 1\), and while since version 0.18.0 it has been possible to pass \(\alpha\) directly, it’s often easier to think about either the **span**, **center of mass** (com) or **half-life** of an EW moment:
\[
\alpha = \begin{cases} 
\frac{2}{s+1}, & \text{for span } s \geq 1 \\
\frac{1}{1+c}, & \text{for center of mass } c \geq 0 \\
1 - \exp \frac{-\log 0.5}{h}, & \text{for half-life } h > 0
\end{cases}
\]

One must specify precisely one of **span**, **center of mass**, **half-life** and **alpha** to the EW functions:

- **Span** corresponds to what is commonly called an “N-day EW moving average”.
- **Center of mass** has a more physical interpretation and can be thought of in terms of span: \(c = (s - 1)/2\).
- **Half-life** is the period of time for the exponential weight to reduce to one half.
- **Alpha** specifies the smoothing factor directly.

Here is an example for a univariate time series:
EWM has a `min_periods` argument, which has the same meaning it does for all the `.expanding` and `.rolling` methods: no output values will be set until at least `min_periods` non-null values are encountered in the (expanding) window.

EWM also has an `ignore_na` argument, which determines how intermediate null values affect the calculation of the weights. When `ignore_na=False` (the default), weights are calculated based on absolute positions, so that intermediate null values affect the result. When `ignore_na=True`, weights are calculated by ignoring intermediate null values. For example, assuming `adjust=True`, if `ignore_na=False`, the weighted average of 3, NaN, 5 would be calculated as

\[
\frac{(1 - \alpha)^2 \cdot 3 + 1 \cdot 5}{(1 - \alpha)^2 + 1}.
\]

Whereas if `ignore_na=True`, the weighted average would be calculated as

\[
\frac{(1 - \alpha) \cdot 3 + 1 \cdot 5}{(1 - \alpha) + 1}.
\]

The `var()`, `std()`, and `cov()` functions have a `bias` argument, specifying whether the result should contain biased or unbiased statistics. For example, if `bias=True`, `ewmvar(x)` is calculated as `ewmvar(x) = \[
(1 - \alpha)^2 \cdot 3 + 1 \cdot 5
\] \[
(1 - \alpha)^2 + 1
\]`.
ewma(x**2) - ewma(x)**2; whereas if bias=False (the default), the biased variance statistics are scaled by debiasing factors

\[
\frac{\left(\sum_{i=0}^{t} w_i\right)^2}{\left(\sum_{i=0}^{t} w_i\right)^2 - \sum_{i=0}^{t} w_i^2}
\]

(For \(w_i = 1\), this reduces to the usual \(N/(N - 1)\) factor, with \(N = t + 1\).) See Weighted Sample Variance on Wikipedia for further details.
In this section, we will discuss missing (also referred to as NA) values in pandas.

Note: The choice of using NaN internally to denote missing data was largely for simplicity and performance reasons. It differs from the MaskedArray approach of, for example, scikits.timeseries. We are hopeful that NumPy will soon be able to provide a native NA type solution (similar to R) performant enough to be used in pandas.

See the cookbook for some advanced strategies.

15.1 Missing data basics

15.1.1 When / why does data become missing?

Some might quibble over our usage of missing. By “missing” we simply mean NA (“not available”) or “not present for whatever reason”. Many data sets simply arrive with missing data, either because it exists and was not collected or it never existed. For example, in a collection of financial time series, some of the time series might start on different dates. Thus, values prior to the start date would generally be marked as missing.

In pandas, one of the most common ways that missing data is introduced into a data set is by reindexing. For example:

```
In [1]: df = pd.DataFrame(np.random.randn(5, 3), index=['a', 'c', 'e', 'f', 'h'],
   ...:                  columns=['one', 'two', 'three'])
   ...

In [2]: df['four'] = 'bar'

In [3]: df['five'] = df['one'] > 0

In [4]: df
Out[4]:
   one  two  three  four  five
   a  -0.166778  0.501113 -0.355322  bar  False
   c  -0.337890  0.580967  0.983801  bar  False
   e   0.057802  0.761948 -0.712964  bar   True
   f  -0.443160 -0.974602  1.047704  bar  False
   h  -0.717852 -1.053898 -0.019369  bar  False

In [5]: df2 = df.reindex(['a', 'b', 'c', 'd', 'e', 'f', 'g', 'h'])

In [6]: df2
Out[6]:
```
### 15.1.2 Values considered “missing”

As data comes in many shapes and forms, pandas aims to be flexible with regard to handling missing data. While NaN is the default missing value marker for reasons of computational speed and convenience, we need to be able to easily detect this value with data of different types: floating point, integer, boolean, and general object. In many cases, however, the Python `None` will arise and we wish to also consider that “missing” or “not available” or “NA”.

**Note:** If you want to consider `inf` and `-inf` to be “NA” in computations, you can set `pandas.options.mode.use_inf_as_na = True`.

To make detecting missing values easier (and across different array dtypes), pandas provides the `isna()` and `notna()` functions, which are also methods on Series and DataFrame objects:

```
In [7]: df2['one']
Out[7]:
   a -0.166778
   b   NaN
   c -0.337890
   d   NaN
   e  0.057802
   f -0.443160
   g   NaN
   h -0.717852
Name: one, dtype: float64

In [8]: pd.isna(df2['one'])
False    a
True     b
False    c
True     d
False    e
False    f
True     g
False    h
Name: one, dtype: bool
```

```
In [9]: df2['four'].notna()
   a  True
   b  False
```
c  True
d  False
e  True
f  True
g  False
h  True
Name: four, dtype: bool

In [10]: df2.isna()

→
   one  two  three  four  five
a  False  False  False  False  False
b  True   True   True   True   True
c  False  False  False  False  False
d  True   True   True   True   True
e  False  False  False  False  False
f  False  False  False  False  False
g  True   True   True   True   True
h  False  False  False  False  False
Name: four, dtype: bool

Warning: One has to be mindful that in Python (and NumPy), the nan’s don’t compare equal, but None’s do. Note that pandas/NumPy uses the fact that np.nan != np.nan, and treats None like np.nan.

In [11]: None == None
Out[11]: True

In [12]: np.nan == np.nan
Out[12]: False

So as compared to above, a scalar equality comparison versus a None/nan doesn’t provide useful information.

In [13]: df2['one'] == np.nan
Out[13]:
   a  False
   b  False
   c  False
   d  False
   e  False
   f  False
   g  False
   h  False
Name: one, dtype: bool

15.2 Datetimes

For datetime64[ns] types, NaT represents missing values. This is a pseudo-native sentinel value that can be represented by NumPy in a singular dtype (datetime64[ns]). pandas objects provide intercompatibility between NaT and NaN.

In [14]: df2 = df.copy()

In [15]: df2['timestamp'] = pd.Timestamp('20120101')

(continues on next page)
15.3 Inserting missing data

You can insert missing values by simply assigning to containers. The actual missing value used will be chosen based on the dtype.

For example, numeric containers will always use NaN regardless of the missing value type chosen:

```
In [20]: s = pd.Series([1, 2, 3])
In [21]: s.loc[0] = None
In [22]: s
Out[22]:
0    NaN
1     2.0
2     3.0
dtype: float64
```

Likewise, datetime containers will always use NaT.

For object containers, pandas will use the value given:

```
In [23]: s = pd.Series(["a", "b", "c"])
In [24]: s.loc[0] = None
```
In [25]: s.loc[1] = np.nan

In [26]: s
Out[26]:
   0  None
   1  NaN
   2   c
   dtype: object

15.4 Calculations with missing data

Missing values propagate naturally through arithmetic operations between pandas objects.

In [27]: a
Out[27]:
   one   two
  a  NaN  0.501113
  c  NaN  0.580967
  e  0.057802  0.761948
  f  0.443160  0.974602
  h  0.443160 -1.053898

In [28]: b

In [29]: a + b

The descriptive statistics and computational methods discussed in the data structure overview (and listed here and here) are all written to account for missing data. For example:

• When summing data, NA (missing) values will be treated as zero.

• If the data are all NA, the result will be 0.

• Cumulative methods like cumsum() and cumprod() ignore NA values by default, but preserve them in the resulting arrays. To override this behaviour and include NA values, use skipna=False.

In [30]: df
Out[30]:
(continues on next page)
In [31]: df['one'].sum()
\n\n→ -0.38535826528461409

In [32]: df.mean(1)
\n\n→
   a    0.072895
   c    0.782384
   e    0.035595
   f   -0.123353
   h   -0.536633
   dtype: float64

In [33]: df.cumsum()
\n\n→
   one  two  three
   a NaN  0.501113 -0.355322
   c NaN  1.082080  0.628479
   e  0.057802  1.844028 -0.084485
   f -0.385358  0.869426  0.963219
   h NaN -0.184472  0.943850

In [34]: df.cumsum(skipna=False)
\n\n→
   one  two  three
   a NaN  0.501113 -0.355322
   c NaN  1.082080  0.628479
   e NaN  1.844028 -0.084485
   f NaN  0.869426  0.963219
   h NaN -0.184472  0.943850

15.4.1 Sum/Prod of Empties/Nans

Warning: This behavior is now standard as of v0.22.0 and is consistent with the default in *numpy*; previously sum/prod of all-NA or empty Series/DataFrames would return NaN. See *v0.22.0 whatstnew* for more.

The sum of an empty or all-NA Series or column of a DataFrame is 0.

In [35]: pd.Series([np.nan]).sum()
Out[35]: 0.0

In [36]: pd.Series([]).sum()
\n\nOut[36]: 0.0
The product of an empty or all-NA Series or column of a DataFrame is 1.

```python
In [37]: pd.Series([np.nan]).prod()
Out[37]: 1.0

In [38]: pd.Series([]).prod()
```

### 15.4.2 NA values in GroupBy

NA groups in GroupBy are automatically excluded. This behavior is consistent with R, for example:

```python
In [39]: df
Out[39]:
           one     two     three
a      NaN  0.501113 -0.355322
b      NaN  0.580967  0.983801
c  0.057802  0.761948 -0.712964
d -0.443160 -0.974602  1.047704
e  0.057802  0.761948 -0.712964
f -0.443160 -0.974602  1.047704
g      NaN -1.053898 -0.019369

In [40]: df.groupby('one').mean()
```

See the groupby section [here](#) for more information.

### 15.5 Cleaning / filling missing data

Pandas objects are equipped with various data manipulation methods for dealing with missing data.

#### 15.5.1 Filling missing values: fillna

`fillna()` can “fill in” NA values with non-NA data in a couple of ways, which we illustrate:

**Replace NA with a scalar value**

```python
In [41]: df2
Out[41]:
           one     two     three     four     five         timestamp
a      NaN  0.501113 -0.355322    NaN          NaN
b      NaN  0.580967  0.983801    NaN          NaN
c  0.057802  0.761948 -0.712964    NaN          NaN
d -0.443160 -0.974602  1.047704    NaN          NaN
e  0.057802  0.761948 -0.712964    NaN          NaN
f -0.443160 -0.974602  1.047704    NaN          NaN
g      NaN -1.053898 -0.019369    NaN          NaN
h      NaN -1.053898 -0.019369    NaN          NaN

In [42]: df2.fillna(0)
```
Fill gaps forward or backward

Using the same filling arguments as `reindexing`, we can propagate non-NA values forward or backward:

In [44]: df
Out[44]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>0.057802</td>
<td>0.761948</td>
<td>-0.712964</td>
</tr>
<tr>
<td>-0.443160</td>
<td>-0.974602</td>
<td>1.047704</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

In [45]: df.fillna(method='pad')

Out[45]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>0.057802</td>
<td>0.761948</td>
<td>-0.712964</td>
</tr>
<tr>
<td>-0.443160</td>
<td>-0.974602</td>
<td>1.047704</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

Limit the amount of filling

If we only want consecutive gaps filled up to a certain number of data points, we can use the `limit` keyword:

In [46]: df
Out[46]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

In [47]: df.fillna(method='pad', limit=1)

Out[47]:

<table>
<thead>
<tr>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>
To remind you, these are the available filling methods:

<table>
<thead>
<tr>
<th>Method</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>pad / ffill</td>
<td>Fill values forward</td>
</tr>
<tr>
<td>bfill / backfill</td>
<td>Fill values backward</td>
</tr>
</tbody>
</table>

With time series data, using pad/ffill is extremely common so that the “last known value” is available at every time point.

`ffill()` is equivalent to `fillna(method='ffill')` and `bfill()` is equivalent to `fillna(method='bfill')`

### 15.5.2 Filling with a PandasObject

You can also fillna using a dict or Series that is alignable. The labels of the dict or index of the Series must match the columns of the frame you wish to fill. The use case of this is to fill a DataFrame with the mean of that column.

````
In [48]: dff = pd.DataFrame(np.random.randn(10,3), columns=list('ABC'))
In [49]: dff.iloc[3:5,0] = np.nan
In [50]: dff.iloc[4:6,1] = np.nan
In [51]: dff.iloc[5:8,2] = np.nan
In [52]: dff
Out[52]:
     A         B         C
0  0.758887  2.340598  0.219039
1 -1.235583  0.031785  0.701683
2 -1.557016 -0.636986 -1.238610
3   NaN      -1.002278  0.654052
4   NaN        NaN     1.053999
5  0.651981   NaN      NaN
6  0.109001  -0.533294   NaN
7 -1.037831  -1.150016   NaN
8 -0.687693  -1.150016  -0.121113
9 -0.258742  -0.706329  0.402547

In [53]: dff.fillna(dff.mean())
````

(continues on next page)
In [54]: dff.fillna(dff.mean()[\'B\':\'C\'])

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.758887</td>
<td>2.340598</td>
<td>0.219039</td>
</tr>
<tr>
<td>1</td>
<td>-1.235583</td>
<td>0.031785</td>
<td>0.701683</td>
</tr>
<tr>
<td>2</td>
<td>-1.557016</td>
<td>-0.636986</td>
<td>-1.238610</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>-1.002278</td>
<td>0.654052</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>0.033067</td>
<td>1.053999</td>
</tr>
<tr>
<td>5</td>
<td>0.651981</td>
<td>0.033067</td>
<td>0.238800</td>
</tr>
<tr>
<td>6</td>
<td>NaN</td>
<td>-0.533294</td>
<td>0.238800</td>
</tr>
<tr>
<td>7</td>
<td>-1.037831</td>
<td>-1.150016</td>
<td>0.238800</td>
</tr>
<tr>
<td>8</td>
<td>-0.687693</td>
<td>1.921056</td>
<td>-0.121113</td>
</tr>
<tr>
<td>9</td>
<td>-0.258742</td>
<td>-0.706329</td>
<td>0.402547</td>
</tr>
</tbody>
</table>

Same result as above, but is aligning the ‘fill’ value which is a Series in this case.

In [55]: dff.where(pd.notna(dff), dff.mean(), axis='columns')

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.758887</td>
<td>2.340598</td>
<td>0.219039</td>
</tr>
<tr>
<td>1</td>
<td>-1.235583</td>
<td>0.031785</td>
<td>0.701683</td>
</tr>
<tr>
<td>2</td>
<td>-1.557016</td>
<td>-0.636986</td>
<td>-1.238610</td>
</tr>
<tr>
<td>3</td>
<td>-0.407125</td>
<td>-1.002278</td>
<td>0.654052</td>
</tr>
<tr>
<td>4</td>
<td>-0.407125</td>
<td>0.033067</td>
<td>1.053999</td>
</tr>
<tr>
<td>5</td>
<td>0.651981</td>
<td>0.033067</td>
<td>0.238800</td>
</tr>
<tr>
<td>6</td>
<td>-0.407125</td>
<td>-0.533294</td>
<td>0.238800</td>
</tr>
<tr>
<td>7</td>
<td>-1.037831</td>
<td>-1.150016</td>
<td>0.238800</td>
</tr>
<tr>
<td>8</td>
<td>-0.687693</td>
<td>1.921056</td>
<td>-0.121113</td>
</tr>
<tr>
<td>9</td>
<td>-0.258742</td>
<td>-0.706329</td>
<td>0.402547</td>
</tr>
</tbody>
</table>

15.5.3 Dropping axis labels with missing data: dropna

You may wish to simply exclude labels from a data set which refer to missing data. To do this, use **dropna()**:

In [56]: df
doctest:0

Out[56]:

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
<th>three</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>NaN</td>
<td>0.501113</td>
<td>-0.355322</td>
</tr>
<tr>
<td>c</td>
<td>NaN</td>
<td>0.580967</td>
<td>0.983801</td>
</tr>
<tr>
<td>e</td>
<td>NaN</td>
<td>0.000000</td>
<td>0.000000</td>
</tr>
<tr>
<td>f</td>
<td>NaN</td>
<td>0.000000</td>
<td>0.000000</td>
</tr>
<tr>
<td>h</td>
<td>NaN</td>
<td>-1.053898</td>
<td>-0.019369</td>
</tr>
</tbody>
</table>

In [57]: df.dropna(axis=0)
doctest:0

Empty DataFrame
Columns: [one, two, three]
Index: []

In [58]: df.dropna(axis=1)

→ two three
   a  0.501113 -0.355322
   c  0.580967  0.983801
   e  0.000000  0.000000
   f  0.000000  0.000000
   h -1.053898 -0.019369

In [59]: df['one'].dropna()

Series([], Name: one, dtype: float64)

An equivalent dropna() is available for Series. DataFrame.dropna has considerably more options than Series.dropna, which can be examined in the API.

15.5.4 Interpolation

New in version 0.21.0: The limit_area keyword argument was added.

Both Series and DataFrame objects have interpolate() that, by default, performs linear interpolation at missing datapoints.

In [60]: ts
Out[60]:
2000-01-31  0.469112
2000-02-29   NaN
2000-03-31   NaN
2000-04-28   NaN
2000-05-31   NaN
2000-06-30   NaN
2000-07-31   NaN
   ...             ...
2007-10-31 -3.305259
2007-11-30 -5.485119
2007-12-31 -6.854968
2008-01-31 -7.809176
2008-02-29 -6.346480
2008-03-31 -8.089641
2008-04-30 -8.916232
Freq: BM, Length: 100, dtype: float64

In [61]: ts.count()

61

In [62]: ts.interpolate().count()

100

In [63]: ts.interpolate().plot()
Index aware interpolation is available via the `method` keyword:

```
In [64]: ts2
Out[64]:
2000-01-31    0.469112
2000-02-29     NaN
2002-07-31   -5.689738
2005-01-31     NaN
2008-04-30   -8.916232
dtype: float64

In [65]: ts2.interpolate()

→
2000-01-31    0.469112
2000-02-29    -2.610313
2002-07-31   -5.689738
2005-01-31    -7.302985
2008-04-30   -8.916232
dtype: float64
```

```
In [66]: ts2.interpolate(method='time')

→
2000-01-31    0.469112
2000-02-29    0.273272
(...)
```

(continues on next page)
For a floating-point index, use `method='values'`:

```python
In [67]: ser
Out[67]:
   0.0  0.0
   1.0  NaN
   10.0 10.0
   dtype: float64
```

```python
In [68]: ser.interpolate()
```

```python
In [69]: ser.interpolate(method='values')
```

You can also interpolate with a DataFrame:

```python
In [70]: df = pd.DataFrame({'A': [1, 2.1, np.nan, 4.7, 5.6, 6.8],
                      'B': [.25, np.nan, np.nan, 4, 12.2, 14.4]})
```

```python
In [71]: df

```

```python
In [72]: df.interpolate()
```

The `method` argument gives access to fancier interpolation methods. If you have `scipy` installed, you can pass the
name of a 1-d interpolation routine to `method`. You’ll want to consult the full scipy interpolation documentation and reference guide for details. The appropriate interpolation method will depend on the type of data you are working with.

- If you are dealing with a time series that is growing at an increasing rate, `method='quadratic'` may be appropriate.
- If you have values approximating a cumulative distribution function, then `method='pchip'` should work well.
- To fill missing values with goal of smooth plotting, consider `method='akima'`.

**Warning:** These methods require scipy.

```python
In [73]: df.interpolate(method='barycentric')
Out[73]:
   A   B
0  1.00  0.250
1  2.10  -7.660
2  3.53  -4.515
3  4.70   4.000
4  5.60  12.200
5  6.80  14.400

In [74]: df.interpolate(method='pchip')
   →
   A   B
0  1.000000  0.250000
1  2.100000  0.672808
2  3.434545  1.928950
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000

In [75]: df.interpolate(method='akima')
   →
   A   B
0  1.000000  0.250000
1  2.100000  -0.873316
2  3.404545  0.320034
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000
```

When interpolating via a polynomial or spline approximation, you must also specify the degree or order of the approximation:

```python
In [76]: df.interpolate(method='spline', order=2)
Out[76]:
   A   B
0  1.000000  0.250000
1  2.100000  -0.428598
2  3.404545  1.206900
3  4.700000  4.000000
4  5.600000  12.200000
5  6.800000  14.400000
```

(continues on next page)
In [77]: df.interpolate(method='polynomial', order=2)

\begin{verbatim}
A  B
0  1.000000  0.250000
1  2.100000 -2.703846
2  3.451351 -1.453846
3  4.700000  4.000000
4  5.600000 12.200000
5  6.800000 14.400000
\end{verbatim}

Compare several methods:

In [78]: np.random.seed(2)
In [79]: ser = pd.Series(np.arange(1, 10.1, .25)**2 + np.random.randn(37))
In [80]: bad = np.array([4, 13, 14, 15, 16, 17, 18, 20, 29])
In [81]: ser[bad] = np.nan
In [82]: methods = ['linear', 'quadratic', 'cubic']
In [83]: df = pd.DataFrame({m: ser.interpolate(method=m) for m in methods})
In [84]: df.plot()
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c348ca1d0>
Another use case is interpolation at new values. Suppose you have 100 observations from some distribution. And let’s suppose that you’re particularly interested in what’s happening around the middle. You can mix pandas’ reindex and interpolate methods to interpolate at the new values.

```python
In [85]: ser = pd.Series(np.sort(np.random.uniform(size=100)))

# interpolate at new_index
In [86]: new_index = ser.index | pd.Index([49.25, 49.5, 49.75, 50.25, 50.5, 50.75])

In [87]: interp_s = ser.reindex(new_index).interpolate(method='pchip')

In [88]: interp_s[49:51]
Out [88]:
49.00  0.471410
49.25  0.476841
49.50  0.481780
49.75  0.485998
50.00  0.489266
50.25  0.491814
50.50  0.493995
50.75  0.495763
51.00  0.497074
dtype: float64
```
15.5.4.1 Interpolation Limits

Like other pandas fill methods, `interpolate()` accepts a limit keyword argument. Use this argument to limit the number of consecutive NaN values filled since the last valid observation:

```python
In [89]: ser = pd.Series([np.nan, np.nan, 5, np.nan, np.nan, np.nan, 13, np.nan, np.nan])
# fill all consecutive values in a forward direction
In [90]: ser.interpolate()
Out[90]:
0    NaN
1    NaN
2     5.0
3     7.0
4     9.0
5    11.0
6    13.0
7    13.0
8    13.0
dtype: float64

# fill one consecutive value in a forward direction
In [91]: ser.interpolate(limit=1)
Out[91]:
0    NaN
1     5.0
2     5.0
3     NaN
4     NaN
5    11.0
6    13.0
7    13.0
8    NaN
dtype: float64
```

By default, NaN values are filled in a forward direction. Use `limit_direction` parameter to fill backward or from both directions.

```python
# fill one consecutive value backwards
In [92]: ser.interpolate(limit=1, limit_direction='backward')
Out[92]:
0    NaN
1     5.0
2     5.0
3     NaN
4     NaN
5    11.0
6    13.0
7     NaN
8     NaN
dtype: float64

# fill one consecutive value in both directions
In [93]: ser.interpolate(limit=1, limit_direction='both')
```

(continues on next page)
# fill all consecutive values in both directions

```
In [94]: ser.interpolate(limit_direction='both')
```

```
0   5.0
1   5.0
2   5.0
3   7.0
4   NaN
5   11.0
6   13.0
7   13.0
8   NaN
dtype: float64
```

By default, NaN values are filled whether they are inside (surrounded by) existing valid values, or outside existing valid values. Introduced in v0.23 the `limit_area` parameter restricts filling to either inside or outside values.

```
# fill one consecutive inside value in both directions

In [95]: ser.interpolate(limit_direction='both', limit_area='inside', limit=1)
```

```
Out[95]:
0   NaN
1   NaN
2   5.0
3   7.0
4   NaN
5   11.0
6   13.0
7   NaN
8   NaN
dtype: float64
```

```
# fill all consecutive outside values backward

In [96]: ser.interpolate(limit_direction='backward', limit_area='outside')
```

```
Out[96]:
0   5.0
1   5.0
2   5.0
3   NaN
4   NaN
5   NaN
6   13.0
7   NaN
8   NaN
dtype: float64
```

(continues on next page)
# fill all consecutive outside values in both directions
In [97]: ser.interpolate(limit_direction='both', limit_area='outside')

→
0 5.0
1 5.0
2 5.0
3 NaN
4 NaN
5 NaN
6 13.0
7 13.0
8 13.0
dtype: float64

15.5.5 Replacing Generic Values

Often times we want to replace arbitrary values with other values.

`replace()` in Series and `replace()` in DataFrame provides an efficient yet flexible way to perform such replacements.

For a Series, you can replace a single value or a list of values by another value:

In [98]: ser = pd.Series([0., 1., 2., 3., 4.])
In [99]: ser.replace(0, 5)

Out[99]:
0 5.0
1 1.0
2 2.0
3 3.0
4 4.0
dtype: float64

You can replace a list of values by a list of other values:

In [100]: ser.replace([0, 1, 2, 3, 4], [4, 3, 2, 1, 0])

Out[100]:
0 4.0
1 3.0
2 2.0
3 1.0
4 0.0
dtype: float64

You can also specify a mapping dict:

In [101]: ser.replace({0: 10, 1: 100})

Out[101]:
0 10.0
1 100.0
2 2.0
For a DataFrame, you can specify individual values by column:

```python
In [102]: df = pd.DataFrame({'a': [0, 1, 2, 3, 4], 'b': [5, 6, 7, 8, 9]})
In [103]: df.replace({'a': 0, 'b': 5}, 100)
Out[103]:
   a  b
0  100 100
1   1   6
2   2   7
3   3   8
4   4   9
```

Instead of replacing with specified values, you can treat all given values as missing and interpolate over them:

```python
In [104]: ser.replace([1, 2, 3], method='pad')
Out[104]:
0  0.0
1  0.0
2  0.0
3  0.0
4  4.0
dtype: float64
```

### 15.5.6 String/Regular Expression Replacement

**Note:** Python strings prefixed with the `r` character such as `r'hello world'` are so-called “raw” strings. They have different semantics regarding backslashes than strings without this prefix. Backslashes in raw strings will be interpreted as an escaped backslash, e.g., `r'\' == '\'. You should read about them if this is unclear.

Replace the `.` with NaN (str -> str):

```python
In [105]: d = {'a': list(range(4)), 'b': list('ab..'), 'c': ['a', 'b', np.nan, 'd']}
In [106]: df = pd.DataFrame(d)
In [107]: df.replace('.', np.nan)
```

Now do it with a regular expression that removes surrounding whitespace (regex -> regex):

```python
In [108]: df.replace(r'\s*\.', np.nan, regex=True)
```

(continues on next page)
Replace a few different values (list -> list):

```
In [109]: df.replace(['a', '.'], ['b', np.nan])
Out[109]:
    a  b  c
0  0  b  b
1  1  b  b
2  NaN NaN
3  NaN  d
```

list of regex -> list of regex:

```
In [110]: df.replace([r'\.', r'(a)'], ['dot', '\1stuff'], regex=True)
Out[110]:
    a  b  c
0  {stuff {stuff
1  1  b  b
2  dot  NaN
3  dot  d
```

Only search in column 'b' (dict -> dict):

```
In [111]: df.replace({'b': '.'}, {'b': np.nan})
Out[111]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

Same as the previous example, but use a regular expression for searching instead (dict of regex -> dict):

```
In [112]: df.replace({'b': r'\s*\.', r'(a)'}, {'b': np.nan}, regex=True)
Out[112]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

You can pass nested dictionaries of regular expressions that use `regex=True`:

```
In [113]: df.replace({'b': {'b': r'\s*\.'}}, {'b': np.nan}, regex=True)
Out[113]:
    a  b  c
0  0  a  a
1  1  b  b
2  NaN NaN
3  NaN  d
```

Alternatively, you can pass the nested dictionary like so:

```
In [114]: df.replace({'b': {'b': r''}}, {'b': np.nan}, regex=True)
Out[114]:
    a  b  c
0  0  a  a
1  1  b  b
2  .  NaN
3  .  d
```

15.5. Cleaning / filling missing data
In [114]: df.replace(regex={'b': {r'\s*\.?\s*': np.nan}})
Out[114]:
   a  b  c
0  0  a  a
1  1  b  b
2  2 NaN NaN
3  3 NaN  d

You can also use the group of a regular expression match when replacing (dict of regex -> dict of regex), this works for lists as well.

In [115]: df.replace({'b': r'\s*(\.)\s*'}, {'b': r'\1ty'}, regex=True)
Out[115]:
   a  b  c
0  0  a  a
1  1  b  b
2  2  .ty NaN
3  3  .ty  d

You can pass a list of regular expressions, of which those that match will be replaced with a scalar (list of regex -> regex).

In [116]: df.replace([r'\s*\.?\s*', r'a|b'], np.nan, regex=True)
Out[116]:
   a  b  c
0  NaN NaN
1  NaN NaN
2  NaN NaN
3  NaN  d

All of the regular expression examples can also be passed with the to_replace argument as the regex argument. In this case the value argument must be passed explicitly by name or regex must be a nested dictionary. The previous example, in this case, would then be:

In [117]: df.replace(regex=[r'\s*\.?\s*', r'a|b'], value=np.nan)
Out[117]:
   a  b  c
0  NaN NaN
1  NaN NaN
2  NaN NaN
3  NaN  d

This can be convenient if you do not want to pass regex=True every time you want to use a regular expression.

Note: Anywhere in the above replace examples that you see a regular expression a compiled regular expression is valid as well.

15.5.7 Numeric Replacement

replace() is similar to fillna().

In [118]: df = pd.DataFrame(np.random.randn(10, 2))
In [119]: df[np.random.rand(df.shape[0]) > 0.5] = 1.5

(continues on next page)
In [120]: df.replace(1.5, np.nan)
Out[120]:
      0       1
0 -0.844214 -1.021415
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4    NaN       NaN
5    NaN       NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.482465
9    NaN       NaN

Replacing more than one value is possible by passing a list.

In [121]: df00 = df.values[0, 0]

In [122]: df.replace([1.5, df00], [np.nan, 'a'])
Out[122]:
      0       1
0    a   -1.02141
1  0.432396 -0.323580
2  0.423825  0.799180
3  1.262614  0.751965
4    NaN       NaN
5    NaN       NaN
6 -0.498174 -1.060799
7  0.591667 -0.183257
8  1.019855 -1.48247
9    NaN       NaN

In [123]: df[1].dtype

You can also operate on the DataFrame in place:

In [124]: df.replace(1.5, np.nan, inplace=True)

Warning: When replacing multiple bool or datetime64 objects, the first argument to replace (to_replace) must match the type of the value being replaced. For example,

s = pd.Series([True, False, True])
s.replace({'a string': 'new value', True: False}) # raises

TypeError: Cannot compare types 'ndarray(dtype=bool)' and 'str'

will raise a TypeError because one of the dict keys is not of the correct type for replacement.

However, when replacing a single object such as,
In [125]: s = pd.Series([True, False, True])

In [126]: s.replace('a string', 'another string')
Out[126]:
0   True
1   False
2   True
dtype: bool

the original NDFrame object will be returned untouched. We’re working on unifying this API, but for backwards compatibility reasons we cannot break the latter behavior. See GH6354 for more details.

15.6 Missing data casting rules and indexing

While pandas supports storing arrays of integer and boolean type, these types are not capable of storing missing data. Until we can switch to using a native NA type in NumPy, we’ve established some “casting rules”. When a reindexing operation introduces missing data, the Series will be cast according to the rules introduced in the table below.

<table>
<thead>
<tr>
<th>data type</th>
<th>Cast to</th>
</tr>
</thead>
<tbody>
<tr>
<td>integer</td>
<td>float</td>
</tr>
<tr>
<td>boolean</td>
<td>object</td>
</tr>
<tr>
<td>float</td>
<td>no cast</td>
</tr>
<tr>
<td>object</td>
<td>no cast</td>
</tr>
</tbody>
</table>

For example:

In [127]: s = pd.Series(np.random.randn(5), index=[0, 2, 4, 6, 7])

In [128]: s > 0
Out[128]:
0   True
2   True
4   True
6   True
7   True
dtype: bool

In [129]: (s > 0).dtype
   \_____________________________________________________________________________________________Out[129]:
   ...
dtype('bool')

In [130]: crit = (s > 0).reindex(list(range(8)))

In [131]: crit
Out[131]:
0   True
1   NaN
2   True
3   NaN
4   True
5   NaN
6   True

(continues on next page)
Ordinarily NumPy will complain if you try to use an object array (even if it contains boolean values) instead of a boolean array to get or set values from an ndarray (e.g. selecting values based on some criteria). If a boolean vector contains NAs, an exception will be generated:

```
In [133]: reindexed = s.reindex(list(range(8))).fillna(0)
In [134]: reindexed[crit]
---------------------------------------------------------------------------
ValueError Traceback (most recent call last)
<ipython-input-134-0dac417a4890> in <module>()
----> 1 reindexed[crit]

~/sandbox/pandas-docs/pandas/core/series.py in __getitem__(self, key)
     804     key = list(key)
     805 --> 806 if com.is_bool_indexer(key):
     807     key = check_bool_indexer(self.index, key)
     808
~/sandbox/pandas-docs/pandas/core/common.py in is_bool_indexer(key)
     102     if not lib.is_bool_array(key):
     103       if isna(key).any():
---> 104         raise ValueError('cannot index with vector containing ' 'NA / NaN values')
     105     return False
ValueError: cannot index with vector containing NA / NaN values
```

However, these can be filled in using `fillna()` and it will work fine:

```
In [135]: reindexed[crit.fillna(False)]
Out[135]:
0  0.126504
2  0.696198
4  0.697416
6  0.601516
7  0.003659
dtype: float64

In [136]: reindexed[crit.fillna(True)]
```
7  0.003659
dtype: float64
GROUP BY: SPLIT-APPLY-COMBINE

By “group by” we are referring to a process involving one or more of the following steps:

- **Splitting** the data into groups based on some criteria.
- **Applying** a function to each group independently.
- **Combining** the results into a data structure.

Out of these, the split step is the most straightforward. In fact, in many situations we may wish to split the data set into groups and do something with those groups. In the apply step, we might wish to one of the following:

- **Aggregation**: compute a summary statistic (or statistics) for each group. Some examples:
  - Compute group sums or means.
  - Compute group sizes / counts.

- **Transformation**: perform some group-specific computations and return a like-indexed object. Some examples:
  - Standardize data (zscore) within a group.
  - Filling NAs within groups with a value derived from each group.

- **Filtration**: discard some groups, according to a group-wise computation that evaluates True or False. Some examples:
  - Discard data that belongs to groups with only a few members.
  - Filter out data based on the group sum or mean.

- Some combination of the above: GroupBy will examine the results of the apply step and try to return a sensibly combined result if it doesn’t fit into either of the above two categories.

Since the set of object instance methods on pandas data structures are generally rich and expressive, we often simply want to invoke, say, a DataFrame function on each group. The name GroupBy should be quite familiar to those who have used a SQL-based tool (or itertools), in which you can write code like:

```sql
SELECT Column1, Column2, mean(Column3), sum(Column4)
FROM SomeTable
GROUP BY Column1, Column2
```

We aim to make operations like this natural and easy to express using pandas. We’ll address each area of GroupBy functionality then provide some non-trivial examples / use cases.

See the *cookbook* for some advanced strategies.
16.1 Splitting an object into groups

Pandas objects can be split on any of their axes. The abstract definition of grouping is to provide a mapping of labels to group names. To create a GroupBy object (more on what the GroupBy object is later), you may do the following:

```python
# default is axis=0
>>> grouped = obj.groupby(key)
>>> grouped = obj.groupby(key, axis=1)
>>> grouped = obj.groupby([key1, key2])
```

The mapping can be specified many different ways:

- A Python function, to be called on each of the axis labels.
- A list or NumPy array of the same length as the selected axis.
- A dict or Series, providing a label -> group name mapping.
- For DataFrame objects, a string indicating a column to be used to group. Of course `df.groupby('A')` is just syntactic sugar for `df.groupby(df['A'])`, but it makes life simpler.
- For DataFrame objects, a string indicating an index level to be used to group.
- A list of any of the above things.

Collectively we refer to the grouping objects as the keys. For example, consider the following DataFrame:

```python
In [1]: df = pd.DataFrame({'A': ['foo', 'bar', 'foo', 'bar',
                           ..., 'foo', 'bar', 'foo', 'foo'],
                      ...
                   'B': ['one', 'one', 'two', 'three',
                           ..., 'two', 'two', 'one', 'three'],
                      ...
                   'C': np.random.randn(8),
                           ...
                   'D': np.random.randn(8))})
In [2]: df
Out[2]:
     A   B      C         D
   0 foo one  0.469112 -0.861849
   1 bar one -0.282863 -2.104569
   2 foo two -1.509059 -0.494929
   3 bar three -1.135632  1.071804
   4 foo two  1.212112  0.721555
   5 bar two  0.173215  0.706771
   6 foo one  0.119209 -1.039575
   7 foo three -1.044236  0.271860
```

On a DataFrame, we obtain a GroupBy object by calling `groupby()`. We could naturally group by either the A or B columns, or both:
**16.1. Splitting an object into groups**

pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

```python
In [3]: grouped = df.groupby('A')
In [4]: grouped = df.groupby(['A', 'B'])
```

These will split the DataFrame on its index (rows). We could also split by the columns:

```python
In [5]: def get_letter_type(letter):
   ...:     if letter.lower() in 'aeiou':
   ...:         return 'vowel'
   ...:     else:
   ...:         return 'consonant'
   ...:
In [6]: grouped = df.groupby(get_letter_type, axis=1)
```

pandas `Index` objects support duplicate values. If a non-unique index is used as the group key in a groupby operation, all values for the same index value will be considered to be in one group and thus the output of aggregation functions will only contain unique index values:

```python
In [7]: lst = [1, 2, 3, 1, 2, 3]
In [8]: s = pd.Series([1, 2, 3, 10, 20, 30], lst)
In [9]: grouped = s.groupby(level=0)
```

```python
In [10]: grouped.first()
Out[10]:
1 1
2 2
3 3
dtype: int64
```

```python
In [11]: grouped.last()
```

```python
In [12]: grouped.sum()
```

Note that no splitting occurs until it’s needed. Creating the GroupBy object only verifies that you’ve passed a valid mapping.

**Note:** Many kinds of complicated data manipulations can be expressed in terms of GroupBy operations (though can’t be guaranteed to be the most efficient). You can get quite creative with the label mapping functions.
16.1.1 GroupBy sorting

By default the group keys are sorted during the `groupby` operation. You may however pass `sort=False` for potential speedups:

```python
In [13]: df2 = pd.DataFrame({'X' : ['B', 'B', 'A', 'A'], 'Y' : [1, 2, 3, 4]})
In [14]: df2.groupby(['X']).sum()
Out[14]:
     Y
X
A  7
B  3
In [15]: df2.groupby(['X'], sort=False).sum()
     Y
X
B  3
A  7
```

Note that `groupby` will preserve the order in which observations are sorted within each group. For example, the groups created by `groupby()` below are in the order they appeared in the original DataFrame:

```python
In [16]: df3 = pd.DataFrame({'X' : ['A', 'B', 'A', 'B'], 'Y' : [1, 4, 3, 2]})
In [17]: df3.groupby(['X']).get_group('A')
Out[17]:
   X  Y
0  A  1
2  A  3
In [18]: df3.groupby(['X']).get_group('B')
Out[18]:
   X  Y
1  B  4
3  B  2
```

16.1.2 GroupBy object attributes

The `groups` attribute is a dict whose keys are the computed unique groups and corresponding values being the axis labels belonging to each group. In the above example we have:

```python
In [19]: df.groupby('A').groups
Out[19]:
{'bar': Int64Index([1, 3, 5], dtype='int64'),
 'foo': Int64Index([0, 2, 4, 6, 7], dtype='int64')}
In [20]: df.groupby(get_letter_type, axis=1).groups
Out[20]:
['consonant': Index(['B', 'C', 'D'], dtype='object'),
 'vowel': Index(['A'], dtype='object')]
```

Calling the standard Python `len` function on the GroupBy object just returns the length of the `groups` dict, so it is largely just a convenience:
In [21]: grouped = df.groupby(['A', 'B'])

In [22]: grouped.groups
Out[22]:
({'bar', 'one'): Int64Index([1], dtype='int64'),
 ('bar', 'three'): Int64Index([3], dtype='int64'),
 ('bar', 'two'): Int64Index([5], dtype='int64'),
 ('foo', 'one'): Int64Index([0, 6], dtype='int64'),
 ('foo', 'three'): Int64Index([7], dtype='int64'),
 ('foo', 'two'): Int64Index([2, 4], dtype='int64')}

In [23]: len(grouped)

GroupBy will tab complete column names (and other attributes):

In [24]: df
Out[24]:
   height  weight  gender
0  2000-01-01  42.849980  157.500553    male
1  2000-01-02  49.607315  177.340407    male
2  2000-01-03  56.293531  171.524640    male
3  2000-01-04  48.421077  144.251986   female
4  2000-01-05  46.556882  152.526206    male
5  2000-01-06  68.448851  168.272968   female
6  2000-01-07  70.757698  136.431469    male
7  2000-01-08  58.909500  176.499753   female
8  2000-01-09  76.435631  174.094104   female
9  2000-01-10  45.306120  177.540920    male

In [25]: gb = df.groupby('gender')

In [26]: gb.<TAB>

gb.agg  gb.boxplot  gb.cummin  gb.describe  gb.filter  gb.get_group
| gb.std | gb.transform |
| gb.aggregate | gb.count | gb.cumprod | gb.dtype | gb.first | gb.groups |
| gb.hist | gb.max | gb.min | gb.nth | gb.prod | gb.resample |
| gb.sum | gb.var |
| gb.apply | gb.cummmax | gb.cumsmax | gb.fillna | gb.gender | gb.head |
| gb.indices | gb.mean | gb.name | gb.ohlc | gb.quantile | gb.size |
| gb.tail | gb.weight |

16.1.3 GroupBy with MultiIndex

With *hierarchically-indexed data*, it’s quite natural to group by one of the levels of the hierarchy.

Let’s create a Series with a two-level MultiIndex.

In [27]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'],
        ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]

In [28]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
We can then group by one of the levels in `s`.

```python
In [31]: grouped = s.groupby(level=0)

In [32]: grouped.sum()
Out[32]:
   first
bar   one   -0.962232
      two   -0.042379
baz   one   1.237723
      two   -0.009920
foo   one   0.785980
      two   0.495767
qux   one   1.911055
      two   1.548106
dtype: float64
```

If the MultiIndex has names specified, these can be passed instead of the level number:

```python
In [33]: s.groupby(level='second').sum()
Out[33]:
   second
one   0.980950
two   1.991575
dtype: float64
```

The aggregation functions such as `sum` will take the level parameter directly. Additionally, the resulting index will be named according to the chosen level:

```python
In [34]: s.sum(level='second')
Out[34]:
   second
one   0.980950
two   1.991575
dtype: float64
```

Grouping with multiple levels is supported.

```python
In [35]: s
Out[35]:
   first   second   third
bar   doo   one   -1.131345
      two   -0.089329
baz   bee   one   0.337863
      two   -0.945867
```

(continues on next page)
foo  bop  one  -0.932132
two   1.956030
qux  bop  one  0.017587
two   -0.016692
dtype: float64

In [36]: s.groupby(level=['first', 'second']).sum()

Out[36]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>doo</td>
<td>-1.220674</td>
</tr>
<tr>
<td>baz</td>
<td>bee</td>
<td>-0.608004</td>
</tr>
<tr>
<td>foo</td>
<td>bop</td>
<td>1.023898</td>
</tr>
<tr>
<td>qux</td>
<td>bop</td>
<td>0.000895</td>
</tr>
</tbody>
</table>
dtype: float64

New in version 0.20.

Index level names may be supplied as keys.

In [37]: s.groupby(['first', 'second']).sum()

Out[37]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>doo</td>
<td>-1.220674</td>
</tr>
<tr>
<td>baz</td>
<td>bee</td>
<td>-0.608004</td>
</tr>
<tr>
<td>foo</td>
<td>bop</td>
<td>1.023898</td>
</tr>
<tr>
<td>qux</td>
<td>bop</td>
<td>0.000895</td>
</tr>
</tbody>
</table>
dtype: float64

More on the sum function and aggregation later.

### 16.1.4 Grouping DataFrame with Index Levels and Columns

A DataFrame may be grouped by a combination of columns and index levels by specifying the column names as strings and the index levels as pd.Grouper objects.

In [38]: arrays = [['bar', 'bar', 'baz', 'baz', 'foo', 'foo', 'qux', 'qux'], ['one', 'two', 'one', 'two', 'one', 'two', 'one', 'two']]
In [39]: index = pd.MultiIndex.from_arrays(arrays, names=['first', 'second'])
In [40]: df = pd.DataFrame({'A': [1, 1, 1, 1, 2, 2, 3, 3], 'B': np.arange(8)}, index=index)
In [41]: df

Out[41]:

<table>
<thead>
<tr>
<th>first</th>
<th>second</th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>bar</td>
<td>one</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>baz</td>
<td>one</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>bar</td>
<td>two</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>baz</td>
<td>two</td>
<td>1</td>
<td>3</td>
</tr>
</tbody>
</table>

16.1. Splitting an object into groups 833
foo    one   2  4
      two   2  5
qux    one   3  6
      two   3  7

The following example groups df by the second index level and the A column.

```python
In [42]: df.groupby([pd.Grouper(level=1), 'A']).sum()
Out[42]:
    B
second  A
  one  1  2
       2  4
       3  6
  two  1  4
       2  5
       3  7
```

Index levels may also be specified by name.

```python
In [43]: df.groupby([pd.Grouper(level='second'), 'A']).sum()
Out[43]:
    B
second  A
  one  1  2
       2  4
       3  6
  two  1  4
       2  5
       3  7
```

New in version 0.20.

Index level names may be specified as keys directly to `groupby`.

```python
In [44]: df.groupby(['second', 'A']).sum()
Out[44]:
    B
second  A
  one  1  2
       2  4
       3  6
  two  1  4
       2  5
       3  7
```

## 16.1.5 DataFrame column selection in GroupBy

Once you have created the GroupBy object from a DataFrame, you might want to do something different for each of the columns. Thus, using `[]` similar to getting a column from a DataFrame, you can do:

```python
In [45]: grouped = df.groupby(['A'])
In [46]: grouped_C = grouped['C']
In [47]: grouped_D = grouped['D']
```
This is mainly syntactic sugar for the alternative and much more verbose:

```
In [48]: df['C'].groupby(df['A'])
Out[48]: <pandas.core.groupby.groupby.SeriesGroupBy object at 0x1a20482668>
```

Additionally this method avoids recomputing the internal grouping information derived from the passed key.

### 16.2 Iterating through groups

With the GroupBy object in hand, iterating through the grouped data is very natural and functions similarly to `itertools.groupby()`:

```
In [49]: grouped = df.groupby('A')

In [50]: for name, group in grouped:
   ....:     print(name)
   ....:     print(group)
   ....:
bar
   A  B  C  D
   1 bar one 0.254161 1.511763
   3 bar three 0.215897 -0.990582
   5 bar two -0.077118 1.211526
foo
   A  B  C  D
   0 foo one -0.575247 1.346061
   2 foo two -1.143704 1.627081
   4 foo two 1.193555 -0.441652
   6 foo one -0.408530 0.268520
   7 foo three -0.862495 0.024580
```

In the case of grouping by multiple keys, the group name will be a tuple:

```
In [51]: for name, group in df.groupby(['A', 'B']):
   ....:     print(name)
   ....:     print(group)
   ....:     ('bar', 'one')
       A  B  C  D
       1 bar one 0.254161 1.511763
       ('bar', 'three')
       A  B  C  D
       3 bar three 0.215897 -0.990582
       ('bar', 'two')
       A  B  C  D
       5 bar two -0.077118 1.211526
       ('foo', 'one')
       A  B  C  D
       0 foo one -0.575247 1.346061
       6 foo one -0.408530 0.268520
       ('foo', 'three')
       A  B  C  D
       7 foo three -0.862495 0.024580
       ('foo', 'two')
       A  B  C  D
```

(continues on next page)
It's standard Python-fu but remember you can unpack the tuple in the for loop statement if you wish: `for (k1, k2), group in grouped:`.

### 16.3 Selecting a group

A single group can be selected using `get_group()`:

```python
In [52]: grouped.get_group('bar')
Out[52]:
   A    B    C   D
0  bar  one  0.254161 1.511763
1  bar  three  0.215897 -0.990582
2  bar  two  -0.077118 1.211526
```

Or for an object grouped on multiple columns:

```python
In [53]: df.groupby(['A', 'B']).get_group(('bar', 'one'))
Out[53]:
   A     B    C   D
0  bar  one  0.254161 1.511763
```

### 16.4 Aggregation

Once the GroupBy object has been created, several methods are available to perform a computation on the grouped data. These operations are similar to the `aggregating API`, `window functions API`, and `resample API`.

An obvious one is aggregation via the `aggregate()` or equivalently `agg()` method:

```python
In [54]: grouped = df.groupby('A')

In [55]: grouped.aggregate(np.sum)
Out[55]:
   C  D
  A
bar  0.392940 1.732707
foo -1.796421 2.824590

In [56]: grouped = df.groupby(['A', 'B'])

In [57]: grouped.aggregate(np.sum)
Out[57]:
   C  D
  A B
bar one  0.254161 1.511763
   three  0.215897 -0.990582
   two    -0.077118 1.211526
foo one  -0.983776 1.614581
   three  -0.862495  0.024580
   two    0.049851  1.185429
```
As you can see, the result of the aggregation will have the group names as the new index along the grouped axis. In the case of multiple keys, the result is a `MultiIndex` by default, though this can be changed by using the `as_index` option:

```python
In [58]: grouped = df.groupby(['A', 'B'], as_index=False)

In [59]: grouped.aggregate(np.sum)
Out[59]:
   A   B   C   D
0  bar one 0.254161 1.511763
1  bar three 0.215897 -0.990582
2   bar two -0.077118  1.211526
3   foo one -0.983776  1.614581
4   foo three -0.862495  0.024580
5   foo two  0.049851  1.185429

In [60]: df.groupby('A', as_index=False).sum()
Out[60]:
   A   C   D
0  bar  0.392940  1.732707
1   foo -1.796421  2.824590
```

Note that you could use the `reset_index` DataFrame function to achieve the same result as the column names are stored in the resulting `MultiIndex`:

```python
In [61]: df.groupby(['A', 'B']).sum().reset_index()
Out[61]:
   A   B   C   D
0  bar one 0.254161 1.511763
1  bar three 0.215897 -0.990582
2   bar two -0.077118  1.211526
3   foo one -0.983776  1.614581
4   foo three -0.862495  0.024580
5   foo two  0.049851  1.185429
```

Another simple aggregation example is to compute the size of each group. This is included in GroupBy as the `size` method. It returns a Series whose index are the group names and whose values are the sizes of each group.

```python
In [62]: grouped.size()
Out[62]:
   A   B
0  bar one 1
1  bar three 1
2   bar two 1
3   foo one 2
4   foo three 1
5   foo two 2
dtype: int64

In [63]: grouped.describe()
Out[63]:
   C   D
    count mean std  min  25%  50% 75%  max
   -min 25% 50%    75% max
0  0.254161 NaN 0.254161 0.254161 0.254161 0.254161 NaN 1.
  1.511763 1.511763 1.511763 1.511763 1.511763
```

(continues on next page)
Aggregation functions will not return the groups that you are aggregating over if they are named columns, when as_index=True, the default. The grouped columns will be the indices of the returned object.

Passing as_index=False will return the groups that you are aggregating over, if they are named columns.

Aggregating functions are the ones that reduce the dimension of the returned objects. Some common aggregating functions are tabulated below:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>mean()</td>
<td>Compute mean of groups</td>
</tr>
<tr>
<td>sum()</td>
<td>Compute sum of group values</td>
</tr>
<tr>
<td>size()</td>
<td>Compute group sizes</td>
</tr>
<tr>
<td>count()</td>
<td>Compute count of group</td>
</tr>
<tr>
<td>std()</td>
<td>Standard deviation of groups</td>
</tr>
<tr>
<td>var()</td>
<td>Compute variance of groups</td>
</tr>
<tr>
<td>sem()</td>
<td>Standard error of the mean of groups</td>
</tr>
<tr>
<td>describe()</td>
<td>Generates descriptive statistics</td>
</tr>
<tr>
<td>first()</td>
<td>Compute first of group values</td>
</tr>
<tr>
<td>last()</td>
<td>Compute last of group values</td>
</tr>
<tr>
<td>nth()</td>
<td>Take nth value, or a subset if n is a list</td>
</tr>
<tr>
<td>min()</td>
<td>Compute min of group values</td>
</tr>
<tr>
<td>max()</td>
<td>Compute max of group values</td>
</tr>
</tbody>
</table>

The aggregating functions above will exclude NA values. Any function which reduces a Series to a scalar value is an aggregation function and will work, a trivial example is df.groupby('A').agg(lambda ser: 1). Note that nth() can act as a reducer or a filter, see here.

### 16.4.1 Applying multiple functions at once

With grouped Series you can also pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```python
In [64]: grouped = df.groupby('A')

In [65]: grouped['C'].agg([np.sum, np.mean, np.std])
Out[65]:
       sum     mean     std
A
[6 rows x 3 columns]
```
On a grouped DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [66]: grouped.agg([np.sum, np.mean, np.std])
Out[66]:
     C   mean  std  D   mean  std
   sum  sum
A  bar  0.3929  0.1812  foo -1.7964 -0.3593
   foo -1.7964 -0.3593  0.9123
```

The resulting aggregations are named for the functions themselves. If you need to rename, then you can add in a chained operation for a Series like this:

```
In [67]: (grouped['C'].agg([np.sum, np.mean, np.std])
                  .rename(columns={'sum': 'foo',
                                  'mean': 'bar',
                                  'std': 'baz'}))
Out[67]:
     foo  bar  baz
A  bar  0.3929  0.1812  foo -1.7964 -0.3593
     foo -1.7964 -0.3593  0.9123
```

For a grouped DataFrame, you can rename in a similar manner:

```
In [68]: (grouped.agg([np.sum, np.mean, np.std])
                  .rename(columns={'sum': 'foo',
                                  'mean': 'bar',
                                  'std': 'baz'}))
Out[68]:
     C   D
   foo  baz  foo  baz
A  bar  0.3929  1.7327  foo -1.7964  0.9123
     foo  0.1812  1.7327  bar -1.7964  0.1812
     foo  0.1812  1.7327  foo -1.7964  0.1812
```

### 16.4.2 Applying different functions to DataFrame columns

By passing a dict to `agg()` you can apply a different aggregation to the columns of a DataFrame:

```
In [69]: grouped.agg({'C': np.sum,
                  'D': lambda x: np.std(x, ddof=1)})
Out[69]:
     C   D
   A  bar  0.3929  0.1812  foo -1.7964 -0.3593
     foo -1.7964 -0.3593  0.9123
```

(continues on next page)
The function names can also be strings. In order for a string to be valid it must be either implemented on GroupBy or available via \textit{dispatching}:

\begin{verbatim}
In [70]: grouped.agg({'C' : 'sum', 'D' : 'std'})
Out[70]:
   C   D
A  bar  0.392940  1.366330
    foo -1.796421  0.884785
\end{verbatim}

\textbf{Note:} If you pass a dict to \texttt{aggregate}, the ordering of the output columns is non-deterministic. If you want to be sure the output columns will be in a specific order, you can use an \texttt{OrderedDict}. Compare the output of the following two commands:

\begin{verbatim}
In [71]: grouped.agg({'D': 'std', 'C': 'mean'})
Out[71]:
   D   C
A  bar  1.366330  0.130980
    foo  0.884785 -0.359284

In [72]: grouped.agg(OrderedDict([('D', 'std'), ('C', 'mean')]))
\end{verbatim}

\subsection*{16.4.3 Cython-optimized aggregation functions}

Some common aggregations, currently only \texttt{sum}, \texttt{mean}, \texttt{std}, and \texttt{sem}, have optimized Cython implementations:

\begin{verbatim}
In [73]: df.groupby('A').sum()
Out[73]:
   C   D
A  bar  0.392940  1.732707
    foo -1.796421  2.824590

In [74]: df.groupby(['A', 'B']).mean()
\end{verbatim}
Of course sum and mean are implemented on pandas objects, so the above code would work even without the special versions via dispatching (see below).

16.5 Transformation

The transform method returns an object that is indexed the same (same size) as the one being grouped. The transform function must:

- Return a result that is either the same size as the group chunk or broadcastable to the size of the group chunk (e.g., a scalar, grouped.transform(lambda x: x.iloc[-1])).
- Operate column-by-column on the group chunk. The transform is applied to the first group chunk using chunk.apply.
- Not perform in-place operations on the group chunk. Group chunks should be treated as immutable, and changes to a group chunk may produce unexpected results. For example, when using fillna, inplace must be False(grouped.transform(lambda x: x.fillna(inplace=False))).
- (Optionally) operates on the entire group chunk. If this is supported, a fast path is used starting from the second chunk.

For example, suppose we wished to standardize the data within each group:

```python
In [75]: index = pd.date_range('10/1/1999', periods=1100)
In [76]: ts = pd.Series(np.random.normal(0.5, 2, 1100), index)
In [77]: ts = ts.rolling(window=100,min_periods=100).mean().dropna()
In [78]: ts.head()
Out[78]:
2000-01-08  0.779333
2000-01-09  0.778852
2000-01-10  0.786476
2000-01-11  0.782797
2000-01-12  0.798110
Freq: D, dtype: float64
In [79]: ts.tail()
Out[79]:
2002-09-30  0.660294
2002-10-01  0.631095
2002-10-02  0.673601
2002-10-03  0.709213
2002-10-04  0.719369
Freq: D, dtype: float64
```

```python
In [80]: key = lambda x: x.year
In [81]: zscore = lambda x: (x - x.mean()) / x.std()
In [82]: transformed = ts.groupby(key).transform(zscore)
```
We would expect the result to now have mean 0 and standard deviation 1 within each group, which we can easily check:

```python
# Original Data
In [83]: grouped = ts.groupby(key)

In [84]: grouped.mean()
Out[84]:
   2000  0.442441
   2001  0.526246
   2002  0.459365
dtype: float64

In [85]: grouped.std()
Out[85]:
   2000  0.131752
   2001  0.210945
   2002  0.128753
dtype: float64

# Transformed Data
In [86]: grouped_trans = transformed.groupby(key)

In [87]: grouped_trans.mean()
Out[87]:
   2000  1.168208e-15
   2001  1.454544e-15
   2002  1.726657e-15
dtype: float64

In [88]: grouped_trans.std()
Out[88]:
   2000  1.0
   2001  1.0
   2002  1.0
dtype: float64
```

We can also visually compare the original and transformed data sets.

```python
In [89]: compare = pd.DataFrame({'Original': ts, 'Transformed': transformed})

In [90]: compare.plot()
Out[90]: <matplotlib.axes._subplots.AxesSubplot at 0x1c29ffa898>
```
Transformation functions that have lower dimension outputs are broadcast to match the shape of the input array.

\[ \text{In [91]: } \text{data\_range} = \lambda x: x.\text{max}() - x.\text{min}() \]

\[ \text{In [92]: } \text{ts.groupby(key).transform(data\_range)} \]

\[ \text{Out [92]:} \]

<table>

</tbody>
</table>

Freq: D, Length: 1001, dtype: float64

Alternatively the built-in methods can be could be used to produce the same outputs
Another common data transform is to replace missing data with the group mean.

```python
In [94]: data_df
```
```
A  B  C
---  ---  ---
0  1.539708 -1.166480  0.533026
1  1.302092  0.505754     NaN
2 -0.371983  1.104803 -0.651520
3 -1.309622  1.118697 -1.161657
4 -1.924296  0.396437  0.812436
5  0.815643  0.367816 -0.469478
6 -0.030651  1.376106 -0.645129
... ... ... ...
993 0.012359  0.554602 -1.976159
994 0.042312 -1.628835  1.013822
995 -0.093110  0.683847 -0.774753
996 -0.185043  1.438572     NaN
997 -0.394469 -0.642343  0.011374
998 -1.174126  1.857148     NaN
999 0.234564  0.517098  0.393534
```

[1000 rows x 3 columns]

```python
In [95]: countries = np.array(['US', 'UK', 'GR', 'JP'])
```

```python
In [96]: key = countries[np.random.randint(0, 4, 1000)]
```

```python
In [97]: grouped = data_df.groupby(key)
```

# Non-NA count in each group
```python
In [98]: grouped.count()
```
```
A  B  C
---  ---  ---
GR  209  217  189
JP  240  255  217
UK  216  231  193
US  239  250  217
```

(continues on next page)
We can verify that the group means have not changed in the transformed data and that the transformed data contains no NAs.

In [101]: grouped_trans = transformed.groupby(key)

In [102]: grouped.mean()  # original group means

Out[102]:
\[
\begin{array}{ccc}
  & \text{A} & \text{B} & \text{C} \\
  \text{GR} & -0.098371 & -0.015420 & 0.068053 \\
  \text{JP} & 0.069025 & 0.023100 & -0.077324 \\
  \text{UK} & 0.034069 & -0.052580 & -0.116525 \\
  \text{US} & 0.058664 & -0.020399 & 0.028603 \\
\end{array}
\]

In [103]: grouped_trans.mean()  # transformation did not change group means

Out[103]:
\[
\begin{array}{ccc}
  & \text{A} & \text{B} & \text{C} \\
  \text{GR} & -0.098371 & -0.015420 & 0.068053 \\
  \text{JP} & 0.069025 & 0.023100 & -0.077324 \\
  \text{UK} & 0.034069 & -0.052580 & -0.116525 \\
  \text{US} & 0.058664 & -0.020399 & 0.028603 \\
\end{array}
\]

In [104]: grouped.count()  # original has some missing data points

Out[104]:
\[
\begin{array}{ccc}
  & \text{A} & \text{B} & \text{C} \\
  \text{GR} & 209 & 217 & 189 \\
  \text{JP} & 240 & 255 & 217 \\
  \text{UK} & 216 & 231 & 193 \\
  \text{US} & 239 & 250 & 217 \\
\end{array}
\]

In [105]: grouped_trans.count()  # counts after transformation

Out[105]:
\[
\begin{array}{ccc}
  & \text{A} & \text{B} & \text{C} \\
  \text{GR} & 228 & 228 & 228 \\
  \text{JP} & 267 & 267 & 267 \\
  \text{UK} & 247 & 247 & 247 \\
  \text{US} & 258 & 258 & 258 \\
\end{array}
\]

In [106]: grouped_trans.size()  # Verify non-NA count equals group size

Out[106]:
\[
\begin{array}{c}
  \text{GR} & 228 \\
  \text{JP} & 267 \\
  \text{UK} & 247 \\
  \text{US} & 258 \\
\end{array}
\]
dtype: int64

Note: Some functions will automatically transform the input when applied to a GroupBy object, but returning an object of the same shape as the original. Passing \texttt{as_index=False} will not affect these transformation methods.
For example: `fillna`, `ffill`, `bfill`, `shift`.

```python
In [107]: grouped.ffill()
Out[107]:

[1000 rows x 4 columns]

### 16.5.1 New syntax to window and resample operations

New in version 0.18.1.

Working with the resample, expanding or rolling operations on the groupby level used to require the application of helper functions. However, now it is possible to use `resample()`, `expanding()` and `rolling()` as methods on groupbys.

The example below will apply the `rolling()` method on the samples of the column B based on the groups of column A.

```python
                           'B': np.arange(20)})
In [109]: df_re
Out[109]:
   A  B
0  0  0
1  1  1
2  2  2
3  3  3
4  4  4
5  5  5
6  6  6
   ... ...
13  5 13
14  5 14
15  5 15
16  5 16
17  5 17
18  5 18
19  5 19
(continues on next page)```
The `expanding()` method will accumulate a given operation (sum() in the example) for all the members of each particular group.

```
In [111]: df_re.groupby('A').expanding().sum()
```

```
Out[111]:
      A   B
A
0   1.0 0.0
1   2.0 1.0
2   3.0 3.0
3   4.0 6.0
4   5.0 10.0
5   6.0 15.0
6   7.0 21.0
...   ... ...
5 13 20.0 46.0
14 25.0 60.0
15 30.0 75.0
16 35.0 91.0
17 40.0 108.0
18 45.0 126.0
19 50.0 145.0
```

Suppose you want to use the `resample()` method to get a daily frequency in each group of your dataframe and wish to complete the missing values with the `ffill()` method.

```
In [112]: df_re = pd.DataFrame({'date': pd.date_range(start='2016-01-01', periods=4, freq='W'), 'group': [1, 1, 2, 2], (continues on next page)
16.6 Filtration

The `filter` method returns a subset of the original object. Suppose we want to take only elements that belong to groups with a group sum greater than 2.

```python
In [115]: sf = pd.Series([1, 1, 2, 3, 3, 3])
In [116]: sf.groupby(sf).filter(lambda x: x.sum() > 2)
Out[116]:
3  3
4  3
5  3
dtype: int64
```

The argument of `filter` must be a function that, applied to the group as a whole, returns `True` or `False`. Another useful operation is filtering out elements that belong to groups with only a couple members.
In [117]: dff = pd.DataFrame({'A': np.arange(8), 'B': list('aabbbbcc'))

In [118]: dff.groupby('B').filter(lambda x: len(x) > 2)
Out[118]:
   A  B
0  0 b
1  1 b
2  2 b
3  3 b
4  4 b
5  5 b
6  6 c
7  7 c

Alternatively, instead of dropping the offending groups, we can return a like-indexed objects where the groups that do not pass the filter are filled with NaNs.

In [119]: dff.groupby('B').filter(lambda x: len(x) > 2, dropna=False)
Out[119]:
   A  B    C
0 NaN NaN NaN
1 NaN NaN NaN
2  2.0 b   2
3  3.0 b   3
4  4.0 b   4
5  5.0 b   5
6 NaN NaN NaN
7 NaN NaN NaN

For DataFrames with multiple columns, filters should explicitly specify a column as the filter criterion.

In [120]: dff['C'] = np.arange(8)

In [121]: dff.groupby('B').filter(lambda x: len(x['C']) > 2)
Out[121]:
   A  B  C
0  0 a  0
1  1 a  1
2  2 b  2
3  3 b  3
4  4 b  4
5  5 b  5
6  6 c  6
7  7 c  7

Note: Some functions when applied to a groupby object will act as a filter on the input, returning a reduced shape of the original (and potentially eliminating groups), but with the index unchanged. Passing as_index=False will not affect these transformation methods.

For example: head, tail.
16.7 Dispatching to instance methods

When doing an aggregation or transformation, you might just want to call an instance method on each data group. This is pretty easy to do by passing lambda functions:

```
In [123]: grouped = df.groupby('A')

In [124]: grouped.agg(lambda x: x.std())
Out[124]:
      C     D
A-------
bar  0.181231  1.366330
foo  0.912265  0.884785
```

But, it’s rather verbose and can be untidy if you need to pass additional arguments. Using a bit of metaprogramming cleverness, GroupBy now has the ability to “dispatch” method calls to the groups:

```
In [125]: grouped.std()
Out[125]:
      C     D
A-------
bar  0.181231  1.366330
foo  0.912265  0.884785
```

What is actually happening here is that a function wrapper is being generated. When invoked, it takes any passed arguments and invokes the function with any arguments on each group (in the above example, the \texttt{std} function). The results are then combined together much in the style of \texttt{agg} and \texttt{transform} (it actually uses \texttt{apply} to infer the gluing, documented next). This enables some operations to be carried out rather succinctly:

```
In [126]: tsdf = pd.DataFrame(np.random.randn(1000, 3),
                        index=pd.date_range('1/1/2000', periods=1000),
                        columns=['A', 'B', 'C'])

In [127]: tsdf.iloc[::2] = np.nan

In [128]: grouped = tsdf.groupby(lambda x: x.year)

In [129]: grouped.fillna(method='pad')
Out[129]:
      A      B      C
2000-01-01 NaN      NaN      NaN
2000-01-02 -0.353501 -0.080957 -0.876864
2000-01-03 -0.353501 -0.080957 -0.876864
2000-01-04 0.050976 0.044273 -0.559849
2000-01-05 0.050976 0.044273 -0.559849
2000-01-06 0.030091 0.186460 -0.680149
2000-01-07 0.030091 0.186460 -0.680149
   ... ... ... ...
2002-09-20 2.310215 0.157482 -0.064476
2002-09-21 2.310215 0.157482 -0.064476
2002-09-22 0.005011 0.053897 -1.026922
2002-09-23 0.005011 0.053897 -1.026922
2002-09-24 -0.456542 -1.849051 1.559856
2002-09-25 -0.456542 -1.849051 1.559856
2002-09-26 1.123162 0.354660 1.128135
```

(continues on next page)
In this example, we chopped the collection of time series into yearly chunks then independently called `fillna` on the groups.

The `nlargest` and `nsmallest` methods work on Series style groupbys:

```python
In [130]: s = pd.Series([9, 8, 7, 5, 19, 1, 4.2, 3.3])
In [131]: g = pd.Series(list('abababab'))
In [132]: gb = s.groupby(g)
In [133]: gb.nlargest(3)
Out[133]:
   a  4 19.0
   0  9.0
   2  7.0
   b  1  8.0
   3  5.0
   7  3.3
   dtype: float64
In [134]: gb.nsmallest(3)
Out[134]:
   a  6 4.2
   2  7.0
   0  9.0
   b  5 1.0
   7  3.3
   3  5.0
   dtype: float64
```

### 16.8 Flexible apply

Some operations on the grouped data might not fit into either the aggregate or transform categories. Or, you may simply want GroupBy to infer how to combine the results. For these, use the `apply` function, which can be substituted for both aggregate and transform in many standard use cases. However, `apply` can handle some exceptional use cases, for example:

```python
In [135]: df
Out[135]:
   A   B     C     D
0  foo  one -0.575247  1.346061
1  bar  one   0.254161  1.511763
2  foo  two -1.143704  1.627081
3  bar  three  0.215897 -0.990582
4  foo  two  1.193555 -0.441652
5  bar  three -0.077118  1.211526
6  foo  one  -0.408530  0.268520
7  foo  three  0.862495  0.024580
```
```python
In [136]: grouped = df.groupby('A')

# could also just call .describe()
In [137]: grouped['C'].apply(lambda x: x.describe())
Out[137]:
     A
bar  count  3.000000
      mean  0.130980
       std  0.181231
      min -0.077118
     25%  0.069390
     50%  0.215897
    75%  0.235029
     ...
foo  mean -0.359284
      std  0.912265
     min -1.143704
    25%  0.069390
    50%  0.215897
   75%  0.235029
    max  1.193555
Name: C, Length: 16, dtype: float64
```

The dimension of the returned result can also change:

```python
In [138]: grouped = df.groupby('A')['C']

In [139]: def f(group):
   .....:    return pd.DataFrame({'original' : group,
   .....:                       'demeaned' : group - group.mean()})
   .....:

In [140]: grouped.apply(f)
Out[140]:
     original  demeaned
0  -0.575247  -0.215962
1   0.254161  0.123181
2  -1.143704  -0.784420
3   0.215897  0.084917
4   1.193555  1.552839
5  -0.077118  -0.208098
6  -0.408530  -0.503211
7  -0.862495  -0.503211
```

apply on a Series can operate on a returned value from the applied function, that is itself a series, and possibly upcast the result to a DataFrame:

```python
In [141]: def f(x):
   .....:    return pd.Series([ x, x**2 ], index = ['x', 'x^2'])
   .....:

In [142]: s
Out[142]:
0  9.0
1  8.0
2  7.0
```

(continues on next page)
3 5.0
4 19.0
5 1.0
6 4.2
7 3.3
dtype: float64

In [143]: s.apply(f)
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[143]:
\n→
0 9.0 81.00
1 8.0 64.00
2 7.0 49.00
3 5.0 25.00
4 19.0 361.00
5 1.0 1.00
6 4.2 17.64
7 3.3 10.89

Note: apply can act as a reducer, transformer, or filter function, depending on exactly what is passed to it. So depending on the path taken, and exactly what you are grouping. Thus the grouped columns(s) may be included in the output as well as set the indices.

Warning: In the current implementation apply calls func twice on the first group to decide whether it can take a fast or slow code path. This can lead to unexpected behavior if func has side-effects, as they will take effect twice for the first group.

In [144]: d = pd.DataFrame({"a": ["x", "y"], "b":[1,2]})

In [145]: def identity(df):
......: print(df)
......: return df
......:

In [146]: d.groupby("a").apply(identity)
a b
0 x 1
 a b
0 x 1
 a b
1 y 2
Out[146]:
a b
0 x 1
1 y 2
16.9 Other useful features

16.9.1 Automatic exclusion of “nuisance” columns

Again consider the example DataFrame we’ve been looking at:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>foo</td>
<td>one</td>
<td>-0.575247</td>
<td>1.346061</td>
</tr>
<tr>
<td>1</td>
<td>bar</td>
<td>one</td>
<td>0.254161</td>
<td>1.511763</td>
</tr>
<tr>
<td>2</td>
<td>foo</td>
<td>two</td>
<td>-1.143704</td>
<td>1.627081</td>
</tr>
<tr>
<td>3</td>
<td>bar</td>
<td>three</td>
<td>0.215897</td>
<td>-0.990582</td>
</tr>
<tr>
<td>4</td>
<td>foo</td>
<td>two</td>
<td>1.193555</td>
<td>-0.441652</td>
</tr>
<tr>
<td>5</td>
<td>bar</td>
<td>two</td>
<td>-0.077118</td>
<td>1.211526</td>
</tr>
<tr>
<td>6</td>
<td>foo</td>
<td>one</td>
<td>-0.408530</td>
<td>0.268520</td>
</tr>
<tr>
<td>7</td>
<td>foo</td>
<td>three</td>
<td>-0.862495</td>
<td>0.024580</td>
</tr>
</tbody>
</table>

Suppose we wish to compute the standard deviation grouped by the A column. There is a slight problem, namely that we don’t care about the data in column B. We refer to this as a “nuisance” column. If the passed aggregation function can’t be applied to some columns, the troublesome columns will be (silently) dropped. Thus, this does not pose any problems:

```
In [148]: df.groupby('A').std()
Out[148]:
          C   D
A
bar  0.181231  1.366330
foo  0.912265  0.884785
```

Note that `df.groupby('A').colname.std()`. is more efficient than `df.groupby('A').std().colname`, so if the result of an aggregation function is only interesting over one column (here `colname`), it may be filtered *before* applying the aggregation function.

16.9.2 Handling of (un)observed Categorical values

When using a Categorical grouper (as a single or as part of multiplier groupers), the observed keyword controls whether to return a cartesian product of all possible groupers values (observed=False) or only those that are observed groupers (observed=True).

Show all values:

```
In [149]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False).count()
Out[149]:
a     3
b     0
dtype: int64
```

Show only the observed values:

```
In [150]: pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=True).count()
Out[150]:
          a   b
data: int64
```

(continues on next page)
The returned dtype of the grouped will *always* include *all* of the categories that were grouped.

```
In [151]: s = pd.Series([1, 1, 1]).groupby(pd.Categorical(['a', 'a', 'a'], categories=['a', 'b']), observed=False).count()
In [152]: s.index.dtype
Out[152]: CategoricalDtype(categories=['a', 'b'], ordered=False)
```

### 16.9.3 NA and NaT group handling

If there are any NaN or NaT values in the grouping key, these will be automatically excluded. In other words, there will never be an “NA group” or “NaT group”. This was not the case in older versions of pandas, but users were generally discarding the NA group anyway (and supporting it was an implementation headache).

### 16.9.4 Grouping with ordered factors

Categorical variables represented as instance of pandas’s `Categorical` class can be used as group keys. If so, the order of the levels will be preserved:

```
In [153]: data = pd.Series(np.random.randn(100))
In [154]: factor = pd.qcut(data, [0, .25, .5, .75, 1.])
In [155]: data.groupby(factor).mean()
Out[155]:
    (-2.618, -0.684]   -1.331461
    (-0.684, -0.0232] -0.272816
    (-0.0232, 0.541]  0.263607
   (0.541, 2.369]   1.166038
dtype: float64
```

### 16.9.5 Grouping with a Grouper specification

You may need to specify a bit more data to properly group. You can use the `pd.Grouper` to provide this local control.

```
In [156]: import datetime
In [157]: df = pd.DataFrame(
   ....:     'Branch': 'A A A A A A A B'.split(),
   ....:     'Buyer': 'Carl Mark Carl Carl Joe Joe Joe Carl'.split(),
   ....:     'Quantity': [1,3,5,1,8,1,9,3],
   ....:     'Date': [
   ....:         datetime.datetime(2013,1,1,13,0),
   ....:         datetime.datetime(2013,1,1,13,5),
   ....:         datetime.datetime(2013,10,1,20,0),
   ....:         datetime.datetime(2013,10,2,10,0),
   ....:         datetime.datetime(2013,10,1,20,0),
   ....:         datetime.datetime(2013,10,2,10,0),
   ....:     ]

```

(continues on next page)
Groupby a specific column with the desired frequency. This is like resampling.

```python
In [159]: df.groupby([pd.Grouper(freq='1M',key='Date'),'Buyer']).sum()
Out[159]:
   Date   Buyer  Quantity
2013-01-31 Carl  1
           Mark  3
2013-10-31 Carl  6
           Joe   9
2013-12-31 Carl  3
           Joe   9
```

You have an ambiguous specification in that you have a named index and a column that could be potential groupers.

```python
In [160]: df = df.set_index('Date')

In [161]: df['Date'] = df.index + pd.offsets.MonthEnd(2)

In [162]: df.groupby([pd.Grouper(freq='6M',key='Date'),'Buyer']).sum()
Out[162]:
   Date   Buyer  Quantity
2013-02-28 Carl  1
           Mark  3
2014-02-28 Carl  9
           Joe  18
```

```python
In [163]: df.groupby([pd.Grouper(freq='6M',level='Date'),'Buyer']).sum()
```

```text
   Date   Buyer  Quantity
2013-01-31 Carl  1
           Mark  3
2014-01-31 Carl  9
           Joe  18
```
16.9.6 Taking the first rows of each group

Just like for a DataFrame or Series you can call head and tail on a groupby:

```python
In [164]: df = pd.DataFrame([[1, 2], [1, 4], [5, 6]], columns=['A', 'B'])

In [165]: df
Out[165]:
   A  B
0  1  2
1  1  4
2  5  6

In [166]: g = df.groupby('A')

In [167]: g.head(1)
Out[167]:
   A  B
0  1  2
2  5  6

In [168]: g.tail(1)
Out[168]:
   A  B
1  1  4
2  5  6
```

This shows the first or last n rows from each group.

16.9.7 Taking the nth row of each group

To select from a DataFrame or Series the nth item, use `nth()`. This is a reduction method, and will return a single row (or no row) per group if you pass an int for n:

```python
In [169]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])

In [170]: g = df.groupby('A')

In [171]: g.nth(0)
Out[171]:
   B
A
1  NaN
5  6.0

In [172]: g.nth(-1)
Out[172]:
   B
A
1  4.0
5  6.0

In [173]: g.nth(1)
Out[173]:
   B
(continues on next page)
```

16.9. Other useful features
If you want to select the nth not-null item, use the `dropna` kwarg. For a DataFrame this should be either 'any' or 'all' just like you would pass to `dropna`:

```python
# nth(0) is the same as g.first()
In [174]: g.nth(0, dropna='any')
Out[174]:
   A  B
0  1  4.0
5  6.0

In [175]: g.first()
Out[175]:
   A  B
0  1  4.0
5  6.0

# nth(-1) is the same as g.last()
In [176]: g.nth(-1, dropna='any')  # NaNs denote group exhausted when using dropna
   A  B
0  1  4.0
5  6.0

In [177]: g.last()
   A  B
0  1  4.0
5  6.0

In [178]: g.B.nth(0, dropna='all')
   A  B
0  1  4.0
5  6.0
Name: B, dtype: float64
```

As with other methods, passing `as_index=False`, will achieve a filtration, which returns the grouped row.

```python
In [179]: df = pd.DataFrame([[1, np.nan], [1, 4], [5, 6]], columns=['A', 'B'])
In [180]: g = df.groupby('A', as_index=False)
In [181]: g.nth(0)
Out[181]:
   A  B
0  1  NaN
```

(continues on next page)
You can also select multiple rows from each group by specifying multiple nth values as a list of ints.

```python
In [183]: business_dates = pd.date_range(start='4/1/2014', end='6/30/2014', freq='B')
In [184]: df = pd.DataFrame(1, index=business_dates, columns=['a', 'b'])

# get the first, 4th, and last date index for each month
In [185]: df.groupby([df.index.year, df.index.month]).nth([0, 3, -1])
```

```
Out[185]:
            a  b
2014 4 1 1
   4 1 1
   5 1 1
   5 1 1
   6 1 1
   6 1 1
```

### 16.9.8 Enumerate group items

To see the order in which each row appears within its group, use the `cumcount` method:

```python
In [186]: dfg = pd.DataFrame(list('aabba'), columns=['A'])

In [187]: dfg
Out[187]:
   A
0 a
1 a
2 a
3 b
4 b
5 a

In [188]: dfg.groupby('A').cumcount()
```

```
Out[188]:
   A
0 0
1 1
2 2
3 0
4 1
5 3
```

```python
In [189]: dfg.groupby('A').cumcount(ascending=False)
```

(continues on next page)
### 16.9.9 Enumerate groups

New in version 0.20.2.

To see the ordering of the groups (as opposed to the order of rows within a group given by `cumcount`) you can use `ngroup()`.

Note that the numbers given to the groups match the order in which the groups would be seen when iterating over the `groupby` object, not the order they are first observed.

```python
In [190]: dfg = pd.DataFrame(list('aaabba'), columns=['A'])

In [191]: dfg
Out[191]:
   A
0  a
1  a
2  a
3  b
4  b
5  a

In [192]: dfg.groupby('A').ngroup()
Out[192]:
   0  1  2  3  4  5
0   0  0  0  1  1  0
1   0  0  0  1  1  0

dtype: int64

In [193]: dfg.groupby('A').ngroup(ascending=False)
Out[193]:
0  1
1  1
2  1
3  0
4  0
5  1

dtype: int64
```
16.9.10 Plotting

Groupby also works with some plotting methods. For example, suppose we suspect that some features in a DataFrame may differ by group, in this case, the values in column 1 where the group is “B” are 3 higher on average.

```
In [194]: np.random.seed(1234)
In [195]: df = pd.DataFrame(np.random.randn(50, 2))
In [196]: df['g'] = np.random.choice(['A', 'B'], size=50)
In [197]: df.loc[df['g'] == 'B', 1] += 3
```

We can easily visualize this with a boxplot:

```
In [198]: df.groupby('g').boxplot()
Out[198]:
A AxesSubplot(0.1,0.15;0.363636x0.75)
B AxesSubplot(0.536364,0.15;0.363636x0.75)
dtype: object
```

The result of calling `boxplot` is a dictionary whose keys are the values of our grouping column `g` (“A” and “B”). The values of the resulting dictionary can be controlled by the `return_type` keyword of `boxplot`. See the `visualization documentation` for more.
**16.9.11 Piping function calls**

New in version 0.21.0.

Similar to the functionality provided by `DataFrame` and `Series`, functions that take `GroupBy` objects can be chained together using a `pipe` method to allow for a cleaner, more readable syntax. To read about `.pipe` in general terms, see [here](#).

Combining `.groupby` and `.pipe` is often useful when you need to reuse `GroupBy` objects.

As an example, imagine having a `DataFrame` with columns for stores, products, revenue and quantity sold. We’d like to do a groupwise calculation of prices (i.e. revenue/quantity) per store and per product. We could do this in a multi-step operation, but expressing it in terms of piping can make the code more readable. First we set the data:

```python
In [199]: import numpy as np
In [200]: n = 1000
In [201]: df = pd.DataFrame({'Store': np.random.choice(['Store_1', 'Store_2'], n),
                     'Product': np.random.choice(['Product_1', 'Product_2'], n),
                     'Revenue': (np.random.random(n)*50+10).round(2),
                     'Quantity': np.random.randint(1, 10, size=n)})
In [202]: df.head(2)
```

Now, to find prices per store/product, we can simply do:

```python
In [203]: (df.groupby(['Store', 'Product'])
       .pipe(lambda grp: grp.Revenue.sum()/grp.Quantity.sum())
       .unstack().round(2))
```

Piping can also be expressive when you want to deliver a grouped object to some arbitrary function, for example:

```python
(df.groupby(['Store', 'Product']).pipe(report_func))
```

where `report_func` takes a `GroupBy` object and creates a report from that.
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

16.10 Examples
16.10.1 Regrouping by factor
Regroup columns of a DataFrame according to their sum, and sum the aggregated ones.
In [204]: df = pd.DataFrame({'a':[1,0,0], 'b':[0,1,0], 'c':[1,0,0], 'd':[2,3,4]})
In [205]: df
Out[205]:
a b c d
0 1 0 1 2
1 0 1 0 3
2 0 0 0 4
In [206]: df.groupby(df.sum(), axis=1).sum()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[206]:
1 9
0 2 2
1 1 3
2 0 4

16.10.2 Multi-column factorization
By using ngroup(), we can extract information about the groups in a way similar to factorize() (as described
further in the reshaping API) but which applies naturally to multiple columns of mixed type and different sources.
This can be useful as an intermediate categorical-like step in processing, when the relationships between the group
rows are more important than their content, or as input to an algorithm which only accepts the integer encoding.
(For more information about support in pandas for full categorical data, see the Categorical introduction and the API
documentation.)
In [207]: dfg = pd.DataFrame({"A": [1, 1, 2, 3, 2], "B": list("aaaba")})
In [208]: dfg
Out[208]:
A B
0 1 a
1 1 a
2 2 a
3 3 b
4 2 a
In [209]: dfg.groupby(["A", "B"]).ngroup()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[209]:
0
0
1
0
2
1
3
2
4
1
dtype: int64

In [210]: dfg.groupby(["A", [0, 0, 0, 1, 1]]).ngroup()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\

16.10. Examples

863


16.10.3 Groupby by Indexer to ‘resample’ data

Resampling produces new hypothetical samples (resamples) from already existing observed data or from a model that
generates data. These new samples are similar to the pre-existing samples.

In order to resample to work on indices that are non-datetimelike, the following procedure can be utilized.

In the following examples, df.index // 5 returns a binary array which is used to determine what gets selected for the
groupby operation.

Note: The below example shows how we can downsample by consolidation of samples into fewer samples. Here by
using df.index // 5, we are aggregating the samples in bins. By applying std() function, we aggregate the information
contained in many samples into a small subset of values which is their standard deviation thereby reducing the number
of samples.

In [211]: df = pd.DataFrame(np.random.randn(10,2))

In [212]: df
Out[212]:
     0     1
0 -0.793893  0.321153
1  0.342250  1.618906
2 -0.975807  1.918201
3 -0.810847 -1.405919
4 -0.751328  0.528290
5  0.730057 -1.316938
6  0.793893 -1.081009
7  0.505895 -1.701948
8 -1.006349  0.020208
9 -0.810847 -1.316938

In [213]: df.index // 5
Out[213]:
 0 0
1 1

In [214]: df.groupby(df.index // 5).std()
Out[214]:
     0     1
0  0.823647  1.312912
1  0.760109  0.942941

16.10.4 Returning a Series to propagate names

Group DataFrame columns, compute a set of metrics and return a named Series. The Series name is used as the name
for the column index. This is especially useful in conjunction with reshaping operations such as stacking in which the
column index name will be used as the name of the inserted column:

```
In [215]: df = pd.DataFrame({
    ....:     'a': [0, 0, 1, 1, 2, 2, 2, 2, 0, 0, 1, 1],
    ....:     'b': [0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 1, 1],
    ....:     'c': [1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0],
    ....:     'd': [0, 0, 1, 0, 0, 1, 0, 0, 1, 0, 0, 1],
    ....: })

In [216]: def compute_metrics(x):
    ....:     result = {'b_sum': x['b'].sum(), 'c_mean': x['c'].mean()}
    ....:     return pd.Series(result, name='metrics')

In [217]: result = df.groupby('a').apply(compute_metrics)

In [218]: result
Out[218]:
          metrics  b_sum  c_mean
       a
0       2.0    0.5
1       2.0    0.5
2       2.0    0.5

In [219]: result.stack()

Out[219]:
          metrics
       a
0     b_sum  2.0
       c_mean  0.5
1     b_sum  2.0
       c_mean  0.5
2     b_sum  2.0
       c_mean  0.5
dtype: float64
```
pandas provides various facilities for easily combining together Series, DataFrame, and Panel objects with various kinds of set logic for the indexes and relational algebra functionality in the case of join / merge-type operations.

### 17.1 Concatenating objects

The `concat()` function (in the main pandas namespace) does all of the heavy lifting of performing concatenation operations along an axis while performing optional set logic (union or intersection) of the indexes (if any) on the other axes. Note that I say “if any” because there is only a single possible axis of concatenation for Series.

Before diving into all of the details of `concat` and what it can do, here is a simple example:

```python
In [1]: df1 = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                      ...:                     'B': ['B0', 'B1', 'B2', 'B3'],
                      ...:                     'C': ['C0', 'C1', 'C2', 'C3'],
                      ...:                     'D': ['D0', 'D1', 'D2', 'D3']},
                      ...:                     index=[0, 1, 2, 3])
...

In [2]: df2 = pd.DataFrame({'A': ['A4', 'A5', 'A6', 'A7'],
                      ...:                     'B': ['B4', 'B5', 'B6', 'B7'],
                      ...:                     'C': ['C4', 'C5', 'C6', 'C7'],
                      ...:                     'D': ['D4', 'D5', 'D6', 'D7']},
                      ...:                     index=[4, 5, 6, 7])
...

In [3]: df3 = pd.DataFrame({'A': ['A8', 'A9', 'A10', 'A11'],
                      ...:                     'B': ['B8', 'B9', 'B10', 'B11'],
                      ...:                     'C': ['C8', 'C9', 'C10', 'C11'],
                      ...:                     'D': ['D8', 'D9', 'D10', 'D11']},
                      ...:                     index=[8, 9, 10, 11])
...

In [4]: frames = [df1, df2, df3]

In [5]: result = pd.concat(frames)
```
Like its sibling function on ndarrays, `numpy.concatenate`, `pandas.concat` takes a list or dict of homogeneously-typed objects and concatenates them with some configurable handling of “what to do with the other axes”:

```
pd.concat(objs, axis=0, join='outer', join_axes=None, ignore_index=False, keys=None, levels=None, names=None, verify_integrity=False, copy=True)
```

- `objs`: a sequence or mapping of Series, DataFrame, or Panel objects. If a dict is passed, the sorted keys will be used as the `keys` argument, unless it is passed, in which case the values will be selected (see below). Any None objects will be dropped silently unless they are all None in which case a ValueError will be raised.
- `axis`: {0, 1, ...}, default 0. The axis to concatenate along.
- `join`: {‘inner’, ‘outer’}, default ‘outer’. How to handle indexes on other axis(es). Outer for union and inner for intersection.
- `ignore_index`: boolean, default False. If True, do not use the index values on the concatenation axis. The resulting axis will be labeled 0, ..., n - 1. This is useful if you are concatenating objects where the concatenation axis does not have meaningful indexing information. Note the index values on the other axes are still respected in the join.
- `join_axes`: list of Index objects. Specific indexes to use for the other n - 1 axes instead of performing inner/outer set logic.
- `keys`: sequence, default None. Construct hierarchical index using the passed keys as the outermost level. If multiple levels passed, should contain tuples.
- `levels`: list of sequences, default None. Specific levels (unique values) to use for constructing a MultiIndex. Otherwise they will be inferred from the keys.
- `names`: list, default None. Names for the levels in the resulting hierarchical index.
- `verify_integrity`: boolean, default False. Check whether the new concatenated axis contains duplicates. This can be very expensive relative to the actual data concatenation.
• copy: boolean, default True. If False, do not copy data unnecessarily.

Without a little bit of context many of these arguments don’t make much sense. Let’s revisit the above example. Suppose we wanted to associate specific keys with each of the pieces of the chopped up DataFrame. We can do this using the keys argument:

```
In [6]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```

As you can see (if you’ve read the rest of the documentation), the resulting object’s index has a hierarchical index. This means that we can now select out each chunk by key:

```
In [7]: result.loc['y']
Out[7]:
    A  B  C  D
0   4  A4 B4 C4 D4
1   5  A5 B5 C5 D5
2   6  A6 B6 C6 D6
3   7  A7 B7 C7 D7
```

It’s not a stretch to see how this can be very useful. More detail on this functionality below.

**Note:** It is worth noting that `concat()` (and therefore `append()`) makes a full copy of the data, and that constantly reusing this function can create a significant performance hit. If you need to use the operation over several datasets, use a list comprehension.

```
frames = [ process_your_file(f) for f in files ]
result = pd.concat(frames)
```
17.1.1 Set logic on the other axes

When gluing together multiple DataFrames, you have a choice of how to handle the other axes (other than the one being concatenated). This can be done in the following three ways:

- Take the union of them all, `join='outer'`. This is the default option as it results in zero information loss.
- Take the intersection, `join='inner'`.
- Use a specific index, as passed to the `join_axes` argument.

Here is an example of each of these methods. First, the default `join='outer'` behavior:

```python
In [8]: df4 = pd.DataFrame({'B': ['B2', 'B3', 'B6', 'B7'],
                               ...
                         'D': ['D2', 'D3', 'D6', 'D7'],
                         ...
                         'F': ['F2', 'F3', 'F6', 'F7']},
                         index=[2, 3, 6, 7])
In [9]: result = pd.concat([df1, df4], axis=1, sort=False)
```

```
A   B   C   D   df1
---   ---   ---   ---   ---
0   A0   B0   C0   D0
1   A1   B1   C1   D1
2   A2   B2   C2   D2
3   A3   B3   C3   D3

B   D   F   df4
---   ---   ---
2   B2   D2   F2
3   B3   D3   F3
6   B6   D6   F6
7   B7   D7   F7

A   B   C   D   B   D   F   Result
---   ---   ---   ---   ---   ---   ---
0   A0   B0   C0   D0   NaN  NaN  NaN
1   A1   B1   C1   D1   NaN  NaN  NaN
2   A2   B2   C2   D2   A2   B2   F2
3   A3   B3   C3   D3   B3   D3   F3
6   B6   D6   F6   B6   D6   F6
7   B7   D7   F7   B7   D7   F7
```

**Warning:** Changed in version 0.23.0.

The default behavior with `join='outer'` is to sort the other axis (columns in this case). In a future version of pandas, the default will be to not sort. We specified `sort=False` to opt in to the new behavior now.

Here is the same thing with `join='inner'`:

```python
In [10]: result = pd.concat([df1, df4], axis=1, join='inner')
```

```
A   B   C   D   df1
---   ---   ---   ---   ---
0   A0   B0   C0   D0
1   A1   B1   C1   D1
2   A2   B2   C2   D2
3   A3   B3   C3   D3

B   D   F   df4
---   ---   ---
2   B2   D2   F2
3   B3   D3   F3
6   B6   D6   F6
7   B7   D7   F7

A   B   C   D   B   D   F   Result
---   ---   ---   ---   ---   ---   ---
2   A2   B2   C2   D2   A2   B2   F2
3   A3   B3   C3   D3   B3   D3   F3
```

Lastly, suppose we just wanted to reuse the **exact index** from the original DataFrame:
In [11]: result = pd.concat([df1, df4], axis=1, join_axes=[df1.index])

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>

</tbody>
</table>

17.1.2 Concatenating using append

A useful shortcut to `concat()` are the `append()` instance methods on `Series` and `DataFrame`. These methods actually predated `concat`. They concatenate along `axis=0`, namely the index:

In [12]: result = df1.append(df2)

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
<td>C1</td>
<td>D1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>

<td>B3</td>
<td>C3</td>
<td>D3</td>
</tr>
<tr>
<td>4</td>
<td>A4</td>
<td>B4</td>
<td>C4</td>
<td>D4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>B5</td>
<td>C5</td>
<td>D5</td>
</tr>
<tr>
<td>6</td>
<td>A6</td>
<td>B6</td>
<td>C6</td>
<td>D6</td>
</tr>
<tr>
<td>7</td>
<td>A7</td>
<td>B7</td>
<td>C7</td>
<td>D7</td>
</tr>
</tbody>
</table>

In the case of `DataFrame`, the indexes must be disjoint but the columns do not need to be:

In [13]: result = df1.append(df4)
append may take multiple objects to concatenate:

```python
In [14]: result = df1.append([df2, df3])
```

Note: Unlike the `append()` method, which appends to the original list and returns `None`, `append()` here does not modify `df1` and returns its copy with `df2` appended.
17.1.3 Ignoring indexes on the concatenation axis

For DataFrame’s which don’t have a meaningful index, you may wish to append them and ignore the fact that they may have overlapping indexes. To do this, use the `ignore_index` argument:

```python
In [15]: result = pd.concat([df1, df4], ignore_index=True)
```

This is also a valid argument to `DataFrame.append()`:

```python
In [16]: result = df1.append(df4, ignore_index=True)
```

17.1.4 Concatenating with mixed ndims

You can concatenate a mix of Series and DataFrame’s. The Series will be transformed to DataFrame with the column name as the name of the Series.
In [17]: s1 = pd.Series(['X0', 'X1', 'X2', 'X3'], name='X')

In [18]: result = pd.concat([df1, s1], axis=1)

Note: Since we're concatenating a Series to a DataFrame, we could have achieved the same result with DataFrame.assign(). To concatenate an arbitrary number of pandas objects (DataFrame or Series), use concat.

If unnamed Series are passed they will be numbered consecutively.

In [19]: s2 = pd.Series(['_0', '_1', '_2', '_3'])

In [20]: result = pd.concat([df1, s2, s2, s2], axis=1)

Passing ignore_index=True will drop all name references.

In [21]: result = pd.concat([df1, s1], axis=1, ignore_index=True)
17.1.5 More concatenating with group keys

A fairly common use of the keys argument is to override the column names when creating a new DataFrame based on existing Series. Notice how the default behaviour consists on letting the resulting DataFrame inherit the parent Series' name, when these existed.

```python
In [22]: s3 = pd.Series([0, 1, 2, 3], name='foo')
In [23]: s4 = pd.Series([0, 1, 2, 3])
In [24]: s5 = pd.Series([0, 1, 4, 5])
In [25]: pd.concat([s3, s4, s5], axis=1)
Out[25]:
   foo 0 1
0 0 0 0
1 1 1 1
2 2 2 4
3 3 3 5
```

Through the keys argument we can override the existing column names.

```python
In [26]: pd.concat([s3, s4, s5], axis=1, keys=['red','blue','yellow'])
Out[26]:
   red  blue  yellow
0  0     0     0
1  1     1     1
2  2     2     4
3  3     3     5
```

Let’s consider a variation of the very first example presented:

```python
In [27]: result = pd.concat(frames, keys=['x', 'y', 'z'])
```
You can also pass a dict to `concat` in which case the dict keys will be used for the `keys` argument (unless other keys are specified):

In [28]: pieces = {'x': df1, 'y': df2, 'z': df3}

In [29]: result = pd.concat(pieces)
In [30]: result = pd.concat(pieces, keys=['z', 'y'])

The MultiIndex created has levels that are constructed from the passed keys and the index of the DataFrame pieces:

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>A0</td>
<td>B0</td>
<td>C0</td>
<td>D0</td>
</tr>
<tr>
<td>1</td>
<td>A1</td>
<td>B1</td>
<td>C1</td>
<td>D1</td>
</tr>
<tr>
<td>2</td>
<td>A2</td>
<td>B2</td>
<td>C2</td>
<td>D2</td>
</tr>
<tr>
<td>3</td>
<td>A3</td>
<td>B3</td>
<td>C3</td>
<td>D3</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>4</td>
<td>A4</td>
<td>B4</td>
<td>C4</td>
<td>D4</td>
</tr>
<tr>
<td>5</td>
<td>A5</td>
<td>B5</td>
<td>C5</td>
<td>D5</td>
</tr>
<tr>
<td>6</td>
<td>A6</td>
<td>B6</td>
<td>C6</td>
<td>D6</td>
</tr>
<tr>
<td>7</td>
<td>A7</td>
<td>B7</td>
<td>C7</td>
<td>D7</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
</tr>
</thead>
<tbody>
<tr>
<td>8</td>
<td>A8</td>
<td>B8</td>
<td>C8</td>
<td>D8</td>
</tr>
<tr>
<td>9</td>
<td>A9</td>
<td>B9</td>
<td>C9</td>
<td>D9</td>
</tr>
<tr>
<td>10</td>
<td>A10</td>
<td>B10</td>
<td>C10</td>
<td>D10</td>
</tr>
<tr>
<td>11</td>
<td>A11</td>
<td>B11</td>
<td>C11</td>
<td>D11</td>
</tr>
</tbody>
</table>
If you wish to specify other levels (as will occasionally be the case), you can do so using the `levels` argument:

```python
In [32]: result = pd.concat(pieces, keys=['x', 'y', 'z'],
                      levels=[['z', 'y', 'x', 'w']],
                      names=['group_key'])
```

This is fairly esoteric, but it is actually necessary for implementing things like `GroupBy` where the order of a categorical variable is meaningful.

### 17.1.6 Appending rows to a DataFrame

While not especially efficient (since a new object must be created), you can append a single row to a DataFrame by passing a `Series` or dict to `append`, which returns a new DataFrame as above.

```python
In [34]: s2 = pd.Series(['X0', 'X1', 'X2', 'X3'], index=['A', 'B', 'C', 'D'])
In [35]: result = df1.append(s2, ignore_index=True)
```
You should use `ignore_index` with this method to instruct DataFrame to discard its index. If you wish to preserve the index, you should construct an appropriately-indexed DataFrame and append or concatenate those objects.

You can also pass a list of dicts or Series:

```python
In [36]: dicts = [{'A': 1, 'B': 2, 'C': 3, 'X': 4},
.....:   {'A': 5, 'B': 6, 'C': 7, 'Y': 8}]
.....:

In [37]: result = df1.append(dicts, ignore_index=True)
```

### 17.2 Database-style DataFrame joining/merging

pandas has full-featured, **high performance** in-memory join operations idiomatically very similar to relational databases like SQL. These methods perform significantly better (in some cases well over an order of magnitude better) than other open source implementations (like `base::merge.data.frame` in R). The reason for this is careful algorithmic design and the internal layout of the data in `DataFrame`.

See the [cookbook](#) for some advanced strategies.

Users who are familiar with SQL but new to pandas might be interested in a [comparison with SQL](#).

pandas provides a single function, `merge()`, as the entry point for all standard database join operations between `DataFrame` objects:
pd.merge(left, right, how='inner', on=None, left_on=None, right_on=None,
left_index=False, right_index=False, sort=True,
suffixes=('__x', '__y'), copy=True, indicator=False,
validate=None)

• left: A DataFrame object.
• right: Another DataFrame object.
• on: Column or index level names to join on. Must be found in both the left and right DataFrame objects. If not passed and left_index and right_index are False, the intersection of the columns in the DataFrames will be inferred to be the join keys.
• left_on: Columns or index levels from the left DataFrame to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame.
• right_on: Columns or index levels from the right DataFrame to use as keys. Can either be column names, index level names, or arrays with length equal to the length of the DataFrame.
• left_index: If True, use the index (row labels) from the left DataFrame as its join key(s). In the case of a DataFrame with a MultiIndex (hierarchical), the number of levels must match the number of join keys from the right DataFrame.
• right_index: Same usage as left_index for the right DataFrame
• how: One of 'left', 'right', 'outer', 'inner'. Defaults to inner. See below for more detailed description of each method.
• sort: Sort the result DataFrame by the join keys in lexicographical order. Defaults to True, setting to False will improve performance substantially in many cases.
• suffixes: A tuple of string suffixes to apply to overlapping columns. Defaults to ('__x', '__y').
• copy: Always copy data (default True) from the passed DataFrame objects, even when reindexing is not necessary. Cannot be avoided in many cases but may improve performance / memory usage. The cases where copying can be avoided are somewhat pathological but this option is provided nonetheless.
• indicator: Add a column to the output DataFrame called _merge with information on the source of each row. _merge is Categorical-type and takes on a value of 'left_only' for observations whose merge key only appears in 'left' DataFrame, 'right_only' for observations whose merge key only appears in 'right' DataFrame, and 'both' if the observation’s merge key is found in both.
• validate: string, default None. If specified, checks if merge is of specified type.
  - “one_to_one” or “1:1”: checks if merge keys are unique in both left and right datasets.
  - “one_to_many” or “1:m”: checks if merge keys are unique in left dataset.
  - “many_to_one” or “m:1”: checks if merge keys are unique in right dataset.
  - “many_to_many” or “m:m”: allowed, but does not result in checks.
New in version 0.21.0.

Note:  Support for specifying index levels as the on, left_on, and right_on parameters was added in version 0.23.0.

The return type will be the same as left. If left is a DataFrame and right is a subclass of DataFrame, the return type will still be DataFrame.

merge is a function in the pandas namespace, and it is also available as a DataFrame instance method merge(), with the calling DataFrame being implicitly considered the left object in the join.
The related \texttt{join()} method, uses \texttt{merge} internally for the index-on-index (by default) and column(s)-on-index join. If you are joining on index only, you may wish to use \texttt{DataFrame.join} to save yourself some typing.

### 17.2.1 Brief primer on merge methods (relational algebra)

Experienced users of relational databases like SQL will be familiar with the terminology used to describe join operations between two SQL-table like structures (\texttt{DataFrame} objects). There are several cases to consider which are very important to understand:

- **one-to-one** joins: for example when joining two \texttt{DataFrame} objects on their indexes (which must contain unique values).
- **many-to-one** joins: for example when joining an index (unique) to one or more columns in a different \texttt{DataFrame}.
- **many-to-many** joins: joining columns on columns.

\textbf{Note:} When joining columns on columns (potentially a many-to-many join), any indexes on the passed \texttt{DataFrame} objects will be discarded.

It is worth spending some time understanding the result of the **many-to-many** join case. In SQL / standard relational algebra, if a key combination appears more than once in both tables, the resulting table will have the **Cartesian product** of the associated data. Here is a very basic example with one unique key combination:

\begin{verbatim}
In [38]: left = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
                        'A': ['A0', 'A1', 'A2', 'A3'],
                        'B': ['B0', 'B1', 'B2', 'B3']})

In [39]: right = pd.DataFrame({'key': ['K0', 'K1', 'K2', 'K3'],
                          'C': ['C0', 'C1', 'C2', 'C3'],
                          'D': ['D0', 'D1', 'D2', 'D3']})

In [40]: result = pd.merge(left, right, on='key')
\end{verbatim}

Here is a more complicated example with multiple join keys. Only the keys appearing in \texttt{left} and \texttt{right} are present (the intersection), since \texttt{how='inner'} by default:

\begin{verbatim}
In [41]: left = pd.DataFrame({'key1': ['K0', 'K0', 'K1', 'K2'],
                          'key2': ['K0', 'K1', 'K0', 'K1'],
                          'A': ['A0', 'A1', 'A2', 'A3'],
                          'B': ['B0', 'B1', 'B2', 'B3']})
\end{verbatim}

(continues on next page)
In [42]: right = pd.DataFrame({'key1': ['K0', 'K1', 'K1', 'K2'],
...: 'key2': ['K0', 'K0', 'K0', 'K0'],
...: 'C': ['C0', 'C1', 'C2', 'C3'],
...: 'D': ['D0', 'D1', 'D2', 'D3']})

In [43]: result = pd.merge(left, right, on=['key1', 'key2'])

The `how` argument to `merge` specifies how to determine which keys are to be included in the resulting table. If a key combination **does not appear** in either the left or right tables, the values in the joined table will be `NA`. Here is a summary of the `how` options and their SQL equivalent names:

<table>
<thead>
<tr>
<th>Merge method</th>
<th>SQL Join Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>left</td>
<td>LEFT OUTER JOIN</td>
<td>Use keys from left frame only</td>
</tr>
<tr>
<td>right</td>
<td>RIGHT OUTER JOIN</td>
<td>Use keys from right frame only</td>
</tr>
<tr>
<td>outer</td>
<td>FULL OUTER JOIN</td>
<td>Use union of keys from both frames</td>
</tr>
<tr>
<td>inner</td>
<td>INNER JOIN</td>
<td>Use intersection of keys from both frames</td>
</tr>
</tbody>
</table>

In [44]: result = pd.merge(left, right, how='left', on=['key1', 'key2'])

In [45]: result = pd.merge(left, right, how='right', on=['key1', 'key2'])
In [46]: result = pd.merge(left, right, how='outer', on=['key1', 'key2'])

In [47]: result = pd.merge(left, right, how='inner', on=['key1', 'key2'])

Here is another example with duplicate join keys in DataFrames:

In [48]: left = pd.DataFrame({'A': [1, 2], 'B': [2, 2]})
In [49]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [50]: result = pd.merge(left, right, on='B', how='outer')

17.2. Database-style DataFrame joining/merging
17.2.2 Checking for duplicate keys

New in version 0.21.0.

Users can use the validate argument to automatically check whether there are unexpected duplicates in their merge keys. Key uniqueness is checked before merge operations and so should protect against memory overflows. Checking key uniqueness is also a good way to ensure user data structures are as expected.

In the following example, there are duplicate values of \( B \) in the right DataFrame. As this is not a one-to-one merge – as specified in the validate argument – an exception will be raised.

```python
In [51]: left = pd.DataFrame({'A': [1, 2], 'B': [1, 2]})
In [52]: right = pd.DataFrame({'A': [4, 5, 6], 'B': [2, 2, 2]})
In [53]: result = pd.merge(left, right, on='B', how='outer', validate="one_to_one")
...:
MergeError: Merge keys are not unique in right dataset; not a one-to-one merge
```

If the user is aware of the duplicates in the right DataFrame but wants to ensure there are no duplicates in the left DataFrame, one can use the validate='one_to_many' argument instead, which will not raise an exception.

```python
In [53]: pd.merge(left, right, on='B', how='outer', validate="one_to_many")
Out[53]:
     A_x  B  A_y
0     1  1   NaN
1     2  2   4.0
2     2  2   5.0
3     2  2   6.0
```

17.2.3 The merge indicator

`merge()` accepts the argument indicator. If True, a Categorical-type column called _merge will be added to the output object that takes on values:
### Observation Origin

| Merge key only in 'left' frame | left_only |
| Merge key only in 'right' frame | right_only |
| Merge key in both frames       | both      |

In [54]: df1 = pd.DataFrame({'col1': [0, 1], 'col_left':['a', 'b']})

In [55]: df2 = pd.DataFrame({'col1': [1, 2, 2], 'col_right':[2, 2, 2]})

In [56]: pd.merge(df1, df2, on='col1', how='outer', indicator=True)

<table>
<thead>
<tr>
<th>col1</th>
<th>col_left</th>
<th>col_right</th>
<th>_merge</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>

The `indicator` argument will also accept string arguments, in which case the indicator function will use the value of the passed string as the name for the indicator column.

In [57]: pd.merge(df1, df2, on='col1', how='outer', indicator='indicator_column')

<table>
<thead>
<tr>
<th>col1</th>
<th>col_left</th>
<th>col_right</th>
<th>indicator_column</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>a</td>
<td>NaN</td>
<td>left_only</td>
</tr>
<tr>
<td>1</td>
<td>b</td>
<td>2.0</td>
<td>both</td>
</tr>
<tr>
<td>2</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
<tr>
<td>3</td>
<td>NaN</td>
<td>2.0</td>
<td>right_only</td>
</tr>
</tbody>
</table>

### 17.2.4 Merge Dtypes

New in version 0.19.0.

Merging will preserve the dtype of the join keys.

In [58]: left = pd.DataFrame({'key': [1], 'v1': [10]})

In [59]: left

Out[59]:

<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
</tr>
</tbody>
</table>

In [60]: right = pd.DataFrame({'key': [1, 2], 'v1': [20, 30]})

In [61]: right

Out[61]:

<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>20</td>
</tr>
<tr>
<td>1</td>
<td>30</td>
</tr>
</tbody>
</table>

We are able to preserve the join keys:

In [62]: pd.merge(left, right, how='outer')

Out[62]:

<table>
<thead>
<tr>
<th>key</th>
<th>v1</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>10</td>
</tr>
<tr>
<td>1</td>
<td>20</td>
</tr>
<tr>
<td>2</td>
<td>30</td>
</tr>
</tbody>
</table>
0  1  10
1  1  20
2  2  30

```python
In [63]: pd.merge(left, right, how='outer').dtypes
Out[63]:
key    int64
v1     int64
dtype: object
```

Of course if you have missing values that are introduced, then the resulting dtype will be upcast.

```python
In [64]: pd.merge(left, right, how='outer', on='key')
Out[64]:
   key v1_x v1_y
0    1   10  20
1    2 NaN  30
```

```python
In [65]: pd.merge(left, right, how='outer', on='key').dtypes
Out[65]:
key    int64
v1_x  float64
v1_y  int64
dtype: object
```

New in version 0.20.0.

Merging will preserve category dtypes of the mergands. See also the section on `categoricals`.

The left frame.

```python
In [66]: from pandas.api.types import CategoricalDtype
In [67]: X = pd.Series(np.random.choice(['foo', 'bar'], size=(10,)))
In [68]: X = X.astype(CategoricalDtype(categories=['foo', 'bar']))
In [69]: left = pd.DataFrame({'X': X,  
                          'Y': np.random.choice(['one', 'two', 'three'], size=(10,))})
```

```python
In [70]: left
Out[70]:
   X     Y
0  bar  one
1  foo  one
2  foo  three
3  bar  three
4  foo  one
5  bar  one
6  bar  three
7  bar  three
8  bar  three
9  foo  three
```

```python
In [71]: left.dtypes
```

(continues on next page)
The right frame.

```
In [72]: right = pd.DataFrame(
    ....:     'X': pd.Series(['foo', 'bar'],
    ....:                         dtype=CategoricalDtype(['foo', 'bar'])),
    ....:     'Z': [1, 2])
    ....: )
    ....: 
In [73]: right
Out[73]:
   X  Z
0  foo  1
1  bar  2
```

The merged result:

```
In [75]: result = pd.merge(left, right, how='outer')
In [76]: result
Out[76]:
   X    Y   Z
0  bar  one  2
1  bar  three  2
2  bar  one  2
3  bar  three  2
4  bar  three  2
5  foo  one  1
6  foo  three  1
7  foo  one  1
8  foo  three  1
9  foo  three  1
In [77]: result.dtypes
```

Note: The category dtypes must be exactly the same, meaning the same categories and the ordered attribute. Otherwise the result will coerce to object dtype.
Note: Merging on `category` dtypes that are the same can be quite performant compared to `object` dtype merging.

### 17.2.5 Joining on index

`DataFrame.join()` is a convenient method for combining the columns of two potentially differently-indexed DataFrames into a single result DataFrame. Here is a very basic example:

```python
In [78]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                           'B': ['B0', 'B1', 'B2'],
                           index=['K0', 'K1', 'K2'])

In [79]: right = pd.DataFrame({'C': ['C0', 'C2', 'C3'],
                           'D': ['D0', 'D2', 'D3'],
                           index=['K0', 'K2', 'K3'])

In [80]: result = left.join(right)

In [81]: result = left.join(right, how='outer')

The same as above, but with `how='inner'`.

In [82]: result = left.join(right, how='inner')
```
The data alignment here is on the indexes (row labels). This same behavior can be achieved using `merge` plus additional arguments instructing it to use the indexes:

```
In [83]: result = pd.merge(left, right, left_index=True, right_index=True, how='outer')
```

![Diagram showing data alignment on indexes]

```
In [84]: result = pd.merge(left, right, left_index=True, right_index=True, how='inner');
```

### 17.2.6 Joining key columns on an index

`join()` takes an optional `on` argument which may be a column or multiple column names, which specifies that the passed DataFrame is to be aligned on that column in the DataFrame. These two function calls are completely equivalent:

```
left.join(right, on=key_or_keys)
pd.merge(left, right, left_on=key_or_keys, right_index=True, how='left', sort=False)
```

Obviously you can choose whichever form you find more convenient. For many-to-one joins (where one of the DataFrame's is already indexed by the join key), using `join` may be more convenient. Here is a simple example:

```
In [85]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                        'B': ['B0', 'B1', 'B2', 'B3'],
                        'key': ['K0', 'K1', 'K0', 'K1']})

In [86]: right = pd.DataFrame({'C': ['C0', 'C1'],
                         'D': ['D0', 'D1'],
                         index=['K0', 'K1']})

In [87]: result = left.join(right, on='key')
```
In [88]: result = pd.merge(left, right, left_on='key', right_index=True, how='left', sort=False);

To join on multiple keys, the passed DataFrame must have a MultiIndex:

In [89]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
   ...:                        'B': ['B0', 'B1', 'B2', 'B3'],
   ...:                        'key1': ['K0', 'K0', 'K1', 'K2'],
   ...:                        'key2': ['K0', 'K1', 'K0', 'K1']})

In [90]: index = pd.MultiIndex.from_tuples([('K0', 'K0'), ('K1', 'K0'),
   ...:                                         ('K2', 'K0'), ('K2', 'K1')])

In [91]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
   ...:                        'D': ['D0', 'D1', 'D2', 'D3']},
                        index=index)

Now this can be joined by passing the two key column names:

In [92]: result = left.join(right, on=['key1', 'key2'])

The default for DataFrame.join is to perform a left join (essentially a “VLOOKUP” operation, for Excel users), which
uses only the keys found in the calling DataFrame. Other join types, for example inner join, can be just as easily performed:

```
In [93]: result = left.join(right, on=['key1', 'key2'], how='inner')
```

As you can see, this drops any rows where there was no match.

### 17.2.7 Joining a single Index to a Multi-index

You can join a singly-indexed DataFrame with a level of a multi-indexed DataFrame. The level will match on the name of the index of the singly-indexed frame against a level name of the multi-indexed frame.

```
In [94]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                        'B': ['B0', 'B1', 'B2'],
                        index=pd.Index(['K0', 'K1', 'K2'], name='key'))

In [95]: index = pd.MultiIndex.from_tuples([('K0', 'Y0'), ('K1', 'Y1'),
                                       ('K2', 'Y2'), ('K2', 'Y3')],
                                       names=['key', 'Y'])

In [96]: right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                          'D': ['D0', 'D1', 'D2', 'D3'],
                          index=index)

In [97]: result = left.join(right, how='inner')
```

This is equivalent but less verbose and more memory efficient / faster than this.

```
In [98]: result = pd.merge(left.reset_index(), right.reset_index(),
                      on=['key'], how='inner').set_index(['key', 'Y'])
```

17.2. Database-style DataFrame joining/merging
### 17.2.8 Joining with two multi-indexes

This is not implemented via `join` at-the-moment, however it can be done using the following code.

```python
In [99]: index = pd.MultiIndex.from_tuples([('K0', 'X0'), ('K0', 'X1'),
                                       ('K1', 'X2')],
                                          names=['key', 'X'])

In [100]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2'],
                          'B': ['B0', 'B1', 'B2'],
                          'key1': ['K0', 'K1', 'K0'],
                          index=index)

In [101]: result = pd.merge(left.reset_index(), right.reset_index(),
                         on=['key1'], how='inner').set_index(['key', 'X', 'Y'])
```

### 17.2.9 Merging on a combination of columns and index levels

New in version 0.22.

Strings passed as the `on`, `left_on`, and `right_on` parameters may refer to either column names or index level names. This enables merging `DataFrame` instances on a combination of index levels and columns without resetting indexes.

```python
In [102]: left_index = pd.Index(['K0', 'K0', 'K1', 'K2'], name='key1')

In [103]: left = pd.DataFrame({'A': ['A0', 'A1', 'A2', 'A3'],
                         'B': ['B0', 'B1', 'B2', 'B3'],
                         'key2': ['K0', 'K1', 'K0', 'K1'],
                         index=left_index)
```

(continues on next page)
right_index = pd.Index(['K0', 'K1', 'K2', 'K2'], name='key1')

right = pd.DataFrame({'C': ['C0', 'C1', 'C2', 'C3'],
                      'D': ['D0', 'D1', 'D2', 'D3'],
                      'key2': ['K0', 'K0', 'K0', 'K1'],
                      index=right_index)

result = left.merge(right, on=['key1', 'key2'])

Note: When DataFrames are merged on a string that matches an index level in both frames, the index level is preserved as an index level in the resulting DataFrame.

Note: If a string matches both a column name and an index level name, then a warning is issued and the column takes precedence. This will result in an ambiguity error in a future version.

### 17.2.10 Overlapping value columns

The `merge` suffixes argument takes a tuple of list of strings to append to overlapping column names in the input DataFrames to disambiguate the result columns:

left = pd.DataFrame({'k': ['K0', 'K1', 'K2'], 'v': [1, 2, 3]})

right = pd.DataFrame({'k': ['K0', 'K0', 'K3'], 'v': [4, 5, 6]})

result = pd.merge(left, right, on='k')

17.2. Database-style DataFrame joining/merging
In [110]: result = pd.merge(left, right, on='k', suffixes=['_l', '_r'])

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>v</td>
<td>k</td>
</tr>
<tr>
<td>0</td>
<td>K0</td>
<td>1</td>
</tr>
<tr>
<td>1</td>
<td>K1</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>K2</td>
<td>3</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Dataframe.join() has lsuffix and rsuffix arguments which behave similarly.

In [111]: left = left.set_index('k')
In [112]: right = right.set_index('k')
In [113]: result = left.join(right, lsuffix='_l', rsuffix='_r')

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>k</td>
<td>v</td>
<td>v.l</td>
<td>v.r</td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td>4.0</td>
<td></td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td>5.0</td>
<td></td>
</tr>
<tr>
<td>K1</td>
<td>2</td>
<td>NaN</td>
<td></td>
</tr>
<tr>
<td>K2</td>
<td>3</td>
<td>NaN</td>
<td></td>
</tr>
</tbody>
</table>

17.2.11 Joining multiple DataFrame or Panel objects

A list or tuple of DataFrames can also be passed to join() to join them together on their indexes.

In [114]: right2 = pd.DataFrame({'v': [7, 8, 9]}, index=['K1', 'K1', 'K2'])
In [115]: result = left.join([right, right2])

<p>| | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>v</td>
<td>v</td>
<td>v</td>
<td>v.x</td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td>4</td>
<td>K0</td>
</tr>
<tr>
<td>K0</td>
<td>1</td>
<td>5</td>
<td>K0</td>
</tr>
<tr>
<td>K1</td>
<td>2</td>
<td>NaN</td>
<td>K1</td>
</tr>
<tr>
<td>K2</td>
<td>3</td>
<td>NaN</td>
<td>K2</td>
</tr>
<tr>
<td>K2</td>
<td>3</td>
<td>NaN</td>
<td></td>
</tr>
</tbody>
</table>
17.2.12 Merging together values within Series or DataFrame columns

Another fairly common situation is to have two like-indexed (or similarly indexed) Series or DataFrame objects and wanting to “patch” values in one object from values for matching indices in the other. Here is an example:

```python
In [116]: df1 = pd.DataFrame([[np.nan, 3., 5.], [-4.6, np.nan, np.nan],
                         [np.nan, 7., np.nan]])

In [117]: df2 = pd.DataFrame([[-42.6, np.nan, -8.2], [-5., 1.6, 4.]],
                        index=[1, 2])

For this, use the `combine_first()` method:

```python
In [118]: result = df1.combine_first(df2)
```

For this, use the `combine_first()` method:

```
In [118]: result = df1.combine_first(df2)
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values inplace:

```python
In [119]: df1.update(df2)
```

Note that this method only takes values from the right DataFrame if they are missing in the left DataFrame. A related method, `update()`, alters non-NA values inplace:

```
In [119]: df1.update(df2)
```

17.3 Timeseries friendly merging

17.3.1 Merging Ordered Data

A `merge_ordered()` function allows combining time series and other ordered data. In particular it has an optional `fill_method` keyword to fill/interpolate missing data:

```python
In [120]: left = pd.DataFrame({'k': ['K0', 'K1', 'K1', 'K2'],
                         'lv': [1, 2, 3, 4],
                         's': ['a', 'b', 'c', 'd']})

In [121]: right = pd.DataFrame({'k': ['K1', 'K2', 'K4'],
                          'lv': [1, 2, 3, 4],
                          's': ['a', 'b', 'c', 'd']})
```

(continues on next page)
17.3.2 Merging AsOf

New in version 0.19.0.

A `merge_asof()` is similar to an ordered left-join except that we match on nearest key rather than equal keys. For each row in the `leftDataFrame`, we select the last row in the `rightDataFrame` whose `on` key is less than the `left`'s key. Both DataFrames must be sorted by the key.

 Optionally an asof merge can perform a group-wise merge. This matches the `by` key equally, in addition to the nearest match on the `on` key.

For example; we might have `trades` and `quotes` and we want to `asof` merge them.
In [125]: trades
Out[125]:

<table>
<thead>
<tr>

3 2016-05-25 13:30:00.048  GOOG  720.92    100  720.50  720.93
4 2016-05-25 13:30:00.048  AAPL   98.00    100  NaN  NaN
```
18.1 Reshaping by pivoting DataFrame objects

Data is often stored in CSV files or databases in so-called “stacked” or “record” format:

```
In [1]: df
Out[1]:
        date  variable  value
    0 2000-01-03         A   0.469112
    1 2000-01-04         A  -0.282863
    2 2000-01-05         A  -1.509059
    3 2000-01-03         B  -1.135632
    4 2000-01-04         B   1.212112
    5 2000-01-05         B  -0.173215
    6 2000-01-03         C   0.119209
    7 2000-01-04         C  -1.044236
    8 2000-01-05         C  -0.861849
    9 2000-01-03         D  -2.104569
   10 2000-01-04         D  -0.494929
   11 2000-01-05         D   1.071804
```

For the curious here is how the above DataFrame was created:

```python
import pandas.util.testing as tm; tm.N = 3
def unpivot(frame):
    N, K = frame.shape
    data = {'value' : frame.values.ravel('F'),
            'variable' : np.asarray(frame.columns).repeat(N),
            'date' : np.tile(np.asarray(frame.index), K)}
    return pd.DataFrame(data, columns=['date', 'variable', 'value'])

df = unpivot(tm.makeTimeDataFrame())
```

To select out everything for variable A we could do:

```
In [2]: df[df['variable'] == 'A']
Out[2]:
        date  variable  value
    0 2000-01-03         A   0.469112
    1 2000-01-04         A  -0.282863
    2 2000-01-05         A  -1.509059
```

But suppose we wish to do time series operations with the variables. A better representation would be where the columns are the unique variables and an index of dates identifies individual observations. To reshape the data into this form, we use the `DataFrame.pivot()` method (also implemented as a top level function `pivot()`):
If the values argument is omitted, and the input DataFrame has more than one column of values which are not used as column or index inputs to pivot, then the resulting “pivoted” DataFrame will have hierarchical columns whose topmost level indicates the respective value column:

```python
In [4]: df['value2'] = df['value'] * 2
In [5]: pivoted = df.pivot('date', 'variable')
```

You can then select subsets from the pivoted DataFrame:

```python
In [7]: pivoted['value2']
```

Note that this returns a view on the underlying data in the case where the data are homogeneously-typed.

### 18.2 Reshaping by stacking and unstacking

Closely related to the `pivot()` method are the related `stack()` and `unstack()` methods available on Series and DataFrame. These methods are designed to work together with MultiIndex objects (see the section on hierarchical indexing). Here are essentially what these methods do:

- **stack**: “pivot” a level of the (possibly hierarchical) column labels, returning a DataFrame with an index with a new inner-most level of row labels.
- **unstack**: (inverse operation of stack) “pivot” a level of the (possibly hierarchical) row index to the column axis, producing a reshaped DataFrame with a new inner-most level of column labels.

The clearest way to explain is by example. Let’s take a prior example data set from the hierarchical indexing section:
In [8]: tuples = list(zip(*[['bar', 'bar', 'baz', 'baz',
                        'foo', 'foo', 'qux', 'qux'],
                        ['one', 'two', 'one', 'two',
                        'one', 'two', 'one', 'two']]))

In [9]: index = pd.MultiIndex.from_tuples(tuples, names=['first', 'second'])

In [10]: df = pd.DataFrame(np.random.randn(8, 2), index=index, columns=['A', 'B'])

In [11]: df2 = df[:4]

In [12]: df2
Out[12]:
   A   B
first second
bar one 0.721555 -0.706771
two -1.039575  0.271860
baz one -0.424972  0.567020
two  0.276232 -1.087401

The stack function “compresses” a level in the DataFrame’s columns to produce either:

- A Series, in the case of a simple column Index.
- A DataFrame, in the case of a MultiIndex in the columns.

If the columns have a MultiIndex, you can choose which level to stack. The stacked level becomes the new lowest level in a MultiIndex on the columns:

In [13]: stacked = df2.stack()

In [14]: stacked
Out[14]:
   first second
   bar one    A  0.721555
       B -0.706771
      two A -1.039575
           B  0.271860
   baz one    A -0.424972
           B  0.567020
      two A  0.276232
           B -1.087401
dtype: float64

With a “stacked” DataFrame or Series (having a MultiIndex as the index), the inverse operation of stack is unstack, which by default unstacks the last level:

In [15]: stacked.unstack()
Out[15]:
   A    B
first second
bar one 0.721555 -0.706771
two -1.039575  0.271860
baz one -0.424972  0.567020
two  0.276232 -1.087401

(continues on next page)
If the indexes have names, you can use the level names instead of specifying the level numbers:

```
In [18]: stacked.unstack('second')
Out[18]:
   second   one   two
first  
bar   A  0.721555 -1.039575  
      B -0.706771  0.271860  
baz   A -0.424972  0.276232  
      B  0.567020 -1.087401

In [20]: df
Out[20]:
   A
2  a -0.370647
   b -1.157892
1  a -1.344312
   b  0.844885

In [22]: all(df.unstack().stack() == df.sort_index())
```

```
Out[22]: True
```

Notice that the stack and unstack methods implicitly sort the index levels involved. Hence a call to stack and then unstack, or vice versa, will result in a sorted copy of the original DataFrame or Series:

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.

**18.2.1 Multiple Levels**

You may also stack or unstack more than one level at a time by passing a list of levels, in which case the end result is as if each level in the list were processed individually.
In [23]: columns = pd.MultiIndex.from_tuples(
   ...:     [('A', 'cat', 'long'), ('B', 'cat', 'long'),
   ...:     ('A', 'dog', 'short'), ('B', 'dog', 'short')
   ...:   ),
   ...:   names=['exp', 'animal', 'hair_length'])
   ...:
In [24]: df = pd.DataFrame(np.random.randn(4, 4), columns=columns)
In [25]: df
Out[25]:
exp    A     B     A     B
animal  cat   cat   dog   dog
hair_length long  long  short  short
0  1.075770 -0.109050  1.643563 -1.469388
1   0.357021 -0.674600 -1.776904 -0.968914
2 -1.294524  0.413738  0.276662 -0.472035
3  0.013960 -0.362543 -0.006154 -0.923061

In [26]: df.stack(level=['animal', 'hair_length'])

Out[26]:
exp  A     B
animal hair_length
0  cat long  1.075770 -0.109050
  dog short  1.643563 -1.469388
1  cat long  0.357021 -0.674600
  dog short -1.776904 -0.968914
2  cat long -1.294524  0.413738
  dog short  0.276662 -0.472035
3  cat long -0.013960 -0.362543
  dog short -0.006154 -0.923061

The list of levels can contain either level names or level numbers (but not a mixture of the two).

# df.stack(level=['animal', 'hair_length'])
# from above is equivalent to:
In [27]: df.stack(level=[1, 2])

Out[27]:
exp  A     B
animal hair_length
0  cat long  1.075770 -0.109050
  dog short  1.643563 -1.469388
1  cat long  0.357021 -0.674600
  dog short -1.776904 -0.968914
2  cat long -1.294524  0.413738
  dog short  0.276662 -0.472035
3  cat long -0.013960 -0.362543
  dog short -0.006154 -0.923061

18.2.2 Missing Data

These functions are intelligent about handling missing data and do not expect each subgroup within the hierarchical index to have the same set of labels. They also can handle the index being unsorted (but you can make it sorted by calling sort_index, of course). Here is a more complex example:

18.2. Reshaping by stacking and unstacking
In [28]: `columns = pd.MultiIndex.from_tuples([('A', 'cat'), ('B', 'dog'),
....: ('B', 'cat'), ('A', 'dog')],
....: names=['exp', 'animal'])

In [29]: `index = pd.MultiIndex.from_product([('bar', 'baz', 'foo', 'qux'),
....: ('one', 'two')],
....: names=['first', 'second'])

In [30]: `df = pd.DataFrame(np.random.randn(8, 4), index=index, columns=columns)

In [31]: `df2 = df.iloc[[0, 1, 2, 4, 5, 7]]

As mentioned above, `stack` can be called with a `level` argument to select which level in the columns to stack:

In [33]: `df2.stack('exp')

In [34]: `df2.stack('animal')
Unstacking can result in missing values if subgroups do not have the same set of labels. By default, missing values will be replaced with the default fill value for that data type, `NaN` for float, `NaT` for datetimelike, etc. For integer types, by default data will converted to float and missing values will be set to `NaN`.

```python
In [35]: df3 = df.iloc[[0, 1, 4, 7], [1, 2]]

In [36]: df3
Out[36]:

<table>
<thead>
<tr>
<th>exp</th>
<th>animal</th>
<th>dog</th>
<th>cat</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>first</td>
<td></td>
<td></td>
</tr>
<tr>
<td>bar</td>
<td>one</td>
<td>0.805244</td>
<td>-1.206412</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>1.340309</td>
<td>-1.170299</td>
</tr>
<tr>
<td>foo</td>
<td>one</td>
<td>1.607920</td>
<td>1.024180</td>
</tr>
<tr>
<td></td>
<td>two</td>
<td>0.769804</td>
<td>-1.281247</td>
</tr>
</tbody>
</table>

In [37]: df3.unstack()

In [38]: df3.unstack(fill_value=-1e9)
```

New in version 0.18.0.

Alternatively, unstack takes an optional `fill_value` argument, for specifying the value of missing data.

```python
In [38]: df3.unstack(fill_value=-1e9)
```

### 18.2.3 With a MultiIndex

Unstacking when the columns are a MultiIndex is also careful about doing the right thing:

```python
In [39]: df[:3].unstack(0)
```

### 18.2. Reshaping by stacking and unstacking
18.3 Reshaping by Melt

The top-level `melt()` function and the corresponding `DataFrame.melt()` are useful to massage a DataFrame into a format where one or more columns are identifier variables, while all other columns, considered measured variables, are “unpivoted” to the row axis, leaving just two non-identifier columns, “variable” and “value”. The names of those columns can be customized by supplying the `var_name` and `value_name` parameters.

For instance,

```python
In [41]: cheese = pd.DataFrame({'first' : ['John', 'Mary'],
                           'last' : ['Doe', 'Bo'],
                           'height' : [5.5, 6.0],
                           'weight' : [130, 150]})

In [42]: cheese
Out[42]:
   first  last  height  weight
0  John   Doe    5.5     130
1  Mary    Bo     6.0      150

In [43]: cheese.melt(id_vars=['first', 'last'])

→
   first  last  variable  value
0  John   Doe      height    5.5
1  Mary    Bo      height     6.0
2  John   Doe      weight   130.0
3  Mary    Bo      weight   150.0

In [44]: cheese.melt(id_vars=['first', 'last'], var_name='quantity')

→
   first  last  quantity  value
0  John   Doe      height    5.5
1  Mary    Bo      height     6.0
2  John   Doe      weight   130.0
3  Mary    Bo      weight   150.0
```
Another way to transform is to use the `wide_to_long()` panel data convenience function. It is less flexible than `melt()`, but more user-friendly.

```
In [45]: dft = pd.DataFrame({"A1970": {0: "a", 1: "b", 2: "c"},
                       "A1980": {0: "d", 1: "e", 2: "f"},
                       "B1970": {0: 2.5, 1: 1.2, 2: .7},
                       "B1980": {0: 3.2, 1: 1.3, 2: .1},
                       "X": dict(zip(range(3), np.random.randn(3)))
                       })

In [46]: dft["id"] = dft.index

In [47]: dft
Out[47]:
0       a       d      2.5   3.2 -0.121306  0
1       b       e      1.2   1.3 -0.097883  1
2       c       f      0.7   0.1  0.695775  2

In [48]: pd.wide_to_long(dft, ["A", "B"], i="id", j="year")
     ...
 →
   X  A  B
id year
0 1970  -0.121306  a  2.5
1 1970  -0.097883  b  1.2
2 1970   0.695775  c  0.7
0 1980  -0.121306  d  3.2
1 1980  -0.097883  e  1.3
2 1980   0.695775  f  0.1
```

### 18.4 Combining with stats and GroupBy

It should be no shock that combining `pivot / stack / unstack` with `GroupBy` and the basic Series and DataFrame statistical functions can produce some very expressive and fast data manipulations.

```
In [49]: df
Out[49]:
   exp  A  B  A  A
animal cat  dog  cat  dog
first  second
bar  one  0.895717  0.805244  -1.206412  2.565646
     two  1.431256  1.340309   -1.170299  -0.226169
baz  one  0.410835  0.813850    0.132003  -0.827317
     two -0.076467 -1.187678   1.130127  -1.436737
foo  one  -1.413681  1.607920    1.024180  0.569605
     two  0.875906 -2.211372   0.974466   -2.006747
qux  one  -0.410001  -0.078638  0.545952  -1.219217
     two -1.226825  0.769804  -1.281247  -0.727707

In [50]: df.stack().mean(1).unstack()
     ...
 →
animal  cat  dog
(continues on next page)
### 18.5 Pivot tables

While `pivot()` provides general purpose pivoting with various data types (strings, numerics, etc.), pandas also provides `pivot_table()` for pivoting with aggregation of numeric data.

The function `pivot_table()` can be used to create spreadsheet-style pivot tables. See the *cookbook* for some advanced strategies.

It takes a number of arguments:

- **data**: a DataFrame object.
- **values**: a column or a list of columns to aggregate.
- **index**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on the
pivot table index. If an array is passed, it is being used as the same manner as column values.

- **columns**: a column, Grouper, array which has the same length as data, or list of them. Keys to group by on
  the pivot table column. If an array is passed, it is being used as the same manner as column values.

- **aggfunc**: function to use for aggregation, defaulting to `numpy.mean`.

Consider a data set like this:

```python
In [54]: import datetime

In [55]: df = pd.DataFrame({'A': ['one', 'one', 'two', 'three'] * 6,
                        'B': ['A', 'B', 'C'] * 8,
                        'C': ['foo', 'foo', 'foo', 'bar', 'bar', 'bar'] * 4,
                        'D': np.random.randn(24),
                        'E': np.random.randn(24),
                        'F': [datetime.datetime(2013, i, 1) for i in range(1, 13)] +
                           [datetime.datetime(2013, i, 15) for i in range(1, 13)]})

In [56]: df
```

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>one</td>
<td>A</td>
<td>foo</td>
<td>0.341734</td>
<td>-0.317441</td>
<td>2013-01-01</td>
</tr>
<tr>
<td>1</td>
<td>one</td>
<td>B</td>
<td>foo</td>
<td>0.959726</td>
<td>-1.236269</td>
<td>2013-02-01</td>
</tr>
<tr>
<td>2</td>
<td>two</td>
<td>C</td>
<td>foo</td>
<td>-1.110336</td>
<td>0.896171</td>
<td>2013-03-01</td>
</tr>
<tr>
<td>3</td>
<td>three</td>
<td>A</td>
<td>bar</td>
<td>-0.619976</td>
<td>-0.487602</td>
<td>2013-04-01</td>

<td>-0.082240</td>
<td>2013-05-01</td>
</tr>
<tr>
<td>5</td>
<td>one</td>
<td>C</td>
<td>bar</td>
<td>-0.732339</td>
<td>-2.182937</td>
<td>2013-06-01</td>
</tr>
<tr>
<td>6</td>
<td>two</td>
<td>A</td>
<td>foo</td>
<td>0.687738</td>
<td>0.380396</td>
<td>2013-07-01</td>
</tr>
<tr>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
<td>...</td>
</tr>
<tr>
<td>17</td>
<td>one</td>
<td>C</td>
<td>bar</td>
<td>-0.345352</td>
<td>0.206053</td>
<td>2013-06-15</td>
</tr>
<tr>
<td>18</td>
<td>two</td>
<td>A</td>
<td>foo</td>
<td>1.314232</td>
<td>-0.251905</td>
<td>2013-07-15</td>
</tr>
<tr>
<td>19</td>
<td>three</td>
<td>B</td>
<td>foo</td>
<td>0.690579</td>
<td>-2.213588</td>
<td>2013-08-15</td>
</tr>
<tr>
<td>20</td>
<td>one</td>
<td>C</td>
<td>foo</td>
<td>0.995761</td>
<td>1.063327</td>
<td>2013-09-15</td>
</tr>
<tr>
<td>21</td>
<td>one</td>
<td>B</td>
<td>bar</td>
<td>2.396780</td>
<td>1.266143</td>
<td>2013-10-15</td>
</tr>
<tr>
<td>22</td>
<td>two</td>
<td>B</td>
<td>bar</td>
<td>0.014871</td>
<td>0.299368</td>
<td>2013-11-15</td>
</tr>
<tr>
<td>23</td>
<td>three</td>
<td>C</td>
<td>bar</td>
<td>3.357427</td>
<td>-0.863838</td>
<td>2013-12-15</td>
</tr>
</tbody>
</table>

[24 rows x 6 columns]

We can produce pivot tables from this data very easily:

```python
In [57]: pd.pivot_table(df, values='D', index=['A', 'B'], columns=['C'])
```

<table>
<thead>
<tr>
<th></th>
<th>bar</th>
<th>foo</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td></td>
<td></td>
</tr>
<tr>
<td>one</td>
<td></td>
<td></td>
</tr>
<tr>
<td>B</td>
<td>1.120915</td>
<td>-0.514058</td>
</tr>
<tr>
<td></td>
<td>-0.338421</td>
<td>0.002759</td>
</tr>
<tr>
<td></td>
<td>-0.538846</td>
<td>0.699535</td>
</tr>
<tr>
<td>three</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>-1.181568</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>0.433512</td>
</tr>
<tr>
<td></td>
<td>0.588783</td>
<td>NaN</td>
</tr>
<tr>
<td>two</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>1.000995</td>
</tr>
<tr>
<td></td>
<td>0.158248</td>
<td>NaN</td>
</tr>
<tr>
<td></td>
<td>NaN</td>
<td>0.176180</td>
</tr>
</tbody>
</table>

(continues on next page)
The result object is a DataFrame having potentially hierarchical indexes on the rows and columns. If the values column name is not given, the pivot table will include all of the data that can be aggregated in an additional level of hierarchy in the columns:

```
In [60]: df.pivot_table(index=['A', 'B'], columns=['C'])
```

```
C          bar    foo      bar    foo
A B
one A   1.120915 -0.514058 1.393057 -0.021605
      B  -0.338421  0.002759 0.684140 -0.551692
      C  -0.538846  0.699535 -0.988442  0.747859
three A -1.181568    NaN     0.961289     NaN
       B  NaN      0.433512  NaN   -1.064372
       C  0.588783    NaN  -0.131830     NaN
two A   1.000985    NaN     0.064245     NaN
      B  0.158248  -0.097147    NaN     NaN
      C  0.176180    NaN     0.436241     NaN
```

Also, you can use Grouper for index and columns keywords. For detail of Grouper, see Grouping with a Grouper specification.

```
In [61]: df.pivot_table(values='D', index=df['F'].apply(lambda x: x.month), columns='C')
```

```
C bar foo
A one three two
  B 2.241830 -1.028115 -2.363137 NaN NaN 2.001971 2.786113 -0.043211 1.992257
  C -0.676843  0.005518 NaN 0.867024 0.316495 NaN 1.368280 -1.103384 NaN
  C -1.077692  1.399070 1.177566 NaN NaN 0.352360 -1.976883 1.495717 -0.263660 NaN
```

(continues on next page)
You can render a nice output of the table omitting the missing values by calling `to_string` if you wish:

```python
In [62]: table = pd.pivot_table(df, index=['A', 'B'], columns=['C'])
```
```
In [63]: print(table.to_string(na_rep=''))
```

D E
--- ---
C bar foo bar foo
A B
one A 1.120915 -0.514058 1.393057 -0.021605
B -0.338421 0.002759 0.684140 -0.551692
C -0.538846 0.699535 -0.988442 0.747859
three A -1.181568 0.961289
B 0.433512 -1.064372
C 0.588783 -0.131830
two A 1.000985 0.064245
B 0.158248 -0.097147
C 0.176180 0.436241

Note that `pivot_table` is also available as an instance method on DataFrame, i.e. `DataFrame.pivot_table()`.

### 18.5.1 Adding margins

If you pass `margins=True` to `pivot_table`, special All columns and rows will be added with partial group aggregates across the categories on the rows and columns:

```python
In [64]: df.pivot_table(index=['A', 'B'], columns='C', margins=True, aggfunc=np.std)
```

```
Out[64]:
```

D E
--- ---
C bar foo bar foo All
A B
one A 1.804346 1.210272 1.569879 0.179483 0.418374 0.858005
B 0.690376 1.353355 0.898998 1.083825 0.968138 1.101401
C 0.273641 0.418926 0.771139 1.689271 0.446140 1.422136
three A -0.794212 NaN 0.794212 2.049040 NaN 2.049040
B NaN 0.363548 0.363548 NaN 1.625237 1.625237
C 3.915454 NaN 3.915454 1.035215 NaN 1.035215
two A NaN 0.442998 0.442998 NaN 0.447104 0.447104
B 0.202765 NaN 0.202765 0.560757 NaN 0.560757
C NaN 1.819408 1.819408 NaN 0.650439 0.650439
All 1.556686 0.952552 1.246608 1.250924 0.899904 1.059389

18.5. Pivot tables
18.6 Cross tabulations

Use `crosstab()` to compute a cross-tabulation of two (or more) factors. By default `crosstab` computes a frequency table of the factors unless an array of values and an aggregation function are passed.

It takes a number of arguments:

- **index**: array-like, values to group by in the rows.
- **columns**: array-like, values to group by in the columns.
- **values**: array-like, optional, array of values to aggregate according to the factors.
- **aggfunc**: function, optional. If no values array is passed, computes a frequency table.
- **rownames**: sequence, default `None`, must match number of row arrays passed.
- **colnames**: sequence, default `None`, if passed, must match number of column arrays passed.
- **margins**: boolean, default `False`, Add row/column margins (subtotals)
- **normalize**: boolean, {'all', 'index', 'columns'}, or {0,1}, default `False`. Normalize by dividing all values by the sum of values.

Any Series passed will have their name attributes used unless row or column names for the cross-tabulation are specified.

For example:

```python
In [65]: foo, bar, dull, shiny, one, two = 'foo', 'bar', 'dull', 'shiny', 'one', 'two'
In [66]: a = np.array([foo, foo, bar, bar, foo, foo], dtype=object)
In [67]: b = np.array([one, one, two, one, two, one], dtype=object)
In [68]: c = np.array([dull, dull, shiny, dull, dull, shiny], dtype=object)
In [69]: pd.crosstab(a, [b, c], rownames=['a'], colnames=['b', 'c'])
```

<table>
<thead>
<tr>
<th></th>
<th>one</th>
<th>two</th>
</tr>
</thead>
<tbody>
<tr>
<td>dull</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>dull</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>shiny</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>shiny</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

If crosstab receives only two Series, it will provide a frequency table.

```python
In [70]: df = pd.DataFrame({'A': [1, 2, 2, 2, 2], 'B': [3, 3, 4, 4, 4], 'C': [1, 1, np.nan, 1, 1]})
In [71]: df
Out[71]:
   A  B  C
0  1  3  1.0
1  2  3  1.0
2  2  4  NaN
3  2  4  1.0
4  2  4  1.0
In [72]: pd.crosstab(df.A, df.B)
```

(continues on next page)
Any input passed containing `Categorical` data will have **all** of its categories included in the cross-tabulation, even if the actual data does not contain any instances of a particular category.

```python
In [73]: foo = pd.Categorical(['a', 'b'], categories=['a', 'b', 'c'])
In [74]: bar = pd.Categorical(['d', 'e'], categories=['d', 'e', 'f'])
In [75]: pd.crosstab(foo, bar)
Out[75]:
   col_0  d  e
row_0   a  1  0
       b  0  1
```

### 18.6.1 Normalization

New in version 0.18.1.

Frequency tables can also be normalized to show percentages rather than counts using the `normalize` argument:

```python
In [76]: pd.crosstab(df.A, df.B, normalize=True)
Out[76]:
   B 3 4
   A 0.5 0.5
       0.2 0.6
```

`normalize` can also normalize values within each row or within each column:

```python
In [77]: pd.crosstab(df.A, df.B, normalize='columns')
Out[77]:
   B 3 4
   A 0.5 0.5
       0.2 0.6
```

crosstab can also be passed a third `Series` and an aggregation function (`aggfunc`) that will be applied to the values of the third `Series` within each group defined by the first two `Series`:

```python
In [78]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum)
Out[78]:
   B 3 4
   A 1.0 NaN
       1.0 2.0
```
18.6.2 Adding Margins

Finally, one can also add margins or normalize this output.

```python
In [79]: pd.crosstab(df.A, df.B, values=df.C, aggfunc=np.sum, normalize=True, margins=True)

Out[79]:
          B  3  4  All
    A          
    1       0.25  0.0  0.25
    2       0.25  0.5  0.75
  All      0.50  0.5  1.00
```

18.7 Tiling

The `cut()` function computes groupings for the values of the input array and is often used to transform continuous variables to discrete or categorical variables:

```python
In [80]: ages = np.array([10, 15, 13, 12, 23, 25, 28, 59, 60])
In [81]: pd.cut(ages, bins=3)
Out[81]:
[(9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667], (9.95, 26.667],
  (26.667, 43.333], (43.333, 60.0], (43.333, 60.0] ]
Categories (3, interval[float64]): 
  [(9.95, 26.667] < (26.667, 43.333] < (43.333, 60.0] ]
```

If the `bins` keyword is an integer, then equal-width bins are formed. Alternatively we can specify custom bin-edges:

```python
In [82]: c = pd.cut(ages, bins=[0, 18, 35, 70])
In [83]: c
Out[83]:
[(0, 18], (0, 18], (0, 18], (0, 18], (18, 35], (18, 35], (18, 35], (35, 70], (35, 70] ]
Categories (3, interval[int64]): 
  [(0, 18] < (18, 35] < (35, 70] ]
```

New in version 0.20.0.

If the `bins` keyword is an `IntervalIndex`, then these will be used to bin the passed data:

```python
pd.cut([25, 20, 50], bins=c.categories)
```

18.8 Computing indicator / dummy variables

To convert a categorical variable into a “dummy” or “indicator” DataFrame, for example a column in a DataFrame (a Series) which has `k` distinct values, can derive a DataFrame containing `k` columns of 1s and 0s using `get_dummies()`:

```python
In [84]: df = pd.DataFrame({'key': list('bbacab'), 'data1': range(6)})
In [85]: pd.get_dummies(df['key'])
Out[85]:
```

(continues on next page)
Sometimes it’s useful to prefix the column names, for example when merging the result with the original `DataFrame`:

```python
In [86]: dummies = pd.get_dummies(df['key'], prefix='key')
In [87]: dummies
Out[87]:
   key_a  key_b  key_c
0      0      1    0
1      0      1    0
2      1      0    0
3      0      0    1
4      1      0    0
5      0      1    0

In [88]: df[['data1']].join(dummies)
   data1  key_a  key_b  key_c
0      0      0      1    0
1      1      0      1    0
2      2      1      0    0
3      3      0      0    1
4      4      1      0    0
5      5      0      1    0
```

This function is often used along with discretization functions like `cut`:

```python
In [89]: values = np.random.randn(10)
In [90]: values
Out[90]:
array([ 0.4082, -1.0481, -0.0257, -0.9884,  0.0941,  1.2627,  1.29 ,
       0.0824, -0.0558,  0.5366])
In [91]: bins = [0, 0.2, 0.4, 0.6, 0.8, 1]
In [92]: pd.get_dummies(pd.cut(values, bins))
Out[92]:
   (0.0, 0.2]  (0.2, 0.4]  (0.4, 0.6]  (0.6, 0.8]  (0.8, 1.0]
0      0      0      1      0      0
1      0      0      0      0      0
2      0      0      0      0      0
3      0      0      0      0      0
4      1      0      0      0      0
5      0      0      0      0      0
6      0      0      0      0      0
7      1      0      0      0      0
8      0      0      0      0      0
9      0      0      1      0      0
```

18.8. Computing indicator / dummy variables
get_dummies() also accepts a DataFrame. By default all categorical variables (categorical in the statistical sense, those with object or categorical dtype) are encoded as dummy variables.

```
In [93]: df = pd.DataFrame({'A': ['a', 'b', 'a'], 'B': ['c', 'c', 'b'],
                      'C': [1, 2, 3]})
.....:

In [94]: pd.get_dummies(df)
Out[94]:
C   A_a  A_b  B_b  B_c
0   1    1    0    0    1
1   2    0    1    0    1
2   3    1    0    1    0
```

All non-object columns are included untouched in the output. You can control the columns that are encoded with the columns keyword.

```
In [95]: pd.get_dummies(df, columns=['A'])
Out[95]:
   B    C   A_a  A_b
0  c    1    1    0
1  c    2    0    1
2  b    3    1    0
```

Notice that the B column is still included in the output, it just hasn’t been encoded. You can drop B before calling get_dummies if you don’t want to include it in the output.

As with the Series version, you can pass values for the prefix and prefix_sep. By default the column name is used as the prefix, and '_' as the prefix separator. You can specify prefix and prefix_sep in 3 ways:

- string: Use the same value for prefix or prefix_sep for each column to be encoded.
- list: Must be the same length as the number of columns being encoded.
- dict: Mapping column name to prefix.

```
In [96]: simple = pd.get_dummies(df, prefix='new_prefix')

In [97]: simple
Out[97]:
   C  new_prefix_a  new_prefix_b  new_prefix_b  new_prefix_c
0   1               1              0                0                1
1   2               0              1                0                1
2   3               1              0                1                0

In [98]: from_list = pd.get_dummies(df, prefix=['from_A', 'from_B'])

In [99]: from_list
Out[99]:
   C  from_A_a  from_A_b  from_B_b  from_B_c
0   1              1              0                0                1
1   2              0              1                0                1
2   3              1              0                1                0

In [100]: from_dict = pd.get_dummies(df, prefix={'B': 'from_B', 'A': 'from_A'})

In [101]: from_dict
```

(continues on next page)
New in version 0.18.0.

Sometimes it will be useful to only keep k-1 levels of a categorical variable to avoid collinearity when feeding the result to statistical models. You can switch to this mode by turn on `drop_first`.

```python
In [102]: s = pd.Series(list('abcaa'))

In [103]: pd.get_dummies(s)
Out[103]:
   a  b  c
0  1  0  0
1  0  1  0
2  0  0  1
3  1  0  0
4  1  0  0

In [104]: pd.get_dummies(s, drop_first=True)
   b  c
0  0  0
1  1  0
2  0  1
3  0  0
4  0  0
```

When a column contains only one level, it will be omitted in the result.

```python
In [105]: df = pd.DataFrame({'A':list('aaaaa'),'B':list('ababc')})

In [106]: pd.get_dummies(df)
Out[106]:
   A_a  B_a  B_b  B_c
0  1    1    0   0
1  1    0    1   0
2  1    1    0   0
3  1    0    1   0
4  1    0    0   1

In [107]: pd.get_dummies(df, drop_first=True)
   B_b  B_c
0  0    0
1  1    0
2  0    0
3  1    0
4  0    1
```

By default new columns will have `np.uint8` dtype. To choose another dtype, use the `'dtype'` argument:

```python
In [108]: pd.get_dummies(df, drop_first=True, dtype=np.int16)
   B_b  B_c
0  0    0
1  1    0
2  0    0
3  1    0
4  0    1
```
In [108]: df = pd.DataFrame({'A': list('abc'), 'B': [1.1, 2.2, 3.3]})

In [109]: pd.get_dummies(df, dtype=bool).dtypes
Out[109]:
B float64
A_a bool
A_b bool
A_c bool
dtype: object

New in version 0.23.0.

18.9 Factorizing values

To encode 1-d values as an enumerated type use `factorize()`:

In [110]: x = pd.Series(['A', 'A', np.nan, 'B', 3.14, np.inf])

In [111]: x
Out[111]:
0   A
1   A
2  NaN
3   B
4  3.14
5   inf
dtype: object

In [112]: labels, uniques = pd.factorize(x)

In [113]: labels
Out[113]: array([ 0, 0, -1, 1, 2, 3])

In [114]: uniques
Out[114]: Index([u'A', u'B', 3.14, inf], dtype='object')

Note that `factorize` is similar to `numpy.unique`, but differs in its handling of NaN:

Note: The following `numpy.unique` will fail under Python 3 with a `TypeError` because of an ordering bug. See also here.

In [2]: pd.factorize(x, sort=True)
Out[2]:
(array([ 2, 2, -1, 3, 0, 1]),
Index([3.14, inf, u'A', u'B'], dtype='object'))

In [3]: np.unique(x, return_inverse=True)[::-1]
Out[3]:
array([3, 3, 0, 4, 1, 2]), array([nan, 3.14, inf, 'A', 'B'], dtype=object))

Note: If you just want to handle one column as a categorical variable (like R's factor), you can use `df['cat_col'] = pd.Categorical(df['col'])` or `df['cat_col'] = df['col'].astype('category'). For
full docs on `Categorical`, see the `Categorical introduction` and the `API documentation`.
pandas has proven very successful as a tool for working with time series data, especially in the financial data analysis space. Using the NumPy datetime64 and timedelta64 dtypes, we have consolidated a large number of features from other Python libraries like scikits.timeseries as well as created a tremendous amount of new functionality for manipulating time series data.

In working with time series data, we will frequently seek to:

- generate sequences of fixed-frequency dates and time spans
- conform or convert time series to a particular frequency
- compute “relative” dates based on various non-standard time increments (e.g. 5 business days before the last business day of the year), or “roll” dates forward or backward

pandas provides a relatively compact and self-contained set of tools for performing the above tasks.

Create a range of dates:

```python
# 72 hours starting with midnight Jan 1st, 2011
In [1]: rng = pd.date_range('1/1/2011', periods=72, freq='H')
In [2]: rng[:5]
Out[2]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 01:00:00',
'2011-01-01 02:00:00', '2011-01-01 03:00:00',
'2011-01-01 04:00:00'], dtype='datetime64[ns]', freq='H')
```

Index pandas objects with dates:

```python
In [3]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [4]: ts.head()
Out[4]:
2011-01-01 00:00:00  0.469112
2011-01-01 01:00:00 -0.282863
2011-01-01 02:00:00 -1.509059
2011-01-01 03:00:00 -1.135632
2011-01-01 04:00:00  1.212112
Freq: H, dtype: float64
```

Change frequency and fill gaps:

```python
# to 45 minute frequency and forward fill
In [5]: converted = ts.asfreq('45Min', method='pad')
```

(continues on next page)
Resample the series to a daily frequency:

```python
# Daily means
In [7]: ts.resample('D').mean()
Out[7]:
    2011-01-01     -0.319569
    2011-01-02    -0.337703
    2011-01-03     0.117258
Freq: D, dtype: float64
```

### 19.1 Overview

The following table shows the type of time-related classes pandas can handle and how to create them.

<table>
<thead>
<tr>
<th>Class</th>
<th>Remarks</th>
<th>How to create</th>
</tr>
</thead>
<tbody>
<tr>
<td>Timestamp</td>
<td>Represents a single time-</td>
<td>to_datetime, Timestamp</td>
</tr>
<tr>
<td></td>
<td>stamp</td>
<td></td>
</tr>
<tr>
<td>DatetimeIndex</td>
<td>Index of Timestamp</td>
<td>to_datetime, date_range, bdate_range, DatetimeIndex</td>
</tr>
<tr>
<td>Period</td>
<td>Represents a single time</td>
<td>Period</td>
</tr>
<tr>
<td></td>
<td>span</td>
<td></td>
</tr>
<tr>
<td>PeriodIndex</td>
<td>Index of Period</td>
<td>period_range, PeriodIndex</td>
</tr>
</tbody>
</table>

### 19.2 Timestamps vs. Time Spans

Timestamped data is the most basic type of time series data that associates values with points in time. For pandas objects it means using the points in time.

```python
In [8]: pd.Timestamp(datetime(2012, 5, 1))
Out[8]: Timestamp('2012-05-01 00:00:00')

In [9]: pd.Timestamp('2012-05-01')
Out[9]: Timestamp('2012-05-01 00:00:00')

In [10]: pd.Timestamp(2012, 5, 1)
Out[10]: Timestamp('2012-05-01 00:00:00')
```

However, in many cases it is more natural to associate things like change variables with a time span instead. The span represented by `Period` can be specified explicitly, or inferred from datetime string format.

For example:
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

In [11]: pd.Period('2011-01')
Out[11]: Period('2011-01', 'M')

In [12]: pd.Period('2012-05', freq='D')
Out[12]: Period('2012-05-01', 'D')

**Timestamp** and **Period** can serve as an index. Lists of **Timestamp** and **Period** are automatically coerced to **DatetimeIndex** and **PeriodIndex** respectively.

In [14]: ts = pd.Series(np.random.randn(3), dates)
In [15]: type(ts.index)
Out[15]: pandas.core.indexes.datetimes.DatetimeIndex

In [16]: ts.index
Out[16]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

In [17]: ts

    2012-05-01  -0.410001
    2012-05-02  -0.078638
    2012-05-03   0.545952

dtype: float64

In [18]: periods = [pd.Period('2012-01'), pd.Period('2012-02'), pd.Period('2012-03')]
In [19]: ts = pd.Series(np.random.randn(3), periods)
In [20]: type(ts.index)
Out[20]: pandas.core.indexes.period.PeriodIndex

In [21]: ts.index
Out[21]: PeriodIndex(['2012-01', '2012-02', '2012-03'], dtype='period[M]', freq='M')

In [22]: ts

    2012-01  -1.219217
    2012-02  -1.226825
    2012-03   0.769804

Freq: M, dtype: float64

pandas allows you to capture both representations and convert between them. Under the hood, pandas represents timestamps using instances of **Timestamp** and sequences of timestamps using instances of **DatetimeIndex**. For regular time spans, pandas uses **Period** objects for scalar values and **PeriodIndex** for sequences of spans. Better support for irregular intervals with arbitrary start and end points are forth-coming in future releases.

19.2. Timestamps vs. Time Spans 923
19.3 Converting to Timestamps

To convert a `Series` or list-like object of date-like objects e.g. strings, epochs, or a mixture, you can use the `to_datetime` function. When passed a `Series`, this returns a `Series` (with the same index), while a list-like is converted to a `DateTimeIndex`:

```
In [23]: pd.to_datetime(pd.Series(['Jul 31, 2009', '2010-01-10', None]))
Out[23]:
0  2009-07-31
1  2010-01-10
2    NaT
dtype: datetime64[ns]
```

```
In [24]: pd.to_datetime(['2005/11/23', '2010.12.31'])
```

```
→ DatetimeIndex(['2005-11-23', '2010-12-31'], dtype='datetime64[ns]', freq=None)
```

If you use dates which start with the day first (i.e. European style), you can pass the `dayfirst` flag:

```
In [25]: pd.to_datetime(['04-01-2012 10:00'], dayfirst=True)
Out[25]:
 DatetimeIndex(['2012-01-04 10:00:00'], dtype='datetime64[ns]', freq=None)
```

```
In [26]: pd.to_datetime(['14-01-2012', '01-14-2012'], dayfirst=True)
```

```
→ DatetimeIndex(['2012-01-14', '2012-01-14'], dtype='datetime64[ns]', freq=None)
```

**Warning:** You see in the above example that `dayfirst` isn’t strict, so if a date can’t be parsed with the day being first it will be parsed as if `dayfirst` were False.

If you pass a single string to `to_datetime`, it returns a single `Timestamp`. `Timestamp` can also accept string input, but it doesn’t accept string parsing options like `dayfirst` or `format`, so use `to_datetime` if these are required.

```
In [27]: pd.to_datetime('2010/11/12')
Out[27]: Timestamp('2010-11-12 00:00:00')
```

```
In [28]: pd.Timestamp('2010/11/12')
```

```
```

19.3.1 Providing a Format Argument

In addition to the required datetime string, a `format` argument can be passed to ensure specific parsing. This could also potentially speed up the conversion considerably.

```
In [29]: pd.to_datetime('2010/11/12', format='%Y/%m/%d')
Out[29]: Timestamp('2010-11-12 00:00:00')
```

```
In [30]: pd.to_datetime('12-11-2010 00:00', format='%d-%m-%Y %H:%M')
```

```
```

For more information on the choices available when specifying the `format` option, see the Python `datetime` documentation.
19.3.2 Assembling Datetime from Multiple DataFrame Columns

New in version 0.18.1.

You can also pass a DataFrame of integer or string columns to assemble into a Series of Timestamps.

```
In [31]: df = pd.DataFrame({'year': [2015, 2016],
                          'month': [2, 3],
                          'day': [4, 5],
                          'hour': [2, 3]})
```

```
In [32]: pd.to_datetime(df)
Out[32]:
0 2015-02-04 02:00:00
1 2016-03-05 03:00:00
dtype: datetime64[ns]
```

You can pass only the columns that you need to assemble.

```
In [33]: pd.to_datetime(df[['year', 'month', 'day']])
Out[33]:
0 2015-02-04
1 2016-03-05
dtype: datetime64[ns]
```

`pd.to_datetime` looks for standard designations of the datetime component in the column names, including:

- **required**: year, month, day
- **optional**: hour, minute, second, millisecond, microsecond, nanosecond

19.3.3 Invalid Data

The default behavior, `errors='raise'`, is to raise when unparsable:

```
In [2]: pd.to_datetime(['2009/07/31', 'asd'], errors='raise')
ValueError: Unknown string format
```

Pass `errors='ignore'` to return the original input when unparsable:

```
In [34]: pd.to_datetime(['2009/07/31', 'asd'], errors='ignore')
Out[34]: array(['2009/07/31', 'asd'], dtype=object)
```

Pass `errors='coerce'` to convert unparsable data to NaT (not a time):

```
In [35]: pd.to_datetime(['2009/07/31', 'asd'], errors='coerce')
Out[35]: DatetimeIndex(['2009-07-31', 'NaT'], dtype='datetime64[ns]', freq=None)
```

19.3.4 Epoch Timestamps

Pandas supports converting integer or float epoch times to Timestamp and DatetimeIndex. The default unit is nanoseconds, since that is how Timestamp objects are stored internally. However, epochs are often stored in another unit which can be specified. These are computed from the starting point specified by the `origin` parameter.
In [36]: pd.to_datetime([1349720105, 1349806505, 1349892905, 1349979305, 1350065705], unit='s')

In [37]: pd.to_datetime([1349720105100, 1349720105200, 1349720105300, 1349720105400, 1349720105500], unit='ms')

Out[37]: DatetimeIndex(['2012-10-08 18:15:05.100000', '2012-10-08 18:15:05.200000', '2012-10-08 18:15:05.300000', '2012-10-08 18:15:05.400000', '2012-10-08 18:15:05.500000'], dtype='datetime64[ns]', freq=None)

Note: Epoch times will be rounded to the nearest nanosecond.

Warning: Conversion of float epoch times can lead to inaccurate and unexpected results. Python floats have about 15 digits precision in decimal. Rounding during conversion from float to high precision Timestamp is unavoidable. The only way to achieve exact precision is to use a fixed-width types (e.g. an int64).

In [38]: pd.to_datetime([1490195805.433, 1490195805.433502912], unit='s')

Out[38]: DatetimeIndex(['2017-03-22 15:16:45.433000', '2017-03-22 15:16:45.433503'], dtype='datetime64[ns]', freq=None)

In [39]: pd.to_datetime(1490195805433502912, unit='ns')

Out[39]: Timestamp('2017-03-22 15:16:45.433502912')

See also: Using the origin Parameter

19.3.5 From Timestamps to Epoch

To invert the operation from above, namely, to convert from a Timestamp to a ‘unix’ epoch:

In [40]: stamps = pd.date_range('2012-10-08 18:15:05', periods=4, freq='D')

In [41]: stamps

Out[41]: DatetimeIndex(['2012-10-08 18:15:05', '2012-10-09 18:15:05', '2012-10-10 18:15:05', '2012-10-11 18:15:05'], dtype='datetime64[ns]', freq='D')

We convert the DatetimeIndex to an int64 array, then divide by the conversion unit.
19.3.6 Using the `origin` Parameter

New in version 0.20.0.

Using the `origin` parameter, one can specify an alternative starting point for creation of a `DatetimeIndex`. For example, to use 1960-01-01 as the starting date:

```python
In [43]: pd.to_datetime([1, 2, 3], unit='D', origin=pd.Timestamp('1960-01-01'))
Out[43]: DatetimeIndex(['1960-01-02', '1960-01-03', '1960-01-04'], dtype='datetime64[ns]', freq=None)
```

The default is set at `origin='unix'`, which defaults to 1970-01-01 00:00:00. Commonly called ‘unix epoch’ or POSIX time.

```python
In [44]: pd.to_datetime([1, 2, 3], unit='D')
Out[44]: DatetimeIndex(['1970-01-02', '1970-01-03', '1970-01-04'], dtype='datetime64[ns]', freq=None)
```

19.4 Generating Ranges of Timestamps

To generate an index with timestamps, you can use either the `DatetimeIndex` or `Index` constructor and pass in a list of datetime objects:

```python
In [45]: dates = [datetime(2012, 5, 1), datetime(2012, 5, 2), datetime(2012, 5, 3)]
# Note the frequency information
In [46]: index = pd.DatetimeIndex(dates)

In [47]: index
Out[47]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)

# Automatically converted to DatetimeIndex
In [48]: index = pd.Index(dates)

In [49]: index
Out[49]: DatetimeIndex(['2012-05-01', '2012-05-02', '2012-05-03'], dtype='datetime64[ns]', freq=None)
```

In practice this becomes very cumbersome because we often need a very long index with a large number of timestamps. If we need timestamps on a regular frequency, we can use the `date_range()` and `bdate_range()` functions to create a `DatetimeIndex`. The default frequency for `date_range` is a calendar day while the default for `bdate_range` is a business day:
Convenience functions like `date_range` and `bdate_range` can utilize a variety of frequency aliases:
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

In [58]: pd.date_range(start, end, freq='BM')

Out[58]:
dtype='datetime64[ns]', freq='BM')

In [59]: pd.date_range(start, end, freq='W')

Out[59]:
               '2011-02-27', '2011-03-03', '2011-03-10', '2011-03-17',
               '2011-12-11', '2011-12-18', '2011-12-25', '2012-01-01'],
dtype='datetime64[ns]', freq='W-SUN')

In [60]: pd.bdate_range(end=end, periods=20)

Out[60]:
DatetimeIndex(['2011-12-05', '2011-12-06', '2011-12-07', '2011-12-08',
               '2011-12-09', '2011-12-10', '2011-12-11', '2011-12-12',
               '2011-12-13', '2011-12-14', '2011-12-15', '2011-12-16',
               '2011-12-17', '2011-12-18', '2011-12-19', '2011-12-20',
               '2011-12-21', '2011-12-22', '2011-12-23', '2011-12-24',
               '2011-12-25', '2011-12-26', '2011-12-27', '2011-12-28',
               '2011-12-29', '2011-12-30'],
dtype='datetime64[ns]', freq='B')

In [61]: pd.bdate_range(start=start, periods=20)

Out[61]:
               '2011-01-27', '2011-01-28'],
dtype='datetime64[ns]', freq='B')

19.4.1 Custom Frequency Ranges

**Warning:** This functionality was originally exclusive to `cdate_range`, which is deprecated as of version 0.21.0 in favor of `bdate_range`. Note that `cdate_range` only utilizes the `weekmask` and `holidays` parameters when custom business day, ‘C’, is passed as the frequency string. Support has been expanded with `bdate_range` to work with any custom frequency string.

New in version 0.21.0.
bdate_range can also generate a range of custom frequency dates by using the `weekmask` and `holidays` parameters. These parameters will only be used if a custom frequency string is passed.

```python
In [62]: weekmask = 'Mon Wed Fri'
In [63]: holidays = [datetime(2011, 1, 5), datetime(2011, 3, 14)]
In [64]: pd.bdate_range(start, end, freq='C', weekmask=weekmask, holidays=holidays)
Out[64]:
              '2011-01-24', '2011-01-26',
            ...
              '2011-12-09', '2011-12-12', '2011-12-14', '2011-12-16',
              '2011-12-19', '2011-12-21', '2011-12-23', '2011-12-26',
              '2011-12-28', '2011-12-30'],
dtype='datetime64[ns]', length=154, freq='C')
```

```python
In [65]: pd.bdate_range(start, end, freq='CBMS', weekmask=weekmask)
```

```python
In [66]: pd.Timestamp.min
Out[66]: Timestamp('1677-09-21 00:12:43.145225')
In [67]: pd.Timestamp.max
```

See also:

**Custom Business Days**

### 19.5 Timestamp Limitations

Since pandas represents timestamps in nanosecond resolution, the time span that can be represented using a 64-bit integer is limited to approximately 584 years:

```python
In [66]: pd.Timestamp.min
Out[66]: Timestamp('1677-09-21 00:12:43.145225')
```

```python
In [67]: pd.Timestamp.max
```

See also:

**Representing Out-of-Bounds Spans**

### 19.6 Indexing

One of the main uses for DatetimeIndex is as an index for pandas objects. The DatetimeIndex class contains many time series related optimizations:

- A large range of dates for various offsets are pre-computed and cached under the hood in order to make generating subsequent date ranges very fast (just have to grab a slice).
- Fast shifting using the `shift` and `tshift` method on pandas objects.
- Unioning of overlapping `DatetimeIndex` objects with the same frequency is very fast (important for fast data alignment).
- Quick access to date fields via properties such as `year`, `month`, etc.
- Regularization functions like `snap` and very fast `asof` logic.

`DatetimeIndex` objects have all the basic functionality of regular `Index` objects, and a smorgasbord of advanced time series specific methods for easy frequency processing.

**See also:**

**Reindexing methods**

**Note:** While pandas does not force you to have a sorted date index, some of these methods may have unexpected or incorrect behavior if the dates are unsorted.

`DatetimeIndex` can be used like a regular index and offers all of its intelligent functionality like selection, slicing, etc.

```python
In [68]: rng = pd.date_range(start, end, freq='BM')
In [69]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [70]: ts.index
                   dtype='datetime64[ns]', freq='BM')
In [71]: ts[:5].index
                         '2011-05-31'],
                    dtype='datetime64[ns]', freq='BM')
In [72]: ts[::2].index
                         '2011-09-30', '2011-11-30'],
                    dtype='datetime64[ns]', freq='2BM')
```

### 19.6.1 Partial String Indexing

Dates and strings that parse to timestamps can be passed as indexing parameters:

```python
In [73]: ts['1/31/2011']
Out[73]: -1.2812473076599531
In [74]: ts[datetime(2011, 12, 25):]
Out[74]: 2011-12-30 0.687738
Freq: BM, dtype: float64
```

(continues on next page)
To provide convenience for accessing longer time series, you can also pass in the year or year and month as strings:

```
In [76]: ts['2011']
Out [76]:
2011-01-31  -1.281247  
2011-02-28   -0.727707  
2011-03-31  -0.121306  
2011-04-29   -0.097883  
2011-05-31   0.695775  
2011-06-30   0.341734  
2011-07-29   0.959726  
2011-08-31  -1.110336  
2011-09-30  -0.619976  
2011-10-31   0.149748  
2011-11-30  -0.732339  
2011-12-30   0.687738  
Freq: BM, dtype: float64
```

This type of slicing will work on a DataFrame with a DatetimeIndex as well. Since the partial string selection is a form of label slicing, the endpoints will be included. This would include matching times on an included date:

```
In [77]: dft = pd.DataFrame(randn(100000,1),
                      columns=['A'],
                      index=pd.date_range('20130101',periods=100000,freq='T'))

In [78]: dft
Out [78]:
   A
2013-01-01 00:00:00   0.176444
2013-01-01 00:01:00   0.403310
2013-01-01 00:02:00   -0.154951
2013-01-01 00:03:00   0.301624
2013-01-01 00:04:00   -2.179861
2013-01-01 00:05:00   -1.369849
2013-01-01 00:06:00   -0.954208
... ... 
2013-03-11 10:33:00  -0.293083
2013-03-11 10:34:00  -0.059881
2013-03-11 10:35:00   1.252450
2013-03-11 10:36:00   0.046611
(continues on next page)
```
This starts on the very first time in the month, and includes the last date and time for the month:

In [81]: dft['2013-1':'2013-2']

Out[81]:

   A
2013-01-01  00:00:00    0.176444
2013-01-01  00:01:00    0.403310
2013-01-01  00:02:00   -0.154951
2013-01-01  00:03:00    0.301624
2013-01-01  00:04:00   -2.179861
2013-01-01  00:05:00   -1.369849
2013-01-01  00:06:00   -0.954208
... ... 
2013-03-11 10:33:00   -0.293083
2013-03-11 10:34:00   -0.059881
2013-03-11 10:35:00    1.252450
2013-03-11 10:36:00    0.046611
2013-03-11 10:37:00    0.059478
2013-03-11 10:38:00   -0.286539
2013-03-11 10:39:00    0.841669
[84960 rows x 1 columns]

This specifies a stop time that includes all of the times on the last day:

In [82]: dft['2013-1':'2013-2-28']

Out[82]:

   A
2013-01-01  00:00:00    0.176444
2013-02-28 23:53:00    0.103114
2013-02-28 23:54:00   -1.303422
2013-02-28 23:55:00    0.451943
2013-02-28 23:56:00    0.220534
2013-02-28 23:57:00   -1.624220
2013-02-28 23:58:00    0.093915
2013-02-28 23:59:00   -1.087454
[84960 rows x 1 columns]
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

This specifies an exact stop time (and is not the same as the above):

```python
In [83]: dft['2013-1':'2013-2-28 00:00:00']
Out[83]:
                            A
2013-01-01 00:00:00  0.176444
2013-01-01 00:01:00  0.403310
2013-01-01 00:02:00 -0.154951
2013-01-01 00:03:00  0.301624
2013-01-01 00:04:00 -2.179861
2013-01-01 00:05:00 -1.369849
2013-01-01 00:06:00 -0.954208
   ...
2013-02-27 23:54:00  0.897051
2013-02-27 23:55:00 -0.309230
2013-02-27 23:56:00  1.944713
2013-02-27 23:57:00  0.369265
2013-02-27 23:58:00  0.053071
2013-02-27 23:59:00 -0.019734
2013-02-28 00:00:00  1.388189
[83521 rows x 1 columns]
```

We are stopping on the included end-point as it is part of the index:

```python
In [84]: dft['2013-1-15':'2013-1-15 12:30:00']
Out[84]:
                            A
2013-01-15 00:00:00  0.501288
2013-01-15 00:01:00 -0.605198
2013-01-15 00:02:00  0.215146
2013-01-15 00:03:00 -0.215146
2013-01-15 00:04:00  0.164709
2013-01-15 00:05:00 -0.605198
2013-01-15 00:06:00 -0.918009
   ...
2013-01-15 12:24:00  1.358314
2013-01-15 12:25:00 -0.377727
2013-01-15 12:26:00  1.838323
2013-01-15 12:27:00 -0.774090
```

(continues on next page)
New in version 0.18.0.

DatetimeIndex partial string indexing also works on a DataFrame with a MultiIndex:

```
In [85]: dft2 = pd.DataFrame(np.random.randn(20, 1),
   ....:     columns=['A'],
   ....:     index=pd.MultiIndex.from_product([pd.date_range('20130101→',
   ....:     periods=10,)
   ....:              freq='12H'),
   ....:                    ['a', 'b'])))

In [86]: dft2
Out[86]:
   A
2013-01-01  00:00:00 a   -0.659574
   b          1.494522
2013-01-01  12:00:00 a   -0.778425
   b          -0.253355
2013-01-02  00:00:00 a  -2.816159
   b          -1.210929

Out[90]:
```

(continues on next page)
19.6.2 Slice vs. Exact Match

Changed in version 0.20.0.

The same string used as an indexing parameter can be treated either as a slice or as an exact match depending on the resolution of the index. If the string is less accurate than the index, it will be treated as a slice, otherwise as an exact match.

Consider a `Series` object with a minute resolution index:

```python
In [91]: series_minute = pd.Series([1, 2, 3],
     ....:               pd.DatetimeIndex(['2011-12-31 23:59:00',
     ....:               '2012-01-01 00:00:00',
     ....:               '2012-01-01 00:02:00']))

In [92]: series_minute.index.resolution
Out[92]: 'minute'

A timestamp string less accurate than a minute gives a `Series` object.

```python
In [93]: series_minute['2011-12-31 23']
Out[93]:
2011-12-31 23:59:00 1
```
dtype: int64

A timestamp string with minute resolution (or more accurate), gives a scalar instead, i.e. it is not casted to a slice.

```python
In [94]: series_minute['2011-12-31 23:59']
Out[94]:
2011-12-31 23:59:59 1
```
dtype: int64

If index resolution is second, then the minute-accurate timestamp gives a `Series`.

```python
In [96]: series_second = pd.Series([1, 2, 3],
     ....:               pd.DatetimeIndex(['2011-12-31 23:59:59',
     ....:               '2012-01-01 00:00:00',
     ....:               '2012-01-01 00:00:01']))

In [97]: series_second.index.resolution
Out[97]: 'second'

In [98]: series_second['2011-12-31 23:59:59']
Out[98]:
2011-12-31 23:59:59 1
dtype: int64
```
If the timestamp string is treated as a slice, it can be used to index DataFrame with [] as well.

```
In [99]: dft_minute = pd.DataFrame({'a': [1, 2, 3], 'b': [4, 5, 6]},
                          index=series_minute.index)

In [100]: dft_minute['2011-12-31 23']
Out[100]:
     a   b
2011-12-31 23:59:00 1   4
```

**Warning:** However, if the string is treated as an exact match, the selection in DataFrame's [] will be column-wise and not row-wise, see *Indexing Basics*. For example `dft_minute['2011-12-31 23:59']` will raise `KeyError` as '2012-12-31 23:59' has the same resolution as the index and there is no column with such name:

To *always* have unambiguous selection, whether the row is treated as a slice or a single selection, use `.loc`.

```
In [101]: dft_minute.loc['2011-12-31 23:59']
Out[101]:
a  1
b  4
Name: 2011-12-31 23:59:00, dtype: int64
```

Note also that `DatetimeIndex` resolution cannot be less precise than day.

```
in [102]: series_monthly = pd.Series([1, 2, 3],
                           pd.DatetimeIndex(['2011-12',
                           '2012-01',
                           '2012-02']))

in [103]: series_monthly.index.resolution
Out[103]: 'day'

in [104]: series_monthly['2011-12'] # returns Series

\ \ \ \ \ \ \ \ Out[104]:
2011-12-01   1
 dtype: int64
```

### 19.6.3 Exact Indexing

As discussed in previous section, indexing a `DatetimeIndex` with a partial string depends on the “accuracy” of the period, in other words how specific the interval is in relation to the resolution of the index. In contrast, indexing with `Timestamp` or `datetime` objects is exact, because the objects have exact meaning. These also follow the semantics of including both endpoints.

These `Timestamp` and `datetime` objects have exact hours, minutes, and seconds, even though they were not explicitly specified (they are 0).

```
in [105]: dft[datetime(2013, 1, 1):datetime(2013,2,28)]
Out[105]:
```
2013-01-01 00:01:00 0.403310
2013-01-01 00:02:00 -0.154951
2013-01-01 00:03:00 0.301624
2013-01-01 00:04:00 -2.179861
2013-01-01 00:05:00 -1.369849
2013-01-01 00:06:00 -0.954208
... ...
2013-02-27 23:54:00 0.897051

2013-02-28 10:12:00 -0.945450

[83521 rows x 1 columns]
```

19.6.4 Truncating & Fancy Indexing

A `truncate()` convenience function is provided that is similar to slicing. Note that `truncate` assumes a 0 value for any unspecified date component in a `DatetimeIndex` in contrast to slicing which returns any partially matching dates:

```
In [107]: rng2 = pd.date_range('2011-01-01', '2012-01-01', freq='W')
In [108]: ts2 = pd.Series(np.random.randn(len(rng2)), index=rng2)
In [109]: ts2.truncate(before='2011-11', after='2011-12')
```

```
                     A
2011-11-06  -0.773743
2011-11-13  0.247216
2011-11-20  0.591308
```

(continues on next page)
Even complicated fancy indexing that breaks the DatetimeIndex frequency regularity will result in a DatetimeIndex, although frequency is lost:

```
In [111]: ts2[[0, 2, 6]].index
Out[111]: DatetimeIndex(['2011-01-02', '2011-01-16', '2011-02-13'], dtype='datetime64[ns]', freq=None)
```

19.7 Time/Date Components

There are several time/date properties that one can access from Timestamp or a collection of timestamps like a DatetimeIndex.
**Property** | **Description**
---|---
year | The year of the datetime
month | The month of the datetime
day | The days of the datetime
hour | The hour of the datetime
minute | The minutes of the datetime
second | The seconds of the datetime
microsecond | The microseconds of the datetime
nanosecond | The nanoseconds of the datetime
date | Returns datetime.date (does not contain timezone information)
time | Returns datetime.time (does not contain timezone information)
dayofyear | The ordinal day of the year
weekofyear | The week ordinal of the year
week | The week ordinal of the year
dayofweek | The number of the day of the week with Monday=0, Sunday=6
weekday | The number of the day of the week with Monday=0, Sunday=6
weekday_name | The name of the day in a week (ex: Friday)
quarter | Quarter of the date: Jan-Mar = 1, Apr-Jun = 2, etc.
days_in_month | The number of days in the month of the datetime
is_month_start | Logical indicating if first day of month (defined by frequency)
is_month_end | Logical indicating if last day of month (defined by frequency)
is_quarter_start | Logical indicating if first day of quarter (defined by frequency)
is_quarter_end | Logical indicating if last day of quarter (defined by frequency)
is_year_start | Logical indicating if first day of year (defined by frequency)
is_year_end | Logical indicating if last day of year (defined by frequency)
is_leap_year | Logical indicating if the date belongs to a leap year

Furthermore, if you have a Series with datetimelike values, then you can access these properties via the .dt accessor, as detailed in the section on .dt accessors.

### 19.8 DateOffset Objects

In the preceding examples, we created `DatetimeIndex` objects at various frequencies by passing in `frequency strings` like ‘M’, ‘W’, and ‘BM’ to the `freq` keyword. Under the hood, these frequency strings are being translated into an instance of `DateOffset`, which represents a regular frequency increment. Specific offset logic like “month”, “business day”, or “one hour” is represented in its various subclasses.

<table>

</tbody>
</table>

The basic `DateOffset` takes the same arguments as `dateutil.relativedelta`, which works as follows:

```python
In [111]: d = datetime(2008, 8, 18, 9, 0)
In [112]: d + relativedelta(months=4, days=5)
Out[112]: datetime.datetime(2008, 12, 23, 9, 0)
```

We could have done the same thing with `DateOffset`:

```python
In [113]: from pandas.tseries.offsets import *  
In [114]: d + DateOffset(months=4, days=5)  
Out[114]: Timestamp('2008-12-23 09:00:00')
```

The key features of a `DateOffset` object are:

- It can be added / subtracted to/from a datetime object to obtain a shifted date.
- It can be multiplied by an integer (positive or negative) so that the increment will be applied multiple times.
- It has `rollforward()` and `rollback()` methods for moving a date forward or backward to the next or previous “offset date”.

Subclasses of `DateOffset` define the `apply` function which dictates custom date increment logic, such as adding business days:

```python
class BDay(DateOffset):
    """DateOffset increments between business days""
    def apply(self, other):
        ...
```

19.8. DateOffset Objects
The `rollforward` and `rollback` methods do exactly what you would expect:

```python
In [118]: d
Out[118]: datetime.datetime(2008, 8, 18, 9, 0)

In [119]: offset = BMonthEnd()

In [120]: offset.rollforward(d)
Out[120]: Timestamp('2008-08-29 09:00:00')

In [121]: offset.rollback(d)
Out[121]: Timestamp('2008-07-31 09:00:00')
```

It's definitely worth exploring the `pandas.tseries.offsets` module and the various docstrings for the classes. These operations (apply, rollforward and rollback) preserve time (hour, minute, etc) information by default. To reset time, use `normalize=True` when creating the offset instance. If `normalize=True`, the result is normalized after the function is applied.

```python
In [122]: day = Day()

In [123]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[123]: Timestamp('2014-01-02 09:00:00')

In [124]: day = Day(normalize=True)

In [125]: day.apply(pd.Timestamp('2014-01-01 09:00'))
Out[125]: Timestamp('2014-01-02 00:00:00')

In [126]: hour = Hour()

In [127]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[127]: Timestamp('2014-01-01 23:00:00')

In [128]: hour = Hour(normalize=True)

In [129]: hour.apply(pd.Timestamp('2014-01-01 22:00'))
Out[129]: Timestamp('2014-01-01 00:00:00')

In [130]: hour.apply(pd.Timestamp('2014-01-01 23:00'))
Out[130]: Timestamp('2014-01-02 00:00:00')
```

### 19.8.1 Parametric Offsets

Some of the offsets can be “parameterized” when created to result in different behaviors. For example, the `Week` offset for generating weekly data accepts a `weekday` parameter which results in the generated dates always lying on a particular day of the week:

```python
In [131]: d
Out[131]: datetime.datetime(2008, 8, 18, 9, 0)
```
In [132]: d + Week()
Out[132]: Timestamp('2008-08-25 09:00:00')

In [133]: d + Week(weekday=4)
Out[133]: Timestamp('2008-08-22 09:00:00')

In [134]: (d + Week(weekday=4)).weekday()
Out[134]: 4

In [135]: d - Week()
Out[135]: Timestamp('2008-08-11 09:00:00')

The normalize option will be effective for addition and subtraction.

In [136]: d + Week(normalize=True)
Out[136]: Timestamp('2008-08-25 00:00:00')

In [137]: d - Week(normalize=True)
Out[137]: Timestamp('2008-08-11 00:00:00')

Another example is parameterizing YearEnd with the specific ending month:

In [138]: d + YearEnd()
Out[138]: Timestamp('2008-12-31 09:00:00')

In [139]: d + YearEnd(month=6)
Out[139]: Timestamp('2009-06-30 09:00:00')

19.8.2 Using Offsets with Series / DatetimeIndex

Offsets can be used with either a Series or DatetimeIndex to apply the offset to each element.

In [140]: rng = pd.date_range('2012-01-01', '2012-01-03')

In [141]: s = pd.Series(rng)

In [142]: rng
Out[142]: DatetimeIndex(['2012-01-01', '2012-01-02', '2012-01-03'], dtype='datetime64[ns]', freq='D')

In [143]: rng + DateOffset(months=2)
Out[143]: DatetimeIndex(['2012-03-01', '2012-03-02', '2012-03-03'], dtype='datetime64[ns]', freq='D')

In [144]: s + DateOffset(months=2)
Out[144]:
0  2012-03-01
1  2012-03-02

(continues on next page)
If the offset class maps directly to a *Timedelta* (*Day*, *Hour*, *Minute*, *Second*, *Micro*, *Milli*, *Nano*) it can be used exactly like a *Timedelta* - see the *Timedelta section* for more examples.

Note that some offsets (such as *BQuarterEnd*) do not have a vectorized implementation. They can still be used but may calculate significantly slower and will show a *PerformanceWarning*

### 19.8.3 Custom Business Days

The *CDay* or *CustomBusinessDay* class provides a parametric *BusinessDay* class which can be used to create customized business day calendars which account for local holidays and local weekend conventions.

As an interesting example, let’s look at Egypt where a Friday-Saturday weekend is observed.
# They also observe International Workers' Day so let's
# add that for a couple of years
In [153]: holidays = ['2012-05-01', datetime(2013, 5, 1), np.datetime64('2014-05-01')]

In [154]: bday_egypt = CustomBusinessDay(holidays=holidays, weekmask=weekmask_egypt)

In [155]: dt = datetime(2013, 4, 30)

In [156]: dt + 2 * bday_egypt
Out[156]: Timestamp('2013-05-05 00:00:00')

Let's map to the weekday names:

In [157]: dts = pd.date_range(dt, periods=5, freq=bday_egypt)

In [158]: pd.Series(dts.weekday, dts).map(pd.Series('Mon Tue Wed Thu Fri Sat'.split()))
Out[158]:
2013-04-30 Tue
2013-05-02 Thu
2013-05-05 Sun
2013-05-06 Mon
2013-05-07 Tue
Freq: C, dtype: object

Holiday calendars can be used to provide the list of holidays. See the holiday calendar section for more information.

In [159]: from pandas.tseries.holiday import USFederalHolidayCalendar

In [160]: bday_us = CustomBusinessDay(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [161]: dt = datetime(2014, 1, 17)

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [162]: dt + bday_us
Out[162]: Timestamp('2014-01-21 00:00:00')

Monthly offsets that respect a certain holiday calendar can be defined in the usual way.

In [163]: from pandas.tseries.offsets import CustomBusinessMonthBegin

In [164]: bmth_us = CustomBusinessMonthBegin(calendar=USFederalHolidayCalendar())

# Skip new years
In [165]: dt = datetime(2013, 12, 17)

In [166]: dt + bmth_us
Out[166]: Timestamp('2014-01-02 00:00:00')

# Define date index with custom offset
In [167]: pd.DatetimeIndex(start='20100101',end='20120101',freq=bmth_us)

 DatetimeIndex(['2010-01-04', '2010-02-01', '2010-03-01', '2010-04-01',
               '2010-05-03', '2010-06-01', '2010-07-01', '2010-08-02',
               '2010-09-01', '2010-10-01', '2010-11-01', '2010-12-01',
               '2011-01-03', '2011-02-01', '2011-03-01', '2011-04-01'],
              dtype='datetime64[ns]', freq='M')

(continues on next page)
Note: The frequency string ‘C’ is used to indicate that a CustomBusinessDay DateOffset is used, it is important to note that since CustomBusinessDay is a parameterised type, instances of CustomBusinessDay may differ and this is not detectable from the ‘C’ frequency string. The user therefore needs to ensure that the ‘C’ frequency string is used consistently within the user’s application.

19.8.4 Business Hour

The BusinessHour class provides a business hour representation on BusinessDay, allowing to use specific start and end times.

By default, BusinessHour uses 9:00 - 17:00 as business hours. Adding BusinessHour will increment Timestamp by hourly frequency. If target Timestamp is out of business hours, move to the next business hour then increment it. If the result exceeds the business hours end, the remaining hours are added to the next business day.

```
In [168]: bh = BusinessHour()

In [169]: bh
Out[169]: <BusinessHour: BH=09:00-17:00>

# 2014-08-01 is Friday
In [170]: pd.Timestamp('2014-08-01 10:00').weekday()
Out[170]: 4

In [171]: pd.Timestamp('2014-08-01 10:00') + bh
Out[171]: Timestamp('2014-08-01 11:00:00')

# Below example is the same as: pd.Timestamp('2014-08-01 09:00') + bh
In [172]: pd.Timestamp('2014-08-01 08:00') + bh
Out[172]: Timestamp('2014-08-01 10:00:00')

# If the results is on the end time, move to the next business day
In [173]: pd.Timestamp('2014-08-01 16:00') + bh
Out[173]: Timestamp('2014-08-01 17:00:00')

# Remainings are added to the next day
In [174]: pd.Timestamp('2014-08-01 16:30') + bh
Out[174]: Timestamp('2014-08-02 09:30:00')

# Adding 2 business hours
In [175]: pd.Timestamp('2014-08-01 10:00') + BusinessHour(2)
Out[175]: Timestamp('2014-08-01 12:00:00')

# Subtracting 3 business hours
```
You can also specify start and end time by keywords. The argument must be a str with an hour:minute representation or a datetime.time instance. Specifying seconds, microseconds and nanoseconds as business hour results in ValueError.

Passing start time later than end represents midnight business hour. In this case, business hour exceeds midnight and overlap to the next day. Valid business hours are distinguished by whether it started from valid BusinessDay.

Applying BusinessHour.rollforward and rollback to out of business hours results in the next business hour start or previous day’s end. Different from other offsets, BusinessHour.rollforward may output different results from apply by definition.

This is because one day’s business hour end is equal to next day’s business hour start. For example, under the default business hours (9:00 - 17:00), there is no gap (0 minutes) between 2014-08-01 17:00 and 2014-08-04 09:00.
# This adjusts a Timestamp to business hour edge
In [188]: BusinessHour().rollback(pd.Timestamp('2014-08-02 15:00'))
Out[188]: Timestamp('2014-08-01 17:00:00')

In [189]: BusinessHour().rollforward(pd.Timestamp('2014-08-02 15:00'))
Out[189]: Timestamp('2014-08-04 09:00:00')

# It is the same as BusinessHour().apply(pd.Timestamp('2014-08-01 17:00')).
# And it is the same as BusinessHour().apply(pd.Timestamp('2014-08-04 09:00'))
In [190]: BusinessHour().apply(pd.Timestamp('2014-08-02 15:00'))
Out[190]: Timestamp('2014-08-04 10:00:00')

BusinessHour regards Saturday and Sunday as holidays. To use arbitrary holidays, you can use CustomBusinessHour offset, as explained in the following subsection.

### 19.8.5 Custom Business Hour

New in version 0.18.1.

The CustomBusinessHour is a mixture of BusinessHour and CustomBusinessDay which allows you to specify arbitrary holidays. CustomBusinessHour works as the same as BusinessHour except that it skips specified custom holidays.

In [193]: from pandas.tseries.holiday import USFederalHolidayCalendar
In [194]: bhour_us = CustomBusinessHour(calendar=USFederalHolidayCalendar())

# Friday before MLK Day
In [195]: dt = datetime(2014, 1, 17, 15)

In [196]: dt + bhour_us
Out[196]: Timestamp('2014-01-17 16:00:00')

# Tuesday after MLK Day (Monday is skipped because it's a holiday)
In [197]: dt + bhour_us * 2
Out[197]: Timestamp('2014-01-21 09:00:00')

You can use keyword arguments supported by either BusinessHour and CustomBusinessDay.

In [198]: bhour_mon = CustomBusinessHour(start='10:00', weekmask='Tue Wed Thu Fri')

# Monday is skipped because it's a holiday, business hour starts from 10:00

(continues on next page)
In [199]: dt + bhour_mon * 2
Out[199]: Timestamp('2014-01-21 10:00:00')

19.8.6 Offset Aliases

A number of string aliases are given to useful common time series frequencies. We will refer to these aliases as offset aliases.

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>B</td>
<td>business day frequency</td>
</tr>
<tr>
<td>C</td>
<td>custom business day frequency</td>
</tr>
<tr>
<td>D</td>
<td>calendar day frequency</td>
</tr>
<tr>
<td>W</td>
<td>weekly frequency</td>
</tr>
<tr>
<td>M</td>
<td>month end frequency</td>
</tr>
<tr>
<td>SM</td>
<td>semi-month end frequency (15th and end of month)</td>
</tr>
<tr>
<td>BM</td>
<td>business month end frequency</td>
</tr>
<tr>
<td>CBM</td>
<td>custom business month end frequency</td>
</tr>
<tr>
<td>MS</td>
<td>month start frequency</td>
</tr>
<tr>
<td>SMS</td>
<td>semi-month start frequency (1st and 15th)</td>
</tr>
<tr>
<td>BMS</td>
<td>business month start frequency</td>
</tr>
<tr>
<td>CBMS</td>
<td>custom business month start frequency</td>
</tr>
<tr>
<td>Q</td>
<td>quarter end frequency</td>
</tr>
<tr>
<td>BQ</td>
<td>business quarter end frequency</td>
</tr>
<tr>
<td>QS</td>
<td>quarter start frequency</td>
</tr>
<tr>
<td>BQS</td>
<td>business quarter start frequency</td>
</tr>
<tr>
<td>A, Y</td>
<td>year end frequency</td>
</tr>
<tr>
<td>BA, BY</td>
<td>business year end frequency</td>
</tr>
<tr>
<td>AS, YS</td>
<td>year start frequency</td>
</tr>
<tr>
<td>BAS, BYS</td>
<td>business year start frequency</td>
</tr>
<tr>
<td>BH</td>
<td>business hour frequency</td>
</tr>
<tr>
<td>H</td>
<td>hourly frequency</td>
</tr>
<tr>
<td>T, min</td>
<td>minutely frequency</td>
</tr>
<tr>
<td>S</td>
<td>secondly frequency</td>
</tr>
<tr>
<td>L, ms</td>
<td>milliseconds</td>
</tr>
<tr>
<td>U, us</td>
<td>microseconds</td>
</tr>
<tr>
<td>N</td>
<td>nanoseconds</td>
</tr>
</tbody>
</table>

19.8.7 Combining Aliases

As we have seen previously, the alias and the offset instance are fungible in most functions:

In [200]: pd.date_range(start, periods=5, freq='B')
Out[200]:
dtype='datetime64[ns]', freq='B')

In [201]: pd.date_range(start, periods=5, freq=BDay())
You can combine together day and intraday offsets:

```
In [202]: pd.date_range(start, periods=10, freq='2h20min')
Out[202]:
DatetimeIndex(['2011-01-01 00:00:00', '2011-01-01 02:20:00',
               '2011-01-01 04:40:00', '2011-01-01 07:00:00',
               '2011-01-01 09:20:00', '2011-01-01 11:40:00',
               '2011-01-01 14:00:00', '2011-01-01 16:20:00',
               '2011-01-01 18:40:00', '2011-01-01 21:00:00'],
   dtype='datetime64[ns]', freq='140T')
```

```
In [203]: pd.date_range(start, periods=10, freq='1D10U')
```

19.8.8 Anchored Offsets

For some frequencies you can specify an anchoring suffix:

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>W-SUN</td>
<td>weekly frequency (Sundays). Same as ‘W’</td>
</tr>
<tr>
<td>W-MON</td>
<td>weekly frequency (Mondays)</td>
</tr>
<tr>
<td>W-TUE</td>
<td>weekly frequency (Tuesdays)</td>
</tr>
<tr>
<td>W-WED</td>
<td>weekly frequency (Wednesdays)</td>
</tr>
<tr>
<td>W-THU</td>
<td>weekly frequency (Thursdays)</td>
</tr>
<tr>
<td>W-FRI</td>
<td>weekly frequency (Fridays)</td>
</tr>
<tr>
<td>W-SAT</td>
<td>weekly frequency (Saturdays)</td>
</tr>
<tr>
<td>(B)Q(S)-DEC</td>
<td>quarterly frequency, year ends in December. Same as ‘Q’</td>
</tr>
<tr>
<td>(B)Q(S)-JAN</td>
<td>quarterly frequency, year ends in January</td>
</tr>
<tr>
<td>(B)Q(S)-FEB</td>
<td>quarterly frequency, year ends in February</td>
</tr>
<tr>
<td>(B)Q(S)-MAR</td>
<td>quarterly frequency, year ends in March</td>
</tr>
<tr>
<td>(B)Q(S)-APR</td>
<td>quarterly frequency, year ends in April</td>
</tr>
<tr>
<td>(B)Q(S)-MAY</td>
<td>quarterly frequency, year ends in May</td>
</tr>
<tr>
<td>(B)Q(S)-JUN</td>
<td>quarterly frequency, year ends in June</td>
</tr>
</tbody>
</table>

Continued on next page
Table 2 – continued from previous page

<table>
<thead>
<tr>
<th>Alias</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>(B)Q(S)-JUL</td>
<td>quarterly frequency, year ends in July</td>
</tr>
<tr>
<td>(B)Q(S)-AUG</td>
<td>quarterly frequency, year ends in August</td>
</tr>
<tr>
<td>(B)Q(S)-SEP</td>
<td>quarterly frequency, year ends in September</td>
</tr>
<tr>
<td>(B)Q(S)-OCT</td>
<td>quarterly frequency, year ends in October</td>
</tr>
<tr>
<td>(B)Q(S)-NOV</td>
<td>quarterly frequency, year ends in November</td>
</tr>
<tr>
<td>(B)A(S)-DEC</td>
<td>annual frequency, anchored end of December. Same as ‘A’</td>
</tr>
<tr>
<td>(B)A(S)-JAN</td>
<td>annual frequency, anchored end of January</td>
</tr>
<tr>
<td>(B)A(S)-FEB</td>
<td>annual frequency, anchored end of February</td>
</tr>
<tr>
<td>(B)A(S)-MAR</td>
<td>annual frequency, anchored end of March</td>
</tr>
<tr>
<td>(B)A(S)-APR</td>
<td>annual frequency, anchored end of April</td>
</tr>
<tr>
<td>(B)A(S)-MAY</td>
<td>annual frequency, anchored end of May</td>
</tr>
<tr>
<td>(B)A(S)-JUN</td>
<td>annual frequency, anchored end of June</td>
</tr>
<tr>
<td>(B)A(S)-JUL</td>
<td>annual frequency, anchored end of July</td>
</tr>
<tr>
<td>(B)A(S)-AUG</td>
<td>annual frequency, anchored end of August</td>
</tr>
<tr>
<td>(B)A(S)-SEP</td>
<td>annual frequency, anchored end of September</td>
</tr>
<tr>
<td>(B)A(S)-OCT</td>
<td>annual frequency, anchored end of October</td>
</tr>
<tr>
<td>(B)A(S)-NOV</td>
<td>annual frequency, anchored end of November</td>
</tr>
</tbody>
</table>

These can be used as arguments to `date_range`, `bdate_range`, constructors for `Datet imeIndex`, as well as various other timeseries-related functions in pandas.

19.8.9 Anchored Offset Semantics

For those offsets that are anchored to the start or end of specific frequency (`MonthEnd`, `MonthBegin`, `WeekEnd`, etc), the following rules apply to rolling forward and backwards.

When \( n \) is not 0, if the given date is not on an anchor point, it snapped to the next(previous) anchor point, and moved \(|n| - 1\) additional steps forwards or backwards.

```
In [204]: pd.Timestamp('2014-01-02') + MonthBegin(n=1)
Out[204]: Timestamp('2014-02-01 00:00:00')
```

```
In [205]: pd.Timestamp('2014-01-02') + MonthEnd(n=1)
Out[205]: Timestamp('2014-01-31 00:00:00')
```

(continues on next page)
If the given date is on an anchor point, it is moved \(|n|\) points forwards or backwards.

For the case when \(n=0\), the date is not moved if on an anchor point, otherwise it is rolled forward to the next anchor point.
19.8.10 Holidays / Holiday Calendars

Holidays and calendars provide a simple way to define holiday rules to be used with CustomBusinessDay or in other analysis that requires a predefined set of holidays. The AbstractHolidayCalendar class provides all the necessary methods to return a list of holidays and only rules need to be defined in a specific holiday calendar class. Furthermore, the start_date and end_date class attributes determine over what date range holidays are generated. These should be overwritten on the AbstractHolidayCalendar class to have the range apply to all calendar subclasses. USFederalHolidayCalendar is the only calendar that exists and primarily serves as an example for developing other calendars.

For holidays that occur on fixed dates (e.g., US Memorial Day or July 4th) an observance rule determines when that holiday is observed if it falls on a weekend or some other non-observed day. Defined observance rules are:

<table>
<thead>
<tr>
<th>Rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>nearest_workday</td>
<td>move Saturday to Friday and Sunday to Monday</td>
</tr>
<tr>
<td>sunday_to_monday</td>
<td>move Sunday to following Monday</td>
</tr>
<tr>
<td>next_monday_or_tuesday</td>
<td>Saturday to Monday and Sunday/Monday to Tuesday</td>
</tr>
<tr>
<td>previous_friday</td>
<td>move Saturday and Sunday to previous Friday</td>
</tr>
<tr>
<td>next_monday</td>
<td>move Saturday and Sunday to following Monday</td>
</tr>
</tbody>
</table>

An example of how holidays and holiday calendars are defined:

```
In [220]: from pandas.tseries.holiday import Holiday, USMemorialDay,
.....: AbstractHolidayCalendar, nearest_workday, MO
.....:
In [221]: class ExampleCalendar(AbstractHolidayCalendar):
.....:    rules = [
.....:        USMemorialDay,
.....:        Holiday('July 4th', month=7, day=4, observance=nearest_workday),
.....:        Holiday('Columbus Day', month=10, day=1,
.....:                      offset=DateOffset(weekday=MO(2))), #same as 2*Week(weekday=2)
.....:    ]
.....:
In [222]: cal = ExampleCalendar()
```

```
In [223]: cal.holidays(datetime(2012, 1, 1), datetime(2012, 12, 31))
Out[223]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype=˓→'datetime64[ns]', freq=None)
```

Using this calendar, creating an index or doing offset arithmetic skips weekends and holidays (i.e., Memorial Day/July 4th). For example, the below defines a custom business day offset using the ExampleCalendar. Like any other offset, it can be used to create a DatetimeIndex or added to datetim or Timestamp objects.

```
In [224]: from pandas.tseries.offsets import CDay
In [225]: pd.DatetimeIndex(start='7/1/2012', end='7/10/2012',
.....:                      freq=CDay(calendar=cal)).to_pydatetime()
Out[225]: array([datetime.datetime(2012, 7, 2, 0, 0),
                   datetime.datetime(2012, 7, 3, 0, 0),
                   datetime.datetime(2012, 7, 5, 0, 0),
                   datetime.datetime(2012, 7, 6, 0, 0),
                   datetime.datetime(2012, 7, 9, 0, 0),
                   (continues on next page)
```

19.8. DateOffset Objects
Ranges are defined by the `start_date` and `end_date` class attributes of `AbstractHolidayCalendar`. The defaults are shown below.

```
In [231]: AbstractHolidayCalendar.start_date
Out[231]: Timestamp('1970-01-01 00:00:00')

In [232]: AbstractHolidayCalendar.end_date
Out[232]: Timestamp('2030-12-31 00:00:00')
```

These dates can be overwritten by setting the attributes as `datetime/Timestamp/string`.

```
In [233]: AbstractHolidayCalendar.start_date = datetime(2012, 1, 1)
In [234]: AbstractHolidayCalendar.end_date = datetime(2012, 12, 31)
In [235]: cal.holidays()
Out[235]: DatetimeIndex(['2012-05-28', '2012-07-04', '2012-10-08'], dtype='datetime64[ns]', freq=None)
```

Every calendar class is accessible by name using the `get_calendar` function which returns a holiday class instance. Any imported calendar class will automatically be available by this function. Also, `HolidayCalendarFactory` provides an easy interface to create calendars that are combinations of calendars or calendars with additional rules.

```
In [236]: from pandas.tseries.holiday import get_calendar, HolidayCalendarFactory,\
       USLaborDay

In [237]: cal = get_calendar('ExampleCalendar')
In [238]: cal.rules
Out[238]: [Holiday: MemorialDay (month=5, day=31, offset=<DateOffset: weekday=MO(-1)>),
         Holiday: July 4th (month=7, day=4, observance=<function nearest_workday at 0x1c330299d8>),
         Holiday: Columbus Day (month=10, day=1, offset=<DateOffset: weekday=MO(+2)>)]
In [239]: new_cal = HolidayCalendarFactory('NewExampleCalendar', cal, USLaborDay)
```
19.9 Time Series-Related Instance Methods

19.9.1 Shifting / Lagging

One may want to *shift* or *lag* the values in a time series back and forward in time. The method for this is *shift()*, which is available on all of the pandas objects.

In [241]: ts = ts[:5]

In [242]: ts.shift(1)

Out[242]:
2011-01-31    NaN
2011-02-28  -1.281247
2011-03-31  -0.727707
2011-04-29  -0.121306
2011-05-31  -0.097883
Freq: BM, dtype: float64

The *shift* method accepts an *freq* argument which can accept a *DateOffset* class or other timedelta-like object or also an *offset alias*:

In [243]: ts.shift(5, freq=offsets.BDay())

Out[243]:
2011-02-07  -1.281247
2011-03-07  -0.727707
2011-04-07  -0.121306
2011-05-06  -0.097883
2011-06-07   0.695775
Freq: BM, dtype: float64

In [244]: ts.shift(5, freq='BM')

Out[244]:
2011-05-31  -0.097883
2011-06-30   0.695775
Freq: BM, dtype: float64

Rather than changing the alignment of the data and the index, *DataFrame* and *Series* objects also have a *tshift()* convenience method that changes all the dates in the index by a specified number of offsets:

In [245]: ts.tshift(5, freq='D')

Out[245]:
2011-06-30  -1.281247
2011-07-29  -0.727707
2011-08-31  -0.121306
2011-09-30  -0.097883
2011-10-31   0.695775
Freq: BM, dtype: float64
2011-02-05  -1.281247
2011-03-05  -0.727707
2011-04-05  -0.121306
2011-05-04  -0.097883
2011-06-05   0.695775
dtype: float64

Note that with `tshift`, the leading entry is no longer NaN because the data is not being realigned.

### 19.9.2 Frequency Conversion

The primary function for changing frequencies is the `asfreq()` method. For a `DatetimeIndex`, this is basically just a thin, but convenient wrapper around `reindex()` which generates a `date_range` and calls `reindex`.

```python
In [246]: dr = pd.date_range('1/1/2010', periods=3, freq=3 * offsets.BDay())
In [247]: ts = pd.Series(randn(3), index=dr)
In [248]: ts
Out[248]:
2010-01-01  0.155932
2010-01-06  1.486218
2010-01-11 -2.148675
Freq: 3B, dtype: float64

In [249]: ts.asfreq(BDay())
   →
2010-01-01  0.155932
2010-01-04 NaN
2010-01-05 NaN
2010-01-06  1.486218
2010-01-07 NaN
2010-01-08 NaN
2010-01-11 -2.148675
Freq: B, dtype: float64
```

`asfreq` provides a further convenience so you can specify an interpolation method for any gaps that may appear after the frequency conversion.

```python
In [250]: ts.asfreq(BDay(), method='pad')
Out[250]:
2010-01-01  0.155932
2010-01-04  0.155932
2010-01-05  0.155932
2010-01-06  1.486218
2010-01-07  1.486218
2010-01-08  1.486218
2010-01-11 -2.148675
Freq: B, dtype: float64
```

### 19.9.3 Filling Forward / Backward

Related to `asfreq` and `reindex` is `fillna()`, which is documented in the missing data section.
19.9.4 Converting to Python Datetimes

DatetimeIndex can be converted to an array of Python native `datetime.datetime` objects using the `to_pydatetime` method.

19.10 Resampling

**Warning:** The interface to `.resample` has changed in 0.18.0 to be more groupby-like and hence more flexible. See the `whatsnew` docs for a comparison with prior versions.

Pandas has a simple, powerful, and efficient functionality for performing resampling operations during frequency conversion (e.g., converting secondly data into 5-minutely data). This is extremely common in, but not limited to, financial applications.

`.resample()` is a time-based groupby, followed by a reduction method on each of its groups. See some `cookbook examples` for some advanced strategies.

Starting in version 0.18.1, the `resample()` function can be used directly from `DataFrameGroupBy` objects, see the `groupby docs`.

**Note:** `.resample()` is similar to using a `rolling()` operation with a time-based offset, see a discussion [here](#).

19.10.1 Basics

```
In [251]: rng = pd.date_range('1/1/2012', periods=100, freq='S')
In [252]: ts = pd.Series(np.random.randint(0, 500, len(rng)), index=rng)
In [253]: ts.resample('5Min').sum()
Out[253]:
2012-01-01  25653
Freq: 5T, dtype: int64
```

The `resample` function is very flexible and allows you to specify many different parameters to control the frequency conversion and resampling operation.

Any function available via `dispatching` is available as a method of the returned object, including `sum`, `mean`, `std`, `sem`, `max`, `min`, `median`, `first`, `last`, `ohlc`:

```
In [254]: ts.resample('5Min').mean()
Out[254]:
2012-01-01    256.53
Freq: 5T, dtype: float64
```

```
In [255]: ts.resample('5Min').ohlc()
Out[255]:
          open    high    low   close
2012-01-01  296   496      6   449
```

```
In [256]: ts.resample('5Min').max()
```

(continues on next page)
For downsampling, closed can be set to ‘left’ or ‘right’ to specify which end of the interval is closed:

```
In [256]: ts.resample('5Min', closed='right').mean()
Out[256]:
2012-01-01  496
Freq: 5T, dtype: int64
```

```
In [257]: ts.resample('5Min', closed='left').mean()
```

Parameters like label and loffset are used to manipulate the resulting labels. label specifies whether the result is labeled with the beginning or the end of the interval. loffset performs a time adjustment on the output labels.

```
In [259]: ts.resample('5Min').mean()  # by default label='left'
Out[259]:
2012-01-01  256.53
Freq: 5T, dtype: float64
```

```
In [260]: ts.resample('5Min', label='left').mean()
```

```
In [261]: ts.resample('5Min', label='left', loffset='1s').mean()
```

Note: The default values for label and closed is ‘left’ for all frequency offsets except for ‘M’, ‘A’, ‘Q’, ‘BM’, ‘BA’, ‘BQ’, and ‘W’ which all have a default of ‘right’.

```
In [262]: rng2 = pd.date_range('1/1/2012', end='3/31/2012', freq='D')
In [263]: ts2 = pd.Series(range(len(rng2)), index=rng2)
# default: label='right', closed='right'
In [264]: ts2.resample('M').max()
Out[264]:
2012-01-31  30
2012-02-29  59
2012-03-31  90
Freq: M, dtype: int64
```

```
In [265]: ts2.resample('SM').max()  # default: label='left', closed='left'
```

(continues on next page)
The `axis` parameter can be set to 0 or 1 and allows you to resample the specified axis for a `DataFrame`. The `kind` can be set to ‘timestamp’ or ‘period’ to convert the resulting index to/from timestamp and time span representations. By default `resample` retains the input representation. The `convention` can be set to ‘start’ or ‘end’ when resampling period data (detail below). It specifies how low frequency periods are converted to higher frequency periods.

### 19.10.2 Upsampling

For upsampling, you can specify a way to upsample and the `limit` parameter to interpolate over the gaps that are created:

```python
# from secondly to every 250 milliseconds
In [267]: ts[:2].resample('250L').asfreq()
Out[267]:
         00:00:00.000  00:00:00.250  00:00:00.500  00:00:00.750  00:00:01.000
2012-01-01              296.0       NaN       NaN       NaN       NaN
2012-01-01              296.0       NaN       NaN       NaN       NaN
Freq: 250L, dtype: float64
```

```python
In [268]: ts[:2].resample('250L').ffill()
```

(continues on next page)
19.10.3 Sparse Resampling

Sparse timeseries are the ones where you have a lot fewer points relative to the amount of time you are looking to resample. Naively upsampling a sparse series can potentially generate lots of intermediate values. When you don’t want to use a method to fill these values, e.g. `fill_method` is `None`, then intermediate values will be filled with `NaN`.

Since `resample` is a time-based groupby, the following is a method to efficiently resample only the groups that are not all `NaN`.

```python
In [270]: rng = pd.date_range('2014-1-1', periods=100, freq='D') + pd.Timedelta('1s')
In [271]: ts = pd.Series(range(100), index=rng)
```

If we want to resample to the full range of the series:

```python
In [272]: ts.resample('3T').sum()
```

We can instead only resample those groups where we have points as follows:

```python
In [273]: from functools import partial
In [274]: from pandas.tseries.frequencies import to_offset
In [275]: def round(t, freq):
    ...:     freq = to_offset(freq)
    ...:     return pd.Timestamp(t.value // freq.delta.value * freq.delta.value)
```

(continues on next page)
In [276]: ts.groupby(partial(round, freq='3T')).sum()
Out[276]:
2014-01-01  0
2014-01-02  1
2014-01-03  2
2014-01-04  3
2014-01-05  4
2014-01-06  5
2014-01-07  6
....
2014-04-04  93
2014-04-05  94
2014-04-06  95
2014-04-07  96
2014-04-08  97
2014-04-09  98
2014-04-10  99
Length: 100, dtype: int64

19.10.4 Aggregation

Similar to the aggregating API, groupby API, and the window functions API, a Resampler can be selectively resampled.

Resampling a DataFrame, the default will be to act on all columns with the same function.

In [277]: df = pd.DataFrame(np.random.randn(1000, 3),
    index=pd.date_range('1/1/2012', freq='S', periods=1000),
    columns=['A', 'B', 'C'])

In [278]: r = df.resample('3T')

In [279]: r.mean()
Out[279]:
     A        B        C
2012-01-01 00:00:00 -0.038580 -0.085117 -0.024750
2012-01-01 00:03:00  0.052387 -0.061477  0.029548
2012-01-01 00:06:00  0.121377 -0.010630 -0.043691
2012-01-01 00:09:00 -0.106814 -0.053819  0.097222
2012-01-01 00:12:00  0.032560  0.080543  0.167380
2012-01-01 00:15:00  0.060486 -0.057602 -0.106213

We can select a specific column or columns using standard getitem.

In [280]: r['A'].mean()
Out[280]:
     A
2012-01-01 00:00:00 -0.038580
2012-01-01 00:03:00  0.052387
2012-01-01 00:06:00  0.121377
2012-01-01 00:09:00 -0.106814
2012-01-01 00:12:00  0.032560
2012-01-01 00:15:00  0.060486

(continues on next page)

19.10. Resampling
Freq: 3T, Name: A, dtype: float64

```
In [281]: r[’A’,’B’].mean()
A  B
2012-01-01 00:00:00 -0.038580 -0.085117
2012-01-01 00:03:00  0.052387 -0.061477
2012-01-01 00:06:00  0.121377 -0.010630
2012-01-01 00:09:00 -0.106814 -0.053819
2012-01-01 00:12:00  0.032560  0.080543
2012-01-01 00:15:00  0.060486 -0.057602
```

You can pass a list or dict of functions to do aggregation with, outputting a DataFrame:

```
In [282]: r[’A’].agg([np.sum, np.mean, np.std])
Out[282]:
               sum   mean   std
2012-01-01 00:00:00 -6.944481 -0.038580  0.985150
2012-01-01 00:03:00  9.429707  0.052387  1.078022
2012-01-01 00:06:00 21.847876  0.121377  0.996365
2012-01-01 00:09:00 -19.226593 -0.106814  0.914070
2012-01-01 00:12:00  5.860874  0.032560  1.100055
2012-01-01 00:15:00  6.048588  0.060486  1.001532
```

On a resampled DataFrame, you can pass a list of functions to apply to each column, which produces an aggregated result with a hierarchical index:

```
In [283]: r.agg([np.sum, np.mean])
Out[283]:
          A    B    C
          sum  mean  sum  mean  sum  mean
2012-01-01 00:00:00 -6.944481 -0.038580 -15.320993 -0.085117 -4.454941 -0.024750
2012-01-01 00:03:00  9.429707  0.052387 -11.065916 -0.061477  5.318688  0.029548
2012-01-01 00:06:00 21.847876  0.121377 -1.913420 -0.010630 -7.864429 -0.043691
2012-01-01 00:09:00 -19.226593 -0.106814 -9.687468 -0.053819 17.499920  0.097222
2012-01-01 00:12:00  5.860874  0.032560 14.497725  0.080543 30.128432  0.167380
2012-01-01 00:15:00  6.048588  0.060486 -5.760208 -0.057602 -10.621260 -0.106213
```

By passing a dict to `aggregate` you can apply a different aggregation to the columns of a DataFrame:

```
In [284]: r.agg({’A’ : np.sum,
        ’B’ : lambda x: np.std(x, ddof=1)})
```

```
Out[284]:
          A    B
2012-01-01 00:00:00 -6.944481  1.087752
2012-01-01 00:03:00  9.429707  1.014552
2012-01-01 00:06:00 21.847876  0.954588
2012-01-01 00:09:00 -19.226593  1.027990
2012-01-01 00:12:00  5.860874  0.632560
2012-01-01 00:15:00  6.048588  0.60486
```

The function names can also be strings. In order for a string to be valid it must be implemented on the resampled object:
Furthermore, you can also specify multiple aggregation functions for each column separately.

**In [286]:**

```python
r.agg({'A' : ['sum','std'], 'B' : ['mean','std'] })
```

**Out[286]:**

<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
<th></th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>sum</td>
<td>std</td>
<td>mean</td>
<td>std</td>
</tr>
<tr>
<td>2012-01-01</td>
<td>-6.944481</td>
<td>0.985150</td>
<td>-0.085117</td>
<td>1.087752</td>
</tr>
<tr>
<td>2012-01-01</td>
<td>9.429707</td>
<td>1.078022</td>
<td>-0.061477</td>
<td>1.014552</td>
</tr>
<tr>

<td>1.100553</td>
<td>0.080543</td>
<td>1.021503</td>
</tr>
<tr>
<td>2012-01-01</td>
<td>6.048588</td>
<td>1.001532</td>
<td>-0.057602</td>
<td>1.004984</td>
</tr>
</tbody>
</table>

If a DataFrame does not have a datetimelike index, but instead you want to resample based on datetimelike column in the frame, it can passed to the `on` keyword.

**In [287]:**

```python
df = pd.DataFrame({'date': pd.date_range('2015-01-01', freq='W', periods=5),
                  'a': np.arange(5),
                  index=pd.MultiIndex.from_arrays([np.arange(5),
                                                    pd.date_range('2015-01-01', freq='W',
                                                      periods=5)],
                                                    names=['v','d']))
```

**Out[287]:**

<p>| | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>date</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>v</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>d</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>1</td>
<td>2015-01-04</td>
<td>2015-01-04</td>
<td>0</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>2015-01-11</td>
<td>2015-01-11</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>2015-01-18</td>
<td>2015-01-18</td>
<td>2</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>2015-01-25</td>
<td>2015-01-25</td>
<td>3</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>2015-02-01</td>
<td>2015-02-01</td>
<td>4</td>
<td></td>
</tr>
</tbody>
</table>

**In [288]:**

```python
df.resample('M', on='date').sum()
```

**Out[288]:**

<table>
<thead>
<tr>
<th>date</th>
<th>a</th>
</tr>
</thead>
<tbody>
<tr>
<td>2015-01-31</td>
<td>6</td>
</tr>
<tr>
<td>2015-02-28</td>
<td>4</td>
</tr>
</tbody>
</table>

Similarly, if you instead want to resample by a datetimelike level of MultiIndex, its name or location can be passed to the `level` keyword.

**In [290]:**

```python
df.resample('M', level='d').sum()
```

(continues on next page)
19.11 Time Span Representation

Regular intervals of time are represented by Period objects in pandas while sequences of Period objects are collected in a PeriodIndex, which can be created with the convenience function period_range.

19.11.1 Period

A Period represents a span of time (e.g., a day, a month, a quarter, etc). You can specify the span via freq keyword using a frequency alias like below. Because freq represents a span of Period, it cannot be negative like “-3D”.

<table>
<thead>
<tr>
<th>In [291]:</th>
<th>pd.Period('2012', freq='A-DEC')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[291]:</td>
<td>Period('2012', 'A-DEC')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [292]:</th>
<th>pd.Period('2012-1-1', freq='D')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[292]:</td>
<td>Period('2012-01-01', 'D')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [293]:</th>
<th>pd.Period('2012-1-1 19:00', freq='H')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[293]:</td>
<td>Period('2012-01-01 19:00', 'H')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [294]:</th>
<th>pd.Period('2012-1-1 19:00', freq='5H')</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[294]:</td>
<td>Period('2012-01-01 19:00', '5H')</td>
</tr>
</tbody>
</table>

Adding and subtracting integers from periods shifts the period by its own frequency. Arithmetic is not allowed between Period with different freq (span).

<table>
<thead>
<tr>
<th>In [295]:</th>
<th>p = pd.Period('2012', freq='A-DEC')</th>
</tr>
</thead>
<tbody>
<tr>
<td>In [296]:</td>
<td>p + 1</td>
</tr>
<tr>
<td>Out[296]:</td>
<td>Period('2013', 'A-DEC')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [297]:</th>
<th>p - 3</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[297]:</td>
<td>Period('2009', 'A-DEC')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [298]:</th>
<th>p = pd.Period('2012-01', freq='2M')</th>
</tr>
</thead>
<tbody>
<tr>
<td>In [299]:</td>
<td>p + 2</td>
</tr>
<tr>
<td>Out[299]:</td>
<td>Period('2012-05', '2M')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [300]:</th>
<th>p - 1</th>
</tr>
</thead>
<tbody>
<tr>
<td>Out[300]:</td>
<td>Period('2011-11', '2M')</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>In [301]:</th>
<th>p == pd.Period('2012-01', freq='3M')</th>
</tr>
</thead>
</table>

(continues on next page)
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

In [301]: p == pd.Period('2012-01', freq='3M')

~/sandbox/pandas-docs/pandas/_libs/tslibs/period.pyx in pandas._libs.tslibs.period._
   →Period._richcmp__()
IncompatibleFrequency: Input has different freq=3M from Period(freq=2M)

If `Period` freq is daily or higher (D, H, T, S, L, U, N), offsets and timedelta-like can be added if the result can have the same freq. Otherwise, `ValueError` will be raised.

In [302]: p = pd.Period('2014-07-01 09:00', freq='H')
In [303]: p + Hour(2)
Out[303]: Period('2014-07-01 11:00', 'H')
In [304]: p + timedelta(minutes=120)
   
Out[304]: Period('2014-07-01 11:00', 'H')
In [305]: p + np.timedelta64(7200, 's')
   
Out[305]: Period('2014-07-01 11:00', 'H')

In [1]: p + Minute(5)
Traceback...  
ValueError: Input has different freq from Period(freq=H)

If `Period` has other freqs, only the same offsets can be added. Otherwise, `ValueError` will be raised.

In [306]: p = pd.Period('2014-07', freq='M')
In [307]: p + MonthEnd(3)
Out[307]: Period('2014-10', 'M')

In [1]: p + MonthBegin(3)
Traceback...  
ValueError: Input has different freq from Period(freq=M)

Taking the difference of `Period` instances with the same frequency will return the number of frequency units between them:

Out[308]: 10

19.11.2 PeriodIndex and period_range

Regular sequences of `Period` objects can be collected in a `PeriodIndex`, which can be constructed using the `period_range` convenience function:

In [309]: prng = pd.period_range('1/1/2011', '1/1/2012', freq='M')
In [310]: prng

(continues on next page)
The `PeriodIndex` constructor can also be used directly:

```python
In [311]: pd.PeriodIndex(['2011-1', '2011-2', '2011-3'], freq='M')
Out[311]: PeriodIndex(['2011-01', '2011-02', '2011-03'], dtype='period[M]', freq='M')
```

Passing multiplied frequency outputs a sequence of `Period` which has multiplied span.

```python
In [312]: pd.PeriodIndex(start='2014-01', freq='3M', periods=4)
```

If `start` or `end` are `Period` objects, they will be used as anchor endpoints for a `PeriodIndex` with frequency matching that of the `PeriodIndex` constructor.

```python
In [313]: pd.PeriodIndex(start=pd.Period('2017Q1', freq='Q'),
...: end=pd.Period('2017Q2', freq='Q'), freq='M')
....:
Out[313]: PeriodIndex(['2017-03', '2017-04', '2017-05', '2017-06'], dtype='period[M]', ← freq='M')
```

Just like `DatetimeIndex`, a `PeriodIndex` can also be used to index pandas objects:

```python
In [314]: ps = pd.Series(np.random.randn(len(prng)), prng)
In [315]: ps
Out[315]:
2011-01    0.258318
2011-02   -2.503700
2011-03   -0.303053
2011-04    0.270509
2011-05   -0.129044
2011-06   -1.406335
2011-07   -1.310412
2011-08    1.004841
2011-09    1.001558
2011-10   -0.087453
Freq: M, dtype: float64
```

`PeriodIndex` supports addition and subtraction with the same rule as `Period`.

```python
In [316]: idx = pd.period_range('2014-07-01 09:00', periods=5, freq='H')
In [317]: idx
Out[317]:
PeriodIndex(['2014-07-01 09:00', '2014-07-01 10:00', '2014-07-01 11:00',
 '2014-07-01 12:00', '2014-07-01 13:00'],
 dtype='period[H]', freq='H')
```
In [318]: idx + Hour(2)
   → PeriodIndex([‘2014-07-01 11:00’, ‘2014-07-01 12:00’, ‘2014-07-01 13:00’,
                  ‘2014-07-01 14:00’, ‘2014-07-01 15:00’],
                  dtype=’period[H]’, freq=’H’)

In [319]: idx = pd.period_range(‘2014-07’, periods=5, freq=’M’)

In [320]: idx

In [321]: idx + MonthEnd(3)

PeriodIndex has its own dtype named period, refer to Period Dtypes.

19.11.3 Period Dtypes

New in version 0.19.0.

PeriodIndex has a custom period dtype. This is a pandas extension dtype similar to the timezone aware dtype (datetime64[ns, tz]).

The period dtype holds the freq attribute and is represented with period[freq] like period[D] or period[M], using frequency strings.

In [322]: pi = pd.period_range(‘2016-01-01’, periods=3, freq=’M’)

In [323]: pi
   → PeriodIndex([‘2016-01’, ‘2016-02’, ‘2016-03’], dtype=’period[M]’, freq=’M’)

In [324]: pi.dtype
   → period[M]

The period dtype can be used in .astype(...). It allows one to change the freq of a PeriodIndex like .asfreq() and convert a DatetimeIndex to PeriodIndex like to_period():

# change monthly freq to daily freq
In [325]: pi.astype(‘period[D]’)
   → PeriodIndex([‘2016-01-31’, ‘2016-02-29’, ‘2016-03-31’], dtype=’period[D]’,
                  freq=’D’)

# convert to DatetimeIndex
In [326]: pi.astype(‘datetime64[ns]’)
   → DatetimeIndex([‘2016-01-01’, ‘2016-02-01’, ‘2016-03-01’], dtype=’datetime64[ns]’,
                  freq=’MS’)

# convert to PeriodIndex
In [327]: dti = pd.date_range(‘2011-01-01’, freq=’M’, periods=3)
19.11.4 PeriodIndex Partial String Indexing

You can pass in dates and strings to Series and DataFrame with PeriodIndex, in the same manner as DatetimeIndex. For details, refer to DatetimeIndex Partial String Indexing.

Passing a string representing a lower frequency than PeriodIndex returns partial sliced data.
As with `DatetimeIndex`, the endpoints will be included in the result. The example below slices data starting from 10:00 to 11:59.

```python
In [337]: dfp['2013-01-01 10H':'2013-01-01 11H']
Out[337]:
   A
2013-01-01 10:00  -0.148998
2013-01-01 10:01   2.154810
2013-01-01 10:02  -1.605646
2013-01-01 10:03   0.021024
2013-01-01 10:04  -0.623737
2013-01-01 10:05   1.451612
2013-01-01 10:06   1.062463
...  ...  ...  
2013-01-01 10:53   0.273119
2013-01-01 10:54  -0.994071
2013-01-01 10:55  -1.222179
2013-01-01 10:56  -1.167118
2013-01-01 10:57   0.262822
2013-01-01 10:58  -0.283786
2013-01-01 10:59   1.190726
[60 rows x 1 columns]
```
19.11.5 Frequency Conversion and Resampling with PeriodIndex

The frequency of Period and PeriodIndex can be converted via the asfreq method. Let’s start with the fiscal year 2011, ending in December:

```python
In [338]: p = pd.Period('2011', freq='A-DEC')
In [339]: p
Out[339]: Period('2011', 'A-DEC')
```

We can convert it to a monthly frequency. Using the how parameter, we can specify whether to return the starting or ending month:

```python
In [340]: p.asfreq('M', how='start')
Out[340]: Period('2011-01', 'M')
In [341]: p.asfreq('M', how='end')
Out[341]: Period('2011-12', 'M')
```

The shorthands ‘s’ and ‘e’ are provided for convenience:

```python
In [342]: p.asfreq('M', 's')
Out[342]: Period('2011-01', 'M')
In [343]: p.asfreq('M', 'e')
Out[343]: Period('2011-12', 'M')
```

Converting to a “super-period” (e.g., annual frequency is a super-period of quarterly frequency) automatically returns the super-period that includes the input period:

```python
In [344]: p = pd.Period('2011-12', freq='A-NOV')
In [345]: p.asfreq('M')
```

Note that since we converted to an annual frequency that ends the year in November, the monthly period of December 2011 is actually in the 2012 A-NOV period.

Period conversions with anchored frequencies are particularly useful for working with various quarterly data common to economics, business, and other fields. Many organizations define quarters relative to the month in which their fiscal year starts and ends. Thus, first quarter of 2011 could start in 2010 or a few months into 2011. Via anchored frequencies, pandas works for all quarterly frequencies Q–JAN through Q–DEC.

Q–DEC define regular calendar quarters:
19.12 Converting Between Representations

Timestamped data can be converted to PeriodIndex-ed data using `to_period` and vice-versa using `to_timestamp`:

```
In [352]: rng = pd.date_range('1/1/2012', periods=5, freq='M')
In [353]: ts = pd.Series(np.random.randn(len(rng)), index=rng)
In [354]: ts
Out[354]:
2012-01-31 -0.898547
2012-02-29 -1.332247
2012-03-31 -0.741645
2012-04-30  0.094321
2012-05-31 -0.438813
Freq: M, dtype: float64

In [355]: ps = ts.to_period()
In [356]: ps
Out[356]:
2012-01  -0.898547
2012-02  -1.332247
2012-03  -0.741645
2012-04   0.094321
2012-05  -0.438813
Freq: M, dtype: float64
```

(continues on next page)
Remember that ‘s’ and ‘e’ can be used to return the timestamps at the start or end of the period:

```
In [358]: ps.to_timestamp('D', how='s')
Out[358]:
2012-01-01 -0.898547
2012-02-01 -1.332247
2012-03-01 -0.741645
2012-04-01 0.094321
2012-05-01 -0.438813
Freq: MS, dtype: float64
```

Converting between period and timestamp enables some convenient arithmetic functions to be used. In the following example, we convert a quarterly frequency with year ending in November to 9am of the end of the month following the quarter end:

```
In [359]: prng = pd.period_range('1990Q1', '2000Q4', freq='Q-NOV')
In [360]: ts = pd.Series(np.random.randn(len(prng)), prng)
In [361]: ts.index = (prng.asfreq('M', 'e') + 1).asfreq('H', 's') + 9
In [362]: ts.head()
Out[362]:
1990-03-01 09:00 -0.564874
1990-06-01 09:00 -1.426510
1990-09-01 09:00 1.295437
1990-12-01 09:00 1.124017
1991-03-01 09:00 0.840428
Freq: H, dtype: float64
```

## 19.13 Representing Out-of-Bounds Spans

If you have data that is outside of the Timestamp bounds, see [Timestamp limitations](#), then you can use a PeriodIndex and/or Series of Periods to do computations.

```
In [363]: span = pd.period_range('1215-01-01', '1381-01-01', freq='D')
In [364]: span
Out[364]:
PeriodIndex(['1215-01-01', '1215-01-02', '1215-01-03', '1215-01-04',
'1215-01-05', '1215-01-06', '1215-01-07', '1215-01-08',
'1215-01-09', '1215-01-10', ...
'1380-12-23', '1380-12-24', '1380-12-25', '1380-12-26',
'1380-12-27', '1380-12-28', '1380-12-29', '1380-12-30',
'1380-12-31', '1381-01-01'],
dtype='period[D]', length=60632, freq='D')
```

To convert from an int64 based YYYYMMDD representation.
In [365]: s = pd.Series([20121231, 20141130, 99991231])

In [366]: s
Out[366]:
0  20121231
1  20141130
2  99991231
dtype: int64

In [367]: def conv(x):
   ....:     return pd.Period(year = x // 10000, month = x//100 % 100, day = x%100,
   ....:                        freq='D')
   ....:

In [368]: s.apply(conv)
Out[368]:
0  2012-12-31
1  2014-11-30
2  9999-12-31
dtype: object

In [369]: s.apply(conv)[2]
Out[369]: Period('9999-12-31', 'D')

These can easily be converted to a PeriodIndex:

In [370]: span = pd.PeriodIndex(s.apply(conv))
In [371]: span
Out[371]: PeriodIndex(['2012-12-31', '2014-11-30', '9999-12-31'],
                      freq='D')

19.14 Time Zone Handling

Pandas provides rich support for working with timestamps in different time zones using pytz and dateutil libraries. dateutil currently is only supported for fixed offset and tzfile zones. The default library is pytz. Support for dateutil is provided for compatibility with other applications e.g. if you use dateutil in other Python packages.

19.14.1 Working with Time Zones

By default, pandas objects are time zone unaware:

In [372]: rng = pd.date_range('3/6/2012 00:00', periods=15, freq='D')

In [373]: rng.tz is None
Out[373]: True

To supply the time zone, you can use the tz keyword to date_range and other functions. Dateutil time zone strings are distinguished from pytz time zones by starting with dateutil/.

- In pytz you can find a list of common (and less common) time zones using from pytz import common_timezones, all_timezones.
• `dateutil` uses the OS timezones so there isn’t a fixed list available. For common zones, the names are the same as `pytz`.

```python
# pytz
In [374]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                             tz='Europe/London')

In [375]: rng_pytz.tz
Out[375]: <DstTzInfo 'Europe/London' LMT-1 day, 23:59:00 STD>

# dateutil
In [376]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                                  tz='dateutil/Europe/London')

In [377]: rng_dateutil.tz
Out[377]: tzfile('/usr/share/zoneinfo/Europe/London')

# dateutil - utc special case
In [378]: rng_utc = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                             tz=dateutil.tz.tzutc())

In [379]: rng_utc.tz
Out[379]: tzutc()
```

Note that the UTC timezone is a special case in `dateutil` and should be constructed explicitly as an instance of `dateutil.tz.tzutc`. You can also construct other timezones explicitly first, which gives you more control over which time zone is used:

```python
# pytz
In [380]: tz_pytz = pytz.timezone('Europe/London')

In [381]: rng_pytz = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                              tz=tz_pytz)

In [382]: rng_pytz.tz == tz_pytz
Out[382]: True

# dateutil
In [383]: tz_dateutil = dateutil.tz.gettz('Europe/London')

In [384]: rng_dateutil = pd.date_range('3/6/2012 00:00', periods=10, freq='D',
                                  tz=tz_dateutil)

In [385]: rng_dateutil.tz == tz_dateutil
Out[385]: True
```

Timestamps, like Python’s `datetime.datetime` object can be either time zone naive or time zone aware. Naive time series and `DatetimeIndex` objects can be localized using `tz_localize`:

```python
In [386]: ts = pd.Series(np.random.randn(len(rng)), rng)

In [387]: ts_utc = ts.tz_localize('UTC')
```

(continues on next page)
In [388]: ts_utc
Out[388]:
2012-03-06 00:00:00+00:00  0.037206
2012-03-07 00:00:00+00:00  2.313998
2012-03-08 00:00:00+00:00  1.458296
2012-03-09 00:00:00+00:00 - 0.620431
2012-03-10 00:00:00+00:00 - 0.000111
2012-03-11 00:00:00+00:00 - 0.342783
2012-03-12 00:00:00+00:00 - 0.664322
2012-03-13 00:00:00+00:00  0.654814
2012-03-14 00:00:00+00:00  1.550680
2012-03-15 00:00:00+00:00  0.174511
2012-03-16 00:00:00+00:00  1.360491
2012-03-17 00:00:00+00:00  0.799737
2012-03-18 00:00:00+00:00  0.494149
2012-03-19 00:00:00+00:00  0.111346
2012-03-20 00:00:00+00:00 - 0.435531
Freq: D, dtype: float64

Again, you can explicitly construct the timezone object first. You can use the `tz_convert` method to convert pandas objects to convert tz-aware data to another time zone:

In [389]: ts_utc.tz_convert('US/Eastern')
Out[389]:
2012-03-05 19:00:00-05:00  0.037206
2012-03-06 19:00:00-05:00  2.313998
2012-03-07 19:00:00-05:00  1.458296
2012-03-08 19:00:00-05:00 - 0.620431
2012-03-09 19:00:00-05:00 - 0.000111
2012-03-10 19:00:00-05:00 - 0.342783
2012-03-11 20:00:00-04:00 - 0.664322
2012-03-12 20:00:00-04:00  0.654814
2012-03-13 20:00:00-04:00  1.550680
2012-03-14 20:00:00-04:00  0.174511
2012-03-15 20:00:00-04:00  1.360491
2012-03-16 20:00:00-04:00  0.799737
2012-03-17 20:00:00-04:00  0.494149
2012-03-18 20:00:00-04:00  0.111346
2012-03-19 20:00:00-04:00 - 0.435531
Freq: D, dtype: float64

**Warning:** Be wary of conversions between libraries. For some zones `pytz` and `dateutil` have different definitions of the zone. This is more of a problem for unusual timezones than for 'standard' zones like US/Eastern.

**Warning:** Be aware that a timezone definition across versions of timezone libraries may not be considered equal. This may cause problems when working with stored data that is localized using one version and operated on with a different version. See [here](#) for how to handle such a situation.

**Warning:** It is incorrect to pass a timezone directly into the `datetime.datetime` constructor (e.g., `datetime.datetime(2011, 1, 1, tz=timezone('US/Eastern'))`). Instead, the datetime needs...
to be localized using the localize method on the timezone.

Under the hood, all timestamps are stored in UTC. Scalar values from a `Datet imeIndex` with a time zone will have their fields (day, hour, minute) localized to the time zone. However, timestamps with the same UTC value are still considered to be equal even if they are in different time zones:

```python
In [390]: rng_eastern = rng_utc.tz_convert('US/Eastern')
In [391]: rng_berlin = rng_utc.tz_convert('Europe/Berlin')
In [392]: rng_eastern[5]  
Out[392]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')
In [393]: rng_berlin[5]  
Out[393]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')
Out[394]: True
```

Like `Series`, `DataFrame`, and `Datet imeIndex`, `Timestamp`'s can be converted to other time zones using ``tz_convert``:

```python
In [395]: rng_eastern[5]  
Out[395]: Timestamp('2012-03-10 19:00:00-0500', tz='US/Eastern', freq='D')
In [396]: rng_berlin[5]  
Out[396]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin', freq='D')
In [397]: rng_eastern[5].tz_convert('Europe/Berlin')  
Out[397]: Timestamp('2012-03-11 01:00:00+0100', tz='Europe/Berlin')
```

Localization of `Timestamp` functions just like `Datet imeIndex` and `Series`:

```python
In [398]: rng[5]  
Out[398]: Timestamp('2012-03-11 00:00:00', freq='D')
In [399]: rng[5].tz_localize('Asia/Shanghai')  
Out[399]: Timestamp('2012-03-11 00:00:00+0800', tz='Asia/Shanghai')
```

Operations between `Series` in different time zones will yield UTC `Series`, aligning the data on the UTC timestamps:

```python
In [400]: eastern = ts_utc.tz_convert('US/Eastern')
In [401]: berlin = ts_utc.tz_convert('Europe/Berlin')
In [402]: result = eastern + berlin
In [403]: result  
Out[403]:  
2012-03-06 00:00:00+00:00 0.074412
```
2012-03-07 00:00:00+00:00  4.627997
2012-03-08 00:00:00+00:00  2.916592
2012-03-09 00:00:00+00:00 -1.240863
2012-03-10 00:00:00+00:00  -0.000221
2012-03-11 00:00:00+00:00  -0.685566
2012-03-12 00:00:00+00:00  -1.328643
2012-03-13 00:00:00+00:00  1.309628
2012-03-14 00:00:00+00:00  3.101359
2012-03-15 00:00:00+00:00  0.349022
2012-03-16 00:00:00+00:00  2.720983
2012-03-17 00:00:00+00:00  1.599475
2012-03-18 00:00:00+00:00  0.898297
2012-03-19 00:00:00+00:00  0.222691
2012-03-20 00:00:00+00:00  -0.871062
Freq: D, dtype: float64

In [404]: result.index

Out[404]:
\nDateTimeIndex(['2012-03-06', '2012-03-07', '2012-03-08', '2012-03-09',
    '2012-03-10', '2012-03-11', '2012-03-12', '2012-03-13',
    '2012-03-14', '2012-03-15', '2012-03-16', '2012-03-17',
    '2012-03-18', '2012-03-19', '2012-03-20'],
dtype='datetime64[ns, UTC]', freq='D')

To remove timezone from tz-aware DatetimeIndex, use tz_localize(None) or tz_convert(None). tz_localize(None) will remove timezone holding local time representations. tz_convert(None) will remove timezone after converting to UTC time.

In [405]: didx = pd.DatetimeIndex(start='2014-08-01 09:00', freq='H', periods=10, tz='US/Eastern')

In [406]: didx

dtype='datetime64[ns]', freq='H')
19.14.2 Ambiguous Times when Localizing

In some cases, localize cannot determine the DST and non-DST hours when there are duplicates. This often happens when reading files or database records that simply duplicate the hours. Passing `ambiguous='infer'` into `tz_localize` will attempt to determine the right offset. Below the top example will fail as it contains ambiguous times and the bottom will infer the right offset.

```python
In [410]: rng_hourly = pd.DatetimeIndex(['11/06/2011 00:00', '11/06/2011 01:00',
                                      '11/06/2011 02:00', '11/06/2011 03:00'])
```

This will fail as there are ambiguous times

```python
In [2]: rng_hourly.tz_localize('US/Eastern')
```

AmbiguousTimeError: Cannot infer dst time from Timestamp('2011-11-06 01:00:00'), try using the 'ambiguous' argument

Infer the ambiguous times

```python
In [411]: rng_hourly_eastern = rng_hourly.tz_localize('US/Eastern', ambiguous='infer')
```

In addition to ‘infer’, there are several other arguments supported. Passing an array-like of bools or 0s/1s where True represents a DST hour and False a non-DST hour, allows for distinguishing more than one DST transition (e.g., if you have multiple records in a database each with their own DST transition). Or passing ‘NaT’ will fill in transition times with not-a-time values. These methods are available in the `DatetimeIndex` constructor as well as `tz_localize`.

```python
In [413]: rng_hourly_dst = np.array([1, 1, 0, 0, 0])
In [414]: rng_hourly.tz_localize('US/Eastern', ambiguous=rng_hourly_dst).tolist()
```

(continues on next page)
Out[414]:
[ Timestamp('2011-11-06 00:00:00-0400', tz='US/Eastern'),
  Timestamp('2011-11-06 01:00:00-0400', tz='US/Eastern'),

              dtype='datetime64[ns]', freq='H')

(continues on next page)
19.14.3 TZ Aware Dtypes

Series/DatetimeIndex with a timezone **naive** value are represented with a dtype of datetime64[ns].

```python
In [421]: s_naive = pd.Series(pd.date_range('20130101', periods=3))
In [422]: s_naive
Out[422]:
0  2013-01-01
1  2013-01-02
2  2013-01-03
dtype: datetime64[ns]
```

Series/DatetimeIndex with a timezone **aware** value are represented with a dtype of datetime64[ns, tz].

```python
In [423]: s_aware = pd.Series(pd.date_range('20130101', periods=3, tz='US/Eastern'))
In [424]: s_aware
Out[424]:
0  2013-01-01 00:00:00-05:00
1  2013-01-02 00:00:00-05:00
2  2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Both of these Series can be manipulated via the .dt accessor, see here.

For example, to localize and convert a naive stamp to timezone aware.

```python
In [425]: s_naive.dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[425]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]
```

Further more you can .astype(...) timezone aware (and naive). This operation is effectively a localize AND convert on a naive stamp, and a convert on an aware stamp.

```python
# localize and convert a naive timezone
In [426]: s_naive.astype('datetime64[ns, US/Eastern]')
Out[426]:
0  2012-12-31 19:00:00-05:00
1  2013-01-01 19:00:00-05:00
2  2013-01-02 19:00:00-05:00
dtype: datetime64[ns, US/Eastern]

# make an aware tz naive
In [427]: s_aware.astype('datetime64[ns]')
→
0  2013-01-01 05:00:00
1  2013-01-02 05:00:00
```

(continues on next page)
# pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

## 19.14. Time Zone Handling

2 2013-01-03 05:00:00
dtype: datetime64[ns]

# convert to a new timezone
In [428]: s_aware.astype('datetime64[ns, CET]')

→
0 2013-01-01 06:00:00+01:00
1 2013-01-02 06:00:00+01:00
2 2013-01-03 06:00:00+01:00
dtype: datetime64[ns, CET]

Note: Using the .values accessor on a Series, returns an NumPy array of the data. These values are converted to UTC, as NumPy does not currently support timezones (even though it is printing in the local timezone!).

In [429]: s_naive.values
Out[429]:
array(['2013-01-01T00:00:00.000000000', '2013-01-02T00:00:00.000000000',
      '2013-01-03T00:00:00.000000000'], dtype='datetime64[ns]')

In [430]: s_aware.values

→
array(['2013-01-01T05:00:00.000000000', '2013-01-02T05:00:00.000000000',
      '2013-01-03T05:00:00.000000000'], dtype='datetime64[ns]')

Further note that once converted to a NumPy array these would lose the tz tenor.

In [431]: pd.Series(s_aware.values)
Out[431]:
0 2013-01-01 05:00:00
timezone:   
dtype: datetime64[ns]

However, these can be easily converted:

In [432]: pd.Series(s_aware.values).dt.tz_localize('UTC').dt.tz_convert('US/Eastern')
Out[432]:
0 2013-01-01 00:00:00-05:00
1 2013-01-02 00:00:00-05:00
2 2013-01-03 00:00:00-05:00
dtype: datetime64[ns, US/Eastern]
Timedeltas are differences in times, expressed in difference units, e.g. days, hours, minutes, seconds. They can be both positive and negative.

Timedelta is a subclass of datetime.timedelta, and behaves in a similar manner, but allows compatibility with np.timedelta64 types as well as a host of custom representation, parsing, and attributes.

20.1 Parsing

You can construct a Timedelta scalar through various arguments:

```python
# strings
In [1]: pd.Timedelta('1 days')
Out[1]: Timedelta('1 days 00:00:00')

In [2]: pd.Timedelta('1 days 00:00:00')
Out[2]: Timedelta('1 days 00:00:00')

In [3]: pd.Timedelta('1 days 2 hours')
Out[3]: Timedelta('1 days 02:00:00')

In [4]: pd.Timedelta('-1 days 2 min 3us')
Out[4]: Timedelta('-2 days +23:57:59.999997')

# like datetime.timedelta
# note: these MUST be specified as keyword arguments
In [5]: pd.Timedelta(days=1, seconds=1)
Out[5]: Timedelta('1 days 00:00:01')

# integers with a unit
In [6]: pd.Timedelta(1, unit='d')
Out[6]: Timedelta('1 days 00:00:00')

# from a datetime.timedelta/np.timedelta64
In [7]: pd.Timedelta(datetime.timedelta(days=1, seconds=1))
Out[7]: Timedelta('1 days 00:00:01')

In [8]: pd.Timedelta(np.timedelta64(1, 'ms'))
```

(continues on next page)
New in version 0.23.0: Added constructor for ISO 8601 Duration strings

*DateOffsets* (Day, Hour, Minute, Second, Milli, Micro, Nano) can also be used in construction.

Further, operations among the scalars yield another scalar Timedelta.

### 20.1.1 to_timedelta

Using the top-level `pd.to_timedelta`, you can convert a scalar, array, list, or Series from a recognized timedelta format/value into a Timedelta type. It will construct Series if the input is a Series, a scalar if the input is scalar-like, otherwise it will output a TimedeltaIndex.

You can parse a single string to a Timedelta:

```python
In [16]: pd.to_timedelta('1 days 06:05:01.00003')
Out[16]: Timedelta('1 days 06:05:01.000030')
```

or a list/array of strings:

```python
In [17]: pd.to_timedelta(['1.5us'])
Out[17]: Timedelta('0 days 00:00:00.000015')
```
In [18]: pd.to_timedelta(['1 days 06:05:01.00003', '15.5us', 'nan'])
Out[18]: TimedeltaIndex(['1 days 06:05:01.000030', '0 days 00:00:00.000015', NaT],
   dtype='timedelta64[ns]', freq=None)

The unit keyword argument specifies the unit of the Timedelta:

In [19]: pd.to_timedelta(np.arange(5), unit='s')
Out[19]: TimedeltaIndex(['00:00:00', '00:00:01', '00:00:02', '00:00:03', '00:00:04'],
   dtype='timedelta64[ns]', freq=None)

In [20]: pd.to_timedelta(np.arange(5), unit='d')
Out[20]: TimedeltaIndex(['0 days', '1 days', '2 days', '3 days', '4 days'],
   dtype='timedelta64[ns]', freq=None)

20.1.2 Timedelta limitations

Pandas represents Timedeltas in nanosecond resolution using 64 bit integers. As such, the 64 bit integer limits determine the Timedelta limits.

In [21]: pd.Timedelta.min
Out[21]: Timedelta('-106752 days +00:12:43.145224')

In [22]: pd.Timedelta.max
Out[22]: Timedelta('106751 days +23:47:16.854775')

20.2 Operations

You can operate on Series/DataFrames and construct timedelta64[ns] Series through subtraction operations on datetime64[ns] Series, or Timestamps.

In [23]: s = pd.Series(pd.date_range('2012-1-1', periods=3, freq='D'))

In [24]: td = pd.Series([pd.Timedelta(days=i) for i in range(3)])

In [25]: df = pd.DataFrame(dict(A = s, B = td))

In [26]: df
Out[26]:
   A      B
0 2012-01-01 0 days
1 2012-01-02 1 days
2 2012-01-03 2 days

In [27]: df['C'] = df['A'] + df['B']

In [28]: df
Out[28]:
   A      B      C
0 2012-01-01 0 days 2012-01-01
1 2012-01-02 1 days 2012-01-03
2 2012-01-03 2 days 2012-01-05
(continues on next page)
In [29]: df.dtypes

A     datetime64[ns]
B    timedelta64[ns]
C    datetime64[ns]
dtype: object

In [30]: s - s.max()

0   -2 days
1   -1 days
2     0 days
dtype: timedelta64[ns]

In [31]: s - datetime.datetime(2011, 1, 1, 3, 5)

0  364days 20:55:00
1  365days 20:55:00
2  366days 20:55:00
dtype: timedelta64[ns]

In [32]: s + datetime.timedelta(minutes=5)

0  2012-01-01 00:05:00
1  2012-01-02 00:05:00
2  2012-01-03 00:05:00
dtype: datetime64[ns]

Operations with scalars from a `timedelta64[ns]` series:

In [35]: y = s - s[0]

In [36]: y

Out[36]:
0   0 days
1   1 days
Series of timedeltas with NaT values are supported:

```python
In [37]: y = s - s.shift()

In [38]: y
Out[38]:
0   NaT
1   1 days
2   1 days
dtype: timedelta64[ns]
```

Elements can be set to NaT using `np.nan` analogously to datetimes:

```python
In [39]: y[1] = np.nan

In [40]: y
Out[40]:
0   NaT
1   NaT
2   1 days
dtype: timedelta64[ns]
```

Operands can also appear in a reversed order (a singular object operated with a Series):

```python
In [41]: s.max() - s
Out[41]:
0   2 days
1   1 days
2   0 days
dtype: timedelta64[ns]

In [42]: pd.datetime(2011, 1, 1, 3, 5) - s
Out[42]:
0   -365 days +03:05:00
1   -366 days +03:05:00
2   -367 days +03:05:00
dtype: timedelta64[ns]

In [43]: pd.datetime.timedelta(minutes=5) + s
Out[43]:
0   2012-01-01 00:05:00
1   2012-01-02 00:05:00
2   2012-01-03 00:05:00
dtype: datetime64[ns]
```

```
min, max and the corresponding idxmin, idxmax operations are supported on frames:

In [44]: A = s - pd.Timestamp('20120101') - pd.Timedelta('00:05:05')

In [45]: B = s - pd.Series(pd.date_range('2012-1-2', periods=3, freq='D'))

In [46]: df = pd.DataFrame(dict(A=A, B=B))
```

(continues on next page)
In [47]: df
Out[47]:
   A    B
0 -1 days 23:54:55 -1 days
1 0 days   23:54:55 -1 days
2 1 days   23:54:55 -1 days

In [48]: df.min()
\A   -1 days 23:54:55
\B   -1 days 00:00:00
\dtype: timedelta64[ns]

In [49]: df.min(axis=1)
\A   0 -1 days
\B   0 -1 days
\dtype: timedelta64[ns]

In [50]: df.idxmin()
\A  0
\B  0
\dtype: int64

In [51]: df.idxmax()
\A  2
\B  0
\dtype: int64

min, max, idxmin, idxmax operations are supported on Series as well. A scalar result will be a Timedelta.

In [52]: df.min().max()
Out[52]: Timedelta('-1 days +23:54:55')

In [53]: df.min(axis=1).min()
\Out[53]: Timedelta('-1 days +00:00:00')

In [54]: df.min().idxmax()
\Out[54]: 'A'

In [55]: df.min(axis=1).idxmin()
\Out[55]: 0

You can fillna on timedeltas. Integers will be interpreted as seconds. You can pass a timedelta to get a particular value.

In [56]: y.fillna(0)
Out[56]:
0 0 days
1 0 days
2 1 days
dtype: timedelta64[ns]

In [57]: y.fillna(10)
Out[57]:
0 0 days 00:00:10
1 0 days 00:00:10
2 1 days 00:00:00
dtype: timedelta64[ns]

In [58]: y.fillna(pd.Timedelta('-1 days, 00:00:05'))
Out[58]:
0 -1 days +00:00:05
1 -1 days +00:00:05
2 1 days 00:00:00
dtype: timedelta64[ns]

You can also negate, multiply and use abs on Timedeltas:

In [59]: td1 = pd.Timedelta('-1 days 2 hours 3 seconds')
In [60]: td1
Out[60]: Timedelta('-2 days +21:59:57')
In [61]: -1 * td1
Out[61]: Timedelta('1 days 02:00:03')
In [62]: - td1
Out[62]: Timedelta('1 days 02:00:03')
In [63]: abs(td1)
Out[63]: Timedelta('1 days 02:00:03')

20.3 Reductions

Numeric reduction operation for timedelta64[ns] will return Timedelta objects. As usual NaT are skipped during evaluation.

In [64]: y2 = pd.Series(pd.to_timedelta(['-1 days +00:00:05', 'nat', '-1 days +00:00:05', '1 days']))
In [65]: y2
Out[65]:
0 -1 days +00:00:05
1 NaT
2 -1 days +00:00:05
3 1 days 00:00:00
dtype: timedelta64[ns]
20.4 Frequency Conversion

Timedelta Series, TimedeltaIndex, and Timedelta scalars can be converted to other ‘frequencies’ by dividing by another timedelta, or by astyping to a specific timedelta type. These operations yield Series and propagate NaT -> nan. Note that division by the NumPy scalar is true division, while astyping is equivalent of floor division.

```python
In [70]: td = pd.Series(pd.date_range('20130101', periods=4)) - 

.....: pd.Series(pd.date_range('20121201', periods=4))

In [71]: td[2] += datetime.timedelta(minutes=5, seconds=3)

In [72]: td[3] = np.nan

In [73]: td
Out[73]:
0    31 days 00:00:00
1    31 days 00:00:00
2    31 days 00:05:03
3     NaT
dtype: timedelta64[ns]

# to days
In [74]: td / np.timedelta64(1, 'D')

→
0    31.000000
1    31.000000
2    31.003507
3     NaN
dtype: float64

In [75]: td.astype('timedelta64[D]')

→
0    31.0
1    31.0
2    31.0
```

(continues on next page)
Dividing or multiplying a `timedelta64[ns]` Series by an integer or integer Series yields another `timedelta64[ns]` dtypes Series.

Rounded division (floor-division) of a `timedelta64[ns]` Series by a scalar `Timedelta` gives a series of integers.
0 9.0
1 9.0
2 9.0
3 NaN
dtype: float64

In [82]: pd.Timedelta(days=3, hours=4) // td
Out[82]:
0 0.0
1 0.0
2 0.0
3 NaN
dtype: float64

The mod (%) and divmod operations are defined for Timedelta when operating with another timedelta-like or with a numeric argument.

In [83]: pd.Timedelta(hours=37) % datetime.timedelta(hours=2)
Out[83]: Timedelta('0 days 01:00:00')

# divmod against a timedelta-like returns a pair (int, Timedelta)
In [84]: divmod(datetime.timedelta(hours=2), pd.Timedelta(minutes=11))
Out[84]: (10, Timedelta('0 days 00:10:00'))

# divmod against a numeric returns a pair (Timedelta, Timedelta)
In [85]: divmod(pd.Timedelta(hours=25), 86400000000000)
Out[85]: (Timedelta('0 days 00:00:00.000000'), Timedelta('0 days 01:00:00'))

20.5 Attributes

You can access various components of the Timedelta or TimedeltaIndex directly using the attributes days, seconds, microseconds, nanoseconds. These are identical to the values returned by datetime.timedelta, in that, for example, the .seconds attribute represents the number of seconds >= 0 and < 1 day. These are signed according to whether the Timedelta is signed.

These operations can also be directly accessed via the .dt property of the Series as well.

Note: Note that the attributes are NOT the displayed values of the Timedelta. Use .components to retrieve the displayed values.

For a Series:

In [86]: td.dt.days
Out[86]:
0 31.0
1 31.0
2 31.0
3 NaN
dtype: float64

In [87]: td.dt.seconds
You can access the value of the fields for a scalar Timedelta directly.

```python
In [88]: tds = pd.Timedelta('31 days 5 min 3 sec')
In [89]: tds.days
Out[89]: 31
In [90]: tds.seconds
Out[90]: 303
In [91]: (-tds).seconds
Out[91]: 86097
```

You can use the `.components` property to access a reduced form of the timedelta. This returns a DataFrame indexed similarly to the Series. These are the *displayed* values of the Timedelta.

```python
In [92]: tds.dt.components
Out[92]:
          days    hours    minutes   seconds  milliseconds  micro\n0         31.0      0.0        0.0      0.0             0.0  0.0
1         31.0      0.0        0.0      0.0             0.0  0.0
2         31.0      0.0        5.0      3.0             0.0  0.0
3        NaN      NaN        NaN        NaN             NaN  NaN
In [93]: tds.dt.components.seconds
Out[93]:
            0          1          2
0        0.0        0.0        0.0
1        0.0        0.0        0.0
2        0.0        0.0        0.0
3         NaN        NaN        NaN
Name: seconds, dtype: float64
```

You can convert a Timedelta to an ISO 8601 Duration string with the `.isoformat` method.

New in version 0.20.0.

```python
In [94]: pd.Timedelta(days=6, minutes=50, seconds=3,
                  milliseconds=10, microseconds=10,
                  nanoseconds=12).isoformat()
Out[94]: 'P6DT0H50M3.010010012S'
```

## 20.6 TimedeltaIndex

To generate an index with time delta, you can use either the TimedeltaIndex or the timedelta_range constructor.
Using TimedeltaIndex you can pass string-like, Timedelta, timedelta, or np.timedelta64 objects. Passing np.nan/pd.NaT/nat will represent missing values.

```python
In [95]: pd.TimedeltaIndex(['1 days', '1 days, 00:00:05',
                        np.timedelta64(2,'D'),
                        datetime.timedelta(days=2, seconds=2))
Out[95]:
TimedeltaIndex(['1 days 00:00:00', '1 days 00:00:05', '2 days 00:00:00',
                '2 days 00:00:02'],
dtype='timedelta64[ns]', freq=None)
```

Similarly to date_range, you can construct regular ranges of a TimedeltaIndex:

```python
In [96]: pd.timedelta_range(start='1 days', periods=5, freq='D')
Out[96]:
TimedeltaIndex(['1 days', '2 days', '3 days', '4 days', '5 days'],
dtype='timedelta64[ns]', freq='D')

In [97]: pd.timedelta_range(start='1 days', end='2 days', freq='30T')
```

20.6.1 Using the TimedeltaIndex

Similarly to other of the datetime-like indices, DatetimeIndex and PeriodIndex, you can use TimedeltaIndex as the index of pandas objects.

```python
In [98]: s = pd.Series(np.arange(100),
               index=pd.timedelta_range('1 days', periods=100, freq='h'))

In [99]: s
Out[99]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
... (continues on next page)
```
Selections work similarly, with coercion on string-likes and slices:

```python
In [100]: s['1 day':'2 day']
Out[100]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
1 days 06:00:00    6
2 days 17:00:00    41
2 days 18:00:00    42
2 days 19:00:00    43
2 days 20:00:00    44
2 days 21:00:00    45
2 days 22:00:00    46
2 days 23:00:00    47
Freq: H, Length: 48, dtype: int64
```

In [101]: s['1 day 01:00:00']

```python
In [102]: s[pd.Timedelta('1 day 1h')]
```

Furthermore you can use partial string selection and the range will be inferred:

```python
In [103]: s['1 day':'1 day 5 hours']
Out[103]:
1 days 00:00:00    0
1 days 01:00:00    1
1 days 02:00:00    2
1 days 03:00:00    3
1 days 04:00:00    4
1 days 05:00:00    5
Freq: H, dtype: int64
```
20.6.2 Operations

Finally, the combination of TimedeltaIndex with DatetimeIndex allow certain combination operations that are NaT preserving:

```python
In [104]: tdi = pd.TimedeltaIndex(['1 days', pd.NaT, '2 days'])
In [105]: tdi.tolist()
Out[105]: [Timedelta('1 days 00:00:00'), NaT, Timedelta('2 days 00:00:00')]
In [106]: dti = pd.date_range('20130101', periods=3)
In [107]: dti.tolist()
Out[107]: [Timestamp('2013-01-01 00:00:00', freq='D'),
         Timestamp('2013-01-02 00:00:00', freq='D'),
         Timestamp('2013-01-03 00:00:00', freq='D')]
In [108]: (dti + tdi).tolist()
    → [Timestamp('2013-01-02 00:00:00'), NaT, Timestamp('2013-01-05 00:00:00')]
In [109]: (dti - tdi).tolist()
    → [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2013-01-01 00:00:00')]
```

20.6.3 Conversions

Similarly to frequency conversion on a Series above, you can convert these indices to yield another Index.

```python
In [110]: tdi / np.timedelta64(1,'s')
Out[110]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
In [111]: tdi.astype('timedelta64[s]')
Out[111]: Float64Index([86400.0, nan, 172800.0], dtype='float64')
```

Scalars type ops work as well. These can potentially return a different type of index.

```python
# adding or timedelta and date -> datelike
In [112]: tdi + pd.Timestamp('20130101')
Out[112]: DatetimeIndex(['2013-01-02', 'NaT', '2013-01-03'], dtype='datetime64[ns]',
    → freq=None)

# subtraction of a date and a timedelta -> datelike
# note that trying to subtract a date from a Timedelta will raise an exception
In [113]: (pd.Timestamp('20130101') - tdi).tolist()
    → [Timestamp('2012-12-31 00:00:00'), NaT, Timestamp('2012-12-30 00:00:00')]

# timedelta + timedelta -> timedelta
In [114]: tdi + pd.Timedelta('10 days')
    → TimedeltaIndex(['11 days', NaT, '12 days'], dtype='timedelta64[ns]', freq=None)

# division can result in a Timedelta if the divisor is an integer
```

(continues on next page)
20.7 Resampling

Similar to timeseries resampling, we can resample with a TimedeltaIndex.

In [117]: s.resample('D').mean()
Out[117]:
   1 days  11.5
   2 days  35.5
   3 days  59.5
   4 days  83.5
   5 days  97.5
Freq: D, dtype: float64
CATEGORICAL DATA

This is an introduction to pandas categorical data type, including a short comparison with R’s factor.

Categoricals are a pandas data type corresponding to categorical variables in statistics. A categorical variable takes on a limited, and usually fixed, number of possible values (categories, levels in R). Examples are gender, social class, blood type, country affiliation, observation time or rating via Likert scales.

In contrast to statistical categorical variables, categorical data might have an order (e.g. ‘strongly agree’ vs ‘agree’ or ‘first observation’ vs. ‘second observation’), but numerical operations (additions, divisions, . . . ) are not possible.

All values of categorical data are either in categories or np.nan. Order is defined by the order of categories, not lexical order of the values. Internally, the data structure consists of a categories array and an integer array of codes which point to the real value in the categories array.

The categorical data type is useful in the following cases:

• A string variable consisting of only a few different values. Converting such a string variable to a categorical variable will save some memory, see here.

• The lexical order of a variable is not the same as the logical order (“one”, “two”, “three”). By converting to a categorical and specifying an order on the categories, sorting and min/max will use the logical order instead of the lexical order, see here.

• As a signal to other Python libraries that this column should be treated as a categorical variable (e.g. to use suitable statistical methods or plot types).

See also the API docs on categoricals.

21.1 Object Creation

21.1.1 Series Creation

Categorical Series or columns in a DataFrame can be created in several ways:

By specifying dtype="category" when constructing a Series:

```
In [1]: s = pd.Series(["a","b","c","a"], dtype="category")

In [2]: s
Out[2]:
0  a
1  b
2  c
3  a
```
By converting an existing `Series` or column to a category `dtype`:

```python
In [3]: df = pd.DataFrame({'A': ['a', 'b', 'c', 'a']})
In [4]: df['B'] = df['A'].astype('category')
In [5]: df
Out[5]:
   A  B
0  a  a
1  b  b
2  c  c
3  a  a
```

By using special functions, such as `cut()`, which groups data into discrete bins. See the example on tiling in the docs.

```python
In [6]: df = pd.DataFrame({'value': np.random.randint(0, 100, 20)})
In [7]: labels = ['{0} - {1}'.format(i, i + 9) for i in range(0, 100, 10)]
In [8]: df['group'] = pd.cut(df.value, range(0, 105, 10), right=False, labels=labels)
In [9]: df.head(10)
Out[9]:
   value group
0    65   60 - 69
1    49   40 - 49
2    56   50 - 59
3    43   40 - 49
4    43   40 - 49
5    91   90 - 99
6    32   30 - 39
7    87   80 - 89
8    36   30 - 39
9     8    0 - 9
```

By passing a `pandas.Categorical` object to a `Series` or assigning it to a `DataFrame`.

```python
In [10]: raw_cat = pd.Categorical(['a', 'b', 'c', 'a'], categories=['b', 'c', 'd'], ordered=False)
   ....:
   ....:
In [11]: s = pd.Series(raw_cat)
In [12]: s
Out[12]:
0  NaN
1  b
2  c
3  NaN
dtype: category
Categories (3, object): [b, c, d]
```

(continues on next page)
Categorical data has a specific category dtype:

In [16]: df.dtypes
Out[16]:
A category
B category
dtype: object

21.1.2 DataFrame Creation

Similar to the previous section where a single column was converted to categorical, all columns in a DataFrame can be batch converted to categorical either during or after construction.

This can be done during construction by specifying dtype="category" in the DataFrame constructor:

In [17]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')}, dtype="category")

In [18]: df.dtypes
Out[18]:
A category
B category
dtype: object

Note that the categories present in each column differ; the conversion is done column by column, so only labels present in a given column are categories:

In [19]: df['A']
Out[19]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [20]: df['B']
Out[20]:
0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (3, object): [b, c, d]

New in version 0.23.0.

Analogously, all columns in an existing DataFrame can be batch converted using `DataFrame.astype()`:

```python
In [21]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd'))
In [22]: df_cat = df.astype('category')
In [23]: df_cat.dtypes
Out[23]:
A category
B category
dtype: object
```

This conversion is likewise done column by column:

```python
In [24]: df_cat['A']
Out[24]:
0   a
1   b
2   c
3   a
Name: A, dtype: category
Categories (3, object): [a, b, c]

In [25]: df_cat['B']
Out[25]:
0   b
1   c
2   c
3   d
Name: B, dtype: category
Categories (3, object): [b, c, d]
```

### 21.1.3 Controlling Behavior

In the examples above where we passed `dtype='category'`, we used the default behavior:

1. Categories are inferred from the data.
2. Categories are unordered.

To control those behaviors, instead of passing 'category', use an instance of `CategoricalDtype`.

```python
In [26]: from pandas.api.types import CategoricalDtype
In [27]: s = pd.Series(['a', 'b', 'c', 'a'])
In [28]: cat_type = CategoricalDtype(categories=['b', 'c', 'd'], ordered=True)
```

(continues on next page)
Similarly, a `CategoricalDtype` can be used with a `DataFrame` to ensure that categories are consistent among all columns.

```python
In [31]: df = pd.DataFrame({'A': list('abca'), 'B': list('bccd')})
In [32]: cat_type = CategoricalDtype(categories=list('abcd'), ordered=True)
In [33]: df_cat = df.astype(cat_type)
```

```python
In [34]: df_cat['A']
Out[34]:
0  a
1  b
2  c
3  a
Name: A, dtype: category
Categories (4, object): [a < b < c < d]
```

```python
In [35]: df_cat['B']
```

```python
\n0  b
1  c
2  c
3  d
Name: B, dtype: category
Categories (4, object): [a < b < c < d]
```

**Note:** To perform table-wise conversion, where all labels in the entire DataFrame are used as categories for each column, the `categories` parameter can be determined programmatically by `categories = pd.unique(df.values.ravel())`.

If you already have codes and categories, you can use the `from_codes()` constructor to save the factorize step during normal constructor mode:

```python
In [36]: splitter = np.random.choice([0,1], 5, p=[0.5,0.5])
In [37]: s = pd.Series(pd.Categorical.from_codes(splitter, categories=['train', 'test']))
```
21.1.4 Regaining Original Data

To get back to the original `Series` or NumPy array, use `Series.astype(original_dtype)` or `np.asarray(categorical)`:

```python
In [38]: s = pd.Series(['a','b','c','a'])

In [39]: s
Out[39]:
0  a  
1  b  
2  c  
3  a  
dtype: object

In [40]: s2 = s.astype('category')

In [41]: s2
Out[41]:
0  a  
1  b  
2  c  
3  a  
dtype: category
Categories (3, object): [a, b, c]

In [42]: s2.astype(str)
Out[42]:
0  a  
1  b  
2  c  
3  a  
dtype: object

In [43]: np.asarray(s2)
Out[43]: array(['a', 'b', 'c', 'a'], dtype=object)
```

**Note:** In contrast to R’s `factor` function, categorical data is not converting input values to strings; categories will end up the same data type as the original values.

**Note:** In contrast to R’s `factor` function, there is currently no way to assign/change labels at creation time. Use `categories` to change the categories after creation time.

### 21.2 CategoricalDtype

Changed in version 0.21.0.

A categorical’s type is fully described by

1. `categories`: a sequence of unique values and no missing values
2. ordered: a boolean

This information can be stored in a `CategoricalDtype`. The `categories` argument is optional, which implies that the actual categories should be inferred from whatever is present in the data when the `pandas.Categorical` is created. The categories are assumed to be unordered by default.

```python
In [44]: from pandas.api.types import CategoricalDtype
In [45]: CategoricalDtype(['a', 'b', 'c'])
Out[45]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=None)
In [46]: CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[46]: CategoricalDtype(categories=['a', 'b', 'c'], ordered=True)
In [47]: CategoricalDtype()
Out[47]: CategoricalDtype(categories=None, ordered=None)
```

A `CategoricalDtype` can be used in any place pandas expects a `dtype`. For example `pandas.read_csv()`, `pandas.DataFrame.astype()`, or in the `Series` constructor.

**Note:** As a convenience, you can use the string `'category'` in place of a `CategoricalDtype` when you want the default behavior of the categories being unordered, and equal to the set values present in the array. In other words, `dtype='category'` is equivalent to `dtype=CategoricalDtype()`.

### 21.2.1 Equality Semantics

Two instances of `CategoricalDtype` compare equal whenever they have the same categories and order. When comparing two unordered categoricals, the order of the categories is not considered.

```python
In [48]: c1 = CategoricalDtype(['a', 'b', 'c'], ordered=False)
   # Equal, since order is not considered when ordered=False
In [49]: c1 == CategoricalDtype(['b', 'c', 'a'], ordered=False)
Out[49]: True
   # Unequal, since the second CategoricalDtype is ordered
In [50]: c1 == CategoricalDtype(['a', 'b', 'c'], ordered=True)
Out[50]: False
```

All instances of `CategoricalDtype` compare equal to the string `'category'`.

```python
In [51]: c1 == 'category'
Out[51]: True
```

**Warning:** Since `dtype='category'` is essentially `CategoricalDtype(None, False)`, and since all instances `CategoricalDtype` compare equal to `'category'`, all instances of `CategoricalDtype` compare equal to a `CategoricalDtype(None, False)`, regardless of categories or ordered.
21.3 Description

Using `describe()` on categorical data will produce similar output to a Series or DataFrame of type string.

```python
In [52]: cat = pd.Categorical(["a", "c", "c", np.nan], categories=["b", "a", "c"])
In [53]: df = pd.DataFrame({"cat":cat, "s":["a", "c", "c", np.nan]})
In [54]: df.describe()
Out[54]:
     cat    s
count   3   3
unique  2   2
top    c    c
freq   2   2
```

```python
In [55]: df["cat"].describe()
Out[55]:
   count 3
   unique 2
   top  c
   freq  2
Name: cat, dtype: object
```

21.4 Working with categories

Categorical data has a `categories` and a `ordered` property, which list their possible values and whether the ordering matters or not. These properties are exposed as `s.cat.categories` and `s.cat.ordered`. If you don’t manually specify categories and ordering, they are inferred from the passed arguments.

```python
In [56]: s = pd.Series(["a","b","c","a"], dtype="category")
In [57]: s.cat.categories
Out[57]: Index(['a', 'b', 'c'], dtype='object')
In [58]: s.cat.ordered
Out[58]: False
```

It’s also possible to pass in the categories in a specific order:

```python
In [59]: s = pd.Series(pd.Categorical(["a","b","c","a"], categories=["c","b","a"]))
In [60]: s.cat.categories
Out[60]: Index(['c', 'b', 'a'], dtype='object')
In [61]: s.cat.ordered
Out[61]: False
```

**Note:** New categorical data are **not** automatically ordered. You must explicitly pass `ordered=True` to indicate an ordered `Categorical`. 

1006 Chapter 21. Categorical Data
Note: The result of `unique()` is not always the same as `Series.cat.categories`, because `Series.unique()` has a couple of guarantees, namely that it returns categories in the order of appearance, and it only includes values that are actually present.

```python
In [62]: s = pd.Series(list('babc')).astype(CategoricalDtype(list('abcd')))

In [63]: s
Out[63]:
0  b
1  a
2  b
3  c
dtype: category
Categories (4, object): [a, b, c, d]

# categories
In [64]: s.cat.categories
Index(['a', 'b', 'c', 'd'], dtype='object')

# uniques
In [65]: s.unique()
[ b, a, c]
Categories (3, object): [b, a, c]
```

### 21.4.1 Renaming categories

Renaming categories is done by assigning new values to the `Series.cat.categories` property or by using the `rename_categories()` method:

```python
In [66]: s = pd.Series(["a","b","c","a"], dtype="category")

In [67]: s
Out[67]:
0  a
1  b
2  c
3  a
dtype: category
Categories (3, object): [a, b, c]

In [68]: s.cat.categories = ["Group %s" % g for g in s.cat.categories]

In [69]: s
Out[69]:
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```
In [70]: s.cat.rename_categories([1,2,3])

→
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [1, 2, 3]

In [71]: s

→
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

# You can also pass a dict-like object to map the renaming
In [72]: s.cat.rename_categories({1: 'x', 2: 'y', 3: 'z'})

→
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

In [73]: s

→
0  Group a
1  Group b
2  Group c
3  Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]

Note: In contrast to R's `factor`, categorical data can have categories of other types than string.

Note: Be aware that assigning new categories is an inplace operation, while most other operations under `Series.cat` per default return a new `Series` of dtype `category`.

Categories must be unique or a `ValueError` is raised:

In [74]: try:
   ....:     s.cat.categories = [1,1,1]
   ....: except ValueError as e:
   ....:     print("ValueError: " + str(e))
   ....:
ValueError: Categorical categories must be unique

Categories must also not be NaN or a ValueError is raised:

```
In [75]: try:
    ....: s.cat.categories = [1,2,np.nan]
    ....: except ValueError as e:
    ....:   print("ValueError: " + str(e))
    ....:
ValueError: Categorical categories cannot be null
```

21.4.2 Appending new categories

Appending categories can be done by using the add_categories() method:

```
In [76]: s = s.cat.add_categories([4])
In [77]: s.cat.categories
Out[77]: Index(['Group a', 'Group b', 'Group c', 4], dtype='object')
In [78]: s
Out[78]:
0 Group a
1 Group b
2 Group c
3 Group a
dtype: category
Categories (4, object): [Group a, Group b, Group c, 4]
```

21.4.3 Removing categories

Removing categories can be done by using the remove_categories() method. Values which are removed are replaced by np.nan:

```
In [79]: s = s.cat.remove_categories([4])
In [80]: s
Out[80]:
0 Group a
1 Group b
2 Group c
3 Group a
dtype: category
Categories (3, object): [Group a, Group b, Group c]
```

21.4.4 Removing unused categories

Removing unused categories can also be done:

```
In [81]: s = pd.Series(pd.Categorical(['a','b','a'], categories=['a','b','c','d']))
```
21.4.5 Setting categories

If you want to do remove and add new categories in one step (which has some speed advantage), or simply set the categories to a predefined scale, use `set_categories()`.

```python
In [84]: s = pd.Series(['one','two','four', '-'], dtype='category')

In [85]: s
Out[85]:
0   one
1   two
2   four
3   
dtype: category
Categories (4, object): [one, two, four]

In [86]: s = s.cat.set_categories(['one','two','three','four'])

In [87]: s
Out[87]:
0   one
1   two
2   four
3   NaN
```

**Note:** Be aware that `Categorical.set_categories()` cannot know whether some category is omitted intentionally or because it is misspelled or (under Python3) due to a type difference (e.g., NumPy S1 dtype and Python strings). This can result in surprising behaviour!
21.5 Sorting and Order

If categorical data is ordered (s.cat.ordered == True), then the order of the categories has a meaning and certain operations are possible. If the categorical is unordered, .min()/.max() will raise a TypeError.

```python
In [88]: s = pd.Series(pd.Categorical(["a","b","c","a"], ordered=False))
In [89]: s.sort_values(inplace=True)
In [90]: s = pd.Series(["a","b","c","a"]).astype(⋯:
               CategoricalDtype(ordered=True)
               )
       In [91]: s.sort_values(inplace=True)

In [92]: s
Out[92]:
          0   a
          3   a
          1   b
          2   c
dtype: category
Categories (3, object): [a < b < c]

In [93]: s.min(), s.max()

Out[93]:
('a', 'c')
```

You can set categorical data to be ordered by using as_ordered() or unordered by using as_unordered(). These will by default return a new object.

```python
In [94]: s.cat.as_ordered()
Out[94]:
          0   a
          3   a
          1   b
          2   c
dtype: category
Categories (3, object): [a < b < c]

In [95]: s.cat.as_unordered()

Out[95]:
          0   a
          3   a
          1   b
          2   c
dtype: category
Categories (3, object): [a, b, c]
```

Sorting will use the order defined by categories, not any lexical order present on the data type. This is even true for strings and numeric data:

```python
In [96]: s = pd.Series([1,2,3,1], dtype="category")
In [97]: s = s.cat.set_categories([2,3,1], ordered=True)
```

(continues on next page)
In [98]: s
Out[98]:
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [99]: s.sort_values(inplace=True)
In [100]: s
Out[100]:
1  2
2  3
0  1
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]

In [101]: s.min(), s.max()
\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\\Out[101]:
˓→(2, 1)

21.5.1 Reordering

Reordering the categories is possible via the Categorical.reorder_categories() and the Categorical.set_categories() methods. For Categorical.reorder_categories(), all old categories must be included in the new categories and no new categories are allowed. This will necessarily make the sort order the same as the categories order.

In [102]: s = pd.Series([1,2,3,1], dtype="category")
In [103]: s = s.cat.reorder_categories([2,3,1], ordered=True)
In [104]: s
Out[104]:
0  1
1  2
2  3
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [105]: s.sort_values(inplace=True)
In [106]: s
Out[106]:
1  2
2  3
0  1
3  1
dtype: category
Categories (3, int64): [2 < 3 < 1]
In [107]: s.min(), s.max()

(2, 1)

Note: Note the difference between assigning new categories and reordering the categories: the first renames categories and therefore the individual values in the Series, but if the first position was sorted last, the renamed value will still be sorted last. Reordering means that the way values are sorted is different afterwards, but not that individual values in the Series are changed.

Note: If the Categorical is not ordered, Series.min() and Series.max() will raise TypeError. Numeric operations like +, -, *, / and operations based on them (e.g. Series.median(), which would need to compute the mean between two values if the length of an array is even) do not work and raise a TypeError.

21.5.2 Multi Column Sorting

A categorical dtyped column will participate in a multi-column sort in a similar manner to other columns. The ordering of the categorical is determined by the categories of that column.

In [108]: dfs = pd.DataFrame({'A': pd.Categorical(list('bbeebbaa'), categories=['e', 'a', 'b'], ordered=True),
                        'B': [1,2,1,2,2,1,2,1] })

In [109]: dfs.sort_values(by=['A', 'B'])

Out[109]:
          A  B
2   e  1
3   e  2
7   a  1
6   a  2
0   b  1
5   b  1
1   b  2
4   b  2

Reordering the categories changes a future sort.

In [110]: dfs['A'] = dfs['A'].cat.reorder_categories(['a','b','e'])

In [111]: dfs.sort_values(by=['A', 'B'])

Out[111]:
          A  B
7   a  1
6   a  2
0   b  1
5   b  1
1   b  2
4   b  2
2   e  1
3   e  2
21.6 Comparisons

Comparing categorical data with other objects is possible in three cases:

- Comparing equality (== and ! =) to a list-like object (list, Series, array, …) of the same length as the categorical data.
- All comparisons (==, ! =, >, >=, <, and <=) of categorical data to another categorical Series, when ordered=True and the categories are the same.
- All comparisons of a categorical data to a scalar.

All other comparisons, especially “non-equality” comparisons of two categoricals with different categories or a categorical with any list-like object, will raise a TypeError.

Note: Any “non-equality” comparisons of categorical data with a Series, np.array, list or categorical data with different categories or ordering will raise a TypeError because custom categories ordering could be interpreted in two ways: one with taking into account the ordering and one without.

```
In [112]: cat = pd.Series([1,2,3]).astype(CategoricalDtype([3, 2, 1], ordered=True))
...

In [113]: cat_base = pd.Series([2,2,2]).astype(CategoricalDtype([3, 2, 1], ordered=True))
...

In [114]: cat_base2 = pd.Series([2,2,2]).astype(CategoricalDtype(ordered=True))
...

In [115]: cat
Out[115]:
0 1
1 2
2 3
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [116]: cat_base
\                                                       \Out[116]:
→ 0 2
1 2
2 2
dtype: category
Categories (3, int64): [3 < 2 < 1]

In [117]: cat_base2
\                                                       
→ 0 2
1 2
```

(continues on next page)
Comparing to a categorical with the same categories and ordering or to a scalar works:

```
In [118]: cat > cat_base
Out[118]:
0   True
1   False
2   False
dtype: bool

In [119]: cat > 2
Out[119]:
0   True
1   False
2   False
dtype: bool
```

Equality comparisons work with any list-like object of same length and scalars:

```
In [120]: cat == cat_base
Out[120]:
0   False
1   True
2   False
dtype: bool

In [121]: cat == np.array([1,2,3])
Out[121]:
0   True
1   True
2   True
dtype: bool

In [122]: cat == 2
```

This doesn’t work because the categories are not the same:

```
In [123]: try:
    ....:     cat > cat_base2
    ....:     except TypeError as e:
    ....:         print("TypeError: " + str(e))
    ....:TypeError: Categoricals can only be compared if 'categories' are the same. Categories are different lengths
```

If you want to do a “non-equality” comparison of a categorical series with a list-like object which is not categorical data, you need to be explicit and convert the categorical data back to the original values:
In [124]: base = np.array([1,2,3])

In [125]: try:
    ....:     cat > base
    ....: except TypeError as e:
    ....:     print("TypeError: " + str(e))
    ....:
TypeError: Cannot compare a Categorical for op __gt__ with type <class 'numpy.ndarray'>.
If you want to compare values, use 'np.asarray(cat) <op> other'.

In [126]: np.asarray(cat) > base

Out[126]: array([False, False, False], dtype=bool)

When you compare two unordered categoricals with the same categories, the order is not considered:

In [127]: c1 = pd.Categorical(["a", "b"], categories=['a', 'b'], ordered=False)
In [128]: c2 = pd.Categorical(["a", "b"], categories=['b', 'a'], ordered=False)
In [129]: c1 == c2
Out[129]: array([ True, True], dtype=bool)

21.7 Operations

Apart from Series.min(), Series.max() and Series.mode(), the following operations are possible with categorical data:

Series methods like Series.value_counts() will use all categories, even if some categories are not present in the data:

In [130]: s = pd.Series(pd.Categorical(["a","b","c","c"], categories=['c','a','b','d']))
In [131]: s.value_counts()
Out[131]:
c    2
b    1
a    1
d    0
dtype: int64

Groupby will also show “unused” categories:

In [132]: cats = pd.Categorical(["a","b","b","b","c","c","c"], categories=['a','b','c',",","d"])
In [133]: df = pd.DataFrame({"cats":cats, "values" : [1,2,2,2,3,4,5]})
In [134]: df.groupby("cats").mean()
Out[134]:
       values
cats   
a    1.0
(continues on next page)
In [135]: cats2 = pd.Categorical(["a","a","b","b"], categories=["a","b","c"])  
In [136]: df2 = pd.DataFrame({"cats":cats2,"B":["c","d","c","d"], "values":[1,2,3,4]})  
In [137]: df2.groupby(["cats","B"]).mean()  
Out[137]:

<table>
<thead>
<tr>
<th>cats B</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>a c</td>
<td>1.0</td>
</tr>
<tr>
<td>d</td>
<td>2.0</td>
</tr>
<tr>
<td>b c</td>
<td>3.0</td>
</tr>
<tr>
<td>d</td>
<td>4.0</td>
</tr>
<tr>
<td>c c</td>
<td>NaN</td>
</tr>
<tr>
<td>d</td>
<td>NaN</td>
</tr>
</tbody>
</table>

Pivot tables:  
In [138]: raw_cat = pd.Categorical(["a","a","b","b"], categories=["a","b","c"])  
In [139]: df = pd.DataFrame({"A":raw_cat,"B":["c","d","c","d"], "values":[1,2,3,4]})  
In [140]: pd.pivot_table(df, values='values', index=['A', 'B'])  
Out[140]:

<table>
<thead>
<tr>
<th>A B</th>
<th>values</th>
</tr>
</thead>
<tbody>
<tr>
<td>a c</td>
<td>1</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
</tr>
<tr>
<td>b c</td>
<td>3</td>
</tr>
<tr>
<td>d</td>
<td>4</td>
</tr>
</tbody>
</table>

21.8 Data munging

The optimized pandas data access methods .loc, .iloc, .at, and .iat, work as normal. The only difference is the return type (for getting) and that only values already in categories can be assigned.

21.8.1 Getting

If the slicing operation returns either a DataFrame or a column of type Series, the category dtype is preserved.

In [141]: idx = pd.Index(["h","i","j","k","l","m","n",])  
In [142]: cats = pd.Series(["a","b","b","b","c","c","c"], dtype="category", index=idx)  
In [143]: values= [1,2,2,2,3,4,]  
In [144]: df = pd.DataFrame({"cats":cats,"values":values}, index=idx)  
In [145]: df.iloc[2:4,:]  
Out[145]:

(continues on next page)
cats  values
j  b  2
k  b  2

In [146]: df.iloc[2:4,:].dtypes
Out[146]:
cats  category
values  int64
dtype: object

In [147]: df.loc["h":"j","cats"]
Out[147]:
˓→
h a
i b
j b
Name: cats, dtype: category
Categories (3, object): [a, b, c]

In [148]: df[df["cats"] == "b"]
Out[148]:
˓→
cats  values
i  b  2
j  b  2
k  b  2

An example where the category type is not preserved is if you take one single row: the resulting Series is of dtype object:

# get the complete "h" row as a Series
In [149]: df.loc["h", :]
Out[149]:
cats  a
values  1
Name: h, dtype: object

Returning a single item from categorical data will also return the value, not a categorical of length “1”.

In [150]: df.iat[0,0]
Out[150]: 'a'

In [151]: df["cats"].cat.categories = ["x","y","z"]

In [152]: df.at["h","cats"] # returns a string
Out[152]: 'x'

Note: The is in contrast to R’s factor function, where factor(c(1,2,3))[1] returns a single value factor.

To get a single value Series of type category, you pass in a list with a single value:

In [153]: df.loc["h","cats"]
Out[153]:
h  x
21.8.2 String and datetime accessors

The accessors `.dt` and `.str` will work if the `s.cat.categories` are of an appropriate type:

```python
In [154]: str_s = pd.Series(list('aabb'))
In [155]: str_cat = str_s.astype('category')
In [156]: str_cat
Out[156]:
0  a
1  a
2  b
3  b
dtype: category
Categories (2, object): [a, b]
```

```python
In [157]: str_cat.str.contains("a")
Out[157]:
0   True
1   True
2  False
3  False
dtype: bool
```

```python
In [158]: date_s = pd.Series(pd.date_range('1/1/2015', periods=5))
In [159]: date_cat = date_s.astype('category')
In [160]: date_cat
Out[160]:
0  2015-01-01
1  2015-01-02
2  2015-01-03
3  2015-01-04
4  2015-01-05
dtype: category
```

```python
In [161]: date_cat.dt.day
Out[161]:
0   1
1   2
2   3
3   4
4   5
dtype: int64
```

Note: The returned Series (or DataFrame) is of the same type as if you used the `.str.<method>` / `.dt.`
<method> on a Series of that type (and not of type category!).

That means, that the returned values from methods and properties on the accessors of a Series and the returned values from methods and properties on the accessors of this Series transformed to one of type category will be equal:

```
In [162]: ret_s = str_s.str.contains("a")
In [163]: ret_cat = str_cat.str.contains("a")
In [164]: ret_s.dtype == ret_cat.dtype
Out[164]: True
In [165]: ret_s == ret_cat

Out[165]:
0    True
1    True
2    True
3    True
dtype: bool
```

**Note:** The work is done on the categories and then a new Series is constructed. This has some performance implication if you have a Series of type string, where lots of elements are repeated (i.e. the number of unique elements in the Series is a lot smaller than the length of the Series). In this case it can be faster to convert the original Series to one of type category and use .str.<method> or .dt.<property> on that.

### 21.8.3 Setting

Setting values in a categorical column (or Series) works as long as the value is included in the categories:

```
In [166]: idx = pd.Index(["h","i","j","k","l","m","n"])
In [167]: cats = pd.Categorical(["a","a","a","a","a","a","a"], categories=["a","b"], ordered=True)
In [168]: values = [1,1,1,1,1,1,1]
In [169]: df = pd.DataFrame({"cats":cats,"values":values}, index=idx)
In [170]: df.iloc[2:4,:] = [["b",2],["b",2]]
In [171]: df
Out[171]:
   cats  values
  h   a     1
  i   a     1
  j   b     2
  k   b     2
  l   a     1
  m   a     1
  n   a     1
In [172]: try:
.....:   df.iloc[2:4,:] = [["c",3],["c",3]]
```

(continues on next page)
```
......: except ValueError as e:
......:   print("ValueError: ", e)
......:
# Cannot setitem on a Categorical with a new category, set the categories first

Setting values by assigning categorical data will also check that the categories match:

```
In [173]: df.loc["j":"k","cats"] = pd.Categorical(["a","a"], categories=["a","b"],

In [174]: df
Out[174]:
cats values
h a 1
i a 1
j a 2
k a 2
l a 1
m a 1
n a 1

In [175]: try:
......:   df.loc["j":"k","cats"] = pd.Categorical(["b","b"], categories=["a","b",
˓→"c"])
......: except ValueError as e:
......:   print("ValueError: ", e)
......:
# Cannot set a Categorical with another, without identical categories

Assigning a Categorical to parts of a column of other types will use the values:
```
In [176]: df = pd.DataFrame({"a": [1,1,1,1,1], "b": ["a","a","a","a","a"]})

In [177]: df.loc[1:2,"a"] = pd.Categorical(["b","b"], categories=["a","b"])

In [178]: df.loc[2:3,"b"] = pd.Categorical(["b","b"], categories=["a","b"])

In [179]: df
Out[179]:
a  b
0 1 a
1 b a
2 b b
3 1 b
4 1 a

In [180]: df.dtypes
Out[180]:
a object
b object
dtype: object
```
## 21.8.4 Merging

You can concat two `DataFrames` containing categorical data together, but the categories of these categoricals need to be the same:

```python
In [181]: cat = pd.Series(["a","b"], dtype="category")
In [182]: vals = [1,2]
In [183]: df = pd.DataFrame({"cats":cat, "vals":vals})
In [184]: res = pd.concat([df,df])
In [185]: res
```

```
   cats  vals
0    a    1
1    b    2
0    a    1
1    b    2
```

```python
In [186]: res.dtypes
```

```
cats  category
vals   int64
```

dtype: object

In this case the categories are not the same, and therefore an error is raised:

```python
In [187]: df_different = df.copy()
In [188]: df_different["cats"].cat.categories = ["c","d"]
In [189]: try:
.....:     pd.concat([df,df_different])
.....: except ValueError as e:
.....:     print("ValueError: " + str(e))
```
By default, the resulting categories will be ordered as they appear in the data. If you want the categories to be lexsorted, use `sort_categories=True` argument.

```python
In [194]: union_categoricals([a, b], sort_categories=True)
Out[194]:
[a, b, a, b]
Categories (3, object): [a, b, c]
```

`union_categoricals` also works with the “easy” case of combining two categoricals of the same categories and order information (e.g. what you could also append for).

```python
In [195]: a = pd.Categorical(["a", "b"], ordered=True)
In [196]: b = pd.Categorical(["a", "b", "a"], ordered=True)
In [197]: union_categoricals([a, b])
Out[197]:
[a, b, a, b, a]
Categories (2, object): [a < b]
```

The below raises `TypeError` because the categories are ordered and not identical.

```python
In [1]: a = pd.Categorical(["a", "b"], ordered=True)
In [2]: b = pd.Categorical(["a", "b", "c"], ordered=True)
In [3]: union_categoricals([a, b])
Out[3]:
TypeError: to union ordered Categoricals, all categories must be the same
```

New in version 0.20.0.

Ordered categoricals with different categories or orderings can be combined by using the `ignore_ordered=True` argument.

```python
In [198]: a = pd.Categorical(["a", "b", "c"], ordered=True)
In [199]: b = pd.Categorical(["c", "b", "a"], ordered=True)
In [200]: union_categoricals([a, b], ignore_order=True)
Out[200]:
[a, b, c, c, b, a]
Categories (3, object): [a, b, c]
```

`union_categoricals()` also works with a `CategoricalIndex`, or `Series` containing categorical data, but note that the resulting array will always be a plain `Categorical`:

```python
In [201]: a = pd.Series(["b", "c"], dtype='category')
In [202]: b = pd.Series(["a", "b"], dtype='category')
In [203]: union_categoricals([a, b])
Out[203]:
[b, c, a, b]
Categories (3, object): [b, c, a]
```
### pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

**Note:** `union_categoricals` may recode the integer codes for categories when combining categoricals. This is likely what you want, but if you are relying on the exact numbering of the categories, be aware.

```python
In [204]: c1 = pd.Categorical(["b", "c"])
In [205]: c2 = pd.Categorical(["a", "b"])
In [206]: c1
Out[206]: [b, c]
Categories (2, object): [b, c]

# "b" is coded to 0
In [207]: c1.codes
Out[207]: array([0, 1], dtype=int8)

In [208]: c2
Out[208]: [a, b]
Categories (2, object): [a, b]

# "b" is coded to 1
In [209]: c2.codes
Out[209]: array([0, 1], dtype=int8)

In [210]: c = union_categoricals([c1, c2])
In [211]: c
Out[211]: [b, c, a, b]
Categories (3, object): [b, c, a]

# "b" is coded to 0 throughout, same as c1, different from c2
In [212]: c.codes
Out[212]: array([0, 1, 2, 0], dtype=int8)
```

### 21.8.6 Concatenation

This section describes concatenations specific to category dtype. See *Concatenating objects* for general description.

By default, Series or DataFrame concatenation which contains the same categories results in category dtype, otherwise results in object dtype. Use `.astype` or `union_categoricals` to get category result.

```python
# same categories
In [213]: s1 = pd.Series(['a', 'b'], dtype='category')
In [214]: s2 = pd.Series(['a', 'b', 'a'], dtype='category')
In [215]: pd.concat([s1, s2])
Out[215]:
0  a
```

(continues on next page)
Following table summarizes the results of Categoricals related concatenations.

<table>
<thead>
<tr>
<th>arg1</th>
<th>arg2</th>
<th>result</th>
</tr>
</thead>
<tbody>
<tr>
<td>category</td>
<td>category (identical categories)</td>
<td>category</td>
</tr>
<tr>
<td>category</td>
<td>category (different categories, both not ordered)</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category</td>
<td>category (different categories, either one is ordered)</td>
<td>object (dtype is inferred)</td>
</tr>
<tr>
<td>category</td>
<td>not category</td>
<td>object (dtype is inferred)</td>
</tr>
</tbody>
</table>

21.9 Getting Data In/Out

You can write data that contains category dtypes to a HDFStore. See here for an example and caveats.

It is also possible to write data to and reading data from Stata format files. See here for an example and caveats.

Writing to a CSV file will convert the data, effectively removing any information about the categorical (categories and ordering). So if you read back the CSV file you have to convert the relevant columns back to category and assign the right categories and categories ordering.

In [220]: s = pd.Series(pd.Categorical(['a', 'b', 'b', 'a', 'a', 'd']))

# rename the categories
In [221]: s.cat.categories = ["very good", "good", "bad"]

# reorder the categories and add missing categories
In [222]: s = s.cat.set_categories(["very bad", "bad", "medium", "good", "very good"])

In [223]: df = pd.DataFrame({"cats":s, "vals":[1,2,3,4,5,6]})

In [224]: csv = StringIO()

In [225]: df.to_csv(csv)

In [226]: df2 = pd.read_csv(StringIO(csv.getvalue()))

In [227]: df2.dtypes
Out[227]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Unnamed:</td>
<td>int64</td>
</tr>
<tr>
<td>cats</td>
<td>object</td>
</tr>
<tr>
<td>vals</td>
<td>int64</td>
</tr>
<tr>
<td>dtype:</td>
<td>object</td>
</tr>
</tbody>
</table>

In [228]: df2["cats"]

0  very good
1  good
2  good
3  very good
4  very good
5  bad
Name: cats, dtype: object

# Redo the category
In [229]: df2["cats"] = df2["cats"].astype("category")

In [230]: df2["cats"].cat.set_categories(["very bad", "bad", "medium", "good", "very good"], inplace=True)

In [231]: df2.dtypes
Out[231]:

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Unnamed:</td>
<td>int64</td>
</tr>
<tr>
<td>cats</td>
<td>category</td>
</tr>
<tr>
<td>vals</td>
<td>int64</td>
</tr>
<tr>
<td>dtype:</td>
<td>object</td>
</tr>
</tbody>
</table>

In [232]: df2["cats"]

0  very good
1  good
2  good
3  very good
4  very good
5  bad
Name: cats, dtype: category
Categories (5, object): [very bad, bad, medium, good, very good]
The same holds for writing to a SQL database with `to_sql`.

## 21.10 Missing Data

pandas primarily uses the value `np.nan` to represent missing data. It is by default not included in computations. See the Missing Data section.

Missing values should not be included in the Categorical’s `categories`, only in the `values`. Instead, it is understood that NaN is different, and is always a possibility. When working with the Categorical’s `codes`, missing values will always have a code of `-1`.

```python
In [233]: s = pd.Series(["a", "b", np.nan, "a"], dtype="category")

# only two categories
In [234]: s
Out[234]:
0    a
1    b
2    NaN
3    a
dtype: category
Categories (2, object): [a, b]

In [235]: s.cat.codes
Out[235]:
          0  1  2  3
0         0  1 -1  0
dtype: int8
```

Methods for working with missing data, e.g. `isna()`, `fillna()`, `dropna()`, all work normally:

```python
In [236]: s = pd.Series(["a", "b", np.nan], dtype="category")

In [237]: s
Out[237]:
0    a
1    b
2    NaN
dtype: category
Categories (2, object): [a, b]

In [238]: pd.isna(s)
Out[238]:
0   False
1   False
2    True
dtype: bool

In [239]: s.fillna("a")
Out[239]:
0    a
```

(continues on next page)
21.11 Differences to R’s factor

The following differences to R’s factor functions can be observed:

- R’s levels are named categories.
- R’s levels are always of type string, while categories in pandas can be of any dtype.
- It’s not possible to specify labels at creation time. Use `s.cat.rename_categories(new_labels)` afterwards.
- In contrast to R’s factor function, using categorical data as the sole input to create a new categorical series will not remove unused categories but create a new categorical series which is equal to the passed in one!
- R allows for missing values to be included in its levels (pandas’ categories). Pandas does not allow NaN categories, but missing values can still be in the values.

21.12 Gotchas

21.12.1 Memory Usage

The memory usage of a Categorical is proportional to the number of categories plus the length of the data. In contrast, an object dtype is a constant times the length of the data.

```python
In [240]: s = pd.Series(['foo','bar']*1000)

# object dtype
In [241]: s.nbytes
Out[241]: 16000

# category dtype
In [242]: s.astype('category').nbytes
Out[242]: 2016
```

Note: If the number of categories approaches the length of the data, the Categorical will use nearly the same or more memory than an equivalent object dtype representation.

```python
In [243]: s = pd.Series(['foo%04d' % i for i in range(2000)])

# object dtype
In [244]: s.nbytes
Out[244]: 16000

# category dtype
In [245]: s.astype('category').nbytes
Out[245]: 20000
```
21.12.2 *Categorical* is not a *numpy* array

Currently, categorical data and the underlying *Categorical* is implemented as a Python object and not as a low-level NumPy array dtype. This leads to some problems.

NumPy itself doesn’t know about the new *dtype*:

```
In [246]: try:
    .....:     np.dtype("category")
    .....:     except TypeError as e:
    .....:         print("TypeError: " + str(e))
    .....:
TypeError: data type "category" not understood
```

```
In [247]: dtype = pd.Categorical(["a"]).dtype
```

```
In [248]: try:
    .....:     np.dtype(dtype)
    .....:     except TypeError as e:
    .....:         print("TypeError: " + str(e))
    .....:
TypeError: data type not understood
```

Dtype comparisons work:

```
In [249]: dtype == np.str_
Out[249]: False
```

```
In [250]: np.str_ == dtype
```

```
To check if a Series contains Categorical data, use `hasattr(s, 'cat')`:
```
```
In [251]: hasattr(pd.Series(['a'], dtype='category'), 'cat')
Out[251]: True
```

```
In [252]: hasattr(pd.Series(['a']), 'cat')
```

Using NumPy functions on a *Series* of type *category* should not work as *Categoricals* are not numeric data (even in the case that `.categories` is numeric).

```
In [253]: s = pd.Series(pd.Categorical([1,2,3,4]))
```

```
In [254]: try:
    .....:     np.sum(s)
    .....:     except TypeError as e:
    .....:         print("TypeError: " + str(e))
    .....:
TypeError: Categorical cannot perform the operation sum
```

**Note:** If such a function works, please file a bug at https://github.com/pandas-dev/pandas!
21.12.3 dtype in apply

Pandas currently does not preserve the dtype in apply functions: If you apply along rows you get a Series of object dtype (same as getting a row -> getting one element will return a basic type) and applying along columns will also convert to object.

```
In [255]: df = pd.DataFrame({"a":[1,2,3,4],
                        ......:
                        "b":["a","b","c","d"],
                        ......:
                        "cats":pd.Categorical([1,2,3,2]))

In [256]: df.apply(lambda row: type(row["cats"]), axis=1)
Out[256]:
0  <class 'int'>
1  <class 'int'>
2  <class 'int'>
3  <class 'int'>
dtype: object

In [257]: df.apply(lambda col: col.dtype, axis=0)
Out[257]:
→
a  int64
b  object
cats  category
dtype: object
```

21.12.4 Categorical Index

CategoricalIndex is a type of index that is useful for supporting indexing with duplicates. This is a container around a Categorical and allows efficient indexing and storage of an index with a large number of duplicated elements. See the advanced indexing docs for a more detailed explanation.

Setting the index will create a CategoricalIndex:

```
In [258]: cats = pd.Categorical([1,2,3,4], categories=[4,2,3,1])

In [259]: strings = ["a","b","c","d"]

In [260]: values = [4,2,3,1]

In [261]: df = pd.DataFrame({"strings":strings, "values":values}, index=cats)

In [262]: df.index
Out[262]: CategoricalIndex([1, 2, 3, 4], categories=[4, 2, 3, 1], ordered=False, dtype='category')

# This now sorts by the categories order
In [263]: df.sort_index()
Out[263]:
→
strings  values
4   d   1
2   b   2
3   c   3
1   a   4
```

pandas: powerful Python data analysis toolkit, Release 0.23.0rc1
21.12.5 Side Effects

Constructing a Series from a Categorical will not copy the input Categorical. This means that changes to the Series will in most cases change the original Categorical:

```
In [264]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])
In [265]: s = pd.Series(cat, name="cat")
In [266]: cat
Out[266]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [267]: s.iloc[0:2] = 10
In [268]: cat
Out[268]:
[10, 10, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [269]: df = pd.DataFrame(s)
In [270]: df["cat"].cat.categories = [1,2,3,4,5]
In [271]: cat
Out[271]:
[5, 5, 3, 5]
Categories (5, int64): [1, 2, 3, 4, 5]
```

Use copy=True to prevent such a behaviour or simply don’t reuse Categoricals:

```
In [272]: cat = pd.Categorical([1,2,3,10], categories=[1,2,3,4,10])
In [273]: s = pd.Series(cat, name="cat", copy=True)
In [274]: cat
Out[274]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
In [275]: s.iloc[0:2] = 10
In [276]: cat
Out[276]:
[1, 2, 3, 10]
Categories (5, int64): [1, 2, 3, 4, 10]
```

Note: This also happens in some cases when you supply a NumPy array instead of a Categorical: using an int array (e.g. np.array([1,2,3,4])) will exhibit the same behavior, while using a string array (e.g. np.array(["a","b","c","a"])) will not.
VISUALIZATION

We use the standard convention for referencing the matplotlib API:

```python
In [1]: import matplotlib.pyplot as plt
```

We provide the basics in pandas to easily create decent looking plots. See the ecosystem section for visualization libraries that go beyond the basics documented here.

**Note:** All calls to `np.random` are seeded with 123456.

### 22.1 Basic Plotting: `plot`

We will demonstrate the basics, see the cookbook for some advanced strategies.

The `plot` method on Series and DataFrame is just a simple wrapper around `plt.plot()`:

```python
In [2]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', periods=1000))
In [3]: ts = ts.cumsum()
In [4]: ts.plot()
Out[4]: <matplotlib.axes._subplots.AxesSubplot at 0x1c292c4630>
```
If the index consists of dates, it calls `gcf().autofmt_xdate()` to try to format the x-axis nicely as per above.

On DataFrame, `plot()` is a convenience to plot all of the columns with labels:

```python
In [5]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list('ABCD'))
In [6]: df = df.cumsum()
In [7]: plt.figure(); df.plot();
```
You can plot one column versus another using the x and y keywords in `plot()`:

```python
In [8]: df3 = pd.DataFrame(np.random.randn(1000, 2), columns=['B', 'C']).cumsum()
In [9]: df3['A'] = pd.Series(list(range(len(df))))
In [10]: df3.plot(x='A', y='B')
```

Out[10]: `<matplotlib.axes._subplots.AxesSubplot at 0x1c25460be0>`
22.2 Other Plots

Plotting methods allow for a handful of plot styles other than the default line plot. These methods can be provided as the `kind` keyword argument to `plot()`, and include:

- `bar` or `barh` for bar plots
- `hist` for histogram
- `box` for boxplot
- `kde` or `density` for density plots
- `area` for area plots
- `scatter` for scatter plots
- `hexbin` for hexagonal bin plots
- `pie` for pie plots

For example, a bar plot can be created the following way:
You can also create these other plots using the methods `DataFrame.plot.<kind>` instead of providing the `kind` keyword argument. This makes it easier to discover plot methods and the specific arguments they use:

```
In [13]: df = pd.DataFrame()
In [14]: df.plot.<TAB>
df.plot.area  df.plot.barh  df.plot.density  df.plot.hist  df.plot.line
    df.plot.scatter
    df.plot.bar  df.plot.box  df.plot.hexbin  df.plot.kde  df.plot.pie
```

In addition to these `kind`s, there are the `DataFrame.hist()`, and `DataFrame.boxplot()` methods, which use a separate interface.

Finally, there are several `plotting functions` in the `pandas.plotting` module that take a `Series` or `DataFrame` as an argument. These include:

- Scatter Matrix
- Andrews Curves
- Parallel Coordinates
- Lag Plot
• Autocorrelation Plot
• Bootstrap Plot
• RadViz

Plots may also be adorned with errorbars or tables.

### 22.2.1 Bar plots

For labeled, non-time series data, you may wish to produce a bar plot:

```python
In [15]: plt.figure();

In [16]: df.iloc[5].plot.bar(); plt.axhline(0, color='k')
Out[16]: <matplotlib.lines.Line2D at 0x1c33d7a320>
```

Calling a DataFrame’s `plot.bar()` method produces a multiple bar plot:

```python
In [17]: df2 = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [18]: df2.plot.bar();
```
To produce a stacked bar plot, pass `stacked=True`:

```python
In [19]: df2.plot.bar(stacked=True);
```
To get horizontal bar plots, use the `barh` method:

```python
In [20]: df2.plot.barh(stacked=True);
```
22.2.2 Histograms

Histograms can be drawn by using the `DataFrame.plot.hist()` and `Series.plot.hist()` methods.

In [21]: df4 = pd.DataFrame({'a': np.random.randn(1000) + 1, 'b': np.random.randn(1000),
                      'c': np.random.randn(1000) - 1}, columns=['a', 'b', 'c'])

In [22]: plt.figure();

In [23]: df4.plot.hist(alpha=0.5)
Out[23]: <matplotlib.axes._subplots.AxesSubplot at 0x1c32642550>
A histogram can be stacked using `stacked=True`. Bin size can be changed using the `bins` keyword.

```
In [24]: plt.figure();

In [25]: df4.plot.hist(stacked=True, bins=20)
Out[25]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2545f0b8>
```
You can pass other keywords supported by matplotlib `hist`. For example, horizontal and cumulative histograms can be drawn by `orientation='horizontal'` and `cumulative=True`.

```
In [26]: plt.figure();

In [27]: df4['a'].plot.hist(orientation='horizontal', cumulative=True)
Out[27]: <matplotlib.axes._subplots.AxesSubplot at 0x1c215a4cf8>
```
See the `hist` method and the matplotlib `hist` documentation for more.

The existing interface `DataFrame.hist` to plot histogram still can be used.

```python
In [28]: plt.figure();

In [29]: df['A'].diff().hist()
Out[29]: <matplotlib.axes._subplots.AxesSubplot at 0x1c33ed7f98>
```
**DataFrame.hist()** plots the histograms of the columns on multiple subplots:

In [30]: plt.figure()
Out[30]: <Figure size 640x480 with 0 Axes>

In [31]: df.diff().hist(color='k', alpha=0.5, bins=50)
Out[31]: array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c3343d9b0>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c32c4a198>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x1c33322518>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c34910198>]],
       dtype=object)
The `by` keyword can be specified to plot grouped histograms:

```python
In [32]: data = pd.Series(np.random.randn(1000))
In [33]: data.hist(by=np.random.randint(0, 4, 1000), figsize=(6, 4))
Out[33]:
array([[<matplotlib.axes._subplots.AxesSubplot object at 0x1c327a7e80>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c2aae3be0>],
       [<matplotlib.axes._subplots.AxesSubplot object at 0x1c32ae63c8>,
        <matplotlib.axes._subplots.AxesSubplot object at 0x1c32aa2eb8>]],
       dtype=object)
```
22.2.3 Box Plots

Boxplot can be drawn calling `Series.plot.box()` and `DataFrame.plot.box()`, or `DataFrame.boxplot()` to visualize the distribution of values within each column.

For instance, here is a boxplot representing five trials of 10 observations of a uniform random variable on [0,1).

```
In [34]: df = pd.DataFrame(np.random.rand(10, 5), columns=['A', 'B', 'C', 'D', 'E'])
In [35]: df.plot.box()
Out[35]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2d1499e8>
```
Boxplot can be colorized by passing `color` keyword. You can pass a `dict` whose keys are `boxes`, `whiskers`, `medians` and `caps`. If some keys are missing in the `dict`, default colors are used for the corresponding artists. Also, boxplot has `sym` keyword to specify fliers style.

When you pass other type of arguments via `color` keyword, it will be directly passed to matplotlib for all the `boxes`, `whiskers`, `medians` and `caps` colorization.

The colors are applied to every boxes to be drawn. If you want more complicated colorization, you can get each drawn artists by passing `return_type`.

```python
In [36]: color = dict(boxes='DarkGreen', whiskers='DarkOrange',
    ....:         medians='DarkBlue', caps='Gray')
    ....:

In [37]: df.plot.box(color=color, sym='r+')
Out[37]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2f5a8780>
```
Also, you can pass other keywords supported by matplotlib `boxplot`. For example, horizontal and custom-positioned boxplot can be drawn by `vert=False` and `positions` keywords.

```
In [38]: df.plot.box(vert=False, positions=[1, 4, 5, 6, 8])
Out[38]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2d24c5f8>
```
See the `boxplot` method and the `matplotlib` boxplot documentation for more.

The existing interface `DataFrame.boxplot` to plot boxplot still can be used.

```python
In [39]: df = pd.DataFrame(np.random.rand(10,5))
In [40]: plt.figure();
In [41]: bp = df.boxplot()
```
You can create a stratified boxplot using the `by` keyword argument to create groupings. For instance,

```
In [42]: df = pd.DataFrame(np.random.rand(10,2), columns=['Col1', 'Col2'])
In [43]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [44]: plt.figure();
In [45]: bp = df.boxplot(by='X')
```
You can also pass a subset of columns to plot, as well as group by multiple columns:

```python
In [46]: df = pd.DataFrame(np.random.rand(10,3), columns=['Col1', 'Col2', 'Col3'])
In [47]: df['X'] = pd.Series(['A','A','A','A','A','B','B','B','B','B'])
In [48]: df['Y'] = pd.Series(['A','B','A','B','A','B','A','B','A','B'])
In [49]: plt.figure();
In [50]: bp = df.boxplot(column=['Col1','Col2'], by=['X','Y'])
```
Warning: The default changed from 'dict' to 'axes' in version 0.19.0.

In `boxplot`, the return type can be controlled by the `return_type` keyword. The valid choices are {'axes', 'dict', 'both', None}. Faceting, created by `DataFrame.boxplot` with the `by` keyword, will affect the output type as well:

<table>
<thead>
<tr>
<th><code>return_type</code></th>
<th>Faceted</th>
<th>Output type</th>
</tr>
</thead>
<tbody>
<tr>
<td>None</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>None</td>
<td>Yes</td>
<td>2-D ndarray of axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>No</td>
<td>axes</td>
</tr>
<tr>
<td>'axes'</td>
<td>Yes</td>
<td>Series of axes</td>
</tr>
<tr>
<td>'dict'</td>
<td>No</td>
<td>dict of artists</td>
</tr>
<tr>
<td>'dict'</td>
<td>Yes</td>
<td>Series of dicts of artists</td>
</tr>
<tr>
<td>'both'</td>
<td>No</td>
<td>namedtuple</td>
</tr>
<tr>
<td>'both'</td>
<td>Yes</td>
<td>Series of namedtuples</td>
</tr>
</tbody>
</table>

`Groupby.boxplot` always returns a Series of `return_type`.

```python
In [51]: np.random.seed(1234)

In [52]: df_box = pd.DataFrame(np.random.randn(50, 2))
```
In [53]: df_box['g'] = np.random.choice(['A', 'B'], size=50)
In [54]: df_box.loc[df_box['g'] == 'B', 1] += 3
In [55]: bp = df_box.boxplot(by='g')

The subplots above are split by the numeric columns first, then the value of the g column. Below the subplots are first split by the value of g, then by the numeric columns.

In [56]: bp = df_box.groupby('g').boxplot()
22.2.4 Area Plot

You can create area plots with `Series.plot.area()` and `DataFrame.plot.area()`. Area plots are stacked by default. To produce stacked area plot, each column must be either all positive or all negative values.

When input data contains NaN, it will be automatically filled by 0. If you want to drop or fill by different values, use `dataframe.dropna()` or `dataframe.fillna()` before calling `plot`.

```python
In [57]: df = pd.DataFrame(np.random.rand(10, 4), columns=['a', 'b', 'c', 'd'])
In [58]: df.plot.area();
```
To produce an unstacked plot, pass `stacked=False`. Alpha value is set to 0.5 unless otherwise specified:

```
In [59]: df.plot.area(stacked=False);
```
22.2.5 Scatter Plot

Scatter plot can be drawn by using the `DataFrame.plot.scatter()` method. Scatter plot requires numeric columns for the x and y axes. These can be specified by the x and y keywords.

```
In [60]: df = pd.DataFrame(np.random.rand(50, 4), columns=['a', 'b', 'c', 'd'])
In [61]: df.plot.scatter(x='a', y='b');
```
To plot multiple column groups in a single axes, repeat `plot` method specifying target `ax`. It is recommended to specify `color` and `label` keywords to distinguish each groups.

```
In [62]: ax = df.plot.scatter(x='a', y='b', color='DarkBlue', label='Group 1');
In [63]: df.plot.scatter(x='c', y='d', color='DarkGreen', label='Group 2', ax=ax);
```
The keyword `c` may be given as the name of a column to provide colors for each point:

```
In [64]: df.plot.scatter(x='a', y='b', c='c', s=50);
```
You can pass other keywords supported by matplotlib `scatter`. The example below shows a bubble chart using a column of the DataFrame as the bubble size.

```
In [65]: df.plot.scatter(x='a', y='b', s=df['c']*200);
```
You can create hexagonal bin plots with `DataFrame.plot.hexbin()`. Hexbin plots can be a useful alternative to scatter plots if your data are too dense to plot each point individually.

```python
In [66]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [67]: df['b'] = df['b'] + np.arange(1000)
In [68]: df.plot.hexbin(x='a', y='b', gridsize=25)
Out[68]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3373ed30>
```
A useful keyword argument is gridsize; it controls the number of hexagons in the x-direction, and defaults to 100. A larger gridsize means more, smaller bins.

By default, a histogram of the counts around each \((x, y)\) point is computed. You can specify alternative aggregations by passing values to the \(C\) and reduce\_C\_function arguments. \(C\) specifies the value at each \((x, y)\) point and reduce\_C\_function is a function of one argument that reduces all the values in a bin to a single number (e.g. mean, max, sum, std). In this example the positions are given by columns \(a\) and \(b\), while the value is given by column \(z\). The bins are aggregated with NumPy’s max function.

```python
In [69]: df = pd.DataFrame(np.random.randn(1000, 2), columns=['a', 'b'])
In [70]: df['b'] = df['b'] = df['b'] + np.arange(1000)
In [71]: df['z'] = np.random.uniform(0, 3, 1000)
In [72]: df.plot.hexbin(x='a', y='b', C='z', reduce_C_function=np.max,
          ....:           gridsize=25)
          ....:
Out[72]: <matplotlib.axes._subplots.AxesSubplot at 0x1c336ec198>
```
See the `hexbin` method and the matplotlib hexbin documentation for more.

### 22.2.7 Pie plot

You can create a pie plot with `DataFrame.plot.pie()` or `Series.plot.pie()`. If your data includes any NaN, they will be automatically filled with 0. A `ValueError` will be raised if there are any negative values in your data.

```python
In [73]: series = pd.Series(3 * np.random.rand(4), index=['a', 'b', 'c', 'd'], name='series')

In [74]: series.plot.pie(figsize=(6, 6))
Out[74]: <matplotlib.axes._subplots.AxesSubplot at 0x1c324bf00>
```
For pie plots it’s best to use square figures, i.e. a figure aspect ratio 1. You can create the figure with equal width and height, or force the aspect ratio to be equal after plotting by calling `ax.set_aspect('equal')` on the returned axes object.

Note that pie plot with `DataFrame` requires that you either specify a target column by the `y` argument or `subplots=True`. When `y` is specified, pie plot of selected column will be drawn. If `subplots=True` is specified, pie plots for each column are drawn as subplots. A legend will be drawn in each pie plots by default; specify `legend=False` to hide it.

```
In [75]: df = pd.DataFrame(3 * np.random.rand(4, 2), index=['a', 'b', 'c', 'd'],
                     columns=['x', 'y'])

In [76]: df.plot.pie(subplots=True, figsize=(8, 4))
Out[76]:
array([<matplotlib.axes._subplots.AxesSubplot object at 0x1c2f564ba8>,
       <matplotlib.axes._subplots.AxesSubplot object at 0x181eed3fd0>], dtype=object)
```
You can use the `labels` and `colors` keywords to specify the labels and colors of each wedge.

**Warning:** Most pandas plots use the `label` and `color` arguments (note the lack of “s” on those). To be consistent with `matplotlib.pyplot.pie()` you must use `labels` and `colors`.

If you want to hide wedge labels, specify `labels=None`. If `fontsize` is specified, the value will be applied to wedge labels. Also, other keywords supported by `matplotlib.pyplot.pie()` can be used.

```python
In [77]: series.plot.pie(labels=['AA', 'BB', 'CC', 'DD'], colors=['r', 'g', 'b', 'c'], ...
   ...:     autopct='%.2f', fontsize=20, figsize=(6, 6))
   ...
Out[77]: <matplotlib.axes._subplots.AxesSubplot at 0x1c27bb4748>
```
If you pass values whose sum total is less than 1.0, matplotlib draws a semicircle.

\[\text{In [78]}\] series = pd.Series([0.1] * 4, index=['a', 'b', 'c', 'd'], name='series2')

\[\text{In [79]}\] series.plot.pie(figsize=(6, 6))

\[\text{Out [79]}\] <matplotlib.axes._subplots.AxesSubplot at 0x1c281cf898>
See the matplotlib pie documentation for more.

### 22.3 Plotting with Missing Data

Pandas tries to be pragmatic about plotting **DataFrames** or **Series** that contain missing data. Missing values are dropped, left out, or filled depending on the plot type.
### 22.4 Plotting Tools

These functions can be imported from `pandas.plotting` and take a `Series` or `DataFrame` as an argument.

#### 22.4.1 Scatter Matrix Plot

You can create a scatter plot matrix using the `scatter_matrix` method in `pandas.plotting`:

```python
In [80]: from pandas.plotting import scatter_matrix

In [81]: df = pd.DataFrame(np.random.randn(1000, 4), columns=['a', 'b', 'c', 'd'])

In [82]: scatter_matrix(df, alpha=0.2, figsize=(6, 6), diagonal='kde')
```

If any of these defaults are not what you want, or if you want to be explicit about how missing values are handled, consider using `fillna()` or `dropna()` before plotting.
22.4.2 Density Plot

You can create density plots using the `Series.plot.kde()` and `DataFrame.plot.kde()` methods.

```python
In [83]: ser = pd.Series(np.random.randn(1000))
In [84]: ser.plot.kde()
Out[84]: <matplotlib.axes._subplots.AxesSubplot at 0x1c2db16358>
```
Andrews curves allow one to plot multivariate data as a large number of curves that are created using the attributes of samples as coefficients for Fourier series, see the Wikipedia entry for more information. By coloring these curves differently for each class it is possible to visualize data clustering. Curves belonging to samples of the same class will usually be closer together and form larger structures.

Note: The “Iris” dataset is available here.
22.4.4 Parallel Coordinates

Parallel coordinates is a plotting technique for plotting multivariate data, see the Wikipedia entry for an introduction. Parallel coordinates allows one to see clusters in data and to estimate other statistics visually. Using parallel coordinates points are represented as connected line segments. Each vertical line represents one attribute. One set of connected line segments represents one data point. Points that tend to cluster will appear closer together.

```python
In [89]: from pandas.plotting import parallel_coordinates
In [90]: data = pd.read_csv('data/iris.data')
In [91]: plt.figure()
Out[91]: <Figure size 640x480 with 0 Axes>
In [92]: parallel_coordinates(data, 'Name')
```

```
\endas\AxesSubplot at 0xc34b7a58>
```
22.4.5 Lag Plot

Lag plots are used to check if a data set or time series is random. Random data should not exhibit any structure in the lag plot. Non-random structure implies that the underlying data are not random. The lag argument may be passed, and when lag=1 the plot is essentially data[:-1] vs. data[1:].

```python
In [93]: from pandas.plotting import lag_plot
In [94]: plt.figure()
Out[94]: <Figure size 640x480 with 0 Axes>
In [95]: data = pd.Series(0.1 * np.random.rand(1000) +
   ....: 0.9 * np.sin(np.linspace(-99 * np.pi, 99 * np.pi, num=1000)))
   ....:
In [96]: lag_plot(data)
Out[96]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38af6940>
```
22.4.6 Autocorrelation Plot

Autocorrelation plots are often used for checking randomness in time series. This is done by computing autocorrelations for data values at varying time lags. If time series is random, such autocorrelations should be near zero for any and all time-lag separations. If time series is non-random then one or more of the autocorrelations will be significantly non-zero. The horizontal lines displayed in the plot correspond to 95% and 99% confidence bands. The dashed line is 99% confidence band. See the Wikipedia entry for more about autocorrelation plots.

```python
In [97]: from pandas.plotting import autocorrelation_plot

In [98]: plt.figure()
Out[98]: <Figure size 640x480 with 0 Axes>

In [99]: data = pd.Series(0.7 * np.random.rand(1000) +
                      0.3 * np.sin(np.linspace(-9 * np.pi, 9 * np.pi, num=1000)))

In [100]: autocorrelation_plot(data)
Out[100]: <matplotlib.axes._subplots.AxesSubplot at 0x1c38af6d68>
```
22.4.7 Bootstrap Plot

Bootstrap plots are used to visually assess the uncertainty of a statistic, such as mean, median, midrange, etc. A random subset of a specified size is selected from a data set, the statistic in question is computed for this subset and the process is repeated a specified number of times. Resulting plots and histograms are what constitutes the bootstrap plot.

```python
In [101]: from pandas.plotting import bootstrap_plot

In [102]: data = pd.Series(np.random.rand(1000))

In [103]: bootstrap_plot(data, size=50, samples=500, color='grey')
```

Out[103]: <Figure size 640x480 with 6 Axes>
22.4.8 RadViz

RadViz is a way of visualizing multi-variate data. It is based on a simple spring tension minimization algorithm. Basically you set up a bunch of points in a plane. In our case they are equally spaced on a unit circle. Each point represents a single attribute. You then pretend that each sample in the data set is attached to each of these points by a spring, the stiffness of which is proportional to the numerical value of that attribute (they are normalized to unit interval). The point in the plane, where our sample settles to (where the forces acting on our sample are at an equilibrium) is where a dot representing our sample will be drawn. Depending on which class that sample belongs it will be colored differently. See the R package Radviz for more information.

Note: The “Iris” dataset is available here.

In [104]: from pandas.plotting import radviz

In [105]: data = pd.read_csv('data/iris.data')

In [106]: plt.figure()
Out[106]: <Figure size 640x480 with 0 Axes>

In [107]: radviz(data, 'Name')

---

22.4. Plotting Tools 1075
22.5 Plot Formatting

22.5.1 Setting the plot style

From version 1.5 and up, matplotlib offers a range of preconfigured plotting styles. Setting the style can be used to easily give plots the general look that you want. Setting the style is as easy as calling `matplotlib.style.use(my_plot_style)` before creating your plot. For example you could write `matplotlib.style.use('ggplot')` for ggplot-style plots.

You can see the various available style names at `matplotlib.style.available` and it’s very easy to try them out.

22.5.2 General plot style arguments

Most plotting methods have a set of keyword arguments that control the layout and formatting of the returned plot:

```python
In [108]: plt.figure(); ts.plot(style='k--', label='Series');
```
For each kind of plot (e.g. line, bar, scatter) any additional arguments keywords are passed along to the corresponding matplotlib function (ax.plot(), ax.bar(), ax.scatter()). These can be used to control additional styling, beyond what pandas provides.

### 22.5.3 Controlling the Legend

You may set the `legend` argument to `False` to hide the legend, which is shown by default.

```
In [109]: df = pd.DataFrame(np.random.randn(1000, 4), index=ts.index, columns=list('ABCD'))

In [110]: df = df.cumsum()

In [111]: df.plot(legend=False)
Out[111]: <matplotlib.axes._subplots.AxesSubplot at 0x1c39669550>
```
22.5.4 Scales

You may pass `logy` to get a log-scale Y axis.

```python
In [112]: ts = pd.Series(np.random.randn(1000), index=pd.date_range('1/1/2000', periods=1000))

In [113]: ts = np.exp(ts.cumsum())

In [114]: ts.plot(logy=True)
Out[114]: <matplotlib.axes._subplots.AxesSubplot at 0x1c39746438>
```
22.5.5 Plotting on a Secondary Y-axis

To plot data on a secondary y-axis, use the `secondary_y` keyword:

```
In [115]: df.A.plot()
Out[115]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3992d7b8>

In [116]: df.B.plot(secondary_y=True, style='g')
```

See also the `logx` and `loglog` keyword arguments.
To plot some columns in a DataFrame, give the column names to the secondary_y keyword:

```python
In [117]: plt.figure()
Out[117]: <Figure size 640x480 with 0 Axes>

In [118]: ax = df.plot(secondary_y=['A', 'B'])

In [119]: ax.set_ylabel('CD scale')
Out[119]: Text(0,0.5,'CD scale')

In [120]: ax.right_ax.set_ylabel('AB scale')
Out[120]: Text(0,0.5,'AB scale')
```
Note that the columns plotted on the secondary y-axis is automatically marked with “(right)” in the legend. To turn off the automatic marking, use the `mark_right=False` keyword:

```python
In [121]: plt.figure()
Out[121]: <Figure size 640x480 with 0 Axes>

In [122]: df.plot(secondary_y=['A', 'B'], mark_right=False)
```

```
Out[122]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3a43c4a8>
```
22.5.6 Suppressing Tick Resolution Adjustment

pandas includes automatic tick resolution adjustment for regular frequency time-series data. For limited cases where pandas cannot infer the frequency information (e.g., in an externally created twinx), you can choose to suppress this behavior for alignment purposes.

Here is the default behavior, notice how the x-axis tick labeling is performed:

```python
In [123]: plt.figure()
Out[123]: <Figure size 640x480 with 0 Axes>
In [124]: df.A.plot()
```

```matlab
Out[124]: <matplotlib.axes._subplots.AxesSubplot at 0x1c394f1da0>
```
Using the `x_compat` parameter, you can suppress this behavior:

```python
In [125]: plt.figure()
Out[125]: <Figure size 640x480 with 0 Axes>

In [126]: df.A.plot(x_compat=True)
```

```
\\\\\\\\\\\\\\\\\\\\\\\Out[126]: <matplotlib.axes._subplots
˓→AxesSubplot at 0x1c2ccb25f8>
```
If you have more than one plot that needs to be suppressed, the `use` method in `pandas.plotting.plot_params` can be used in a `with` statement:

```python
In [127]: plt.figure()
Out[127]: <Figure size 640x480 with 0 Axes>

In [128]: with pd.plotting.plot_params.use('x_compat', True):
    ....:     df.A.plot(color='r')
    ....:     df.B.plot(color='g')
    ....:     df.C.plot(color='b')
    ....:     
```
22.5.7 Automatic Date Tick Adjustment

New in version 0.20.0.

TimedeltaIndex now uses the native matplotlib tick locator methods, it is useful to call the automatic date tick adjustment from matplotlib for figures whose ticklabels overlap.

See the `autofmt_xdate` method and the matplotlib documentation for more.

22.5.8 Subplots

Each Series in a DataFrame can be plotted on a different axis with the `subplots` keyword:

```python
In [129]: df.plot(subplots=True, figsize=(6, 6));
```
22.5.9 Using Layout and Targeting Multiple Axes

The layout of subplots can be specified by the `layout` keyword. It can accept `(rows, columns)`. The `layout` keyword can be used in `hist` and `boxplot` also. If the input is invalid, a `ValueError` will be raised.

The number of axes which can be contained by rows x columns specified by `layout` must be larger than the number of required subplots. If layout can contain more axes than required, blank axes are not drawn. Similar to a NumPy array’s `reshape` method, you can use `-1` for one dimension to automatically calculate the number of rows or columns needed, given the other.

```
In [130]: df.plot(subplots=True, layout=(2, 3), figsize=(6, 6), sharex=False);
```
The above example is identical to using:

```
In [131]: df.plot(subplots=True, layout=(2, -1), figsize=(6, 6), sharex=False);
```

The required number of columns (3) is inferred from the number of series to plot and the given number of rows (2).

You can pass multiple axes created beforehand as list-like via `ax` keyword. This allows more complicated layouts. The passed axes must be the same number as the subplots being drawn.

When multiple axes are passed via the `ax` keyword, `layout`, `sharex` and `sharey` keywords don’t affect to the output. You should explicitly pass `sharex=False` and `sharey=False`, otherwise you will see a warning.

```
In [132]: fig, axes = plt.subplots(4, 4, figsize=(6, 6));

In [133]: plt.subplots_adjust(wspace=0.5, hspace=0.5);

In [134]: target1 = [axes[0][0], axes[1][1], axes[2][2], axes[3][3]]
```
Another option is passing an `ax` argument to `Series.plot()` to plot on a particular axis:

```python
In [138]: fig, axes = plt.subplots(nrows=2, ncols=2)
In [139]: df['A'].plot(ax=axes[0,0]); axes[0,0].set_title('A');
In [140]: df['B'].plot(ax=axes[0,1]); axes[0,1].set_title('B');
```

(continues on next page)
22.5.10 Plotting With Error Bars

Plotting with error bars is supported in `DataFrame.plot()` and `Series.plot()`.

Horizontal and vertical error bars can be supplied to the `xerr` and `yerr` keyword arguments to `plot()`. The error values can be specified using a variety of formats:

- As a `DataFrame` or `dict` of errors with column names matching the `columns` attribute of the plotting `DataFrame` or matching the `name` attribute of the `Series`.
- As a `str` indicating which of the columns of plotting `DataFrame` contain the error values.
- As raw values (`list`, `tuple`, or `np.ndarray`). Must be the same length as the plotting `DataFrame/Series`.

Asymmetrical error bars are also supported, however raw error values must be provided in this case. For a `M` length `Series`, a `Mx2` array should be provided indicating lower and upper (or left and right) errors. For a `MxN` `DataFrame`, asymmetrical errors should be in a `Mx2xN` array.

Here is an example of one way to easily plot group means with standard deviations from the raw data.
# Generate the data
In [143]: ix3 = pd.MultiIndex.from_arrays([['a', 'a', 'a', 'a', 'b', 'b', 'b', 'b'], ['foo', 'foo', 'bar', 'bar', 'foo', 'foo', 'bar', 'bar']], names=['letter', 'word'])

In [144]: df3 = pd.DataFrame({'data1': [3, 2, 4, 3, 2, 4, 3, 2], 'data2': [6, 5, 7, 5, 4, 5, 6, 5]}, index=ix3)

# Group by index labels and take the means and standard deviations for each group
In [145]: gp3 = df3.groupby(level=('letter', 'word'))

In [146]: means = gp3.mean()
In [147]: errors = gp3.std()

In [148]: means
Out[148]:
    data1  data2
letter  word
  a   bar   3.5   6.0
    foo   2.5   5.5
  b   bar   2.5   5.5
    foo   3.0   4.5

In [149]: errors

In [150]: fig, ax = plt.subplots()

In [151]: means.plot.bar(yerr=errors, ax=ax)
Out[151]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3b449b38>
22.5.11 Plotting Tables

Plotting with matplotlib table is now supported in `DataFrame.plot()` and `Series.plot()` with a `table` keyword. The `table` keyword can accept `bool`, `DataFrame` or `Series`. The simple way to draw a table is to specify `table=True`. Data will be transposed to meet matplotlib's default layout.

```
In [152]: fig, ax = plt.subplots(1, 1)

In [153]: df = pd.DataFrame(np.random.rand(5, 3), columns=['a', 'b', 'c'])

In [154]: ax.get_xaxis().set_visible(False) # Hide Ticks

In [155]: df.plot(table=True, ax=ax)
```

```
Out[155]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3b4de0b8>
```
Also, you can pass a different `DataFrame` or `Series` to the `table` keyword. The data will be drawn as displayed in print method (not transposed automatically). If required, it should be transposed manually as seen in the example below.

```
In [156]: fig, ax = plt.subplots(1, 1)

In [157]: ax.get_xaxis().set_visible(False)  # Hide Ticks

In [158]: df.plot(table=np.round(df.T, 2), ax=ax)
Out[158]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3b56d4a8>
```
There also exists a helper function `pandas.plotting.table`, which creates a table from `DataFrame` or `Series`, and adds it to a `matplotlib.Axes` instance. This function can accept keywords which the `matplotlib` table has.

```python
In [159]: from pandas.plotting import table

In [160]: fig, ax = plt.subplots(1, 1)

In [161]: table(ax, np.round(df.describe(), 2),
               loc='upper right', colWidths=[0.2, 0.2, 0.2])

Out[161]: <matplotlib.table.Table at 0x1c3b633208>

In [162]: df.plot(ax=ax, ylim=(0, 2), legend=None)
```

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>0.13</td>
<td>0.9</td>
<td>0.45</td>
<td>0.54</td>
<td>0.13</td>
</tr>
<tr>
<td>B</td>
<td>0.97</td>
<td>0.38</td>
<td>0.84</td>
<td>0.37</td>
<td>0.86</td>
</tr>
</tbody>
</table>

22.5. Plot Formatting
Note: You can get table instances on the axes using `axes.tables` property for further decorations. See the matplotlib table documentation for more.

### 22.5.12 Colormaps

A potential issue when plotting a large number of columns is that it can be difficult to distinguish some series due to repetition in the default colors. To remedy this, DataFrame plotting supports the use of the `colormap` argument, which accepts either a Matplotlib colormap or a string that is a name of a colormap registered with Matplotlib. A visualization of the default matplotlib colormaps is available here.

As matplotlib does not directly support colormaps for line-based plots, the colors are selected based on an even spacing determined by the number of columns in the DataFrame. There is no consideration made for background color, so some colormaps will produce lines that are not easily visible.

To use the cubehelix colormap, we can pass `colormap='cubehelix'`.

In [163]: df = pd.DataFrame(np.random.randn(1000, 10), index=ts.index)
In [164]: df = df.cumsum()
In [165]: plt.figure()
Out[165]: <Figure size 640x480 with 0 Axes>
In [166]: df.plot(colormap='cubehelix')

(continues on next page)
Alternatively, we can pass the colormap itself:

```python
In [167]: from matplotlib import cm

In [168]: plt.figure()
Out[168]: <Figure size 640x480 with 0 Axes>

In [169]: df.plot(colormap=cm.cubehelix)
```

![Plot example](image-url)
Colormaps can also be used with other plot types, like bar charts:

```python
In [170]: dd = pd.DataFrame(np.random.randn(10, 10)).applymap(abs)
In [171]: dd = dd.cumsum()
In [172]: plt.figure()
Out[172]: <Figure size 640x480 with 0 Axes>
In [173]: dd.plot.bar(colormap='Greens')
```

1096 Chapter 22. Visualization
Parallel coordinates charts:

```
In [174]: plt.figure()
Out[174]: <Figure size 640x480 with 0 Axes>

In [175]: parallel_coordinates(data, 'Name', colormap='gist_rainbow')
```

Image of a parallel coordinates chart.
Andrews curves charts:

```
In [176]: plt.figure()
Out[176]: <Figure size 640x480 with 0 Axes>

In [177]: andrews_curves(data, 'Name', colormap='winter')
Out[177]: <matplotlib.axes._subplots.AxesSubplot at 0x1c3bffb5f8>
```
22.6 Plotting directly with matplotlib

In some situations it may still be preferable or necessary to prepare plots directly with matplotlib, for instance when a certain type of plot or customization is not (yet) supported by pandas. Series and DataFrame objects behave like arrays and can therefore be passed directly to matplotlib functions without explicit casts.

pandas also automatically registers formatters and locators that recognize date indices, thereby extending date and time support to practically all plot types available in matplotlib. Although this formatting does not provide the same level of refinement you would get when plotting via pandas, it can be faster when plotting a large number of points.

```python
In [178]: price = pd.Series(np.random.randn(150).cumsum(),
       index=pd.date_range('2000-1-1', periods=150, freq='B'))
       .....:
In [179]: ma = price.rolling(20).mean()
In [180]: mstd = price.rolling(20).std()
In [181]: plt.figure()
Out [181]: <Figure size 640x480 with 0 Axes>
In [182]: plt.plot(price.index, price, 'k')
```

(continues on next page)
22.7 Trellis plotting interface

**Warning:** The rplot trellis plotting interface has been removed. Please use external packages like seaborn for similar but more refined functionality and refer to our 0.18.1 documentation here for how to convert to using it.
New in version 0.17.1

Provisional: This is a new feature and still under development. We’ll be adding features and possibly making breaking changes in future releases. We’d love to hear your feedback.

This document is written as a Jupyter Notebook, and can be viewed or downloaded here.

You can apply conditional formatting, the visual styling of a DataFrame depending on the data within, by using the DataFrame.style property. This is a property that returns a Styler object, which has useful methods for formatting and displaying DataFrames.

The styling is accomplished using CSS. You write “style functions” that take scalars, DataFrames or Series, and return like-indexed DataFrames or Series with CSS “attribute: value” pairs for the values. These functions can be incrementally passed to the Styler which collects the styles before rendering.

### 23.1 Building Styles

Pass your style functions into one of the following methods:

- Styler.applymap: elementwise
- Styler.apply: column-/row-/table-wise

Both of those methods take a function (and some other keyword arguments) and applies your function to the DataFrame in a certain way. Styler.applymap works through the DataFrame elementwise. Styler.apply passes each column or row into your DataFrame one-at-a-time or the entire table at once, depending on the axis keyword argument. For columnwise use axis=0, rowwise use axis=1, and for the entire table at once use axis=None.

For Styler.applymap your function should take a scalar and return a single string with the CSS attribute-value pair.

For Styler.apply your function should take a Series or DataFrame (depending on the axis parameter), and return a Series or DataFrame with an identical shape where each value is a string with a CSS attribute-value pair.

Let’s see some examples.

In [2]:
```python
import pandas as pd
import numpy as np

np.random.seed(24)
df = pd.DataFrame({'A': np.linspace(1, 10, 10)})
df = pd.concat([df, pd.DataFrame(np.random.randn(10, 4), columns=list('BCDE'))], axis=1)
df.iloc[0, 2] = np.nan
```

Here’s a boring example of rendering a DataFrame, without any (visible) styles:
In [3]: df.style
Out[3]: <pandas.io.formats.style.Styler at 0x10fe3ac88>

Note: The DataFrame.style attribute is a property that returns a Styler object. Styler has a _repr_html_ method defined on it so they are rendered automatically. If you want the actual HTML back for further processing or for writing to file call the .render() method which returns a string.

The above output looks very similar to the standard DataFrame HTML representation. But we’ve done some work behind the scenes to attach CSS classes to each cell. We can view these by calling the .render method.

In [4]: df.style.highlight_null().render().split(\n')[:10]
Out[4]: ['<style type="text/css" >', '
   #T_ed8654f8_4dfc_11e8_b50f_186590cd1c87row0_col2 {', '
      background-color: red;', '
   }<style> ', '
<table id="T_ed8654f8_4dfc_11e8_b50f_186590cd1c87" >', '
<thead> <tr> ', '
   <th class="blank level0" ></th> ', '
   <th class="col_heading level0 col0" >A</th> ', '
   <th class="col_heading level0 col1" >B</th> ', '
   <th class="col_heading level0 col2" >C</th> '
</thead> 
</table>
']

The row0_col2 is the identifier for that particular cell. We’ve also prepended each row/column identifier with a UUID unique to each DataFrame so that the style from one doesn’t collide with the styling from another within the same notebook or page (you can set the uuid if you’d like to tie together the styling of two DataFrames).

When writing style functions, you take care of producing the CSS attribute / value pairs you want. Pandas matches those up with the CSS classes that identify each cell.

Let’s write a simple style function that will color negative numbers red and positive numbers black.

In [5]: def color_negative_red(val):
   
   ""
   Takes a scalar and returns a string with
   the css property 'color: red' for negative
   strings, black otherwise.
   ""
   color = 'red' if val < 0 else 'black'
   return 'color: %s' % color

In this case, the cell’s style depends only on it’s own value. That means we should use the Styler.applymap method which works elementwise.

In [6]: s = df.style.applymap(color_negative_red)

Out[6]: <pandas.io.formats.style.Styler at 0x1120fcbe0>

Notice the similarity with the standard df.applymap, which operates on DataFrames elementwise. We want you to be able to reuse your existing knowledge of how to interact with DataFrames.

Notice also that our function returned a string containing the CSS attribute and value, separated by a colon just like in a <style> tag. This will be a common theme.

Finally, the input shapes matched. Styler.applymap calls the function on each scalar input, and the function returns a scalar output.

Now suppose you wanted to highlight the maximum value in each column. We can’t use .applymap anymore since that operated elementwise. Instead, we’ll turn to .apply which operates columnwise (or rowwise using the axis keyword). Later on we’ll see that something like highlight_max is already defined on Styler so you wouldn’t need to write this yourself.
In [7]: def highlight_max(s):
    ...:
    ...:     '''
    ...:         highlight the maximum in a Series yellow.
    ...:     '''
    ...:     is_max = s == s.max()
    ...:     return ['background-color: yellow' if v else '' for v in is_max]

In [8]: df.style.apply(highlight_max)
Out[8]: <pandas.io.formats.style.Styler at 0x1120eae48>

In this case the input is a Series, one column at a time. Notice that the output shape of highlight_max matches the input shape, an array with len(s) items.

We encourage you to use method chains to build up a style piecewise, before finally rendering at the end of the chain.

In [9]: df.style.
   ...:     applymap(color_negative_red).
   ...:     apply(highlight_max)
Out[9]: <pandas.io.formats.style.Styler at 0x1120ea940>

Above we used Styler.apply to pass in each column one at a time.

Debugging Tip: If you’re having trouble writing your style function, try just passing it into DataFrame.apply. Internally, Styler.apply uses DataFrame.apply so the result should be the same.

What if you wanted to highlight just the maximum value in the entire table? Use .apply(function, axis=None) to indicate that your function wants the entire table, not one column or row at a time. Let’s try that next.

We’ll rewrite our highlight-max to handle either Series (from .apply(axis=0 or 1)) or DataFrames (from .apply(axis=None)). We’ll also allow the color to be adjustable, to demonstrate that .apply, and .applymap pass along keyword arguments.

In [10]: def highlight_max(data, color='yellow'):
    ...:
    ...:     '''
    ...:         highlight the maximum in a Series or DataFrame
    ...:     '''
    ...:     attr = 'background-color: {}'.format(color)
    ...:     if data.ndim == 1:
    ...:         # Series from .apply(axis=0) or axis=1
    ...:         is_max = data == data.max()
    ...:         return [attr if v else '' for v in is_max]
    ...:     else:
    ...:         # from .apply(axis=None)
    ...:         is_max = data == data.max().max()
    ...:         return pd.DataFrame(np.where(is_max, attr, ''),
    ...:                 index=data.index, columns=data.columns)

When using Styler.apply(func, axis=None), the function must return a DataFrame with the same index and column labels.

In [11]: df.style.apply(highlight_max, color='darkorange', axis=None)
Out[11]: <pandas.io.formats.style.Styler at 0x1120fc4e0>

23.1.1 Building Styles Summary

Style functions should return strings with one or more CSS attribute: value delimited by semicolons. Use

- Styler.applymap(func) for elementwise styles
- Styler.apply(func, axis=0) for columnwise styles
- Styler.apply(func, axis=1) for rowwise styles
• Styler.apply(func, axis=None) for tablewise styles

And crucially the input and output shapes of func must match. If x is the input then func(x).shape == x.shape.

23.2 Finer Control: Slicing

Both Styler.apply and Styler.applymap accept a subset keyword. This allows you to apply styles to specific rows or columns, without having to code that logic into your style function.

The value passed to subset behaves similar to slicing a DataFrame.

• A scalar is treated as a column label
• A list (or series or numpy array)
• A tuple is treated as (row_indexer, column_indexer)

Consider using pd.IndexSlice to construct the tuple for the last one.

In [12]: df.style.apply(highlight_max, subset=['B', 'C', 'D'])
Out[12]: <pandas.io.formats.style.Styler at 0x1120b2f28>

For row and column slicing, any valid indexer to .loc will work.

In [13]: df.style.applymap(color_negative_red, subset=pd.IndexSlice[2:5, ['B', 'D']])
Out[13]: <pandas.io.formats.style.Styler at 0x1120b29e8>

Only label-based slicing is supported right now, not positional.

If your style function uses a subset or axis keyword argument, consider wrapping your function in a functools.partial, partialing out that keyword.

my_func2 = functools.partial(my_func, subset=42)

23.3 Finer Control: Display Values

We distinguish the display value from the actual value in Styler. To control the display value, the text is printed in each cell, use Styler.format. Cells can be formatted according to a format spec string or a callable that takes a single value and returns a string.

In [14]: df.style.format("{:2%}")
Out[14]: <pandas.io.formats.style.Styler at 0x1120b2a90>

Use a dictionary to format specific columns.

In [15]: df.style.format({'B': "{:0<4.0f}", 'D': '{:+.2f}'})
Out[15]: <pandas.io.formats.style.Styler at 0x1120ea978>

Or pass in a callable (or dictionary of callables) for more flexible handling.

In [16]: df.style.format({'B': lambda x: "±{:.2f}".format(abs(x))})
Out[16]: <pandas.io.formats.style.Styler at 0x1120eea20>
23.4 Builtin Styles

Finally, we expect certain styling functions to be common enough that we’ve included a few “built-in” to the Styler, so you don’t have to write them yourself.

In [17]: df.style.highlight_null(null_color='red')
Out[17]: <pandas.io.formats.style.Styler at 0x1120ea8d0>

You can create “heatmaps” with the background_gradient method. These require matplotlib, and we’ll use Seaborn to get a nice colormap.

In [18]: import seaborn as sns

   cm = sns.light_palette("green", as_cmap=True)

   s = df.style.background_gradient(cmap=cm)

   s

   Out[18]: <pandas.io.formats.style.Styler at 0x1120b2c50>

Styler.background_gradient takes the keyword arguments low and high. Roughly speaking these extend the range of your data by low and high percent so that when we convert the colors, the colormap’s entire range isn’t used. This is useful so that you can actually read the text still.

In [19]: # Uses the full color range
df.loc[:4].style.background_gradient(cmap='viridis')

   Out[19]: <pandas.io.formats.style.Styler at 0x1120b2da0>

In [20]: # Compress the color range
   (df.loc[:4]
       .style
       .background_gradient(cmap='viridis', low=.5, high=0)
       .highlight_null('red'))

   Out[20]: <pandas.io.formats.style.Styler at 0x1a13db1e80>

There’s also .highlight_min and .highlight_max.

In [21]: df.style.highlight_max(axis=0)
Out[21]: <pandas.io.formats.style.Styler at 0x1a13dbf98>

Use Styler.set_properties when the style doesn’t actually depend on the values.

In [22]: df.style.set_properties(**{'background-color': 'black',
                               'color': 'lawngreen',
                               'border-color': 'white'})

Out[22]: <pandas.io.formats.style.Styler at 0x1a13ec4518>

23.4.1 Bar charts

You can include “bar charts” in your DataFrame.
In [23]: df.style.bar(subset=['A', 'B'], color='#d65f5f')
Out[23]: <pandas.io.formats.style.Styler at 0xlal3ec44a8>

New in version 0.20.0 is the ability to customize further the bar chart: You can now have the `df.style.bar` be centered on zero or midpoint value (in addition to the already existing way of having the min value at the left side of the cell), and you can pass a list of `[color_negative, color_positive]`.

Here’s how you can change the above with the new `align='mid'` option:

In [24]: df.style.bar(subset=['A', 'B'], align='mid', color=['#d65f5f', '#5fba7d'])
Out[24]: <pandas.io.formats.style.Styler at 0xlal3ec4860>

The following example aims to give a highlight of the behavior of the new align options:

In [25]: import pandas as pd
   from IPython.display import HTML

   # Test series
   test1 = pd.Series([-100, -60, -30, -20], name='All Negative')
   test2 = pd.Series([10, 20, 50, 100], name='All Positive')
   test3 = pd.Series([-10, -5, 0, 90], name='Both Pos and Neg')

   head = ""
   <table>
     <thead>
       <th>Align</th>
       <th>All Negative</th>
       <th>All Positive</th>
       <th>Both Neg and Pos</th>
     </thead>
     <tbody>
   
   aligns = ['left', 'zero', 'mid']
   for align in aligns:
       row = "<tr><th>{}</th>".format(align)
       for serie in [test1, test2, test3]:
           s = serie.copy()
           s.name=''
           row += "<td>{}</td>".format(s.to_frame().style.bar(align=align,
                                                       color=['#d65f5f', '#5fba7d'],
                                                       width=100).render()) #testn['width']
       row += '</tr>
       head += row

   head+
   </tbody>
   </table>"

   HTML(head)

Out[25]: <IPython.core.display.HTML object>
23.5 Sharing Styles

Say you have a lovely style built up for a DataFrame, and now you want to apply the same style to a second DataFrame. Export the style with `df1.style.export`, and import it on the second DataFrame with `df1.style.set

```python
In [26]: df2 = -df
   style1 = df.style.applymap(color_negative_red)
   style1
Out[26]: <pandas.io.formats.style.Styler at 0x1a13ec4710>
In [27]: style2 = df2.style
   style2.use(style1.export())
   style2
Out[27]: <pandas.io.formats.style.Styler at 0x1a13fcb2e8>
```

Notice that you’re able share the styles even though they’re data aware. The styles are re-evaluated on the new DataFrame they’ve been used upon.

23.6 Other Options

You’ve seen a few methods for data-driven styling. Styler also provides a few other options for styles that don’t depend on the data.

- precision
- captions
- table-wide styles
- hiding the index or columns

Each of these can be specified in two ways:

- A keyword argument to `Styler.__init__`
- A call to one of the `.set_` or `.hide_` methods, e.g. `.set_caption` or `.hide_columns`

The best method to use depends on the context. Use the `Styler` constructor when building many styled DataFrames that should all share the same properties. For interactive use, the `.set_` and `.hide_` methods are more convenient.

23.6.1 Precision

You can control the precision of floats using pandas’ regular `display.precision` option.

```python
In [28]: with pd.option_context('display.precision', 2):
   html = (df.style
   .applymap(color_negative_red)
   .apply(highlight_max))
   html
Out[28]: <pandas.io.formats.style.Styler at 0x1a13fa6eb8>
```

Or through a `set_precision` method.

```python
In [29]: df.style
   .applymap(color_negative_red)
   .apply(highlight_max)
   .set_precision(2)
```
Setting the precision only affects the printed number; the full-precision values are always passed to your style functions. You can always use `df.round(2).style` if you'd prefer to round from the start.

### 23.6.2 Captions

Regular table captions can be added in a few ways.

```python
In [30]: df.style.set_caption('Colormaps, with a caption.')
   .background_gradient(cmap=cm)
```

Out[30]: `<pandas.io.formats.style.Styler at 0x1a13ec4128>`

### 23.6.3 Table Styles

The next option you have are “table styles”. These are styles that apply to the table as a whole, but don’t look at the data. Certain sytlings, including pseudo-selectors like :hover can only be used this way.

```python
In [31]: from IPython.display import HTML
def hover(hover_color="#ffff99"):    
    return dict(selector="tr:hover",
               props=[("background-color", "%s" % hover_color)])

styles = [    hover(),
    dict(selector="th", props=[("font-size", "150%"),
                               ("text-align", "center")]),
    dict(selector="caption", props=[("caption-side", "bottom")])]

html = (df.style.set_table_styles(styles)
       .set_caption("Hover to highlight."))
```

Out[31]: `<pandas.io.formats.style.Styler at 0x1a13fa6358>`

`table_styles` should be a list of dictionaries. Each dictionary should have the `selector` and `props` keys. The value for `selector` should be a valid CSS selector. Recall that all the styles are already attached to an `id`, unique to each `Styler`. This selector is in addition to that `id`. The value for `props` should be a list of tuples of (`attribute', 'value').

table_styles are extremely flexible, but not as fun to type out by hand. We hope to collect some useful ones either in pandas, or preferable in a new package that builds on top the tools here.

### 23.6.4 Hiding the Index or Columns

The index can be hidden from rendering by calling `Styler.hide_index`. Columns can be hidden from rendering by calling `Styler.hide_columns` and passing in the name of a column, or a slice of columns.

```python
In [32]: df.style.hide_index()
```

Out[32]: `<pandas.io.formats.style.Styler at 0x1a13fc96d8>`

```python
In [33]: df.style.hide_columns(['C','D'])
```
23.6.5 CSS Classes

Certain CSS classes are attached to cells.

- Index and Column names include `index_name` and `level<k>` where `k` is its level in a MultiIndex
- Index label cells include
  - `row_heading`
  - `row<n>` where `n` is the numeric position of the row
  - `level<k>` where `k` is the level in a MultiIndex
- Column label cells include
  - `col_heading`
  - `col<n>` where `n` is the numeric position of the column
  - `level<k>` where `k` is the level in a MultiIndex
- Blank cells include `blank`
- Data cells include `data`

23.6.6 Limitations

- DataFrame only (use `Series.to_frame().style`)
- The index and columns must be unique
- No large repr, and performance isn’t great; this is intended for summary DataFrames
- You can only style the `values`, not the index or columns
- You can only apply styles, you can’t insert new HTML entities

Some of these will be addressed in the future.

23.6.7 Terms

- Style function: a function that’s passed into `Styler.apply` or `Styler.applymap` and returns values like `'css attribute: value'`
- Built in style functions: style functions that are methods on `Styler`
- `table style`: a dictionary with the two keys `selector` and `props`. `selector` is the CSS selector that `props` will apply to. `props` is a list of `(attribute, value)` tuples. A list of table styles passed into `Styler`.

23.7 Fun stuff

Here are a few interesting examples.

`Styler` interacts pretty well with widgets. If you’re viewing this online instead of running the notebook yourself, you’re missing out on interactively adjusting the color palette.
In [34]: from IPython.html import widgets
@widgets.interact
    def f(h_neg=(0, 359, 1), h_pos=(0, 359), s=(0., 99.9), l=(0., 99.9)):
        return df.style.background_gradient(
            cmap=sns.palettes.diverging_palette(h_neg=h_neg, h_pos=h_pos, s=s, l=l,
                                                    as_cmap=True)
        )

In [35]: def magnify():
    return [dict(selector="th",
                props=[('font-size', '4pt')]),
            dict(selector="td",
                props=[('padding', '0em 0em')]),
            dict(selector="th:hover",
                props=[('font-size', '12pt')]),
            dict(selector="tr:hover td:hover",
                props=[('max-width', '200px'),
                        ('font-size', '12pt')])
    ]

In [36]: np.random.seed(25)
cmap = cmap=sns.diverging_palette(5, 250, as_cmap=True)
bigdf = pd.DataFrame(np.random.randn(20, 25)).cumsum()
bigdf.style.background_gradient(cmap, axis=1)
   .set_properties(**{'max-width': '80px', 'font-size': '1pt'})
   .set_caption("Hover to magnify")
   .set_precision(2)
   .set_table_styles(magnify())

Out[36]: <pandas.io.formats.style.Styler at 0x1a13fc9d68>

## 23.8 Export to Excel

*New in version 0.20.0*

*Experimental: This is a new feature and still under development. We’ll be adding features and possibly making breaking changes in future releases. We’d love to hear your feedback.*

Some support is available for exporting styled DataFrames to Excel worksheets using the OpenPyXL or XlsxWriter engines. CSS2.2 properties handled include:

- background-color
- border-style, border-width, border-color and their top, right, bottom, left variants
- color
- font-family
- font-style
- font-weight
- text-align
- text-decoration
23.9 Extensibility

The core of pandas is, and will remain, its “high-performance, easy-to-use data structures”. With that in mind, we hope that DataFrame.style accomplishes two goals

- Provide an API that is pleasing to use interactively and is “good enough” for many tasks
- Provide the foundations for dedicated libraries to build on

If you build a great library on top of this, let us know and we’ll link to it.

23.9.1 Subclassing

If the default template doesn’t quite suit your needs, you can subclass Styler and extend or override the template. We’ll show an example of extending the default template to insert a custom header before each table.

In [38]: from jinja2 import Environment, ChoiceLoader, FileSystemLoaderrom IPython.display import HTML
from pandas.io.formats.style import Styler
In [39]: %mkdir templates

mkdir: templates: File exists

This next cell writes the custom template. We extend the template html.tpl, which comes with pandas.

In [40]: %%%

{{ extends "html.tpl" }}
{{ block table }}
<h1>{{ table_title|default("My Table") }}</h1>
{{ super() }}
{{ endblock table }}

Overwriting templates/myhtml.tpl

Now that we’ve created a template, we need to set up a subclass of Styler that knows about it.

In [41]: class MyStyler(Styler):
   
   env = Environment(
      loader=ChoiceLoader([FileSystemLoader("templates"), # contains ours
                           Styler.loader, # the default
      ])
   )
   
   template = env.get_template("myhtml.tpl")

Notice that we include the original loader in our environment’s loader. That’s because we extend the original template, so the Jinja environment needs to be able to find it.

Now we can use that custom styler. It’s __init__ takes a DataFrame.

In [42]: MyStyler(df)

Out[42]: <__main__.MyStyler at 0x1a1bae3438>

Our custom template accepts a table_title keyword. We can provide the value in the .render method.

In [43]: HTML(MyStyler(df).render(table_title="Extending Example"))

Out[43]: <IPython.core.display.HTML object>

For convenience, we provide the Styler.from_custom_template method that does the same as the custom subclass.

In [44]: EasyStyler = Styler.from_custom_template("templates", "myhtml.tpl")

EasyStyler(df)

Out[44]: <pandas.io.formats.style.Styler.from_custom_template.<locals>.MyStyler at 0x1a1e141c88>

Here’s the template structure:

In [45]: with open("template_structure.html") as f:
   
   structure = f.read()

   HTML(structure)

Out[45]: <IPython.core.display.HTML object>

See the template in the GitHub repo for more details.
IO TOOLS (TEXT, CSV, HDF5, …)

The pandas I/O API is a set of top level reader functions accessed like `pandas.read_csv()` that generally return a pandas object. The corresponding writer functions are object methods that are accessed like `DataFrame.to_csv()`. Below is a table containing available readers and writers.

<table>
<thead>
<tr>
<th>Format Type</th>
<th>Data Description</th>
<th>Reader</th>
<th>Writer</th>
</tr>
</thead>
<tbody>
<tr>
<td>text</td>
<td>CSV</td>
<td>read_csv</td>
<td>to_csv</td>
</tr>
<tr>
<td>text</td>
<td>JSON</td>
<td>read_json</td>
<td>to_json</td>
</tr>
<tr>
<td>text</td>
<td>HTML</td>
<td>read_html</td>
<td>to_html</td>
</tr>
<tr>
<td>text</td>
<td>Local clipboard</td>
<td>read_clipboard</td>
<td>to_clipboard</td>
</tr>
<tr>
<td>binary</td>
<td>MS Excel</td>
<td>read_excel</td>
<td>to_excel</td>
</tr>
<tr>
<td>binary</td>
<td>HDF5 Format</td>
<td>read_hdf</td>
<td>to_hdf</td>
</tr>
<tr>
<td>binary</td>
<td>Feather Format</td>
<td>read_feather</td>
<td>to_feather</td>
</tr>
<tr>
<td>binary</td>
<td>Parquet Format</td>
<td>read_parquet</td>
<td>to_parquet</td>
</tr>
<tr>
<td>binary</td>
<td>Msgpack</td>
<td>read_msgpack</td>
<td>to_msgpack</td>
</tr>
<tr>
<td>binary</td>
<td>Stata</td>
<td>read_stata</td>
<td>to_stata</td>
</tr>
<tr>
<td>binary</td>
<td>SAS</td>
<td>read_sas</td>
<td></td>
</tr>
<tr>
<td>binary</td>
<td>Python Pickle Format</td>
<td>read_pickle</td>
<td>to_pickle</td>
</tr>
<tr>
<td>SQL</td>
<td>SQL</td>
<td>read_sql</td>
<td>to_sql</td>
</tr>
<tr>
<td>SQL</td>
<td>Google Big Query</td>
<td>read_gbq</td>
<td>to_gbq</td>
</tr>
</tbody>
</table>

*Here is an informal performance comparison for some of these IO methods.*

**Note:** For examples that use the `StringIO` class, make sure you import it according to your Python version, i.e. `from StringIO import StringIO` for Python 2 and `from io import StringIO` for Python 3.

### 24.1 CSV & Text files

The two workhorse functions for reading text files (a.k.a. flat files) are `read_csv()` and `read_table()`. They both use the same parsing code to intelligently convert tabular data into a `DataFrame` object. See the *cookbook* for some advanced strategies.

#### 24.1.1 Parsing options

The functions `read_csv()` and `read_table()` accept the following common arguments:
24.1.1.1 Basic

filepath_or_buffer [various] Either a path to a file (a str, pathlib.Path, or py._path.local. LocalPath), URL (including http, ftp, and S3 locations), or any object with a read() method (such as an open file or StringIO).

sep [str, defaults to ', ' for read_csv(), \t for read_table()] Delimiter to use. If sep is None, the C engine cannot automatically detect the separator, but the Python parsing engine can, meaning the latter will be used and automatically detect the separator by Python’s builtin sniffer tool, csv.Sniffer. In addition, separators longer than 1 character and different from '\s+' will be interpreted as regular expressions and will also force the use of the Python parsing engine. Note that regex delimiters are prone to ignoring quoted data. Regex example: '\r\t'.

delimiter [str, default None] Alternative argument name for sep.

delim_whitespace [boolean, default False] Specifies whether or not whitespace (e.g. ' ' or '\t') will be used as the delimiter. Equivalent to setting sep='\s+'. If this option is set to True, nothing should be passed in for the delimiter parameter.

New in version 0.18.1: support for the Python parser.

24.1.1.2 Column and Index Locations and Names

header [int or list of ints, default 'infer'] Row number(s) to use as the column names, and the start of the data. Default behavior is to infer the column names: if no names are passed the behavior is identical to header=0 and column names are inferred from the first line of the file, if column names are passed explicitly then the behavior is identical to header=None. Explicitly pass header=0 to be able to replace existing names.

The header can be a list of ints that specify row locations for a multi-index on the columns e.g. [0,1,3]. Intervening rows that are not specified will be skipped (e.g. 2 in this example is skipped). Note that this parameter ignores commented lines and empty lines if skip_blank_lines=True, so header=0 denotes the first line of data rather than the first line of the file.

names [array-like, default None] List of column names to use. If file contains no header row, then you should explicitly pass header=None. Duplicates in this list will cause a UserWarning to be issued.

index_col [int or sequence or False, default None] Column to use as the row labels of the DataFrame. If a sequence is given, a MultiIndex is used. If you have a malformed file with delimiters at the end of each line, you might consider index_col=False to force pandas to not use the first column as the index (row names).

usecols [list-like or callable, default None] Return a subset of the columns. If list-like, all elements must either be positional (i.e. integer indices into the document columns) or strings that correspond to column names provided either by the user in names or inferred from the document header row(s). For example, a valid list-like usecols parameter would be [0, 1, 2] or ['foo', 'bar', 'baz'].

Element order is ignored, so usecols=[0, 1] is the same as [1, 0]. To instantiate a DataFrame from data with element order preserved use pd.read_csv(data, usecols=['foo', 'bar'])[['foo', 'bar']] for columns in ['foo', 'bar'] order or pd.read_csv(data, usecols=['foo', 'bar'])[['bar', 'foo']] for ['bar', 'foo'] order.

If callable, the callable function will be evaluated against the column names, returning names where the callable function evaluates to True:
Using this parameter results in much faster parsing time and lower memory usage.

**squeeze** [boolean, default `False`] If the parsed data only contains one column then return a `Series`.

**prefix** [str, default `None`] Prefix to add to column numbers when no header, e.g. ‘X’ for X0, X1,…

**mangle_dupe_cols** [boolean, default `True`] Duplicate columns will be specified as ‘X’, ‘X.1’…’X.N’, rather than ‘X’…’X’. Passing in `False` will cause data to be overwritten if there are duplicate names in the columns.

### 24.1.1.3 General Parsing Configuration

**dtype** [Type name or dict of column -> type, default `None`] Data type for data or columns. E.g. `{‘a’: np.float64, ‘b’: np.int32}` (unsupported with engine='python'). Use `str` or `object` to preserve and not interpret dtype.

New in version 0.20.0: support for the Python parser.

**engine** ['c', 'python'] Parser engine to use. The C engine is faster while the Python engine is currently more feature-complete.

**converters** [dict, default `None`] Dict of functions for converting values in certain columns. Keys can either be integers or column labels.

**true_values** [list, default `None`] Values to consider as `True`.

**false_values** [list, default `None`] Values to consider as `False`.

**skipinitialspace** [boolean, default `False`] Skip spaces after delimiter.

**skiprows** [list-like or integer, default `None`] Line numbers to skip (0-indexed) or number of lines to skip (int) at the start of the file.

If callable, the callable function will be evaluated against the row indices, returning `True` if the row should be skipped and `False` otherwise:

```
In [4]: data =onald >col1,col2,col3\na,b,1\na,b,2\nc,d,3'

In [5]: pd.read_csv(StringIO(data))
Out[5]:
    col1  col2  col3
0    a     b     1
1    a     b     2
2    c     d     3
```

(continues on next page)
skipfooter [int, default 0] Number of lines at bottom of file to skip (unsupported with engine=’c’).

nrows [int, default None] Number of rows of file to read. Useful for reading pieces of large files.

low_memory [boolean, default True] Internally process the file in chunks, resulting in lower memory use while parsing, but possibly mixed type inference. To ensure no mixed types either set False, or specify the type with the dtype parameter. Note that the entire file is read into a single DataFrame regardless, use the chunksize or iterator parameter to return the data in chunks. (Only valid with C parser)

memory_map [boolean, default False] If a filepath is provided for filepath_or_buffer, map the file object directly onto memory and access the data directly from there. Using this option can improve performance because there is no longer any I/O overhead.

24.1.1.4 NA and Missing Data Handling

na_values [scalar, str, list-like, or dict, default None] Additional strings to recognize as NA/NaN. If dict passed, specific per-column NA values. See na values const below for a list of the values interpreted as NaN by default.

keep_default_na [boolean, default True] Whether or not to include the default NaN values when parsing the data. Depending on whether na_values is passed in, the behavior is as follows:

• If keep_default_na is True, and na_values are specified, na_values is appended to the default NaN values used for parsing.
• If keep_default_na is True, and na_values are not specified, only the default NaN values are used for parsing.
• If keep_default_na is False, and na_values are specified, only the NaN values specified na_values are used for parsing.
• If keep_default_na is False, and na_values are not specified, no strings will be parsed as NaN.

Note that if na_filter is passed in as False, the keep_default_na and na_values parameters will be ignored.

na_filter [boolean, default True] Detect missing value markers (empty strings and the value of na_values). In data without any NAs, passing na_filter=False can improve the performance of reading a large file.

verbose [boolean, default False] Indicate number of NA values placed in non-numeric columns.

skip_blank_lines [boolean, default True] If True, skip over blank lines rather than interpreting as NaN values.

24.1.1.5 Datetime Handling

parse_dates [boolean or list of ints or names or list of lists or dict, default False.]

• If True -> try parsing the index.
• If [1, 2, 3] -> try parsing columns 1, 2, 3 each as a separate date column.
• If [[1, 3]] -> combine columns 1 and 3 and parse as a single date column.
• If {'foo': [1, 3]} -> parse columns 1, 3 as date and call result ‘foo’. A fast-path exists for iso8601-formatted dates.

infer_datetime_format [boolean, default False] If True and parse_dates is enabled for a column, attempt to infer the datet ime format to speed up the processing.
keep_date_col [boolean, default False] If True and parse_dates specifies combining multiple columns then keep the original columns.

date_parser [function, default None] Function to use for converting a sequence of string columns to an array of datetime instances. The default uses dateutil.parser.parser to do the conversion. Pandas will try to call date_parser in three different ways, advancing to the next if an exception occurs: 1) Pass one or more arrays (as defined by parse_dates) as arguments; 2) concatenate (row-wise) the string values from the columns defined by parse_dates into a single array and pass that; and 3) call date_parser once for each row using one or more strings (corresponding to the columns defined by parse_dates) as arguments.

dayfirst [boolean, default False] DD/MM format dates, international and European format.

24.1.1.6 Iteration

iterator [boolean, default False] Return TextFileReader object for iteration or getting chunks with get_chunk().

chunksize [int, default None] Return TextFileReader object for iteration. See iterating and chunking below.

24.1.1.7 Quoting, Compression, and File Format

compression [{'infer', 'gzip', 'bz2', 'zip', 'xz', None}, default 'infer'] For on-the-fly decompression of on-disk data. If 'infer', then use gzip, bz2, zip, or xz if filepath_or_buffer is a string ending in '.gz', '.bz2', '.zip', or '.xz', respectively, and no decompression otherwise. If using 'zip', the ZIP file must contain only one data file to be read in. Set to None for no decompression.

New in version 0.18.1: support for 'zip' and 'xz' compression.

thousands [str, default None] Thousands separator.

decimal [str, default ' ' ] Character to recognize as decimal point. E.g. use ' ', ' ' for European data.

float_precision [string, default None] Specifies which converter the C engine should use for floating-point values. The options are None for the ordinary converter, high for the high-precision converter, and round_trip for the round-trip converter.

lineterminator [str (length 1), default None] Character to break file into lines. Only valid with C parser.

quotechar [str (length 1)] The character used to denote the start and end of a quoted item. Quoted items can include the delimiter and it will be ignored.

quoting [int or csv.QUOTE_* instance, default 0] Control field quoting behavior per csv.QUOTE_* constants. Use one of QUOTE_MINIMAL (0), QUOTE_ALL (1), QUOTE_NONNUMERIC (2) or QUOTE_NONE (3).

doublequote [boolean, default True] When quotechar is specified and quoting is not QUOTE_NONE, indicate whether or not to interpret two consecutive quotechar elements inside a field as a single quotechar element.

escapechar [str (length 1), default None] One-character string used to escape delimiter when quoting is QUOTE_NONE.

comment [str, default None] Indicates remainder of line should not be parsed. If found at the beginning of a line, the line will be ignored altogether. This parameter must be a single character. Like empty lines (as long as skip_blank_lines=True), fully commented lines are ignored by the parameter header but not by skiprows. For example, if comment=' # ', parsing '#empty\na,b,c\n1,2,3' with header=0 will result in 'a,b,c' being treated as the header.

encoding [str, default None] Encoding to use for UTF when reading/writing (e.g. 'utf-8'). List of Python standard encodings.
dialect [str or csv.Dialect instance, default None] If provided, this parameter will override values (default or not) for the following parameters: delimiter, doublequote, escapechar, skipinitialspace, quotechar, and quoting. If it is necessary to override values, a ParserWarning will be issued. See csv.Dialect documentation for more details.

tupleize_cols [boolean, default False]

Deprecated since version 0.21.0.

This argument will be removed and will always convert to MultiIndex

Leave a list of tuples on columns as is (default is to convert to a MultiIndex on the columns).

24.1.1.8 Error Handling

error_bad_lines [boolean, default True] Lines with too many fields (e.g. a csv line with too many commas) will by default cause an exception to be raised, and no DataFrame will be returned. If False, then these “bad lines” will dropped from the DataFrame that is returned. See bad lines below.

warn_bad_lines [boolean, default True] If error_bad_lines is False, and warn_bad_lines is True, a warning for each “bad line” will be output.

24.1.2 Specifying column data types

You can indicate the data type for the whole DataFrame or individual columns:

```
In [7]: data = 'a,b,c
1,2,3
4,5,6
7,8,9'

In [8]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [9]: df = pd.read_csv(StringIO(data), dtype=object)

In [10]: df
Out[10]:
   a  b  c
0  1  2  3
1  4  5  6
2  7  8  9

In [11]: df['a'][0]
Out[11]: '1'

In [12]: df = pd.read_csv(StringIO(data), dtype={'b': object, 'c': np.float64})

In [13]: df.dtypes
Out[13]:
   a   int64
   b    object
   c  float64
dtype: object
```

Fortunately, pandas offers more than one way to ensure that your column(s) contain only one dtype. If you’re unfamiliar with these concepts, you can see here to learn more about dtypes, and here to learn more about object conversion in pandas.
For instance, you can use the **converters** argument of `read_csv()`:

```
In [14]: data = "col_1\n1\n2\n'A'\n4.22"

In [15]: df = pd.read_csv(StringIO(data), converters={'col_1': str})

In [16]: df
Out[16]:
   col_1
0    1
1    2
2    A
3  4.22

In [17]: df['col_1'].apply(type).value_counts()
Out[17]:
<class 'str'>    4
Name: col_1, dtype: int64
```

Or you can use the **to_numeric()** function to coerce the dtypes after reading in the data,

```
In [18]: df2 = pd.read_csv(StringIO(data))

In [19]: df2['col_1'] = pd.to_numeric(df2['col_1'], errors='coerce')

In [20]: df2
Out[20]:
   col_1
0   1.00
1   2.00
2   NaN
3   4.22

In [21]: df2['col_1'].apply(type).value_counts()
Out[21]:
<class 'float'>    4
Name: col_1, dtype: int64
```

which will convert all valid parsing to floats, leaving the invalid parsing as NaN.

Ultimately, how you deal with reading in columns containing mixed dtypes depends on your specific needs. In the case above, if you wanted to NaN out the data anomalies, then **to_numeric()** is probably your best option. However, if you wanted for all the data to be coerced, no matter the type, then using the **converters** argument of `read_csv()` would certainly be worth trying.

New in version 0.20.0: support for the Python parser.

The **dtype** option is supported by the ‘python’ engine.

---

**Note:** In some cases, reading in abnormal data with columns containing mixed dtypes will result in an inconsistent dataset. If you rely on pandas to infer the dtypes of your columns, the parsing engine will go and infer the dtypes for different chunks of the data, rather than the whole dataset at once. Consequently, you can end up with column(s) with mixed dtypes. For example,

```
In [22]: df = pd.DataFrame({'col_1': list(range(500000)) + ['a', 'b'] +
                   list(range(500000)))

In [23]: df.to_csv('foo.csv')
```
In [24]: mixed_df = pd.read_csv('foo.csv')
In [25]: mixed_df['col_1'].apply(type).value_counts()
Out[25]:
<class 'int'> 737858
<class 'str'> 262144
Name: col_1, dtype: int64
In [26]: mixed_df['col_1'].dtype
Out[26]:
\ dtype('O')
will result with mixed_df containing an int dtype for certain chunks of the column, and str for others due to the mixed dtypes from the data that was read in. It is important to note that the overall column will be marked with a dtype of object, which is used for columns with mixed dtypes.

24.1.3 Specifying Categorical dtype

New in version 0.19.0.

Categorical columns can be parsed directly by specifying dtype='category' or dtype=CategoricalDtype(categories, ordered).

In [27]: data = 'col1,col2,col3
   :a,b,1
   :a,b,2
   :c,d,3'
In [28]: pd.read_csv(StringIO(data))
Out[28]:
   col1  col2  col3
0    a    b     1
1    a    b     2
2    c    d     3
In [29]: pd.read_csv(StringIO(data)).dtypes
Out[29]:
\ col1   object
col2   object
col3    int64
dtype: object
In [30]: pd.read_csv(StringIO(data), dtype='category').dtypes
Out[30]:
\ col1    category
col2    category
col3    category
dtype: object
Individual columns can be parsed as a Categorical using a dict specification:

In [31]: pd.read_csv(StringIO(data), dtype={'col1': 'category'}).dtypes
Out[31]:
coll    category
New in version 0.21.0.

Specifying `dtype='category'` will result in an unordered `Categorical` whose categories are the unique values observed in the data. For more control on the categories and order, create a `CategoricalDtype` ahead of time, and pass that for that column’s `dtype`.

```
In [32]: from pandas.api.types import CategoricalDtype
In [33]: dtype = CategoricalDtype(['d', 'c', 'b', 'a'], ordered=True)
In [34]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).dtypes
```
```
Out[34]:
        col1  category
        col2  object
        col3  int64
       dtype: object
```

When using `dtype=CategoricalDtype`, “unexpected” values outside of `dtype.categories` are treated as missing values.

```
In [35]: dtype = CategoricalDtype(['a', 'b', 'd'])  # No 'c'
In [36]: pd.read_csv(StringIO(data), dtype={'col1': dtype}).col1
```
```
Out[36]:
0    a
1    a
2   NaN
Name: col1, dtype: category
Categories (3, object): [a, b, d]
```

This matches the behavior of `Categorical.set_categories()`.

**Note:** With `dtype='category'`, the resulting categories will always be parsed as strings (object dtype). If the categories are numeric they can be converted using the `to_numeric()` function, or as appropriate, another converter such as `to_datetime()`.

When `dtype` is a `CategoricalDtype` with homogenous categories (all numeric, all datetimes, etc.), the conversion is done automatically.

```
In [37]: df = pd.read_csv(StringIO(data), dtype='category')
In [38]: df.dtypes
```
```
Out[38]:
        col1  category
        col2  category
        col3  int64
dtype: object
```

```
In [39]: df['col3']
```
```
Out[39]:
0  1
1  2
```
2 3
Name: col3, dtype: category
Categories (3, object): [1, 2, 3]

In [40]: df['col3'].cat.categories = pd.to_numeric(df['col3'].cat.categories)

In [41]: df['col3']
Out[41]:
0 1
1 2
2 3
Name: col3, dtype: category
Categories (3, int64): [1, 2, 3]

24.1.4 Naming and Using Columns

24.1.4.1 Handling column names

A file may or may not have a header row. pandas assumes the first row should be used as the column names:

In [42]: data = 'a,b,c
1,2,3
4,5,6
7,8,9'

In [43]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [44]: pd.read_csv(StringIO(data))

Out[44]:
a b c
0 1 2 3
1 4 5 6
2 7 8 9

By specifying the names argument in conjunction with header you can indicate other names to use and whether or not to throw away the header row (if any):

In [45]: print(data)
a,b,c
1,2,3
4,5,6
7,8,9

In [46]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=0)

Out[46]:
foo bar baz
0 1 2 3
1 4 5 6
2 7 8 9

In [47]: pd.read_csv(StringIO(data), names=['foo', 'bar', 'baz'], header=None)

...
If the header is in a row other than the first, pass the row number to `header`. This will skip the preceding rows:

```
In [48]: data = 'skip this skip it
   ...: a,b,c
   ...: 1,2,3
   ...: 4,5,6
   ...: 7,8,9'

In [49]: pd.read_csv(StringIO(data), header=1)
Out[49]:
   a  b  c
  0  1  2  3
  1  4  5  6
  2  7  8  9
```

**Note:** Default behavior is to infer the column names: if no names are passed the behavior is identical to `header=0` and column names are inferred from the first nonblank line of the file, if column names are passed explicitly then the behavior is identical to `header=None`.

### 24.1.5 Duplicate names parsing

If the file or header contains duplicate names, pandas will by default distinguish between them so as to prevent overwriting data:

```
In [50]: data = 'a,b,a
   ...: 0,1,2
   ...: 3,4,5'

In [51]: pd.read_csv(StringIO(data))
Out[51]:
   a  b  a.1
  0  0  1  2
  1  3  4  5
```

There is no more duplicate data because `mangle_dupe_cols=True` by default, which modifies a series of duplicate columns ‘X’, ..., ‘X’ to become ‘X’, ‘X.1’, ..., ‘X.N’. If `mangle_dupe_cols=False`, duplicate data can arise:

```
In [2]: data = 'a,b,a
   ...: 0,1,2
   ...: 3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
Out[3]:
   a  b  a
  0  2  1  2
  1  5  4  5
```

To prevent users from encountering this problem with duplicate data, a `ValueError` exception is raised if `mangle_dupe_cols != True`:

```
In [2]: data = 'a,b,a
   ...: 0,1,2
   ...: 3,4,5'
In [3]: pd.read_csv(StringIO(data), mangle_dupe_cols=False)
   ...: ValueError: Setting mangle_dupe_cols=False is not supported yet
```
24.1.5.1 Filtering columns (usecols)

The `usecols` argument allows you to select any subset of the columns in a file, either using the column names, position numbers or a callable:

New in version 0.20.0: support for callable `usecols` arguments

```python
In [52]: data = 'a,b,c,d\n1,2,3,foo\n4,5,6,bar\n7,8,9,baz'
```

```python
In [53]: pd.read_csv(StringIO(data))
Out[53]:
       a  b  c  d
0   1   2   3  foo
1   4   5   6  bar
2   7   8   9  baz
```

```python
In [54]: pd.read_csv(StringIO(data), usecols=['b', 'd'])
```

```python
In [55]: pd.read_csv(StringIO(data), usecols=[0, 2, 3])
```

```python
In [56]: pd.read_csv(StringIO(data), usecols=lambda x: x.upper() in ['A', 'C'])
```

The `usecols` argument can also be used to specify which columns not to use in the final result:

```python
In [57]: pd.read_csv(StringIO(data), usecols=lambda x: x not in ['a', 'c'])
```

In this case, the callable is specifying that we exclude the “a” and “c” columns from the output.

24.1.6 Comments and Empty Lines

24.1.6.1 Ignoring line comments and empty lines

If the `comment` parameter is specified, then completely commented lines will be ignored. By default, completely blank lines will be ignored as well.
In [58]: data = 'a,b,c
   
   # commented line
   1,2,3
   4,5,6

In [59]: print(data)
a,b,c
   
   # commented line
   1,2,3
   4,5,6

In [60]: pd.read_csv(StringIO(data), comment='#')
Out[60]:
   a  b  c
0  1  2  3
1  4  5  6

If `skip_blank_lines=False`, then `read_csv` will not ignore blank lines:

In [61]: data = 'a,b,c

   1,2,3

   4,5,6

In [62]: pd.read_csv(StringIO(data), skip_blank_lines=False)
Out[62]:
   a  b  c
0  NaN NaN NaN
1  1.0  2.0  3.0
2  NaN NaN NaN
3  NaN NaN NaN
4  4.0  5.0  6.0

**Warning:** The presence of ignored lines might create ambiguities involving line numbers; the parameter `header` uses row numbers (ignoring commented/empty lines), while `skiprows` uses line numbers (including commented/empty lines):

In [63]: data = '#comment
   
a,b,c
   
   A,B,C
   
   1,2,3

In [64]: pd.read_csv(StringIO(data), comment='#', header=1)
Out[64]:
   A  B  C
0  1  2  3

In [65]: data = 'A,B,C
   
   #comment
   
a,b,c
   
   1,2,3

In [66]: pd.read_csv(StringIO(data), comment='#', skiprows=2)
Out[66]:
   a  b  c
0  1  2  3

If both `header` and `skiprows` are specified, `header` will be relative to the end of `skiprows`. For example:
24.1.6.2 Comments

Sometimes comments or meta data may be included in a file:

In [70]: print(open('tmp.csv').read())
ID,level,category
Patient1,123000,x # really unpleasant
Patient2,23000,y # wouldn't take his medicine
Patient3,1234018,z # awesome

By default, the parser includes the comments in the output:

In [71]: df = pd.read_csv('tmp.csv')

In [72]: df
Out[72]:
   ID    level  category
0  0 Patient1 123000 x # really unpleasant
1  1 Patient2 23000 y # wouldn't take his medicine
2  2 Patient3 1234018 z # awesome

We can suppress the comments using the comment keyword:

In [73]: df = pd.read_csv('tmp.csv', comment='#')

In [74]: df
Out[74]:
   ID    level  category
0  0 Patient1 123000 x
1  1 Patient2 23000 y
2  2 Patient3 1234018 z
24.1.7 Dealing with Unicode Data

The encoding argument should be used for encoded unicode data, which will result in byte strings being decoded to unicode in the result:

```python
In [75]: data = b'word,length

Träumen,7
Grüße,5'.decode('utf8').encode('latin-1')

In [76]: df = pd.read_csv(BytesIO(data), encoding='latin-1')

In [77]: df
Out[77]:
word length
0 Träumen 7
1 Grüße 5
```

Some formats which encode all characters as multiple bytes, like UTF-16, won’t parse correctly at all without specifying the encoding. Full list of Python standard encodings.

24.1.8 Index columns and trailing delimiters

If a file has one more column of data than the number of column names, the first column will be used as the DataFrame’s row names:

```python
In [79]: data = 'a,b,c

4,apple,bat,5.7
8,orange,cow,10'

In [80]: pd.read_csv(StringIO(data))
Out[80]:
a  b  c
4  apple  bat  5.7
8  orange  cow  10.0
```

```python
In [81]: data = 'index,a,b,c

4,apple,bat,5.7
8,orange,cow,10'

In [82]: pd.read_csv(StringIO(data), index_col=0)
Out[82]:
index            a  b  c
4   apple  bat  5.7
8  orange  cow  10.0
```

Ordinarily, you can achieve this behavior using the index_col option.

There are some exception cases when a file has been prepared with delimiters at the end of each data line, confusing the parser. To explicitly disable the index column inference and discard the last column, pass index_col=False:

```python
In [83]: data = 'a,b,c

4,apple,bat,
8,orange,cow,'

In [84]: print(data)
a, b, c
4, apple, bat,
8, orange, cow,
```

(continues on next page)
If a subset of data is being parsed using the `usecols` option, the `index_col` specification is based on that subset, not the original data.

```python
In [87]: data = 'a,b,c
   : 4,apple,bat,
   : 8,orange,cow,'

In [88]: print(data)
a,b,c
4,apple,bat,
8,orange,cow,
```

```python
In [89]: pd.read_csv(StringIO(data), usecols=['b', 'c'])
```

```
Out[89]:
   b  c
0  bat NaN
1  cow NaN
```

```python
In [90]: pd.read_csv(StringIO(data), usecols=['b', 'c'], index_col=0)
```

```
Out[90]:
   b  c
0  bat NaN
1  cow NaN
```

### 24.1.9 Date Handling

#### 24.1.9.1 Specifying Date Columns

To better facilitate working with datetime data, `read_csv()` and `read_table()` use the keyword arguments `parse_dates` and `date_parser` to allow users to specify a variety of columns and date/time formats to turn the input text data into `datetime` objects.

The simplest case is to just pass in `parse_dates=True`:

```python
# Use a column as an index, and parse it as dates.
In [91]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True)

In [92]: df
```

```
Out[92]:
          A  B  C
date
2009-01-01 a  1  2
2009-01-02 b  3  4
2009-01-03 c  4  5
```
# These are Python datetime objects

```python
In [93]: df.index

Out[93]:
\[\text{DatetimexIndex(['2009-01-01', '2009-01-02', '2009-01-03'], dtype='datetime64[ns]',
\[\name='date', freq=None)}\]
```

It is often the case that we may want to store date and time data separately, or store various date fields separately. The `parse_dates` keyword can be used to specify a combination of columns to parse the dates and/or times from.

You can specify a list of column lists to `parse_dates`, the resulting date columns will be prepended to the output (so as to not affect the existing column order) and the new column names will be the concatenation of the component column names:

```python
In [94]: print(open('tmp.csv').read())
KORD,19990127, 19:00:00, 18:56:00, 0.8100
KORD,19990127, 20:00:00, 19:56:00, 0.0100
KORD,19990127, 21:00:00, 20:56:00, -0.5900
KORD,19990127, 21:00:00, 21:18:00, -0.9900
KORD,19990127, 22:00:00, 21:56:00, -0.5900
KORD,19990127, 23:00:00, 22:56:00, -0.5900
In [95]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]])
In [96]: df
Out[96]:
\begin{verbatim}
   1_2   1_3   0   1   2   3   4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59
\end{verbatim}
```

By default the parser removes the component date columns, but you can choose to retain them via the `keep_date_col` keyword:

```python
In [97]: df = pd.read_csv('tmp.csv', header=None, parse_dates=[[1, 2], [1, 3]],
    ...: keep_date_col=True)
    ...:
In [98]: df
Out[98]:
\begin{verbatim}
   1_2   1_3   0 1 2 3 4
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD 19990127 19:00:00 18:56:00 0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD 19990127 20:00:00 19:56:00 0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD 19990127 21:00:00 20:56:00 -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD 19990127 21:00:00 21:18:00 -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD 19990127 22:00:00 21:56:00 -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD 19990127 23:00:00 22:56:00 -0.59
\end{verbatim}
```

Note that if you wish to combine multiple columns into a single date column, a nested list must be used. In other words, `parse_dates=[1, 2]` indicates that the second and third columns should each be parsed as separate date columns while `parse_dates=[[1, 2]]` means the two columns should be parsed into a single column.

You can also use a dict to specify custom name columns:
It is important to remember that if multiple text columns are to be parsed into a single date column, then a new column is prepended to the data. The `index_col` specification is based off of this new set of columns rather than the original data columns:

```python
In [102]: date_spec = {'nominal': [1, 2], 'actual': [1, 3]}
In [103]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec, index_col=0)  # index is the nominal column
In [104]: df
```

```
   actual 0 4
nominal
0 1999-01-27 19:00:00 1999-01-27 18:56:00 KORD  0.81
1 1999-01-27 20:00:00 1999-01-27 19:56:00 KORD  0.01
2 1999-01-27 21:00:00 1999-01-27 20:56:00 KORD -0.59
3 1999-01-27 21:00:00 1999-01-27 21:18:00 KORD -0.99
4 1999-01-27 22:00:00 1999-01-27 21:56:00 KORD -0.59
5 1999-01-27 23:00:00 1999-01-27 22:56:00 KORD -0.59
```

**Note:** If a column or index contains an unparsable date, the entire column or index will be returned unaltered as an object data type. For non-standard datetime parsing, use `to_datetime()` after `pd.read_csv`.

**Note:** The `read_csv` has a fast path for parsing datetime strings in iso8601 format, e.g. “2000-01-01T00:01:02+00:00” and similar variations. If you can arrange for your data to store datetimes in this format, load times will be significantly faster, ~20× has been observed.

**Note:** When passing a dict as the `parse_dates` argument, the order of the columns prepended is not guaranteed, because `dict` objects do not impose an ordering on their keys. On Python 2.7+ you may use `collections.OrderedDict` instead of a regular `dict` if this matters to you. Because of this, when using a `dict` for ‘parse_dates’ in conjunction with the `index_col` argument, it’s best to specify `index_col` as a column label rather than as an index on the resulting frame.
24.1.9.2 Date Parsing Functions

Finally, the parser allows you to specify a custom `date_parser` function to take full advantage of the flexibility of the date parsing API:

```python
In [105]: import pandas.io.date_converters as conv

In [106]: df = pd.read_csv('tmp.csv', header=None, parse_dates=date_spec,
                     date_parser=conv.parse_date_time)

In [107]: df
```

<table>
<thead>
<tr>
<th>nominal</th>
<th>actual</th>
<th>0</th>
<th>4</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1999-01-27 19:00:00</td>
<td>1999-01-27 18:56:00</td>
<td>KORD</td>
<td>0.81</td>
</tr>
<tr>
<td>1 1999-01-27 20:00:00</td>
<td>1999-01-27 19:56:00</td>
<td>KORD</td>
<td>0.01</td>
</tr>
<tr>
<td>2 1999-01-27 21:00:00</td>
<td>1999-01-27 20:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
<tr>
<td>3 1999-01-27 21:00:00</td>
<td>1999-01-27 21:18:00</td>
<td>KORD</td>
<td>-0.99</td>
</tr>
<tr>
<td>4 1999-01-27 22:00:00</td>
<td>1999-01-27 21:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
<tr>
<td>5 1999-01-27 23:00:00</td>
<td>1999-01-27 22:56:00</td>
<td>KORD</td>
<td>-0.59</td>
</tr>
</tbody>
</table>

Pandas will try to call the `date_parser` function in three different ways. If an exception is raised, the next one is tried:

1. `date_parser` is first called with one or more arrays as arguments, as defined using `parse_dates` (e.g., `date_parser([['2013', '2013'], ['1', '2']])`).
2. If #1 fails, `date_parser` is called with all the columns concatenated row-wise into a single array (e.g., `date_parser([['2013 1', '2013 2']])`).
3. If #2 fails, `date_parser` is called once for every row with one or more string arguments from the columns indicated with `parse_dates` (e.g., `date_parser('2013', '1')` for the first row, `date_parser('2013', '2')` for the second, etc.).

Note that performance-wise, you should try these methods of parsing dates in order:

1. Try to infer the format using `infer_datetime_format=True` (see section below).
2. If you know the format, use `pd.to_datetime()`: `date_parser=lambda x: pd.to_datetime(x, format=...)`.
3. If you have a really non-standard format, use a custom `date_parser` function. For optimal performance, this should be vectorized, i.e., it should accept arrays as arguments.

You can explore the date parsing functionality in `date_converters.py` and add your own. We would love to turn this module into a community supported set of date/time parsers. To get you started, `date_converters.py` contains functions to parse dual date and time columns, year/month/day columns, and year/month/day/hour/minute/second columns. It also contains a `generic_parser` function so you can curry it with a function that deals with a single date rather than the entire array.

24.1.9.3 Inferring Datetime Format

If you have `parse_dates` enabled for some or all of your columns, and your datetime strings are all formatted the same way, you may get a large speed up by setting `infer_datetime_format=True`. If set, pandas will attempt to guess the format of your datetime strings, and then use a faster means of parsing the strings. 5-10x parsing speeds have been observed. pandas will fallback to the usual parsing if either the format cannot be guessed or the format that was guessed cannot properly parse the entire column of strings. So in general, `infer_datetime_format` should not have any negative consequences if enabled.
Here are some examples of datetime strings that can be guessed (All representing December 30th, 2011 at 00:00:00):

- “20111230”
- “2011/12/30”
- “20111230 00:00:00”
- “12/30/2011 00:00:00”
- “30/Dec/2011 00:00:00”
- “30/December/2011 00:00:00”

Note that infer_datetime_format is sensitive to dayfirst. With dayfirst=True, it will guess “01/12/2011” to be December 1st. With dayfirst=False (default) it will guess “01/12/2011” to be January 12th.

```python
# Try to infer the format for the index column
In [108]: df = pd.read_csv('foo.csv', index_col=0, parse_dates=True,
                        ...:                infer_datetime_format=True)
                        
In [109]: df
Out[109]:
   A  B  C
date
2009-01-01 a 1 2
2009-01-02 b 3 4
2009-01-03 c 4 5
```

24.1.9.4 International Date Formats

While US date formats tend to be MM/DD/YYYY, many international formats use DD/MM/YYYY instead. For convenience, a dayfirst keyword is provided:

```python
In [110]: print(open('tmp.csv').read())
date,value,cat
1/6/2000,5,a
2/6/2000,10,b
3/6/2000,15,c

In [111]: pd.read_csv('tmp.csv', parse_dates=[0])

In [112]: pd.read_csv('tmp.csv', dayfirst=True, parse_dates=[0])
```

```python
     date  value  cat
0 2000-01-06   5  a
1 2000-02-06  10  b
2 2000-03-06  15  c
```

```python
     date   value  cat
0 2000-06-01   5  a
1 2000-06-02  10  b
2 2000-06-03  15  c
```
24.1.10 Specifying method for floating-point conversion

The parameter `float_precision` can be specified in order to use a specific floating-point converter during parsing with the C engine. The options are the ordinary converter, the high-precision converter, and the round-trip converter (which is guaranteed to round-trip values after writing to a file). For example:

```python
In [113]: val = '0.3066101993807095471566981359501369297504425048828125'

In [114]: data = 'a,b,c\n1,2,{0}'.format(val)

In [115]: abs(pd.read_csv(StringIO(data), engine='c', float_precision=None)['c'][0] - float(val))
Out[115]: 1.1102230246251565e-16

In [116]: abs(pd.read_csv(StringIO(data), engine='c', float_precision='high')['c'][0] - float(val))
Out[116]: 5.5511151231257827e-17

In [117]: abs(pd.read_csv(StringIO(data), engine='c', float_precision='round_trip')['c'][0] - float(val))
Out[117]: 0.0
```

24.1.11 Thousand Separators

For large numbers that have been written with a thousands separator, you can set the `thousands` keyword to a string of length 1 so that integers will be parsed correctly:

By default, numbers with a thousands separator will be parsed as strings:

```python
In [118]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z

In [119]: df = pd.read_csv('tmp.csv', sep='|')

In [120]: df
Out[120]:
    ID  level category
0  Patient1   123 000   x
1  Patient2    23 000   y
2  Patient3   1,234 018   z

In [121]: df.level.dtype
Out[121]: dtype('O')
```

The `thousands` keyword allows integers to be parsed correctly:

```python
In [122]: print(open('tmp.csv').read())
ID|level|category
Patient1|123,000|x
Patient2|23,000|y
Patient3|1,234,018|z
```

(continues on next page)
24.1.12 NA Values

To control which values are parsed as missing values (which are signified by NaN), specify a string in na_values. If you specify a list of strings, then all values in it are considered to be missing values. If you specify a number (a float, like 5.0 or an integer like 5), the corresponding equivalent values will also imply a missing value (in this case effectively [5.0, 5] are recognized as NaN).

To completely override the default values that are recognized as missing, specify keep_default_na=False.

The default NaN recognized values are ['-1.#IND', '1.#QNAN', '1.#IND', '-1.#QNAN', '#N/A', '#N/A', 'N/A', 'n/a', 'NA', '#NA', 'NULL', 'null', 'NaN', '-NaN', 'nan', '-nan', ''].

Let us consider some examples:

```
read_csv(path, na_values=[5])
```

In the example above 5 and 5.0 will be recognized as NaN, in addition to the defaults. A string will first be interpreted as a numerical 5, then as a NaN.

```
read_csv(path, keep_default_na=False, na_values='''''
```

Above, only an empty field will be recognized as NaN.

```
read_csv(path, keep_default_na=False, na_values=['NA', '0'])
```

Above, both NA and 0 as strings are NaN.

```
read_csv(path, na_values=['Nope'])
```

The default values, in addition to the string "Nope" are recognized as NaN.

24.1.13 Infinity

inf like values will be parsed as np.inf (positive infinity), and -inf as -np.inf (negative infinity). These will ignore the case of the value, meaning Inf, will also be parsed as np.inf.

24.1.14 Returning Series

Using the squeeze keyword, the parser will return output with a single column as a Series:
In [126]: print(open('tmp.csv').read())
level
Patient1,123000
Patient2,23000
Patient3,1234018

In [127]: output = pd.read_csv('tmp.csv', squeeze=True)

In [128]: output
Out[128]:
Patient1 123000
Patient2 23000
Patient3 1234018
Name: level, dtype: int64

In [129]: type(output)
Out[129]: pandas.core.series.Series

24.1.15 Boolean values

The common values True, False, TRUE, and FALSE are all recognized as boolean. Occasionally you might want to recognize other values as being boolean. To do this, use the true_values and false_values options as follows:

In [130]: data= 'a,b,c

1,Yes,2
3,No,4'

In [131]: print(data)
a,b,c
1,Yes,2
3,No,4

In [132]: pd.read_csv(StringIO(data))

In [133]: pd.read_csv(StringIO(data), true_values=['Yes'], false_values=['No'])

24.1.16 Handling “bad” lines

Some files may have malformed lines with too few fields or too many. Lines with too few fields will have NA values filled in the trailing fields. Lines with too many fields will raise an error by default:

In [27]: data = 'a,b,c

1,2,3
4,5,6,7
8,9,10'

In [28]: pd.read_csv(StringIO(data))
---------------------------------------------------------------------------
ParserError
ParserError: Error tokenizing data. C error: Expected 3 fields in line 3, saw 4
You can elect to skip bad lines:

```
In [29]: pd.read_csv(StringIO(data), error_bad_lines=False)
Skipping line 3: expected 3 fields, saw 4

Out[29]:
    a  b  c
0  1  2  3
1  8  9 10
```

You can also use the `usecols` parameter to eliminate extraneous column data that appear in some lines but not others:

```
In [30]: pd.read_csv(StringIO(data), usecols=[0, 1, 2])

Out[30]:
    a  b  c
0  1  2  3
1  4  5  6
2  8  9 10
```

### 24.1.17 Dialect

The `dialect` keyword gives greater flexibility in specifying the file format. By default it uses the Excel dialect but you can specify either the dialect name or a `csv.Dialect` instance.

Suppose you had data with unenclosed quotes:

```
In [134]: print(data)
label1,label2,label3
index1,"a,c,e
index2,b,d,f
```

By default, `read_csv` uses the Excel dialect and treats the double quote as the quote character, which causes it to fail when it finds a newline before it finds the closing double quote.

We can get around this using `dialect`:

```
In [135]: dia = csv.excel()
In [136]: dia.quoting = csv.QUOTE_NONE
In [137]: pd.read_csv(StringIO(data), dialect=dia)
Out[137]:
    label1 label2 label3
index1 "a c e
index2  b d f
```

All of the dialect options can be specified separately by keyword arguments:

```
In [138]: data = 'a,b,c~1,2,3~4,5,6'
In [139]: pd.read_csv(StringIO(data), lineterminator='~')
Out[139]:
    a  b  c
0  1  2  3
1  4  5  6
```

Another common dialect option is `skipinitialspace`, to skip any whitespace after a delimiter:
In [140]: data = 'a, b, c

1, 2, 3

4, 5, 6'

In [141]: print(data)
a, b, c
1, 2, 3
4, 5, 6

In [142]: pd.read_csv(StringIO(data), skipinitialspace=True)
Out[142]:
\a b c
0 1 2 3
1 4 5 6

The parsers make every attempt to “do the right thing” and not be fragile. Type inference is a pretty big deal. If a column can be coerced to integer dtype without altering the contents, the parser will do so. Any non-numeric columns will come through as object dtype as with the rest of pandas objects.

### 24.1.18 Quoting and Escape Characters

Quotes (and other escape characters) in embedded fields can be handled in any number of ways. One way is to use backslashes; to properly parse this data, you should pass the escapechar option:

In [143]: data = 'a,b

"hello, "Bob\", nice to see you",5'

In [144]: print(data)
a,b
"hello, "Bob\", nice to see you",5

In [145]: pd.read_csv(StringIO(data), escapechar='\')
Out[145]:
a b
0 hello, "Bob", nice to see you 5

### 24.1.19 Files with Fixed Width Columns

While `read_csv()` reads delimited data, the `read_fwf()` function works with data files that have known and fixed column widths. The function parameters to `read_fwf` are largely the same as `read_csv` with two extra parameters, and a different usage of the `delimiter` parameter:

- `colspecs`: A list of pairs (tuples) giving the extents of the fixed-width fields of each line as half-open intervals (i.e., [from, to]). String value ‘infer’ can be used to instruct the parser to try detecting the column specifications from the first 100 rows of the data. Default behavior, if not specified, is to infer.

- `widths`: A list of field widths which can be used instead of ‘colspecs’ if the intervals are contiguous.

- `delimiter`: Characters to consider as filler characters in the fixed-width file. Can be used to specify the filler character of the fields if it is not spaces (e.g., ‘~’).

Consider a typical fixed-width data file:

In [146]: print(open('bar.csv').read())
id8141 360.242940 149.910199 11950.7
id1594 444.953632 166.985655 11788.4
id1849 364.136849 183.628767 11806.2
id1230 413.836124 184.375703 11916.8
id1948 502.953953 173.237159 12468.3

24.1. CSV & Text files
In order to parse this file into a DataFrame, we simply need to supply the column specifications to the `read_fwf` function along with the file name:

```python
# Column specifications are a list of half-intervals
In [147]: colspecs = [(0, 6), (8, 20), (21, 33), (34, 43)]

In [148]: df = pd.read_fwf('bar.csv', colspecs=colspecs, header=None, index_col=0)

In [149]: df
```

Note how the parser automatically picks column names `X.<column number>` when `header=None` argument is specified. Alternatively, you can supply just the column widths for contiguous columns:

```python
# Widths are a list of integers
In [150]: widths = [6, 14, 13, 10]

In [151]: df = pd.read_fwf('bar.csv', widths=widths, header=None)

In [152]: df
```

The parser will take care of extra white spaces around the columns so it’s ok to have extra separation between the columns in the file.

By default, `read_fwf` will try to infer the file’s `colspecs` by using the first 100 rows of the file. It can do it only in cases when the columns are aligned and correctly separated by the provided `delimiter` (default delimiter is whitespace).

```python
In [153]: df = pd.read_fwf('bar.csv', header=None, index_col=0)

In [154]: df
```

New in version 0.20.0.

`read_fwf` supports the `dtype` parameter for specifying the types of parsed columns to be different from the inferred type.
In [155]: pd.read_fwf('bar.csv', header=None, index_col=0).dtypes
Out[155]:
1    float64
2    float64
3    float64
dtype: object

In [156]: pd.read_fwf('bar.csv', header=None, dtype={2: 'object'}).dtypes
Out[156]:
0    object
1    float64
2    object
3    float64
dtype: object

24.1.20 Indexes

24.1.20.1 Files with an “implicit” index column

Consider a file with one less entry in the header than the number of data column:

In [157]: print(open('foo.csv').read())
A,B,C
20090101,a,1,2
20090102,b,3,4
20090103,c,4,5

In this special case, read_csv assumes that the first column is to be used as the index of the DataFrame:

In [158]: pd.read_csv('foo.csv')
Out[158]:
   A  B  C
0 20090101  a  1  2
1 20090102  b  3  4
2 20090103  c  4  5

Note that the dates weren’t automatically parsed. In that case you would need to do as before:

In [159]: df = pd.read_csv('foo.csv', parse_dates=True)

In [160]: df.index
Out[160]: DatetimeIndex(['2009-01-01', '2009-01-02', '2009-01-03'],
dtype='datetime64[ns]', freq=None)

24.1.20.2 Reading an index with a MultiIndex

Suppose you have data indexed by two columns:

In [161]: print(open('data/mindex_ex.csv').read())
year,indiv,zit,xit
1977,"A",1.2,.6
1977,"B",1.5,.5
1977,"C",1.7,.8
1978,"A",.2,.06

(continues on next page)
1978,"B",.7,.2
1978,"C",.8,.3
1978,"D",.9,.5
1978,"E",1.4,.9
1979,"C",.2,.15
1979,"D",.14,.05
1979,"E",.5,.15
1979,"F",1.2,.5
1979,"G",3.4,1.9
1979,"H",5.4,2.7
1979,"I",6.4,1.2

The `index_col` argument to `read_csv` and `read_table` can take a list of column numbers to turn multiple columns into a MultiIndex for the index of the returned object:

```python
In [162]: df = pd.read_csv("data/mindex_ex.csv", index_col=[0,1])
In [163]: df
Out[163]:
   zit  xit
year indiv
1977 A   1.20  0.60
   B   1.50  0.50
   C   1.70  0.80
1978 A   0.20  0.06
   B   0.70  0.20
   C   0.80  0.30
   D   0.90  0.50
   E   1.40  0.90
1979 C   0.20  0.15
   D   0.14  0.05
   E   0.50  0.15
   F   1.20  0.50
   G   3.40  1.90
   H   5.40  2.70
   I   6.40  1.20
```

By specifying list of row locations for the `header` argument, you can read in a MultiIndex for the columns. Specifying non-consecutive rows will skip the intervening rows.

```python
In [165]: from pandas.util.testing import makeCustomDataframe as mkdf
```
In [166]: df = mkdf(5, 3, r_idx_nlevels=2, c_idx_nlevels=4)

In [167]: df.to_csv('mi.csv')

In [168]: print(open('mi.csv').read())
C0,,C_l0_g0,C_l0_g1,C_l0_g2
C1,,C_l1_g0,C_l1_g1,C_l1_g2
C2,,C_l2_g0,C_l2_g1,C_l2_g2
C3,,C_l3_g0,C_l3_g1,C_l3_g2
R0,R1,,
R_l0_g0,R_l1_g0,R0C0,R0C1,R0C2
R_l0_g1,R_l1_g1,R1C0,R1C1,R1C2
R_l0_g2,R_l1_g2,R2C0,R2C1,R2C2
R_l0_g3,R_l1_g3,R3C0,R3C1,R3C2
R_l0_g4,R_l1_g4,R4C0,R4C1,R4C2

In [169]: pd.read_csv('mi.csv', header=[0, 1, 2, 3], index_col=[0, 1])

read_csv is also able to interpret a more common format of multi-columns indices.

In [170]: print(open('mi2.csv').read())
,a,a,a,b,c,c
,q,r,s,t,u,v
one,1,2,3,4,5,6
two,7,8,9,10,11,12

In [171]: pd.read_csv('mi2.csv', header=[0, 1], index_col=0)

Note: If an index_col is not specified (e.g. you don’t have an index, or wrote it with df.to_csv(..., index=False)), then any names on the columns index will be lost.

24.1.21 Automatically “sniffing” the delimiter

read_csv is capable of inferring delimited (not necessarily comma-separated) files, as pandas uses the csv. Sniffer class of the csv module. For this, you have to specify sep=None.
24.1.22 Reading multiple files to create a single DataFrame

It’s best to use `concat()` to combine multiple files. See the cookbook for an example.

24.1.23 Iterating through files chunk by chunk

Suppose you wish to iterate through a (potentially very large) file lazily rather than reading the entire file into memory, such as the following:

```python
In [174]: print(open('tmp.sv').read())
0:0.4691122999071863|0.2828633443286633|1.5090585031735124|1.1356323710171934
1:1.2121120250208506|0.17321464905330858|0.11920871129693428|1.0442359662799567
2:-0.861848963477999|2.1045692188948086|0.4949292740687813|1.071803807037338
3:0.721551622443669|0.7067111363600845|0.395749851146963|0.27185988554282986
4:-0.42497232978883753|0.56702439793672|0.27623201927771873|1.0874006912859915
5:0.673689780883706|0.1136480496888855|1.4784265524372235|0.5249876671147047
6:0.4047052186802365|0.770459895204836|1.7150020161164375|1.039268435147725
7:-0.3706468582364644|1.1578922506419993|1.344311812731667|0.8448851414248841
8:1.0757697837155533|0.1090499752802223|1.6435630703622064|1.1693879595399115
9:0.35702056413309086|0.674601037299882|1.776903716971867|0.9689138124473498
```

```python
In [175]: table = pd.read_table('tmp.sv', sep='|')
```

(continues on next page)
By specifying a chunksize to read_csv or read_table, the return value will be an iterable object of type TextFileReader:

```
In [177]: reader = pd.read_table('tmp.sv', sep='|', chunksize=4)
In [178]: reader
Out[178]: <pandas.io.parsers.TextFileReader at 0x1c27821358>
In [179]: for chunk in reader:
.....:     print(chunk)
.....:
\                                                                                       Unnamed: 0 0 1 2 3
→ 0 0 0.469112 -0.282863 -1.509059 -1.135632                                    3
1 1 1.212112 -0.173215 0.119209 -1.044236                                    2
2 2 -0.861849 -2.104569 -0.494929 1.071804                                    3
3 3 0.721555 -0.706771 -1.344312 0.844885                                    1
4 4 -0.424972 0.567020 0.276232 -1.087401                                    3
5 5 0.404705 0.577046 -1.715002 -1.039268                                    3
6 6 -0.370647 -1.157892 -1.344312 0.844885                                    1
7 7 1.075770 -0.109050 1.643563 -1.469388                                    3
8 8 0.357021 -0.674600 -1.776904 -0.968914                                    3
```

Specifying iterator=True will also return the TextFileReader object:

```
In [180]: reader = pd.read_table('tmp.sv', sep='|', iterator=True)
In [181]: reader.get_chunk(5)
Out[181]:
```

```
0 0 0.469112 -0.282863 -1.509059 -1.135632                                    3
1 1 1.212112 -0.173215 0.119209 -1.044236                                    2
2 2 -0.861849 -2.104569 -0.494929 1.071804                                    3
3 3 0.721555 -0.706771 -1.344312 0.844885                                    1
4 4 -0.424972 0.567020 0.276232 -1.087401                                    3
```
24.1.24 Specifying the parser engine

Under the hood pandas uses a fast and efficient parser implemented in C as well as a Python implementation which is currently more feature-complete. Where possible pandas uses the C parser (specified as `engine='c'`), but may fall back to Python if C-unsupported options are specified. Currently, C-unsupported options include:

- `sep` other than a single character (e.g. regex separators)
- `skipfooter`
- `sep=None with delim_whitespace=False`

Specifying any of the above options will produce a `ParserWarning` unless the python engine is selected explicitly using `engine='python'`.

24.1.25 Reading remote files

You can pass in a URL to a CSV file:

```python
df = pd.read_csv('https://download.bls.gov/pub/time.series/cu/cu.item', sep='\t')
```

S3 URLs are handled as well:

```python
df = pd.read_csv('s3://pandas-test/tips.csv')
```

24.1.26 Writing out Data

24.1.26.1 Writing to CSV format

The `Series` and `DataFrame` objects have an instance method `to_csv` which allows storing the contents of the object as a comma-separated-values file. The function takes a number of arguments. Only the first is required.

- `path_or_buf`: A string path to the file to write or a `StringIO`
- `sep`: Field delimiter for the output file (default ",")
- `na_rep`: A string representation of a missing value (default '')
- `float_format`: Format string for floating point numbers
- `cols`: Columns to write (default None)
- `header`: Whether to write out the column names (default True)
- `index`: Whether to write row (index) names (default True)
- `index_label`: Column label(s) for index column(s) if desired. If None (default), and `header` and `index` are True, then the index names are used. (A sequence should be given if the `DataFrame` uses MultiIndex).
- `mode`: Python write mode, default ‘w’
- `encoding`: A string representing the encoding to use if the contents are non-ASCII, for Python versions prior to 3
- `line_terminator`: Character sequence denoting line end (default ‘\n’)
- `quoting`: Set quoting rules as in csv module (default csv.QUOTE_MINIMAL). Note that if you have set a `float_format` then floats are converted to strings and csv.QUOTE_NONNUMERIC will treat them as non-numeric
• `quotechar`: Character used to quote fields (default ‘”’)
• `doublequote`: Control quoting of `quotechar` in fields (default True)
• `escapechar`: Character used to escape `sep` and `quotechar` when appropriate (default None)
• `chunksize`: Number of rows to write at a time
• `tupleize_cols`: If False (default), write as a list of tuples, otherwise write in an expanded line format suitable for `read_csv`
• `date_format`: Format string for datetime objects

### 24.1.26.2 Writing a formatted string

The `DataFrame` object has an instance method `to_string` which allows control over the string representation of the object. All arguments are optional:

- `buf` default None, for example a `StringIO` object
- `columns` default None, which columns to write
- `col_space` default None, minimum width of each column.
- `na_rep` default NaN, representation of NA value
- `formatters` default None, a dictionary (by column) of functions each of which takes a single argument and returns a formatted string
- `float_format` default None, a function which takes a single (float) argument and returns a formatted string; to be applied to floats in the `DataFrame`
- `sparsify` default True, set to False for a `DataFrame` with a hierarchical index to print every multiindex key at each row.
- `index_names` default True, will print the names of the indices
- `index` default True, will print the index (ie, row labels)
- `header` default True, will print the column labels
- `justify` default `left`, will print column headers left- or right-justified

The `Series` object also has a `to_string` method, but with only the `buf, na_rep, float_format` arguments. There is also a `length` argument which, if set to `True`, will additionally output the length of the `Series`.

### 24.2 JSON

Read and write JSON format files and strings.

### 24.2.1 Writing JSON

A `Series` or `DataFrame` can be converted to a valid JSON string. Use `to_json` with optional parameters:

- `path_or_buf`: the pathname or buffer to write the output This can be `None` in which case a JSON string is returned
- `orient`: **Series**:
pandas: powerful Python data analysis toolkit, Release 0.23.0rc1

- default is `index`
- allowed values are `{split, records, index}`

**DataFrame:**
- default is `columns`
- allowed values are `{split, records, index, columns, values, table}`

The format of the JSON string

<table>
<thead>
<tr>
<th>split</th>
<th>dict like <code>{index -&gt; [index], columns -&gt; [columns], data -&gt; [values]}</code></th>
</tr>
</thead>
<tbody>
<tr>
<td>records</td>
<td>list like <code>[[column -&gt; value], ..., [column -&gt; value]]</code></td>
</tr>
<tr>
<td>index</td>
<td>dict like <code>{index -&gt; [column -&gt; value]}</code></td>
</tr>
<tr>
<td>columns</td>
<td>dict like <code>{column -&gt; [index -&gt; value]}</code></td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
</tbody>
</table>

- `date_format`: string, type of date conversion, `epoch` for timestamp, `iso` for ISO8601.
- `double_precision`: The number of decimal places to use when encoding floating point values, default 10.
- `force_ascii`: force encoded string to be ASCII, default True.
- `date_unit`: The time unit to encode to, governs timestamp and ISO8601 precision. One of `s`, `ms`, `us` or `ns` for seconds, milliseconds, microseconds and nanoseconds respectively. Default `ms`.
- `default_handler`: The handler to call if an object cannot otherwise be converted to a suitable format for JSON. Takes a single argument, which is the object to convert, and returns a serializable object.
- `lines`: If `records` orient, then will write each record per line as json.

Note NaN’s, NaT’s and None will be converted to null and datetime objects will be converted based on the `date_format` and `date_unit` parameters.

```python
In [182]: dfj = pd.DataFrame(randn(5, 2), columns=list('AB'))
In [183]: json = dfj.to_json()
In [184]: json
Out[184]: 'A:
0: -1.2945235903,
1: 0.2766617129,
2: -0.0139597524,
3: -0.0061535699,
4: 0.8957173022,
B: 
0: 0.4137381054,
1: -0.472034511,
2: -0.3625429925,
3: -0.923060654,
4: 0.8052440254}
```

### 24.2.1.1 Orient Options

There are a number of different options for the format of the resulting JSON file / string. Consider the following `DataFrame` and `Series`:

```python
In [185]: dfjo = pd.DataFrame(dict(A=range(1, 4), B=range(4, 7), C=range(7, 10)),
                        columns=list('ABC'), index=list('xyz'))
In [186]: dfjo
Out[186]:
   A  B  C
x 1  4  7
y 2  5  8
z 3  6  9
```

(continues on next page)
In 

sjo = pd.Series(dict(x=15, y=16, z=17), name='D')

In 

sjo

Out

x 15
y 16
z 17
Name: D, dtype: int64

Column oriented (the default for DataFrame) serializes the data as nested JSON objects with column labels acting as the primary index:

In 

dfjo.to_json(orient="columns")

Out

"A":{"x":1,"y":2,"z":3},"B":{"x":4,"y":5,"z":6},"C":{"x":7,"y":8,"z":9}

# Not available for Series

Index oriented (the default for Series) similar to column oriented but the index labels are now primary:

In 

dfjo.to_json(orient="index")

Out

"x":{"A":1,"B":4,"C":7},"y":{"A":2,"B":5,"C":8},"z":{"A":3,"B":6,"C":9}

In 

sjo.to_json(orient="index")

Out

˓→{"x":15,"y":16,"z":17}

Record oriented serializes the data to a JSON array of column -> value records, index labels are not included. This is useful for passing DataFrame data to plotting libraries, for example the JavaScript library d3.js:

In 

dfjo.to_json(orient="records")

Out

In 

sjo.to_json(orient="records")

Out

˓→[15,16,17]

Value oriented is a bare-bones option which serializes to nested JSON arrays of values only, column and index labels are not included:

In 

dfjo.to_json(orient="values")

Out

[[1,4,7],[2,5,8],[3,6,9]]

# Not available for Series

Split oriented serializes to a JSON object containing separate entries for values, index and columns. Name is also included for Series:

In 

dfjo.to_json(orient="split")

Out

{"columns":["A","B","C"],"index":["x","y","z"],"data":[[1,4,7],[2,5,8],[3,6,9]]}

In 

sjo.to_json(orient="split")

Out

˓→{"name":"D","index":["x","y","z"],"data":[15,16,17]}
Table oriented serializes to the JSON Table Schema, allowing for the preservation of metadata including but not limited to dtypes and index names.

Note: Any orient option that encodes to a JSON object will not preserve the ordering of index and column labels during round-trip serialization. If you wish to preserve label ordering use the split option as it uses ordered containers.

### 24.2.1.2 Date Handling

Writing in ISO date format:

```python
In [197]: dfd = pd.DataFrame(randn(5, 2), columns=list('AB'))

In [198]: dfd['date'] = pd.Timestamp('20130101')

In [199]: dfd = dfd.sort_index(1, ascending=False)

In [200]: json = dfd.to_json(date_format='iso')

In [201]: json
Out[201]: '{"date":{"0":"2013-01-01T00:00:00.000Z","1":"2013-01-01T00:00.000Z","2":
"2013-01-01T00:00.000Z","3":"2013-01-01T00:00.000Z","4":"2013-01-01T00:00.000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-
0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.
-4108345112,"4":0.1320031703}}'
```

Writing in ISO date format, with microseconds:

```python
In [202]: json = dfd.to_json(date_format='iso', date_unit='us')

In [203]: json
Out[203]: '{"date":{"0":"2013-01-01T00:00:00.000000Z","1":"2013-01-01T00:00.000000Z","2":
"2013-01-01T00:00.000000Z","3":"2013-01-01T00:00.000000Z","4":"2013-01-01T00:00.000000Z"},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-
0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}}'
```

Epoch timestamps, in seconds:

```python
In [204]: json = dfd.to_json(date_format='epoch', date_unit='s')

In [205]: json
Out[205]: '{"date":{"0":1356998400,"1":1356998400,"2":1356998400,"3":1356998400,"4":1356998400},"B":{"0":2.5656459463,"1":1.3403088498,"2":-0.2261692849,"3":0.8138502857,"4":-
0.8273169356},"A":{"0":-1.2064117817,"1":1.4312559863,"2":-1.1702987971,"3":0.4108345112,"4":0.1320031703}}'
```

Writing to a file, with a date index and a date column:

```python
In [206]: dfj2 = dfj.copy()

In [207]: dfj2['date'] = pd.Timestamp('20130101')

In [208]: dfj2['ints'] = list(range(5))

In [209]: dfj2['bools'] = True
```

(continues on next page)
24.2.1.3 Fallback Behavior

If the JSON serializer cannot handle the container contents directly it will fall back in the following manner:

- if the dtype is unsupported (e.g. np.complex) then the default_handler, if provided, will be called for each value, otherwise an exception is raised.
- if an object is unsupported it will attempt the following:
  - check if the object has defined a toDict method and call it. A toDict method should return a dict which will then be JSON serialized.
  - invoke the default_handler if one was provided.
  - convert the object to a dict by traversing its contents. However this will often fail with an OverflowError or give unexpected results.

In general the best approach for unsupported objects or dtypes is to provide a default_handler. For example:

```python
In [213]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[213]: '{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}'
```

can be dealt with by specifying a simple default_handler:

```python
In [213]: pd.DataFrame([1.0, 2.0, complex(1.0, 2.0)]).to_json(default_handler=str)
Out[213]: '{"0":"(1+0j)","1":"(2+0j)","2":"(1+2j)"}'
```

24.2.2 Reading JSON

Reading a JSON string to pandas object can take a number of parameters. The parser will try to parse a DataFrame if typ is not supplied or is None. To explicitly force Series parsing, pass typ=series

- filepath_or_buffer: a VALID JSON string or file handle / StringIO. The string could be a URL. Valid URL schemes include http, ftp, S3, and file. For file URLs, a host is expected. For instance, a local file could be file ://localhost/path/to/table.json
- typ: type of object to recover (series or frame), default ‘frame’
- orient:
Series:
- default is index
- allowed values are \{split, records, index\}

DataFrame
- default is columns
- allowed values are \{split, records, index, columns, values, table\}

The format of the JSON string

<table>
<thead>
<tr>
<th></th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>split</td>
<td>dict like [index -&gt; [index], columns -&gt; [columns], data -&gt; [values]]</td>
</tr>
<tr>
<td>records</td>
<td>list like [[column -&gt; value], ...., [column -&gt; value]]</td>
</tr>
<tr>
<td>index</td>
<td>dict like [index -&gt; [column -&gt; value]]</td>
</tr>
<tr>
<td>columns</td>
<td>dict like [column -&gt; [index -&gt; value]]</td>
</tr>
<tr>
<td>values</td>
<td>just the values array</td>
</tr>
<tr>
<td>table</td>
<td>adhering to the JSON Table Schema</td>
</tr>
</tbody>
</table>

- dtype: if True, infer dtypes, if a dict of column to dtype, then use those, if False, then don’t infer dtypes at all, default is True, apply only to the data.
- convert_axes: boolean, try to convert the axes to the proper dtypes, default is True
- convert_dates: a list of columns to parse for dates; If True, then try to parse date-like columns, default is True.
- keep_default_dates: boolean, default True. If parsing dates, then parse the default date-like columns.
- numpy: direct decoding to NumPy arrays. default is False; Supports numeric data only, although labels may be non-numeric. Also note that the JSON ordering MUST be the same for each term if numpy=True.
- precise_float: boolean, default False. Set to enable usage of higher precision (strtod) function when decoding string to double values. Default (False) is to use fast but less precise built-in functionality.
- date_unit: string, the timestamp unit to detect if converting dates. Default None. By default the timestamp precision will be detected, if this is not desired then pass one of ‘s’, ‘ms’, ‘us’ or ‘ns’ to force timestamp precision to seconds, milliseconds, microseconds or nanoseconds respectively.
- lines: reads file as one json object per line.
- encoding: The encoding to use to decode py3 bytes.
- chunksize: when used in combination with lines=True, return a JsonReader which reads in chunksize lines per iteration.

The parser will raise one of ValueError/TypeError/AssertionError if the JSON is not parseable.

If a non-default orient was used when encoding to JSON be sure to pass the same option here so that decoding produces sensible results, see Orient Options for an overview.

24.2.2.1 Data Conversion

The default of convert_axes=True, dtype=True, and convert_dates=True will try to parse the axes, and all of the data into appropriate types, including dates. If you need to override specific dtypes, pass a dict to dtype. convert_axes should only be set to False if you need to preserve string-like numbers (e.g. ‘1’, ‘2’) in an axes.
**Note:** Large integer values may be converted to dates if `convert_dates=True` and the data and/or column labels appear 'date-like'. The exact threshold depends on the `date_unit` specified. 'date-like' means that the column label meets one of the following criteria:

- it ends with '_at'
- it ends with '_time'
- it begins with 'timestamp'
- it is 'modified'
- it is 'date'

**Warning:** When reading JSON data, automatic coercing into dtypes has some quirks:

- an index can be reconstructed in a different order from serialization, that is, the returned order is not guaranteed to be the same as before serialization
- a column that was float data will be converted to integer if it can be done safely, e.g. a column of 1. bool columns will be converted to integer on reconstruction

Thus there are times where you may want to specify specific dtypes via the `dtype` keyword argument.

Reading from a JSON string:

```
In [214]: pd.read_json(json)
Out[214]:
          date      B      A
0  2013-01-01  2.565646 -1.206412
1  2013-01-01  1.340309  1.431256
2  2013-01-01 -0.226169 -1.170299
3  2013-01-01  0.813850  0.410835
4  2013-01-01 -0.827317  0.132003
```

Reading from a file:

```
In [215]: pd.read_json('test.json')
Out[215]:
             A        B    date        ints  bools
2013-01-01 -1.294524  0.413738 2013-01-01      0 True
2013-01-02  0.276662 -0.472035 2013-01-01      1 True
2013-01-03 -0.013960  0.362543 2013-01-01      2 True
2013-01-04 -0.006154  0.923061 2013-01-01      3 True
2013-01-05  0.895717  0.805244 2013-01-01      4 True
```

Don’t convert any data (but still convert axes and dates):

```
In [216]: pd.read_json('test.json', dtype=object).dtypes
Out[216]:
          A      B    date        ints  bools
dtype: object
```
Specify dtypes for conversion:

```python
In [217]: pd.read_json('test.json', dtype={'A': 'float32', 'bools': 'int8'}).dtypes
Out[217]:
A    float32
B    float64
date   datetime64[ns]
ints   int64
bools  int8
dtype: object
```

Preserve string indices:

```python
In [218]: si = pd.DataFrame(np.zeros((4, 4)),
.....:     columns=list(range(4)),
.....:     index=[str(i) for i in range(4)])

In [219]: si
Out[219]:
     0  1  2  3
0  0.0 0.0 0.0 0.0
1  0.0 0.0 0.0 0.0
2  0.0 0.0 0.0 0.0
3  0.0 0.0 0.0 0.0

In [220]: si.index
Out[220]:
Index(['0', '1', '2', '3'], dtype='object')

In [221]: si.columns
Out[221]:
Int64Index([0, 1, 2, 3], dtype='int64')

In [222]: json = si.to_json()

In [223]: sij = pd.read_json(json, convert_axes=False)

In [224]: sij
Out[224]:
     0  1  2  3
0  0.0 0.0 0.0 0.0
1  0.0 0.0 0.0 0.0
2  0.0 0.0 0.0 0.0
3  0.0 0.0 0.0 0.0

In [225]: sij.index
Out[225]:
Index(['0', '1', '2', '3'], dtype='object')

In [226]: sij.columns
Out[226]:
Index(['0', '1', '2', '3'], dtype='object')
```

Dates written in nanoseconds need to be read back in nanoseconds:

```python
In [227]: json = dfj2.to_json(date_unit='ns')
```

(continues on next page)
# Try to parse timestamps as milliseconds -> Won't Work
```
In [228]: dfju = pd.read_json(json, date_unit='ms')
```
```
In [229]: dfju
Out[229]:
   A     B  date  ints  bools
0  1.294524  0.413738  1356998400000000000  0  True
1  0.276662 -0.472035  1356998400000000000  1  True
2 -0.013960 -0.362543  1356998400000000000  2  True
3 -0.006154 -0.923061  1356998400000000000  3  True
4  0.895717  0.805244  1356998400000000000  4  True
```

# Let pandas detect the correct precision
```
In [230]: dfju = pd.read_json(json)
```
```
In [231]: dfju
Out[231]:
   A     B  date  ints  bools
0  2013-01-01  -1.294524  0.413738  2013-01-01  0  True
1  2013-01-02   0.276662 -0.472035  2013-01-01  1  True
2  2013-01-03  -0.013960 -0.362543  2013-01-01  2  True
3  2013-01-04  -0.006154 -0.923061  2013-01-01  3  True
4  2013-01-05   0.895717  0.805244  2013-01-01  4  True
```

# Or specify that all timestamps are in nanoseconds
```
In [232]: dfju = pd.read_json(json, date_unit='ns')
```
```
In [233]: dfju
Out[233]:
   A     B  date  ints  bools
0  2013-01-01  -1.294524  0.413738  2013-01-01  0  True
1  2013-01-02   0.276662 -0.472035  2013-01-01  1  True
2  2013-01-03  -0.013960 -0.362543  2013-01-01  2  True
3  2013-01-04  -0.006154 -0.923061  2013-01-01  3  True
4  2013-01-05   0.895717  0.805244  2013-01-01  4  True
```

### 24.2.2.2 The Numpy Parameter

**Note:** This supports numeric data only. Index and columns labels may be non-numeric, e.g. strings, dates etc.

If `numpy=True` is passed to `read_json` an attempt will be made to sniff an appropriate dtype during deserialization and to subsequently decode directly to NumPy arrays, bypassing the need for intermediate Python objects.

This can provide speedups if you are deserialising a large amount of numeric data:
```
In [234]: randfloats = np.random.uniform(-100, 1000, 10000)
In [235]: randfloats.shape = (1000, 10)
In [236]: dffloats = pd.DataFrame(randfloats, columns=list('ABCDEFGHIJ'))
In [237]: jsonfloats = dffloats.to_json()
```
The speedup is less noticeable for smaller datasets:

```python
In [240]: jsonfloats = dffloats.head(100).to_json()
```

```python
In [241]: timeit pd.read_json(jsonfloats)
```

```python
5.58 ms +- 275 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

```python
In [242]: timeit pd.read_json(jsonfloats, numpy=True)
```

```python
4.62 ms +- 225 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Warning:** Direct NumPy decoding makes a number of assumptions and may fail or produce unexpected output if these assumptions are not satisfied:

- data is numeric.
- data is uniform. The dtype is sniffed from the first value decoded. A `ValueError` may be raised, or incorrect output may be produced if this condition is not satisfied.
- labels are ordered. Labels are only read from the first container, it is assumed that each subsequent row / column has been encoded in the same order. This should be satisfied if the data was encoded using `to_json` but may not be the case if the JSON is from another source.

### 24.2.3 Normalization

pandas provides a utility function to take a dict or list of dicts and **normalize** this semi-structured data into a flat table.

```python
In [243]: from pandas.io.json import json_normalize
```

```python
In [244]: data = [  
            {'id': 1, 'name': {'first': 'Coleen', 'last': 'Volk'}},  
            {'name': {'given': 'Mose', 'family': 'Regner'}},  
            {'id': 2, 'name': 'Faye Raker'}  
        ]
```

```python
In [245]: json_normalize(data)
```

```python
Out[245]:
   id     name family.first name.given name.last  
0  1.0       NaN        NaN     Coleen        NaN     Volk  
1  NaN        NaN     Regner        NaN      Mose        NaN  
2  2.0  Faye Raker        NaN        NaN        NaN        NaN
```

```python
In [246]: data = [  
            {'state': 'Florida',  
             'info': {  
                'governor': 'Rick Scott'  
             }  
        }  
            ,  
            {'name': 'Dade', 'population': 12345},  
            {'name': 'Broward', 'population': 40000}  
        ]
```

(continues on next page)
In [247]: json_normalize(data, 'counties', ['state', 'shortname', ['info', 'governor']])

Out[247]:

<table>
<thead>
<tr>
<th>name</th>
<th>population</th>
<th>state</th>
<th>shortname</th>
<th>info.governor</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dade</td>
<td>12345</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Broward</td>
<td>40000</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Palm Beach</td>
<td>60000</td>
<td>Florida</td>
<td>FL</td>
<td>Rick Scott</td>
</tr>
<tr>
<td>Summit</td>
<td>1234</td>
<td>Ohio</td>
<td>OH</td>
<td>John Kasich</td>
</tr>
<tr>
<td>Cuyahoga</td>
<td>1337</td>
<td>Ohio</td>
<td>OH</td>
<td>John Kasich</td>
</tr>
</tbody>
</table>

24.2.4 Line delimited json

New in version 0.19.0.

pandas is able to read and write line-delimited json files that are common in data processing pipelines using Hadoop or Spark.

New in version 0.21.0.

For line-delimited json files, pandas can also return an iterator which reads in chunksize lines at a time. This can be useful for large files or to read from a stream.

In [248]: jsonl = ''
   ....:  "a": 1, "b": 2
   ....:  "a": 3, "b": 4
   ....:  ...
   ....:

In [249]: df = pd.read_json(jsonl, lines=True)

In [250]: df

Out[250]:
   a  b
0  1  2
1  3  4

In [251]: df.to_json(orient='records', lines=True)

# reader is an iterator that returns 'chunksize' lines each iteration
In [252]: reader = pd.read_json(StringIO(jsonl), lines=True, chunksize=1)

In [253]: reader

Out[253]: <pandas.io.json.json.JsonReader at 0x1c27976f28>

In [254]: for chunk in reader:

24.2.5 Table Schema

New in version 0.20.0.

Table Schema is a spec for describing tabular datasets as a JSON object. The JSON includes information on the field names, types, and other attributes. You can use the orient table to build a JSON string with two fields, schema and data.

```
In [255]: df = pd.DataFrame(
    ....:     {'A': [1, 2, 3],
    ....:       'B': ['a', 'b', 'c'],
    ....:       'C': pd.date_range('2016-01-01', freq='d', periods=3),
    ....:     }, index=pd.Index(range(3), name='idx'))
```

```
In [256]: df
Out[256]:
   A  B       C
idx
0  1  a  2016-01-01
1  2  b  2016-01-02
2  3  c  2016-01-03
```

```
In [257]: df.to_json(orient='table', date_format="iso")
```

The schema field contains the fields key, which itself contains a list of column name to type pairs, including the Index or MultiIndex (see below for a list of types). The schema field also contains a primaryKey field if the (Multi)index is unique.

The second field, data, contains the serialized data with the records orient. The index is included, and any datetimes are ISO 8601 formatted, as required by the Table Schema spec.

The full list of types supported are described in the Table Schema spec. This table shows the mapping from pandas types:
A few notes on the generated table schema:

- The schema object contains a pandas_version field. This contains the version of pandas’ dialect of the schema, and will be incremented with each revision.

- All dates are converted to UTC when serializing. Even timezone naïve values, which are treated as UTC with an offset of 0.

```python
In [258]: from pandas.io.json import build_table_schema

In [259]: s = pd.Series(pd.date_range('2016', periods=4))

In [260]: build_table_schema(s)
Out[260]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Datetimes with a timezone (before serializing), include an additional field tz with the time zone name (e.g. 'US/Central').

```python
In [261]: s_tz = pd.Series(pd.date_range('2016', periods=12,
                                      tz='US/Central'))

In [262]: build_table_schema(s_tz)
Out[262]:
{'fields': [{'name': 'index', 'type': 'integer'},
            {'name': 'values', 'type': 'datetime', 'tz': 'US/Central'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```

- Periods are converted to timestamps before serialization, and so have the same behavior of being converted to UTC. In addition, periods will contain and additional field freq with the period’s frequency, e.g. 'A-DEC'.

```python
In [263]: s_per = pd.Series(1, index=pd.period_range('2016', freq='A-DEC',
                                               periods=4))

In [264]: build_table_schema(s_per)
Out[264]:
{'fields': [{'name': 'index', 'type': 'datetime', 'freq': 'A-DEC'},
            {'name': 'values', 'type': 'integer'}],
 'primaryKey': ['index'],
 'pandas_version': '0.20.0'}
```
• Categoricals use the any type and an enum constraint listing the set of possible values. Additionally, an ordered field is included:

```python
In [265]: s_cat = pd.Series(pd.Categorical(['a', 'b', 'a']))

In [266]: build_table_schema(s_cat)
Out[266]:
{'fields': [{'name': 'index', 'type': 'integer'},
    {'name': 'values', 'type': 'any', 'constraints': {'enum': ['a', 'b']},
    'ordered': False},
    'primaryKey': ['index'],
    'pandas_version': '0.20.0'}
```

• A primaryKey field, containing an array of labels, is included if the index is unique:

```python
In [267]: s_dupe = pd.Series([1, 2], index=[1, 1])

In [268]: build_table_schema(s_dupe)
Out[268]:
{'fields': [{'name': 'index', 'type': 'integer'},
    {'name': 'values', 'type': 'integer'}],
    'pandas_version': '0.20.0'}
```

• The primaryKey behavior is the same with MultiIndexes, but in this case the primaryKey is an array:

```python
In [269]: s_multi = pd.Series(1, index=pd.MultiIndex.from_product([('a', 'b'),
    ....: (0, 1)]))

In [270]: build_table_schema(s_multi)
Out[270]:
{'fields': [{'name': 'level_0', 'type': 'string'},
    {'name': 'level_1', 'type': 'integer'},
    {'name': 'values', 'type': 'integer'}],
    'primaryKey': FrozenList(['level_0', 'level_1']),
    'pandas_version': '0.20.0'}
```

• The default naming roughly follows these rules:
  – For series, the object.name is used. If that’s none, then the name is values
  – For DataFrames, the stringified version of the column name is used
  – For Index (not MultiIndex), index.name is used, with a fallback to index if that is None.
  – For MultiIndex, mi.names is used. If any level has no name, then level_<i> is used.

New in version 0.23.0.

read_json also accepts orient='table' as an argument. This allows for the preservation of metadata such as dtypes and index names in a round-trippable manner.

```python
In [271]: df = pd.DataFrame({'foo': [1, 2, 3, 4],
    ....: 'bar': ['a', 'b', 'c', 'd'],
    ....: 'baz': pd.date_range('2018-01-01', freq='d', periods=4),
    ....: 'qux': pd.Categorical(['a', 'b', 'c', 'c'])}, index=pd.Index(range(4), name='idx'))
```

(continues on next page)
In [272]: df
Out[272]:
   foo  bar  baz  qux
idx  
0    a  2018-01-01  a
1    b  2018-01-02  b
2    c  2018-01-03  c
3    d  2018-01-04  c

In [273]: df.dtypes
Out[273]:
foo    int64
bar    object
baz  datetime64[ns]
qux    category
dtype: object

In [274]: df.to_json('test.json', orient='table')

In [275]: new_df = pd.read_json('test.json', orient='table')

In [276]: new_df
Out[276]:
   foo  bar  baz  qux
idx  
0    a  2018-01-01  a
1    b  2018-01-02  b
2    c  2018-01-03  c
3    d  2018-01-04  c

In [277]: new_df.dtypes
Out[277]:
foo    int64
bar    object
baz  datetime64[ns]
qux    category
dtype: object

Please note that the literal string ‘index’ as the name of an Index is not round-trippable, nor are any names beginning with ‘level_’ within a MultiIndex. These are used by default in DataFrame.to_json() to indicate missing values and the subsequent read cannot distinguish the intent.

In [278]: df.index.name = 'index'

In [279]: df.to_json('test.json', orient='table')

In [280]: new_df = pd.read_json('test.json', orient='table')

In [281]: print(new_df.index.name)
None

24.2. JSON
24.3 HTML

24.3.1 Reading HTML Content

Warning: We highly encourage you to read the HTML Table Parsing gotchas below regarding the issues surrounding the BeautifulSoup4/html5lib/lxml parsers.

The top-level `read_html()` function can accept an HTML string/file/URL and will parse HTML tables into list of pandas DataFrames. Let’s look at a few examples.

Note: `read_html` returns a list of DataFrame objects, even if there is only a single table contained in the HTML content.

Read a URL with no options:

```
In [282]: url = 'http://www.fdic.gov/bank/individual/failed/banklist.html'
In [283]: dfs = pd.read_html(url)
In [284]: dfs
Out[284]:
\[
\begin{array}{llll}
\text{Bank Name} & \text{City} & \text{Closing Date} & \text{Updated Date} \\
\hline
\text{Washington Federal Bank for Savings} & \text{Chicago} & \text{December 15, 2017} & \text{February 21, 2018} \\
\text{The Farmers and Merchants State Bank of Argonia} & \text{Argonia} & \text{October 13, 2017} & \text{February 21, 2018} \\
\text{Fayette County Bank} & \text{Saint Elmo} & \text{May 26, 2017} & \text{July 26, 2017} \\
\text{Guaranty Bank, (d/b/a BestBank in Georgia & Mi...} & \text{Milwaukee} & \text{May 5, 2017} & \text{March 22, 2018} \\
\text{First NBC Bank} & \text{New Orleans} & \text{April 28, 2017} & \text{December 5, 2017} \\
\text{Proficio Bank} & \text{Cottonwood Heights} & \text{March 3, 2017} & \text{March 7, 2018} \\
\text{Seaway Bank and Trust Company} & \text{Chicago} & \text{January 27, 2017} & \text{May 18, 2017} \\
\text{Hamilton Bank, NA En Espanol} & \text{Miami} & \text{January 11, 2002} & \text{September 21, 2015} \\
\text{Sinclair National Bank} & \text{Gravette} & \text{September 7, 2001} & \text{October 6, 2017} \\
\text{Superior Bank, FSB} & \text{Hinsdale} & \text{July 27, 2001} & \text{August 19, 2014} \\
\text{Malta National Bank} & \text{Malta} & \text{May 3, 2001} & \text{November 18, 2002} \\
\text{First Alliance Bank & Trust Co.} & \text{Manchester} & \text{February 2, 2001} & \text{February 18, 2003} \\
\text{National State Bank of Metropolis} & \text{Metropolis} & \text{December 14, 2000} & \text{March 17, 2005} \\
\text{Bank of Honolulu} & \text{Honolulu} & \text{October 13, 2000} & \text{March 17, 2005} \\
\end{array}
\]
```

(continues on next page)
Note: The data from the above URL changes every Monday so the resulting data above and the data below may be slightly different.

Read in the content of the file from the above URL and pass it to `read_html` as a string:

```python
In [285]: with open(file_path, 'r') as f:
    .....:
    dfs = pd.read_html(f.read())
    .....:

In [286]: dfs
Out[286]:
[555 rows x 7 columns]
```

You can even pass in an instance of `StringIO` if you so desire:

```python
In [287]: with open(file_path, 'r') as f:
    .....:
    sio = StringIO(f.read())
    .....:
```
In [288]: dfs = pd.read_html(sio)

In [289]: dfs
Out[289]:

</table>

[505 rows x 7 columns]

Note: The following examples are not run by the IPython evaluator due to the fact that having so many network-accessing functions slows down the documentation build. If you spot an error or an example that doesn’t run, please do not hesitate to report it over on pandas GitHub issues page.

Read a URL and match a table that contains specific text:

match = 'Metcalf Bank'
df_list = pd.read_html(url, match=match)

Specify a header row (by default <th> or <td> elements located within a <thead> are used to form the column index, if multiple rows are contained within <thead> then a multiindex is created); if specified, the header row is taken from the data minus the parsed header elements (<th> elements).

dfs = pd.read_html(url, header=0)

Specify an index column:
Specify a number of rows to skip:
```python
dfs = pd.read_html(url, skiprows=0)
```
Specify a number of rows to skip using a list (`xrange` (Python 2 only) works as well):
```python
dfs = pd.read_html(url, skiprows=range(2))
```
Specify an HTML attribute:
```python
dfs1 = pd.read_html(url, attrs={'id': 'table'})
dfs2 = pd.read_html(url, attrs={'class': 'sortable'})
print(np.array_equal(dfs1[0], dfs2[0]))  # Should be True
```
Specify values that should be converted to NaN:
```python
dfs = pd.read_html(url, na_values=['No Acquirer'])
```
New in version 0.19.
Specify whether to keep the default set of NaN values:
```python
dfs = pd.read_html(url, keep_default_na=False)
```
New in version 0.19.
Specify converters for columns. This is useful for numerical text data that has leading zeros. By default columns that are numerical are cast to numeric types and the leading zeros are lost. To avoid this, we can convert these columns to strings.
```python
url_mcc = 'https://en.wikipedia.org/wiki/Mobile_country_code'
dfs = pd.read_html(url_mcc, match='Telekom Albania', header=0, converters={'MNC': str})
```
New in version 0.19.
Use some combination of the above:
```python
dfs = pd.read_html(url, match='Metcalf Bank', index_col=0)
```
Read in pandas `to_html` output (with some loss of floating point precision):
```python
df = pd.DataFrame(randn(2, 2))
s = df.to_html(float_format='{0:.40g}'.format)
dfin = pd.read_html(s, index_col=0)
```
The `lxml` backend will raise an error on a failed parse if that is the only parser you provide. If you only have a single parser you can provide just a string, but it is considered good practice to pass a list with one string if, for example, the function expects a sequence of strings. You may use:
```python
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml'])
```
Or you could pass `flavor='lxml'` without a list:
```python
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor='lxml')
```
However, if you have bs4 and html5lib installed and pass None or ['lxml', 'bs4'] then the parse will most likely succeed. Note that as soon as a parse succeeds, the function will return.

```python
dfs = pd.read_html(url, 'Metcalf Bank', index_col=0, flavor=['lxml', 'bs4'])
```

### 24.3.2 Writing to HTML files

DataFrame objects have an instance method `to_html` which renders the contents of the DataFrame as an HTML table. The function arguments are as in the method `to_string` described above.

**Note:** Not all of the possible options for `DataFrame.to_html` are shown here for brevity’s sake. See `to_html()` for the full set of options.

```python
In [290]: df = pd.DataFrame(randn(2, 2))

In [291]: df
Out[291]:
   0  1
0 -0.184744  0.496971
1 -0.856240  1.857977

In [292]: print(df.to_html()) # raw html

```

**HTML:**

The `columns` argument will limit the columns shown:

```python
In [293]: print(df.to_html(columns=[0]))
```

(continues on next page)
float_format takes a Python callable to control the precision of floating point values:

```python
In [294]: print(df.to_html(float_format='{0:.10f}'.format))
```

```
<!DOCTYPE html>
<html>
    <head>
        <meta charset="utf-8">
        <title></title>
    </head>
    <body>
        <table border="1" class="dataframe">
            <thead>
                <tr style="text-align: right;">
                    <th></th>
                    <th>0</th>
                    <th>1</th>
                </tr>
            </thead>
            <tbody>
                <tr>
                    <th>0</th>
                    <td>-0.1847438576</td>
                    <td>0.4969711327</td>
                </tr>
                <tr>
                    <th>1</th>
                    <td>-0.8562396763</td>
                    <td>1.8579766508</td>
                </tr>
            </tbody>
        </table>
    </body>
</html>
```

**HTML:**

bold_rows will make the row labels bold by default, but you can turn that off:

```python
In [295]: print(df.to_html(bold_rows=False))
```

```
<!DOCTYPE html>
<html>
    <head>
        <meta charset="utf-8">
        <title></title>
    </head>
    <body>
        <table border="1" class="dataframe">
            <thead>
                <tr style="text-align: right;">
                    <th></th>
                    <th>0</th>
                    <th>1</th>
                </tr>
            </thead>
            <tbody>
                <tr>
                    <th>0</th>
                    <td>-0.1847438576</td>
                    <td>0.4969711327</td>
                </tr>
                <tr>
                    <th>1</th>
                    <td>-0.8562396763</td>
                    <td>1.8579766508</td>
                </tr>
            </tbody>
        </table>
    </body>
</html>
```
The `classes` argument provides the ability to give the resulting HTML table CSS classes. Note that these classes are *appended* to the existing 'dataframe' class.

```python
In [296]: print(df.to_html(classes=['awesome_table_class', 'even_more_awesome_class']))
```

```xml
<table border="1" class="dataframe awesome_table_class even_more_awesome_class">
<thead>
<tr style="text-align: right;">
<th></th>
<th>0</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
<td>0.496971</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
<td>1.857977</td>
</tr>
</tbody>
</table>
```

Finally, the `escape` argument allows you to control whether the “<”, “>” and “&” characters escaped in the resulting HTML (by default it is True). So to get the HTML without escaped characters pass `escape=False`

```python
In [297]: df = pd.DataFrame({'a': list('&<>'), 'b': randn(3)})
```

Escaped:

```python
In [298]: print(df.to_html())
```

```xml
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<th>0</th>
<td>-0.184744</td>
<td>0.496971</td>
</tr>
<tr>
<th>1</th>
<td>-0.856240</td>
<td>1.857977</td>
</tr>
</tbody>
</table>
```

(continues on next page)
Not escaped:

```python
In [299]: print(df.to_html(escape=False))
<table border="1" class="dataframe">
<thead>
<tr style="text-align: right;">  
<th></th>  
<th>a</th>  
<th>b</th>  
</tr>
</thead>
<tbody>
<tr>
<th>0</th>  
<td>&amp;</td>  
<td>-0.474063</td>  
</tr>
<tr>
<th>1</th>  
<td>&lt;</td>  
<td>-0.230305</td>  
</tr>
<tr>
<th>2</th>  
<td>&gt;</td>  
<td>-0.400654</td>  
</tr>
</tbody>
</table>
```

**Note:** Some browsers may not show a difference in the rendering of the previous two HTML tables.

### 24.3.3 HTML TableParsing Gotchas

There are some versioning issues surrounding the libraries that are used to parse HTML tables in the top-level pandas `io` function `read_html`.
Issues with lxml

- Benefits
  - lxml is very fast.
  - lxml requires Cython to install correctly.

- Drawbacks
  - lxml does not make any guarantees about the results of its parse unless it is given strictly valid markup.
  - In light of the above, we have chosen to allow you, the user, to use the lxml backend, but this backend will use html5lib if lxml fails to parse.
  - It is therefore highly recommended that you install both BeautifulSoup4 and html5lib, so that you will still get a valid result (provided everything else is valid) even if lxml fails.

Issues with BeautifulSoup4 using lxml as a backend

- The above issues hold here as well since BeautifulSoup4 is essentially just a wrapper around a parser backend.

Issues with BeautifulSoup4 using html5lib as a backend

- Benefits
  - html5lib is far more lenient than lxml and consequently deals with real-life markup in a much saner way rather than just, e.g., dropping an element without notifying you.
  - html5lib generates valid HTML5 markup from invalid markup automatically. This is extremely important for parsing HTML tables, since it guarantees a valid document. However, that does NOT mean that it is “correct”, since the process of fixing markup does not have a single definition.
  - html5lib is pure Python and requires no additional build steps beyond its own installation.

- Drawbacks
  - The biggest drawback to using html5lib is that it is slow as molasses. However consider the fact that many tables on the web are not big enough for the parsing algorithm runtime to matter. It is more likely that the bottleneck will be in the process of reading the raw text from the URL over the web, i.e., IO (input-output). For very large tables, this might not be true.

24.4 Excel files

The read_excel() method can read Excel 2003 (.xls) and Excel 2007+ (.xlsx) files using the xlrd Python module. The to_excel() instance method is used for saving a DataFrame to Excel. Generally the semantics are similar to working with csv data. See the cookbook for some advanced strategies.

24.4.1 Reading Excel Files

In the most basic use-case, read_excel takes a path to an Excel file, and the sheet_name indicating which sheet to parse.

```python
# Returns a DataFrame
read_excel('path_to_file.xls', sheet_name='Sheet1')
```
24.4.1.1 ExcelFile class

To facilitate working with multiple sheets from the same file, the ExcelFile class can be used to wrap the file and can be passed into read_excel. There will be a performance benefit for reading multiple sheets as the file is read into memory only once.

```python
xlsx = pd.ExcelFile('path_to_file.xls')
df = pd.read_excel(xlsx, 'Sheet1')
```

The ExcelFile class can also be used as a context manager.

```python
with pd.ExcelFile('path_to_file.xls') as xls:
    df1 = pd.read_excel(xls, 'Sheet1')
    df2 = pd.read_excel(xls, 'Sheet2')
```

The sheet_names property will generate a list of the sheet names in the file.

The primary use-case for an ExcelFile is parsing multiple sheets with different parameters:

```python
data = {}
# For when Sheet1's format differs from Sheet2
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = pd.read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = pd.read_excel(xls, 'Sheet2', index_col=1)
```

Note that if the same parsing parameters are used for all sheets, a list of sheet names can simply be passed to read_excel with no loss in performance.

```python
# using the ExcelFile class
data = {}
with pd.ExcelFile('path_to_file.xls') as xls:
    data['Sheet1'] = read_excel(xls, 'Sheet1', index_col=None, na_values=['NA'])
    data['Sheet2'] = read_excel(xls, 'Sheet2', index_col=1)

# equivalent using the read_excel function
data = read_excel('path_to_file.xls', ['Sheet1', 'Sheet2'], index_col=None, na_values=['NA'])
```

24.4.1.2 Specifying Sheets

Note: The second argument is sheet_name, not to be confused with ExcelFile.sheet_names.

Note: An ExcelFile's attribute sheet_names provides access to a list of sheets.

- The arguments sheet_name allows specifying the sheet or sheets to read.
- The default value for sheet_name is 0, indicating to read the first sheet.
- Pass a string to refer to the name of a particular sheet in the workbook.
- Pass an integer to refer to the index of a sheet. Indices follow Python convention, beginning at 0.
- Pass a list of either strings or integers, to return a dictionary of specified sheets.
- Pass a None to return a dictionary of all available sheets.
read_excel can read more than one sheet, by setting sheet_name to either a list of sheet names, a list of sheet positions, or None to read all sheets. Sheets can be specified by sheet index or sheet name, using an integer or string, respectively.

24.4.1.3 Reading a MultiIndex

read_excel can read a MultiIndex index, by passing a list of columns to index_col and a MultiIndex column by passing a list of rows to header. If either the index or columns have serialized level names those will be read in as well by specifying the rows/columns that make up the levels.

For example, to read in a MultiIndex index without names:

```
In [300]: df = pd.DataFrame({'a':[1, 2, 3, 4], 'b':[5, 6, 7, 8]},
                          index=pd.MultiIndex.from_product([['a', 'b'], ['c', 'd']]))
       ....:

In [301]: df.to_excel('path_to_file.xlsx')

In [302]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])

In [303]: df
```

<table>
<thead>
<tr>
<th></th>
<th>a</th>
<th>b</th>
</tr>
</thead>
<tbody>
<tr>
<td>a</td>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>d</td>
<td>2</td>
<td>6</td>
</tr>
<tr>
<td>b</td>
<td>3</td>
<td>7</td>
</tr>
<tr>
<td>d</td>
<td>4</td>
<td>8</td>
</tr>
</tbody>
</table>

If the index has level names, they will parsed as well, using the same parameters.

```
In [304]: df.index = df.index.set_names(['lv1', 'lv2'])

In [305]: df.to_excel('path_to_file.xlsx')
```
In [306]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1])
In [307]: df
Out[307]:
   a  b
l1  l2
  a  1  5
  d  2  6
  b  3  7
  d  4  8

If the source file has both MultiIndex index and columns, lists specifying each should be passed to `index_col` and `header`:

In [308]: df.columns = pd.MultiIndex.from_product([['a'], ['b', 'd']], names=['c1', 'c2'])
In [309]: df.to_excel('path_to_file.xlsx')
In [310]: df = pd.read_excel('path_to_file.xlsx', index_col=[0, 1], header=[0, 1])
In [311]: df
Out[311]:
   c1  a
   c2  b  d
l1  l2
  a  1  5
  d  2  6
  b  3  7
  d  4  8

24.4.1.4 Parsing Specific Columns

It is often the case that users will insert columns to do temporary computations in Excel and you may not want to read in those columns. `read_excel` takes a `usecols` keyword to allow you to specify a subset of columns to parse.

If `usecols` is an integer, then it is assumed to indicate the last column to be parsed.

```
read_excel('path_to_file.xls', 'Sheet1', usecols=2)
```

If `usecols` is a list of integers, then it is assumed to be the file column indices to be parsed.

```
read_excel('path_to_file.xls', 'Sheet1', usecols=[0, 2, 3])
```

Element order is ignored, so `usecols=[0, 1]` is the same as `[1, 0]`.

24.4.1.5 Parsing Dates

Datetime-like values are normally automatically converted to the appropriate dtype when reading the excel file. But if you have a column of strings that look like dates (but are not actually formatted as dates in excel), you can use the `parse_dates` keyword to parse those strings to datetimes:
24.4.1.6 Cell Converters

It is possible to transform the contents of Excel cells via the converters option. For instance, to convert a column to boolean:

```python
read_excel('path_to_file.xls', 'Sheet1', converters={'MyBools': bool})
```

This option handles missing values and treats exceptions in the converters as missing data. Transformations are applied cell by cell rather than to the column as a whole, so the array dtype is not guaranteed. For instance, a column of integers with missing values cannot be transformed to an array with integer dtype, because NaN is strictly a float. You can manually mask missing data to recover integer dtype:

```python
cfun = lambda x: int(x) if x else -1
read_excel('path_to_file.xls', 'Sheet1', converters={'MyInts': cfun})
```

24.4.1.7 dtype Specifications

New in version 0.20.

As an alternative to converters, the type for an entire column can be specified using the dtype keyword, which takes a dictionary mapping column names to types. To interpret data with no type inference, use the type str or object.

```python
read_excel('path_to_file.xls', dtype={'MyInts': 'int64', 'MyText': str})
```

24.4.2 Writing Excel Files

24.4.2.1 Writing Excel Files to Disk

To write a DataFrame object to a sheet of an Excel file, you can use the to_excel instance method. The arguments are largely the same as to_csv described above, the first argument being the name of the excel file, and the optional second argument the name of the sheet to which the DataFrame should be written. For example:

```python
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

Files with a .xls extension will be written using xlwt and those with a .xlsx extension will be written using xlsxwriter (if available) or openpyxl.

The DataFrame will be written in a way that tries to mimic the REPL output. The index_label will be placed in the second row instead of the first. You can place it in the first row by setting the merge_cells option in to_excel() to False:

```python
df.to_excel('path_to_file.xlsx', index_label='label', merge_cells=False)
```

In order to write separate DataFrames to separate sheets in a single Excel file, one can pass anExcelWriter.

```python
with ExcelWriter('path_to_file.xlsx') as writer:
    df1.to_excel(writer, sheet_name='Sheet1')
    df2.to_excel(writer, sheet_name='Sheet2')
```
Note: Wringing a little more performance out of read_excel Internally, Excel stores all numeric data as floats. Because this can produce unexpected behavior when reading in data, pandas defaults to trying to convert integers to floats if it doesn’t lose information (1.0 --> 1). You can pass convert_float=False to disable this behavior, which may give a slight performance improvement.

### 24.4.2.2 Writing Excel Files to Memory

Pandas supports writing Excel files to buffer-like objects such as StringIO or BytesIO using ExcelWriter.

```python
# Safe import for either Python 2.x or 3.x
try:
    from io import BytesIO
except ImportError:
    from cStringIO import StringIO as BytesIO

bio = BytesIO()

# By setting the 'engine' in the ExcelWriter constructor.
writer = ExcelWriter(bio, engine='xlsxwriter')
df.to_excel(writer, sheet_name='Sheet1')

# Save the workbook
writer.save()

# Seek to the beginning and read to copy the workbook to a variable in memory
bio.seek(0)
workbook = bio.read()
```

Note: engine is optional but recommended. Setting the engine determines the version of workbook produced. Setting engine='xlrd' will produce an Excel 2003-format workbook (xls). Using either 'openpyxl' or 'xlsxwriter' will produce an Excel 2007-format workbook (xlsx). If omitted, an Excel 2007-formatted workbook is produced.

### 24.4.3 Excel writer engines

Pandas chooses an Excel writer via two methods:

1. the engine keyword argument
2. the filename extension (via the default specified in config options)

By default, pandas uses the XlsxWriter for .xlsx, openpyxl for .xlsm, and xlwt for .xls files. If you have multiple engines installed, you can set the default engine through setting the config options io.excel.xlsx.writer and io.excel.xls.writer. pandas will fall back on openpyxl for .xlsx files if Xlsxwriter is not available.

To specify which writer you want to use, you can pass an engine keyword argument to to_excel and to ExcelWriter. The built-in engines are:

- openpyxl: version 2.4 or higher is required
- xlsxwriter
- xlwt
# By setting the 'engine' in the DataFrame and Panel 'to_excel()' methods.
```python
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1', engine='xlsxwriter')
```

# By setting the 'engine' in the ExcelWriter constructor.
```python
writer = ExcelWriter('path_to_file.xlsx', engine='xlsxwriter')
```

# Or via pandas configuration.
```python
from pandas import options
options.io.excel.xlsx.writer = 'xlsxwriter'
```
```python
df.to_excel('path_to_file.xlsx', sheet_name='Sheet1')
```

## 24.4.4 Style and Formatting

The look and feel of Excel worksheets created from pandas can be modified using the following parameters on the DataFrame's `to_excel` method.

- **float_format**: Format string for floating point numbers (default `None`).
- **freeze_panes**: A tuple of two integers representing the bottommost row and rightmost column to freeze. Each of these parameters is one-based, so `(1, 1)` will freeze the first row and first column (default `None`).

## 24.5 Clipboard

A handy way to grab data is to use the `read_clipboard()` method, which takes the contents of the clipboard buffer and passes them to the `read_table` method. For instance, you can copy the following text to the clipboard (CTRL-C on many operating systems):

```
A B C
x 1 4 p
y 2 5 q
z 3 6 r
```

And then import the data directly to a DataFrame by calling:

```python
clipdf = pd.read_clipboard()
```

```
In [312]: clipdf
Out[312]:
        A  B  C
0     x  1  4  p
1     y  2  5  q
2     z  3  6  r
```

The `to_clipboard` method can be used to write the contents of a DataFrame to the clipboard. Following which you can paste the clipboard contents into other applications (CTRL-V on many operating systems). Here we illustrate writing a DataFrame into clipboard and reading it back.

```
In [313]: df = pd.DataFrame(randn(5, 3))
In [314]: df
Out[314]:
   0   1   2
0 -1.2  0.1  0.8
1  0.3 -0.5 -1.2
2 -1.5  0.7 -1.0
3 -0.8  0.4  0.2
4  0.7 -1.3  0.4  ```
We can see that we got the same content back, which we had earlier written to the clipboard.

**Note:** You may need to install xclip or xsel (with gtk, PyQt5, PyQt4 or qtpy) on Linux to use these methods.

### 24.6 Pickling

All pandas objects are equipped with `to_pickle` methods which use Python's `cPickle` module to save data structures to disk using the pickle format.

```python
In [317]: df
Out[317]:
    0    1    2
0 -0.288267 -0.084905  0.004772
1  1.382989  0.343635 -1.253994
2 -0.124925  0.212244  0.496654
3  0.525417  1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129
```

The `read_pickle` function in the `pandas` namespace can be used to load any pickled pandas object (or any other pickled object) from file:

```python
In [319]: pd.read_pickle('foo.pkl')
Out[319]:
    0    1    2
0 -0.288267 -0.084905  0.004772
1  1.382989  0.343635 -1.253994
2 -0.124925  0.212244  0.496654
3  0.525417  1.238640 -1.210543
4 -1.175743 -0.172372 -0.734129
```

**Warning:** Loading pickled data received from untrusted sources can be unsafe.
Warning: Several internal refactorings have been done while still preserving compatibility with pickles created with older versions of pandas. However, for such cases, pickled DataFrames, Series etc, must be read with `pd.read_pickle`, rather than `pickle.load`. See here and here for some examples of compatibility-breaking changes. See this question for a detailed explanation.

### 24.6.1 Compressed pickle files

New in version 0.20.0.

`read_pickle()`, `DataFrame.to_pickle()` and `Series.to_pickle()` can read and write compressed pickle files. The compression types of `gzip`, `bz2`, `xz` are supported for reading and writing. The `zip` file format only supports reading and must contain only one data file to be read.

The compression type can be an explicit parameter or be inferred from the file extension. If 'infer', then use `gzip`, `bz2`, `zip`, or `xz` if filename ends in `.gz`, `.bz2`, `.zip`, or `.xz`, respectively.

```python
In [320]: df = pd.DataFrame(
    .....:     'A': np.random.randn(1000),
    .....:     'B': 'foo',
    .....:     'C': pd.date_range('20130101', periods=1000, freq='s'))

In [321]: df
Out[321]:
       A      B      C
0  0.478412  foo  2013-01-01 00:00:00
1 -0.783748  foo  2013-01-01 00:00:01
2  1.403558  foo  2013-01-01 00:00:02
3 -0.539282  foo  2013-01-01 00:00:03
4 -1.651012  foo  2013-01-01 00:00:04
5  0.692072  foo  2013-01-01 00:00:05
6  1.022171  foo  2013-01-01 00:00:06
   ...    ...      ...
993 -1.613932  foo  2013-01-01 00:16:33
994  1.088104  foo  2013-01-01 00:16:34
995 -0.632963  foo  2013-01-01 00:16:35
996 -0.585314  foo  2013-01-01 00:16:36
997 -0.275038  foo  2013-01-01 00:16:37
998 -0.937512  foo  2013-01-01 00:16:38
999  0.632369  foo  2013-01-01 00:16:39
[1000 rows x 3 columns]
```

Using an explicit compression type:

```python
In [322]: df.to_pickle("data.pkl.compress", compression="gzip")

In [323]: rt = pd.read_pickle("data.pkl.compress", compression="gzip")

In [324]: rt
```

(continues on next page)
Inferring compression type from the extension:

```
In [325]: df.to_pickle("data.pkl.xz", compression="infer")

In [326]: rt = pd.read_pickle("data.pkl.xz", compression="infer")

In [327]: rt
Out[327]:
   A     B         C
0  0.478412  foo 2013-01-01 00:00:00
1 -0.783748  foo 2013-01-01 00:00:01
2  1.403558  foo 2013-01-01 00:00:02
3 -0.539282  foo 2013-01-01 00:00:03
4 -1.651012  foo 2013-01-01 00:00:04
5  0.692072  foo 2013-01-01 00:00:05
6  1.022171  foo 2013-01-01 00:00:06
... ... ... ...
993 -1.613932  foo 2013-01-01 00:16:33
994  1.088104  foo 2013-01-01 00:16:34
995 -0.632963  foo 2013-01-01 00:16:35
996 -0.585314  foo 2013-01-01 00:16:36
997 -0.275038  foo 2013-01-01 00:16:37
998 -0.937512  foo 2013-01-01 00:16:38
999  0.632369  foo 2013-01-01 00:16:39

[1000 rows x 3 columns]
```

The default is to ‘infer’:

```
In [328]: df.to_pickle("data.pkl.gz")

In [329]: rt = pd.read_pickle("data.pkl.gz")

In [330]: rt
Out[330]:
   A     B         C
0  0.478412  foo 2013-01-01 00:00:00
```

(continues on next page)
24.7 msgpack

pandas supports the msgpack format for object serialization. This is a lightweight portable binary format, similar to binary JSON, that is highly space efficient, and provides good performance both on the writing (serialization), and reading (deserialization).

**Warning:** This is a very new feature of pandas. We intend to provide certain optimizations in the io of the msgpack data. Since this is marked as an EXPERIMENTAL LIBRARY, the storage format may not be stable until a future release.

In [334]: df = pd.DataFrame(np.random.rand(5, 2), columns=list('AB'))

(continues on next page)
In [335]: df.to_msgpack('foo.msg')

In [336]: pd.read_msgpack('foo.msg')
Out[336]:
<table>
<thead>
<tr>
<th></th>
<th>A</th>
<th>B</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0.170801</td>
<td>0.895366</td>
</tr>
<tr>
<td>1</td>
<td>0.838238</td>
<td>0.052592</td>
</tr>
<tr>
<td>2</td>
<td>0.664140</td>
<td>0.289750</td>
</tr>
<tr>
<td>3</td>
<td>0.449593</td>
<td>0.872087</td>
</tr>
<tr>
<td>4</td>
<td>0.983618</td>
<td>0.744359</td>
</tr>
</tbody>
</table>

In [337]: s = pd.Series(np.random.rand(5), index=pd.date_range('20130101', periods=5))

You can pass a list of objects and you will receive them back on deserialization.

In [338]: pd.to_msgpack('foo.msg', df, 'foo', np.array([1, 2, 3]), s)

In [339]: pd.read_msgpack('foo.msg')
Out[339]:
[ A B
0 0.170801 0.895366
1 0.838238 0.052592
2 0.664140 0.289750
3 0.449593 0.872087
4 0.983618 0.744359, 'foo', array([1, 2, 3]), 2013-01-01 0.548134
2013-01-02 0.503447
2013-01-03 0.348438
2013-01-04 0.707267
2013-01-05 0.261656
Freq: D, dtype: float64]

You can pass `iterator=True` to iterate over the unpacked results:

In [340]: for o in pd.read_msgpack('foo.msg', iterator=True):
   .....:   print(o)
   .....:
   A   B
   0  0.170801  0.895366
   1  0.838238  0.052592
   2  0.664140  0.289750
   3  0.449593  0.872087
   4  0.983618  0.744359
foo
[1 2 3]
2013-01-01  0.548134
2013-01-02  0.503447
2013-01-03  0.348438
2013-01-04  0.707267
2013-01-05  0.261656
Freq: D, dtype: float64

You can pass `append=True` to the writer to append to an existing pack:

In [341]: df.to_msgpack('foo.msg', append=True)

In [342]: pd.read_msgpack('foo.msg')
Out[342]:
(continues on next page)
Unlike other io methods, to_msgpack is available on both a per-object basis, df.to_msgpack() and using the top-level pd.to_msgpack(...) where you can pack arbitrary collections of Python lists, dicts, scalars, while intermixing pandas objects.

```
In [343]: pd.to_msgpack('foo2.msg', {'dict': [{'df': df}, {'string': 'foo'},
.....:
.....:'scalar': 1.}, {'s': s}])

In [344]: pd.read_msgpack('foo2.msg')
```

```
Out[344]:
{'dict': ({'df': A B
0 0.170801 0.895366
1 0.838238 0.052592
2 0.664140 0.289750
3 0.449593 0.872087
4 0.983618 0.744359},
 {'string': 'foo'},
 {'scalar': 1.0},
 {'s': 2013-01-01 0.548134

```

**24.7.1 Read/Write API**

Msgpacks can also be read from and written to strings.

```
In [345]: df.to_msgpack()
Out[345]:
```

Furthermore you can concatenate the strings to produce a list of the original objects.

```
```

1180 Chapter 24. IO Tools (Text, CSV, HDF5, …)
24.8 HDF5 (PyTables)

HDFStore is a dict-like object which reads and writes pandas using the high performance HDF5 format using the excellent PyTables library. See the cookbook for some advanced strategies.

Warning: pandas requires PyTables >= 3.0.0. There is a indexing bug in PyTables < 3.2 which may appear when querying stores using an index. If you see a subset of results being returned, upgrade to PyTables >= 3.2. Stores created previously will need to be rewritten using the updated version.
In a current or later Python session, you can retrieve stored objects:

```python
In [359]: store['df']
Out[359]:
         A         B         C
2000-01-01 0.887163  0.859588 -0.636524
2000-01-02  0.015696 -2.242685  1.150036
2000-01-03  0.991946  0.953324 -2.021255
2000-01-04 -0.334077  0.002118  0.405453
2000-01-05  0.289092  1.321158 -1.546906
2000-01-06 -0.202646  0.655969  0.193421
2000-01-07  0.553439  1.318152 -0.469305
2000-01-08  0.675554 -1.817027 -0.183109
```

Deletion of the object specified by the key:

```python
In [361]: del store['wp']
```

Closing a Store and using a context manager:

```python
In [363]: store.close()
```

(continues on next page)
24.8.1 Read/Write API

HDFStore supports an top-level API using `read_hdf` for reading and `to_hdf` for writing, similar to how `read_csv` and `to_csv` work.

```python
In [367]: df_tl = pd.DataFrame(dict(A=list(range(5)), B=list(range(5))))
In [368]: df_tl.to_hdf('store_tl.h5','table', append=True)
In [369]: pd.read_hdf('store_tl.h5', 'table', where=['index>2'])
Out[369]:
   A  B
0  3  3
1  4  4
```

HDFStore will by default not drop rows that are all missing. This behavior can be changed by setting `dropna=True`.

```python
In [370]: df_with_missing = pd.DataFrame({'col1': [0, np.nan, 2],
   ....:    'col2': [1, np.nan, np.nan]})
In [371]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
   ....:    format='table', mode='w')
In [372]: pd.read_hdf('file.h5', 'df_with_missing')
Out[372]:
   col1  col2
0  0.0  1.0
1  NaN  NaN
2  2.0  NaN
In [373]: df_with_missing.to_hdf('file.h5', 'df_with_missing',
   ....:    format='table', mode='w', dropna=True)
In [374]: pd.read_hdf('file.h5', 'df_with_missing')
Out[374]:
   col1  col2
0  0.0  1.0
1  NaN  NaN
2  2.0  NaN
```

(continues on next page)
This is also true for the major axis of a Panel:

```
In [366]: matrix = [[np.nan, np.nan, np.nan], [1, np.nan, np.nan]],
                      [[np.nan, np.nan, np.nan], [np.nan, 5, 6]],
                      [[np.nan, np.nan, np.nan], [np.nan, 3, np.nan]]

In [377]: panel_with_major_axis_all_missing = pd.Panel(matrix,
                      items=['Item1', 'Item2', 'Item3'],
                      major_axis=[1, 2],
                      minor_axis=['A', 'B', 'C'])

In [378]: panel_with_major_axis_all_missing
Out[378]:
<class 'pandas.core.panel.Panel'>
Dimensions: 3 (items) x 2 (major_axis) x 3 (minor_axis)
Items axis: Item1 to Item3
Major_axis axis: 1 to 2
Minor_axis axis: A to C
```

24.8.2 Fixed Format

The examples above show storing using `put`, which write the HDF5 to PyTables in a fixed array format, called the fixed format. These types of stores are **not** appendable once written (though you can simply remove them and rewrite). Nor are they **queryable**; they must be retrieved in their entirety. They also do not support dataframes with non-unique column names. The fixed format stores offer very fast writing and slightly faster reading than `table` stores. This format is specified by default when using `put` or `to_hdf` or by `format='fixed'` or `format='f'`.

**Warning:** A fixed format will raise a `TypeError` if you try to retrieve using a `where`:

```
pd.DataFrame(randn(10, 2)).to_hdf('test_fixed.h5', 'df')
pd.read_hdf('test_fixed.h5', 'df', where='index>5')
```

`TypeError: cannot pass a where specification when reading a fixed format. this store must be selected in its entirety`
24.8.3 Table Format

HDFStore supports another PyTables format on disk, the table format. Conceptually a table is shaped very much like a DataFrame, with rows and columns. A table may be appended to in the same or other sessions. In addition, delete and query type operations are supported. This format is specified by format='table' or format='t' to append or put or to_hdf.

This format can be set as an option as well pd.set_option('io.hdf.default_format','table') to enable put/append/to_hdf to by default store in the table format.

```
In [382]: store = pd.HDFStore('store.h5')
In [383]: df1 = df[0:4]
In [384]: df2 = df[4:]
# append data (creates a table automatically)
In [385]: store.append('df', df1)
In [386]: store.append('df', df2)
In [387]: store
Out[387]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
# select the entire object
In [388]: store.select('df')
Out[388]:
    A    B    C
2000-01-01  0.887163  0.859588 -0.636524
2000-01-02 -2.242685  1.150036 -2.021255
2000-01-03  0.991946  0.953324 -2.021255
2000-01-04  0.002118  0.405453 -1.546906
2000-01-05 -0.655969  0.193421 -0.183109
2000-01-06  0.553439  1.318152 -0.469305
2000-01-07  0.675554 -1.817027 -0.183109
# the type of stored data
In [389]: store.root.df._v_attrs.pandas_type
Out[389]: …
→'frame_table'
```

Note: You can also create a table by passing format='table' or format='t' to a put operation.

24.8.4 Hierarchical Keys

Keys to a store can be specified as a string. These can be in a hierarchical path-name like format (e.g. foo/bar/bah), which will generate a hierarchy of sub-stores (or Groups in PyTables parlance). Keys can be specified with
out the leading ‘/’ and are **always** absolute (e.g. ‘foo’ refers to ‘/foo’). Removal operations can remove everything in the sub-store and **below**, so be **careful**.

```python
In [390]: store.put('foo/bar/bah', df)
In [391]: store.append('food/orange', df)
In [392]: store.append('food/apple', df)
In [393]: store
Out[393]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5

# a list of keys are returned
In [394]: store.keys()
Out[394]: ['/df', '/food/apple', '/food/orange', '/foo/bar/bah']

# remove all nodes under this level
In [395]: store.remove('food')
In [396]: store
Out[396]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
```

**Warning:** Hierarchical keys cannot be retrieved as dotted (attribute) access as described above for items stored under the root node.

```python
In [8]: store.foo.bar.bah
AttributeError: 'HDFStore' object has no attribute 'foo'

# you can directly access the actual PyTables node but using the root node
In [9]: store.root.foo.bar.bah
Out[9]:
/foo/bar/bah (Group) ''
    children := ['block0_items' (Array), 'block0_values' (Array), 'axis0' (Array), 'axis1' (Array)]
```

Instead, use explicit string based keys:

```python
In [397]: store['foo/bar/bah']
Out[397]:
   A    B    C
0 0.887163 0.859588 -0.636524
1 0.015696 -2.242685 1.150036
2 0.991946 0.953324 -2.021255
3 -0.334077 0.002118 0.405453
4 0.289092 1.321158 -1.546906
5 -0.202646 -0.655969 0.193421
6 0.675554 -1.817027 -0.183109
```
24.8.5 Storing Types

24.8.5.1 Storing Mixed Types in a Table

Storing mixed-dtype data is supported. Strings are stored as a fixed-width using the maximum size of the appended column. Subsequent attempts at appending longer strings will raise a `ValueError`.

Passing `min_itemsize={'values': size}` as a parameter to append will set a larger minimum for the string columns. Storing floats, strings, ints, bools, `datetime64` are currently supported. For string columns, passing `nan_rep = 'nan'` to append will change the default nan representation on disk (which converts to/from `np.nan`), this defaults to `nan`.

```
In [398]: df_mixed = pd.DataFrame({'A': randn(8),
                           'B': randn(8),
                           'C': np.array(randn(8), dtype='float32'),
                           'string': 'string',
                           'int': 1,
                           'bool': True,
                           'datetime64': pd.Timestamp('20010102')},
                           index=list(range(8))

In [399]: df_mixed.loc[df_mixed.index[3:5], ['A', 'B', 'string', 'datetime64']] = np.nan

In [400]: store.append('df_mixed', df_mixed, min_itemsize = {'values': 50})

In [401]: df_mixed1 = store.select('df_mixed')

In [402]: df_mixed1
Out[402]:
   A    B    C     string  int  bool     datetime64
0  0.704721 -1.152659 -0.430096  string  1  True  2001-01-02
1 -0.785435  0.631979  0.767369  string  1  True  2001-01-02
2  0.462060  0.039513  0.984920  string  1  True  2001-01-02
3  NaN     NaN  0.270836  NaN   1  True       NaT
4  NaN     NaN  1.391986  NaN   1  True       NaT
5 -0.926254  1.321106  0.079842  string  1  True  2001-01-02
6  2.007843  0.152631 -0.399965  string  1  True  2001-01-02
7  0.226963  0.164530 -1.027851  string  1  True  2001-01-02

In [403]: df_mixed1.get_dtype_counts()

Out[403]:
    float64    2
    float32    1
    object     1
    int64      1
    bool       1
    datetime64[ns]  1

# we have provided a minimum string column size
In [404]: store.root.df_mixed.table
```

(continues on next page)
description := {

24.8.5.2 Storing Multi-Index DataFrames

Storing multi-index DataFrames as tables is very similar to storing/selecting from homogeneous index DataFrames.

In [405]: index = pd.MultiIndex(levels=[["foo", "bar", "baz", "qux"],
                            [['one', 'two', 'three']],
                            labels=[[0, 0, 0, 1, 1, 2, 2, 3, 3, 3],
                                    [0, 1, 2, 0, 1, 1, 2, 0, 1, 2]],
                            names=['foo', 'bar'])

In [406]: df_mi = pd.DataFrame(np.random.randn(10, 3), index=index,
                            columns=['A', 'B', 'C'])

In [407]: df_mi

Out[407]:
    A         B         C
foo bar
foo one  -0.584718  0.816594 -0.081947
    two  -0.344766  0.528288 -1.068989
    three -0.511881  0.291205  0.566534
bar one  0.503592  0.285296  0.484288
    two  1.363482 -0.781105  0.468018
    three  1.224574 -1.281108  0.875476
baz one  1.224574 -1.281108  0.875476
    two  1.363482 -0.781105  0.468018
    three  1.224574 -1.281108  0.875476
qux one  0.203933 -0.182175  0.680656
    two  1.818499  0.047072  0.394844
    three  0.248432 -0.617707 -0.682884

In [408]: store.append('df_mi', df_mi)

In [409]: store.select('df_mi')

Out[409]:
    A         B         C
foo bar
foo one  -0.584718  0.816594 -0.081947
    two  -0.344766  0.528288 -1.068989
    three -0.511881  0.291205  0.566534
bar one  0.503592  0.285296  0.484288
    two  1.363482 -0.781105  0.468018
    three  1.224574 -1.281108  0.875476
baz one  1.224574 -1.281108  0.875476
    two  1.363482 -0.781105  0.468018
    three  1.224574 -1.281108  0.875476
qux one  0.203933 -0.182175  0.680656
    two  1.818499  0.047072  0.394844
    three  0.248432 -0.617707 -0.682884
two 1.363482 -0.781105 -0.468018

two -1.818499 0.047072 0.394844
three -0.248432 -0.617707 -0.682884

# the levels are automatically included as data columns
In [410]: store.select('df_mi', 'foo=bar')

       A   B     C
foo bar
   bar one  0.503592 0.285296 0.484288
two 1.363482 -0.781105 -0.468018

24.8.6 Querying

24.8.6.1 Querying a Table

select and delete operations have an optional criterion that can be specified to select/delete only a subset of the data. This allows one to have a very large on-disk table and retrieve only a portion of the data.

A query is specified using the Term class under the hood, as a boolean expression.

- index and columns are supported indexers of a DataFrame.
- major_axis, minor_axis, and items are supported indexers of the Panel.
- if data_columns are specified, these can be used as additional indexers.

Valid comparison operators are:

=, ==, !=, >, >=, <, <=

Valid boolean expressions are combined with:

- |: or
- &: and
- ( and ): for grouping

These rules are similar to how boolean expressions are used in pandas for indexing.

Note:

- = will be automatically expanded to the comparison operator ==
- ~ is the not operator, but can only be used in very limited circumstances
- If a list/tuple of expressions is passed they will be combined via &

The following are valid expressions:

- 'index >= date'
- "columns = ['A', 'D']"
- "columns in ['A', 'D']"
• 'columns = A'
• 'columns == A'
• "-(columns = ['A', 'B'])"
• 'index > df.index[3] & string = "bar"
• '(index > df.index[3] & index <= df.index[6]) | string = "bar"
• "ts >= Timestamp('2012-02-01')"
• "major_axis>=20130101"

The indexers are on the left-hand side of the sub-expression:
columns, major_axis, ts

The right-hand side of the sub-expression (after a comparison operator) can be:

• functions that will be evaluated, e.g. Timestamp('2012-02-01')
• strings, e.g. "bar"
• date-like, e.g. 20130101, or "20130101"
• lists, e.g. "['A', 'B']"
• variables that are defined in the local names space, e.g. date

Note: Passing a string to a query by interpolating it into the query expression is not recommended. Simply assign the string of interest to a variable and use that variable in an expression. For example, do this:

```python
string = "HolyMoly"
store.select('df', 'index == string')
```

instead of this:

```python
string = "HolyMoly"
store.select('df', 'index == %s' % string)
```

The latter will not work and will raise a SyntaxError. Note that there’s a single quote followed by a double quote in the string variable.

If you must interpolate, use the '%r' format specifier

```python
store.select('df', 'index == %r % string')
```

which will quote string.

Here are some examples:

```python
In [411]: dfq = pd.DataFrame(randn(10, 4), columns=list('ABCD'),
                        index=pd.date_range('20130101', periods=10))
In [412]: store.append('dfq', dfq, format='table', data_columns=True)
```

Use boolean expressions, with in-line function evaluation.
In [413]: store.select('dfq', "index>pd.Timestamp('20130104') & columns=['A', 'B']")
Out[413]:
   A         B
2013-01-05  1.210384  0.797435
2013-01-06  0.850346  1.176812
2013-01-07  0.984188 -0.121728
2013-01-08  0.796595 -0.474021
2013-01-09 -0.804834 -2.123620
2013-01-10  0.334198  0.536784

Use and inline column reference

In [414]: store.select('dfq', where="A>0 or C>0")
Out[414]:
   A         B         C         D
2013-01-01  0.436258 -1.703013  0.393711 -0.479324
2013-01-02 -0.299016  0.694103  0.678630  0.239556
2013-01-03  0.151227  0.816127  1.893534  0.639633
2013-01-04 -0.962029 -2.085266  1.930247 -1.735349
2013-01-05  1.210384  0.797435 -0.379811  0.702562
2013-01-07  0.984188 -0.121728  2.365769  0.496143
2013-01-08  0.796595 -0.474021 -0.056696  1.357797
2013-01-10  0.334198  0.536784 -0.743830 -0.320204

Works with a Panel as well.

In [415]: store.append('wp', wp)
In [416]: store
Out[416]:<class 'pandas.io.pytables.HDFStore'>
File path: store.h5
In [417]: store.select('wp', "major_axis>pd.Timestamp('20000102') & minor_axis=['A', 'B']")
Out[417]:
Dimensions: 2 (items) x 3 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-05 00:00:00
Minor_axis axis: A to B

The columns keyword can be supplied to select a list of columns to be returned, this is equivalent to passing a 'columns=list_of_columns_to_filter':

In [418]: store.select('df', "columns=['A', 'B']")
Out[418]:
   A         B
2000-01-01  0.887163  0.859588
2000-01-02  0.015696 -2.242685
2000-01-03  0.991946  0.953324
2000-01-04 -0.334077  0.002118
2000-01-05  0.289092  1.321158
2000-01-06 -0.202646 -0.655969
2000-01-07  0.553439  1.318152
2000-01-08  0.675554 -1.817027

start and stop parameters can be specified to limit the total search space. These are in terms of the total number
of rows in a table.

```python
# this is effectively what the storage of a Panel looks like
In [419]: wp.to_frame()
Out[419]:
  Item1  Item2
major minor
2000-01-01 A  1.058969  0.215269
  B  -0.397840  0.841009
  C   0.337438 -1.445810
  D   1.047579 -1.401973
2000-01-02 A  1.045938 -0.100918
  B   0.863717 -0.548242
  C  -0.122092 -0.144620
...  ... ...
2000-01-04 B   0.036142  0.307969
  C  -2.074978 -0.208499
  D   0.247792  1.033801
2000-01-05 A  -0.897157 -2.400454
  B  -0.136795  2.030604
  C   0.018289 -1.142631
  D   0.755414  0.211883
[20 rows x 2 columns]
```

`# limiting the search`

```python
In [420]: store.select('wp', "major_axis>20000102 & minor_axis=['A', 'B']", 
start=0, stop=10)
```

```python
→<class 'pandas.core.panel.Panel'>
Dimensions: 2 (items) x 1 (major_axis) x 2 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-03 00:00:00 to 2000-01-03 00:00:00
Minor_axis axis: A to B
```

**Note:** `select` will raise a `ValueError` if the query expression has an unknown variable reference. Usually this means that you are trying to select on a column that is not a data_column.

`select` will raise a `SyntaxError` if the query expression is not valid.

### 24.8.6.2 Using timedelta64[ns]

You can store and query using the timedelta64[ns] type. Terms can be specified in the format: `<float>(<unit>)`, where float may be signed (and fractional), and unit can be D,s,ms,us,ns for the timedelta. Here’s an example:

```python
In [421]: from datetime import timedelta
In [422]: dftd = pd.DataFrame(dict(A = pd.Timestamp('20130101'), B = [ pd.Timestamp('20130101') + timedelta(days=i, seconds=10) for i in range(10) ]))
In [423]: dftd['C'] = dftd['A'] - dftd['B']
```

(continues on next page)
In [424]: dftd
Out[424]:
   A   B   C
0 2013-01-01 2013-01-01 00:00:10  -1 days   +23:59:50
1 2013-01-01 2013-01-02 00:00:10  -2 days   +23:59:50
2 2013-01-01 2013-01-03 00:00:10  -3 days   +23:59:50
3 2013-01-01 2013-01-04 00:00:10  -4 days   +23:59:50
4 2013-01-01 2013-01-05 00:00:10  -5 days   +23:59:50
5 2013-01-01 2013-01-06 00:00:10  -6 days   +23:59:50
6 2013-01-01 2013-01-07 00:00:10  -7 days   +23:59:50
7 2013-01-01 2013-01-08 00:00:10  -8 days   +23:59:50
8 2013-01-01 2013-01-09 00:00:10  -9 days   +23:59:50
9 2013-01-01 2013-01-10 00:00:10 -10 days   +23:59:50

In [425]: store.append('dftd', dftd, data_columns=True)

In [426]: store.select('dftd', "C<'-3.5D'")
Out[426]:
   A   B   C
4 2013-01-01 2013-01-05 00:00:10  -5 days   +23:59:50
5 2013-01-01 2013-01-06 00:00:10  -6 days   +23:59:50
6 2013-01-01 2013-01-07 00:00:10  -7 days   +23:59:50
7 2013-01-01 2013-01-08 00:00:10  -8 days   +23:59:50
8 2013-01-01 2013-01-09 00:00:10  -9 days   +23:59:50
9 2013-01-01 2013-01-10 00:00:10 -10 days   +23:59:50

24.8.6.3 Indexing

You can create/modify an index for a table with create_table_index after data is already in the table (after and append/put operation). Creating a table index is highly encouraged. This will speed your queries a great deal when you use a select with the indexed dimension as the where.

Note: Indexes are automagically created on the indexables and any data columns you specify. This behavior can be turned off by passing index=False to append.

# we have automagically already created an index (in the first section)
In [427]: i = store.root.df.table.cols.index.index

In [428]: i.optlevel, i.kind
Out[428]: (6, 'medium')

# change an index by passing new parameters
In [429]: store.create_table_index('df', optlevel=9, kind='full')

In [430]: i = store.root.df.table.cols.index.index

In [431]: i.optlevel, i.kind
Out[431]: (9, 'full')

Oftentimes when appending large amounts of data to a store, it is useful to turn off index creation for each append, then recreate at the end.

24.8. HDF5 (PyTables)
In [432]: df_1 = pd.DataFrame(randn(10, 2), columns=list('AB'))
In [433]: df_2 = pd.DataFrame(randn(10, 2), columns=list('AB'))
In [434]: st = pd.HDFStore('appends.h5', mode='w')
In [435]: st.append('df', df_1, data_columns=['B'], index=False)
In [436]: st.append('df', df_2, data_columns=['B'], index=False)
In [437]: st.get_storer('df').table
Out[437]:
/df/table (Table(20,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)

Then create the index when finished appending.

In [438]: st.create_table_index('df', columns=['B'], optlevel=9, kind='full')
In [439]: st.get_storer('df').table
Out[439]:
/df/table (Table(20,)) ''
  description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
    "B": Float64Col(shape=(), dflt=0.0, pos=2)}
  byteorder := 'little'
  chunkshape := (2730,)
  autoindex := True
  colindexes := {
    "B": Index(9, full, shuffle, zlib(1)).is_csi=True}
In [440]: st.close()

See here for how to create a completely-sorted-index (CSI) on an existing store.

### 24.8.6.4 Query via Data Columns

You can designate (and index) certain columns that you want to be able to perform queries (other than the indexable columns, which you can always query). For instance say you want to perform this common operation, on-disk, and return just the frame that matches this query. You can specify data_columns = True to force all columns to be data_columns.

In [441]: df_dc = df.copy()
In [442]: df_dc['string'] = 'foo'
In [443]: df_dc.loc[df_dc.index[4: 6], 'string'] = np.nan
In [444]: df_dc.loc[df_dc.index[7: 9], 'string'] = 'bar'

(continues on next page)
In [445]: df_dc['string2'] = 'cool'

In [446]: df_dc.loc[df_dc.index[1: 3], ['B', 'C']] = 1.0

In [447]: df_dc
Out[447]:
   A        B        C      string  string2
0 2000-01-01 0.887163 0.859588 -0.636524   foo     cool
1 2000-01-02 0.015696 1.000000  1.000000   foo     cool
2 2000-01-03 0.991946 1.000000  1.000000   foo     cool
3 2000-01-04 -0.334077 0.002118  0.405453   foo     cool
4 2000-01-05 0.289092 1.321158 -1.546906  NaN     cool
5 2000-01-06 -0.202646 -0.655969  0.193421  NaN     cool
6 2000-01-07 0.553439 1.318152 -0.469305   foo     cool
7 2000-01-08 0.675554 -1.817027 -0.183109   bar     cool

# on-disk operations
In [448]: store.append('df_dc', df_dc, data_columns = ['B', 'C', 'string', 'string2'])

In [449]: store.select('df_dc', where='B > 0')
Out[449]:
   A        B        C      string  string2
0 2000-01-01 0.887163 0.859588 -0.636524   foo     cool
1 2000-01-02 0.015696 1.000000  1.000000   foo     cool
2 2000-01-03 0.991946 1.000000  1.000000   foo     cool
3 2000-01-04 -0.334077 0.002118  0.405453   foo     cool
4 2000-01-05 0.289092 1.321158 -1.546906  NaN     cool
5 2000-01-06 -0.202646 -0.655969  0.193421  NaN     cool
6 2000-01-07 0.553439 1.318152 -0.469305   foo     cool

# getting creative
In [450]: store.select('df_dc', 'B > 0 & C > 0 & string == foo')
Out[450]:
   A        B        C      string  string2
0 2000-01-02 0.015696 1.000000  1.000000   foo     cool
1 2000-01-03 0.991946 1.000000  1.000000   foo     cool
2 2000-01-04 -0.334077 0.002118  0.405453   foo     cool

# this is in-memory version of this type of selection
In [451]: df_dc[(df_dc.B > 0) & (df_dc.C > 0) & (df_dc.string == 'foo')]
Out[451]:
   A        B        C      string  string2
0 2000-01-02 0.015696 1.000000  1.000000   foo     cool
1 2000-01-03 0.991946 1.000000  1.000000   foo     cool
2 2000-01-04 -0.334077 0.002118  0.405453   foo     cool

# we have automagically created this index and the B/C/string/string2
# columns are stored separately as ``PyTables`` columns
In [452]: store.root.df_dc.table
Out[452]:
   /df_dc/table (Table(8,)) ''
   description := (
   "index": Int64Col(shape=(), dflt=0, pos=0),
   "values_block_0": Float64Col(shape=(1,), dflt=0.0, pos=1),
   "B": Float64Col(shape=(), dflt=0.0, pos=2),
   "C": Float64Col(shape=(), dflt=0.0, pos=3),
   "string": StringCol(shape=(), dflt=..., pos=4),
   "string2": StringCol(shape=(), dflt=..., pos=5))

(continues on next page)
There is some performance degradation by making lots of columns into `data columns`, so it is up to the user to designate these. In addition, you cannot change data columns (nor indexables) after the first append/put operation (Of course you can simply read in the data and create a new table!).

### 24.8.6.5 Iterator

You can pass `iterator=True` or `chunksize=number_in_a_chunk` to `select` and `select_as_multiple` to return an iterator on the results. The default is 50,000 rows returned in a chunk.

```python
for df in store.select('df', chunksize=3):
    print(df)
```

```plaintext
A   B   C
2000-01-01 0.887163 0.859588 -0.636524
2000-01-02 0.015696 -2.242685 1.150036
2000-01-03 0.991946 0.953324 -2.021255
```

Note: You can also use the iterator with `read_hdf` which will open, then automatically close the store when finished iterating.

```python
for df in pd.read_hdf('store.h5','df', chunksize=3):
    print(df)
```

Note, that the chunksize keyword applies to the `source rows`. So if you are doing a query, then the chunksize will subdivide the total rows in the table and the query applied, returning an iterator on potentially unequal sized chunks.

Here is a recipe for generating a query and using it to create equal sized return chunks.

```python
In [454]: dfeq = pd.DataFrame({'number': np.arange(1, 11)})
In [455]: dfeq
Out[455]:
number
```
In [456]: store.append('dfeq', dfeq, data_columns=['number'])

In [457]: def chunks(l, n):
       ....:     return [l[i: i+n] for i in range(0, len(l), n)]

In [458]: evens = [2, 4, 6, 8, 10]

In [459]: coordinates = store.select_as_coordinates('dfeq', 'number=evens')

In [460]: for c in chunks(coordinates, 2):
       ....:     print(store.select('dfeq', where=c))

   number
1    2
3    4
   number
5    6
7    8
   number
9    10

24.8.6.6 Advanced Queries

Select a Single Column

To retrieve a single indexable or data column, use the method select_column. This will, for example, enable you to get the index very quickly. These return a Series of the result, indexed by the row number. These do not currently accept the where selector.

In [461]: store.select_column('df_dc', 'index')
Out[461]:
0 2000-01-01
1 2000-01-02
2 2000-01-03
3 2000-01-04
4 2000-01-05
5 2000-01-06
6 2000-01-07
7 2000-01-08
Name: index, dtype: datetime64[ns]

In [462]: store.select_column('df_dc', 'string')
Selecting coordinates

Sometimes you want to get the coordinates (a.k.a the index locations) of your query. This returns an `Int64Index` of the resulting locations. These coordinates can also be passed to subsequent `where` operations.

```python
In [463]: df_coord = pd.DataFrame(np.random.randn(1000, 2),
                           index=pd.date_range('20000101', periods=1000))

In [464]: store.append('df_coord', df_coord)

In [465]: c = store.select_as_coordinates('df_coord', 'index > 20020101')

In [466]: c

Out [466]:
Int64Index([732, 733, 734, 735, 736, 737, 738, 739, 740, 741,
            990, 991, 992, 993, 994, 995, 996, 997, 998, 999],
            dtype='int64', length=268)

In [467]: store.select('df_coord', where=c)
```

<p>| | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>foo</td>
<td>NaN</td>
</tr>
<tr>
<td>1</td>
<td>foo</td>
<td>NaN</td>
</tr>
<tr>
<td>2</td>
<td>foo</td>
<td>NaN</td>
</tr>
<tr>
<td>3</td>
<td>foo</td>
<td>NaN</td>
</tr>
<tr>
<td>4</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>5</td>
<td>NaN</td>
<td>NaN</td>
</tr>
<tr>
<td>6</td>
<td>foo</td>
<td>bar</td>
</tr>
<tr>
<td>Name: string,</td>
<td></td>
<td></td>
</tr>
<tr>
<td>dtype: object</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

[268 rows x 2 columns]
Selecting using a where mask

Sometime your query can involve creating a list of rows to select. Usually this mask would be a resulting index from an indexing operation. This example selects the months of a datetimeindex which are 5.

```
In [468]: df_mask = pd.DataFrame(np.random.randn(1000, 2),
   .....: index=pd.date_range('20000101', periods=1000))
   .....:
In [469]: store.append('df_mask', df_mask)
In [470]: c = store.select_column('df_mask', 'index')
In [471]: where = c[pd.DatetimeIndex(c).month == 5].index
In [472]: store.select('df_mask', where=where)
Out[472]:
   0   1
2000-05-01 -1.006245 -0.616759
2000-05-02  0.218940  0.717838
2000-05-03  0.013333  1.348060
2000-05-04  0.662176 -1.050645
2000-05-05 -1.034870 -0.243242
2000-05-06 -0.753366 -1.454329
2000-05-07 -1.022920 -0.476989
   ... ... ...
2002-05-25 -0.509090 -0.389376
2002-05-26  0.150674  1.164337
2002-05-27 -0.332944  0.115181
2002-05-28 -1.048127 -0.605733
2002-05-29  1.418754 -0.442835
2002-05-30 -0.433200  0.835001
2002-05-31 -1.041278  1.401811
[93 rows x 2 columns]
```

Storer Object

If you want to inspect the stored object, retrieve via `get_storer`. You could use this programatically to say get the number of rows in an object.

```
In [473]: store.get_storer('df_dc').nrows
Out[473]: 8
```

24.8.6.7 Multiple Table Queries

The methods `append_to_multiple` and `select_as_multiple` can perform appending/selecting from multiple tables at once. The idea is to have one table (call it the selector table) that you index most/all of the columns, and perform your queries. The other table(s) are data tables with an index matching the selector table’s index. You can then perform a very fast query on the selector table, yet get lots of data back. This method is similar to having a very wide table, but enables more efficient queries.

The `append_to_multiple` method splits a given single DataFrame into multiple tables according to `d`, a dictionary that maps the table names to a list of ‘columns’ you want in that table. `None` is used in place of a list, that table will have the remaining unspecified columns of the given DataFrame. The argument `selector` defines which...
table is the selector table (which you can make queries from). The argument `dropna` will drop rows from the input DataFrame to ensure tables are synchronized. This means that if a row for one of the tables being written to is entirely `np.NaN`, that row will be dropped from all tables.

If `dropna` is `False`, **THE USER IS RESPONSIBLE FOR SYNCHRONIZING THE TABLES.** Remember that entirely `np.NaN` rows are not written to the HDFStore, so if you choose to call `dropna=False`, some tables may have more rows than others, and therefore `select_as_multiple` may not work or it may return unexpected results.

```python
In [474]: df_mt = pd.DataFrame(randn(8, 6), index=pd.date_range('1/1/2000', periods=8), columns=['A', 'B', 'C', 'D', 'E', 'F'])
   ....:
   ....:
In [475]: df_mt['foo'] = 'bar'
In [476]: df_mt.loc[df_mt.index[1], ('A', 'B')] = np.nan
# you can also create the tables individually
In [477]: store.append_to_multiple({'df1_mt': ['A', 'B'], 'df2_mt': None}, df_mt, selector='df1_mt')
   ....:
   ....:
In [478]: store
Out[478]: <class 'pandas.io.pytables.HDFStore'>
File path: store.h5
# individual tables were created
In [479]: store.select('df1_mt')
```

```python
  A   B
2000-01-01  0.714697  0.318215
2000-01-02  NaN     NaN
2000-01-03 -0.086919  0.416905

(continues on next page)
24.8.7 Delete from a Table

You can delete from a table selectively by specifying a `where`. In deleting rows, it is important to understand the `PyTables` deletes rows by erasing the rows, then moving the following data. Thus deleting can potentially be a very expensive operation depending on the orientation of your data. This is especially true in higher dimensional objects (Panel and Panel4D). To get optimal performance, it’s worthwhile to have the dimension you are deleting be the first of the indexables.

Data is ordered (on the disk) in terms of the indexables. Here’s a simple use case. You store panel-type data, with dates in the `major_axis` and ids in the `minor_axis`. The data is then interleaved like this:

- date_1 - id_1 - id_2 - ... - id_n
- date_2 - id_1 - ... - id_n

It should be clear that a delete operation on the `major_axis` will be fairly quick, as one chunk is removed, then the following data moved. On the other hand a delete operation on the `minor_axis` will be very expensive. In this case it would almost certainly be faster to rewrite the table using a `where` that selects all but the missing data.

```python
# returns the number of rows deleted
In [482]: store.remove('wp', 'major_axis > 20000102')
Out[482]: 12

In [483]: store.select('wp')
Out[483]:
Dimensions: 2 (items) x 2 (major_axis) x 4 (minor_axis)
Items axis: Item1 to Item2
Major_axis axis: 2000-01-01 00:00:00 to 2000-01-02 00:00:00
Minor_axis axis: A to D
```

**Warning:** Please note that HDF5 DOES NOT RECLAIM SPACE in the h5 files automatically. Thus, repeatedly deleting (or removing nodes) and adding again, WILL TEND TO INCREASE THE FILE SIZE.

To repack and clean the file, use `ptrepack`.

24.8.8 Notes & Caveats

24.8.8.1 Compression

`PyTables` allows the stored data to be compressed. This applies to all kinds of stores, not just tables. Two parameters are used to control compression: `complevel` and `complib`.

`complevel` specifies if and how hard data is to be compressed. `complevel=0` and `complevel=None` disables compression and `0<complevel<10` enables compression.
**compil** specifies which compression library to use. **If nothing is** specified the default library zlib is used. A compression library usually optimizes for either good compression rates or speed and the results will depend on the type of data. Which type of compression to choose depends on your specific needs and data. The list of supported compression libraries:

- **zlib**: The default compression library. A classic in terms of compression, achieves good compression rates but is somewhat slow.
- **lzo**: Fast compression and decompression.
- **bzip2**: Good compression rates.
- **blosc**: Fast compression and decompression.

New in version 0.20.2: Support for alternative blosc compressors:

- **blosc:blosclz**: This is the default compressor for blosc
- **blosc:lz4**: A compact, very popular and fast compressor.
- **blosc:lz4hc**: A tweaked version of LZ4, produces better compression ratios at the expense of speed.
- **blosc:snappy**: A popular compressor used in many places.
- **blosc:zlib**: A classic; somewhat slower than the previous ones, but achieving better compression ratios.
- **blosc:zstd**: An extremely well balanced codec; it provides the best compression ratios among the others above, and at reasonably fast speed.

If compil is defined as something other than the listed libraries a ValueError exception is issued.

---

**Note:** If the library specified with the compil option is missing on your platform, compression defaults to zlib without further ado.

Enable compression for all objects within the file:

```python
glob2 = pd.HDFStore('store_compressed.h5', complevel=9, complelib='blosc:blosclz')
```

Or on-the-fly compression (this only applies to tables) in stores where compression is not enabled:

```python
store.append('df', df, complevel=9, complelib='zlib')
```

---

### 24.8.8.2 ptrepack

PyTables offers better write performance when tables are compressed after they are written, as opposed to turning on compression at the very beginning. You can use the supplied PyTables utility ptrepack. In addition, ptrepack can change compression levels after the fact.

```bash
ptrepack --chunkshape=auto --propindexes --complevel=9 --complib=blosc in.h5 out.h5
```

Furthermore ptrepack in.h5 out.h5 will repack the file to allow you to reuse previously deleted space. Alternatively, one can simply remove the file and write again, or use the copy method.
24.8.8.3 Caveats

**Warning:** `HDFStore` is **not-threadsafe for writing**. The underlying `PyTables` only supports concurrent reads (via threading or processes). If you need reading and writing at the same time, you need to serialize these operations in a single thread in a single process. You will corrupt your data otherwise. See the (GH2397) for more information.

- If you use locks to manage write access between multiple processes, you may want to use `fsync()` before releasing write locks. For convenience you can use `store.flush(fsync=True)` to do this for you.
- Once a table is created its items (Panel) / columns (DataFrame) are fixed; only exactly the same columns can be appended
- Be aware that timezones (e.g., `pytz.timezone('US/Eastern')`) are not necessarily equal across timezone versions. So if data is localized to a specific timezone in the HDFStore using one version of a timezone library and that data is updated with another version, the data will be converted to UTC since these timezones are not considered equal. Either use the same version of timezone library or use `tz_convert` with the updated timezone definition.

**Warning:** `PyTables` will show a `NaturalNameWarning` if a column name cannot be used as an attribute selector. Natural identifiers contain only letters, numbers, and underscores, and may not begin with a number. Other identifiers cannot be used in a `where` clause and are generally a bad idea.

24.8.9 DataTypes

`HDFStore` will map an object dtype to the `PyTables` underlying dtype. This means the following types are known to work:

<table>
<thead>
<tr>
<th>Type</th>
<th>Represents missing values</th>
</tr>
</thead>
<tbody>
<tr>
<td>floating: float64, float32, float16</td>
<td>np.nan</td>
</tr>
<tr>
<td>integer: int64, int32, int8, uint64, uint32, uint8</td>
<td>NaT</td>
</tr>
<tr>
<td>boolean</td>
<td>NaT</td>
</tr>
<tr>
<td>datetime64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>timedelta64[ns]</td>
<td>NaT</td>
</tr>
<tr>
<td>categorical: see the section below</td>
<td></td>
</tr>
<tr>
<td>object: strings</td>
<td>np.nan</td>
</tr>
</tbody>
</table>

*unicode* columns are not supported, and WILL FAIL.

24.8.9.1 Categorical Data

You can write data that contains category dtypes to a `HDFStore`. Queries work the same as if it was an object array. However, the category dtyped data is stored in a more efficient manner.

```
In [484]: dfcat = pd.DataFrame({'A': pd.Series(list('aabbcdba')).astype('category'),
                          'B': np.random.randn(8)})
......:
......:

In [485]: dfcat
```

(continues on next page)
24.8.9.2 String Columns

### min_itemsize

The underlying implementation of HDFStore uses a fixed column width (itemsize) for string columns. A string column itemsize is calculated as the maximum of the length of data (for that column) that is passed to the HDFStore, in the first append. Subsequent appends, may introduce a string for a column larger than the column can hold, an Exception will be raised (otherwise you could have a silent truncation of these columns, leading to loss of information). In the future we may relax this and allow a user-specified truncation to occur.

Pass `min_itemsize` on the first table creation to a-priori specify the minimum length of a particular string column. `min_itemsize` can be an integer, or a dict mapping a column name to an integer. You can pass `values` as a key to allow all `indexables` or `data_columns` to have this `min_itemsize`.

Passing a `min_itemsize` dict will cause all passed columns to be created as `data_columns` automatically.

---

Note: If you are not passing any `data_columns`, then the `min_itemsize` will be the maximum of the length of
In [492]: dfs = pd.DataFrame(dict(A='foo', B='bar'), index=list(range(5)))

In [493]: dfs
Out[493]:
   A  B
0  foo  bar
1  foo  bar
2  foo  bar
3  foo  bar
4  foo  bar

# A and B have a size of 30
In [494]: store.append('dfs', dfs, min_itemsize=30)

In [495]: store.get_storer('dfs').table
Out[495]:
'/dfs/table (Table(5,)) ''

description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=30, shape=(2,), dflt=b'', pos=1)
    byteorder := 'little'
    chunkshape := (963,)
    autoindex := True
    colindexes := {
        "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
        "A": Index(6, medium, shuffle, zlib(1)).is_csi=False
    }
}

# A is created as a data_column with a size of 30
# B is size is calculated
In [496]: store.append('dfs2', dfs, min_itemsize={'A': 30})

In [497]: store.get_storer('dfs2').table
Out[497]:
'/dfs2/table (Table(5,)) ''

description := {
    "index": Int64Col(shape=(), dflt=0, pos=0),
    "values_block_0": StringCol(itemsize=3, shape=(1,), dflt=b'', pos=1),
    "A": StringCol(itemsize=30, shape=(), dflt=b'', pos=2)
    byteorder := 'little'
    chunkshape := (1598,)
    autoindex := True
    colindexes := {
        "index": Index(6, medium, shuffle, zlib(1)).is_csi=False,
        "A": Index(6, medium, shuffle, zlib(1)).is_csi=False
    }
}

nan_rep

String columns will serialize a np.nan (a missing value) with the nan_rep string representation. This defaults to the string value nan. You could inadvertently turn an actual nan value into a missing value.

In [498]: dfss = pd.DataFrame(dict(A=['foo', 'bar', 'nan']))

In [499]: dfss
Out[499]:
   A
0  foo
(continues on next page)
1 bar
2 nan

In [500]: store.append('dfss', dfss)

In [501]: store.select('dfss')
Out[501]:
A
0  foo
1  bar
2  NaN

# here you need to specify a different nan rep
In [502]: store.append('dfss2', dfss, nan_rep='\_nan\_')

In [503]: store.select('dfss2')
Out[503]:
A
0  foo
1  bar
2  nan

24.8.10 External Compatibility

HDFStore writes table format objects in specific formats suitable for producing loss-less round trips to pandas objects. For external compatibility, HDFStore can read native PyTables format tables.

It is possible to write an HDFStore object that can easily be imported into R using the rhdf5 library (Package website). Create a table format store like this:

In [504]: np.random.seed(1)

In [505]: df_for_r = pd.DataFrame({'first': np.random.rand(100),
..:                     'second': np.random.rand(100),
..:                     'class': np.random.randint(0, 2, (100, ))},
..:                     index=range(100))

In [506]: df_for_r.head()
Out[506]:
       first  second  class
0  0.417022  0.326645    0
1  0.720324  0.527058    0
2  0.000114  0.885942    1
3  0.302333  0.357270    1
4  0.146756  0.908535    1

In [507]: store_export = pd.HDFStore('export.h5')

In [508]: store_export.append('df_for_r', df_for_r, data_columns=df_for_r.columns)

In [509]: store_export
Out[509]:
<class 'pandas.io.pytables.HDFStore'>
File path: export.h5
In R this file can be read into a data.frame object using the rhdf5 library. The following example function reads the corresponding column names and data values from the values and assembles them into a data.frame:

```r
# Load values and column names for all datasets from corresponding nodes and # insert them into one data.frame object.
library(rhdf5)
loadhdf5data <- function(h5File) {
  listing <- h5ls(h5File)
  # Find all data nodes, values are stored in *_values and corresponding column # titles in *_items
  data_nodes <- grep("_values", listing$name)
  name_nodes <- grep("_items", listing$name)
  data_paths = paste(listing$group[data_nodes], listing$name[data_nodes], sep = "/")
  name_paths = paste(listing$group[name_nodes], listing$name[name_nodes], sep = "/")
  columns = list()
  for (idx in seq(data_paths)) {
    # NOTE: matrices returned by h5read have to be transposed to obtain # required Fortran order!
    data <- data.frame(t(h5read(h5File, data_paths[idx])))
    names <- t(h5read(h5File, name_paths[idx]))
    entry <- data.frame(data)
    colnames(entry) <- names
    columns <- append(columns, entry)
  }
  data <- data.frame(columns)
  return(data)
}
```

Now you can import the DataFrame into R:

```r
> data = loadhdf5data("transfer.hdf5")
> head(data)
     first    second   class
   1 0.4170220 0.3266449    0
   2 0.7203245 0.5270581    0
   3 0.0001144 0.8859421    1
   4 0.3023326 0.3572698    1
   5 0.1467559 0.9085352    1
   6 0.0923386 0.6233601    1
```

Note: The R function lists the entire HDF5 file’s contents and assembles the data.frame object from all matching nodes, so use this only as a starting point if you have stored multiple DataFrame objects to a single HDF5 file.

### 24.8.11 Performance

- **tables** format come with a writing performance penalty as compared to fixed stores. The benefit is the ability to append/delete and query (potentially very large amounts of data). Write times are generally longer as compared with regular stores. Query times can be quite fast, especially on an indexed axis.
- You can pass `chunksize=<int>` to `append`, specifying the write chunksize (default is 50000). This will
significantly lower your memory usage on writing.

- You can pass `expectedrows=<int>` to the first `append`, to set the TOTAL number of expected rows that PyTables will expected. This will optimize read/write performance.

- Duplicate rows can be written to tables, but are filtered out in selection (with the last items being selected; thus a table is unique on major, minor pairs)

- A PerformanceWarning will be raised if you are attempting to store types that will be pickled by PyTables (rather than stored as endemic types). See Here for more information and some solutions.

## 24.9 Feather

New in version 0.20.0.

Feather provides binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy.

Feather is designed to faithfully serialize and de-serialize DataFrames, supporting all of the pandas dtypes, including extension dtypes such as categorical and datetime with tz.

Several caveats.

- This is a newer library, and the format, though stable, is not guaranteed to be backward compatible to the earlier versions.

- The format will NOT write an `Index`, or `MultiIndex` for the DataFrame and will raise an error if a non-default one is provided. You can `.reset_index()` to store the index or `.reset_index(drop=True)` to ignore it.

- Duplicate column names and non-string columns names are not supported

- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

See the Full Documentation.

```python
In [510]: df = pd.DataFrame({
    'a': list('abc'),
    'b': list(range(1, 4)),
    'c': np.arange(3, 6).astype('u1'),
    'd': np.arange(4.0, 7.0, dtype='float64'),
    'e': [True, False, True],
    'f': pd.Categorical(list('abc')),
    'g': pd.date_range('20130101', periods=3),
    'h': pd.date_range('20130101', periods=3, tz='US/Eastern'),
},
    ...:
In [511]: df
```

```
Out[511]:
   a   b   c   d   e   f   g   h
0  a  1  3   4   True  a  2013-01-01 2013-01-01 00:00:00-05:00 2013-01-01 00:00:00.
1  b  2  4   5   False b  2013-01-02 2013-01-02 00:00:00-05:00 2013-01-01 00:00:00.
2  c  3  5   6   True  c  2013-01-03 2013-01-03 00:00:00-05:00 2013-01-01 00:00:00.
```

(continues on next page)
In [512]: df.dtypes

   a    object
   b    int64

   i  datetime64[ns]
dtype: object

24.10 Parquet

New in version 0.21.0.

Apache Parquet provides a partitioned binary columnar serialization for data frames. It is designed to make reading and writing data frames efficient, and to make sharing data across data analysis languages easy. Parquet can use a variety
of compression techniques to shrink the file size as much as possible while still maintaining good read performance.

Parquet is designed to faithfully serialize and de-serialize `DataFrame`s, supporting all of the pandas dtypes, including extension dtypes such as datetime with tz.

Several caveats.

- Duplicate column names and non-string columns names are not supported.
- Index level names, if specified, must be strings.
- Categorical dtypes can be serialized to parquet, but will de-serialize as `object` dtype.
- Non supported types include `Period` and actual Python object types. These will raise a helpful error message on an attempt at serialization.

You can specify an `engine` to direct the serialization. This can be one of `pyarrow`, or `fastparquet`, or `auto`. If the engine is NOT specified, then the `pd.options.io.parquet.engine` option is checked; if this is also `auto`, then `pyarrow` is tried, and falling back to `fastparquet`.

See the documentation for `pyarrow` and `fastparquet`.

**Note:** These engines are very similar and should read/write nearly identical parquet format files. Currently `pyarrow` does not support timedelta data, `fastparquet>=0.1.4` supports timezone aware datetimes. These libraries differ by having different underlying dependencies (`fastparquet` by using `numba`, while `pyarrow` uses a c-library).

```python
In [517]: df = pd.DataFrame({'a': list('abc'),
                      'b': list(range(1, 4)),
                      'c': np.arange(3, 6).astype('u1'),
                      'd': np.arange(4.0, 7.0, dtype='float64'),
                      'e': [True, False, True],
                      'f': pd.date_range('20130101', periods=3),
                      'g': pd.date_range('20130101', periods=3, tz='US/Eastern')})

In [518]: df
Out[518]:
      a     b    c     d     e
0    a  1  3  4.0  True 2013-01-01 00:00:00-05:00
1    b  2  4  5.0  False 2013-01-02 00:00:00-05:00
2    c  3  5  6.0   True 2013-01-03 00:00:00-05:00

In [519]: df.dtypes
a      object
b    int64
   uint8
   float64
   bool
f    datetime64[ns]
g    datetime64[ns, US/Eastern]
dtype: object
```

Write to a parquet file.
In [520]: df.to_parquet('example_pa.parquet', engine='pyarrow')

In [521]: df.to_parquet('example_fp.parquet', engine='fastparquet')

Read from a parquet file.

In [522]: result = pd.read_parquet('example_fp.parquet', engine='fastparquet')

In [523]: result = pd.read_parquet('example_pa.parquet', engine='pyarrow')

In [524]: result.dtypes
Out[524]:
   a    object
   b   int64
   c   uint8
   d  float64
   e    bool
   f  datetime64[ns]
   g  datetime64[ns, US/Eastern]
   dtype: object

Read only certain columns of a parquet file.

In [525]: result = pd.read_parquet('example_fp.parquet',

   .....:
   engine='fastparquet', columns=['a', 'b'])

   .....:

In [526]: result.dtypes
Out[526]:
   a    object
   b   int64
   dtype: object

24.11 SQL Queries

The pandas.io.sql module provides a collection of query wrappers to both facilitate data retrieval and to reduce dependency on DB-specific API. Database abstraction is provided by SQLAlchemy if installed. In addition you will need a driver library for your database. Examples of such drivers are psycopg2 for PostgreSQL or pymysql for MySQL. For SQLite this is included in Python’s standard library by default. You can find an overview of supported drivers for each SQL dialect in the SQLAlchemy docs.

If SQLAlchemy is not installed, a fallback is only provided for sqlite (and for mysql for backwards compatibility, but this is deprecated and will be removed in a future version). This mode requires a Python database adapter which respect the Python DB-API.

See also some cookbook examples for some advanced strategies.

The key functions are:

<table>
<thead>
<tr>
<th>Function</th>

24.11. SQL Queries 1211
24.11.1 pandas.read_sql_table

`pandas.read_sql_table(table_name, con, schema=None, index_col=None, coerce_float=True, parse_dates=None, columns=None, chunksize=None)`

Read SQL database table into a DataFrame.

Given a table name and a SQLAlchemy connectable, returns a DataFrame. This function does not support DBAPI connections.

**Parameters**

- `table_name`: string
  Name of SQL table in database.
- `con`: SQLAlchemy connectable (or database string URI)
  SQLite DBAPI connection mode not supported.
- `schema`: string, default None
  Name of SQL schema in database to query (if database flavor supports this). Uses default schema if None (default).
- `index_col`: string or list of strings, optional, default: None
  Column(s) to set as index(MultiIndex).
- `coerce_float`: boolean, default True
  Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Can result in loss of Precision.
- `parse_dates`: list or dict, default: None
  - List of column names to parse as dates.
  - Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- `columns`: list, default: None
  List of column names to select from SQL table
- `chunksize`: int, default None
  If specified, returns an iterator where `chunksize` is the number of rows to include in each chunk.

**Returns**

DataFrame

See also:

- `read_sql_query` Read SQL query into a DataFrame.
- `read_sql`
Notes

Any datetime values with time zone information will be converted to UTC.

24.11.2 pandas.read_sql_query

`pandas.read_sql_query(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, chunksize=None)`

Read SQL query into a DataFrame.

Returns a DataFrame corresponding to the result set of the query string. Optionally provide an `index_col` parameter to use one of the columns as the index, otherwise default integer index will be used.

Parameters

- `sql`: string SQL query or SQLAlchemy Selectable (select or text object)
  - SQL query to be executed.
- `con`: SQLAlchemy connectable(engine/connection), database string URI, or sqlite3 DBAPI2 connection Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.
- `index_col`: string or list of strings, optional, default: None
  - Column(s) to set as index(MultiIndex).
- `coerce_float`: boolean, default True
  - Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point. Useful for SQL result sets.
- `params`: list, tuple or dict, optional, default: None
  - List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name' : 'value'}
- `parse_dates`: list or dict, default: None
  - List of column names to parse as dates.
  - Dict of `{column_name: format string}` where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  - Dict of `{column_name: arg dict}`, where the arg dict corresponds to the keyword arguments of `pandas.to_datetime()` Especially useful with databases without native Datetime support, such as SQLite.
- `chunksize`: int, default None
  - If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

Returns

DataFrame

See also:

- `read_sql_table` Read SQL database table into a DataFrame.
read_sql

Notes

Any datetime values with time zone information parsed via the `parse_dates` parameter will be converted to UTC.

24.11.3 pandas.read_sql

Pandas.read_sql(sql, con, index_col=None, coerce_float=True, params=None, parse_dates=None, columns=None, chunksize=None)

Read SQL query or database table into a DataFrame.

This function is a convenience wrapper around `read_sql_table` and `read_sql_query` (for backward compatibility). It will delegate to the specific function depending on the provided input. A SQL query will be routed to `read_sql_query`, while a database table name will be routed to `read_sql_table`. Note that the delegated function might have more specific notes about their functionality not listed here.

**Parameters**

- **sql**: string or SQLAlchemy Selectable (select or text object)
  SQL query to be executed or a table name.

- **con**: SQLAlchemy connectable (engine/connection) or database string URI
  or DBAPI2 connection (fallback mode)
  Using SQLAlchemy makes it possible to use any DB supported by that library. If a DBAPI2 object, only sqlite3 is supported.

- **index_col**: string or list of strings, optional, default: None
  Column(s) to set as index(MultiIndex).

- **coerce_float**: boolean, default True
  Attempts to convert values of non-string, non-numeric objects (like decimal.Decimal) to floating point, useful for SQL result sets.

- **params**: list, tuple or dict, optional, default: None
  List of parameters to pass to execute method. The syntax used to pass parameters is database driver dependent. Check your database driver documentation for which of the five syntax styles, described in PEP 249’s paramstyle, is supported. Eg. for psycopg2, uses %(name)s so use params={'name': 'value'}

- **parse_dates**: list or dict, default: None
  • List of column names to parse as dates.
  • Dict of {column_name: format string} where format string is strftime compatible in case of parsing string times, or is one of (D, s, ns, ms, us) in case of parsing integer timestamps.
  • Dict of {column_name: arg dict}, where the arg dict corresponds to the keyword arguments of pandas.to_datetime() Especially useful with databases without native Datetime support, such as SQLite.

- **columns**: list, default: None
  List of column names to select from SQL table (only used when reading a table).

- **chunksize**: int, default None
If specified, return an iterator where `chunksize` is the number of rows to include in each chunk.

**Returns**

DataFrame

**See also:**

- `read_sql_table` Read SQL database table into a DataFrame.
- `read_sql_query` Read SQL query into a DataFrame.

### 24.11.4 pandas.DataFrame.to_sql

```python
DataFrame.to_sql(name, con, schema=None, if_exists='fail', index=True, index_label=None, chunksize=None, dtype=None)
```

Write records stored in a DataFrame to a SQL database.

Databases supported by SQLAlchemy [R16] are supported. Tables can be newly created, appended to, or overwritten.

**Parameters**

- **name**: string
  Name of SQL table.
- **con**: sqlalchemy.engine.Engine or sqlite3.Connection
  Using SQLAlchemy makes it possible to use any DB supported by that library. Legacy support is provided for sqlite3.Connection objects.
- **schema**: string, optional
  Specify the schema (if database flavor supports this). If None, use default schema.
- **if_exists**: {'fail', 'replace', 'append'}, default 'fail'
  How to behave if the table already exists.
  - fail: Raise a ValueError.
  - replace: Drop the table before inserting new values.
  - append: Insert new values to the existing table.
- **index**: boolean, default True
  Write DataFrame index as a column. Uses `index_label` as the column name in the table.
- **index_label**: string or sequence, default None
  Column label for index column(s). If None is given (default) and `index` is True, then the index names are used. A sequence should be given if the DataFrame uses MultiIndex.
- **chunksize**: int, optional
  Rows will be written in batches of this size at a time. By default, all rows will be written at once.
- **dtype**: dict, optional
  Specifying the datatype for columns. The keys should be the column names and the values should be the SQLAlchemy types or strings for the sqlite3 legacy mode.

**Raises**

- ValueError

---

24.11. SQL Queries 1215
When the table already exists and `if_exists` is ‘fail’ (the default).

```
pandas.read_sql  read a DataFrame from a table
```

References

[R16], [R17]

Examples

Create an in-memory SQLite database.

```python
>>> from sqlalchemy import create_engine
>>> engine = create_engine('sqlite://', echo=False)
```

Create a table from scratch with 3 rows.

```python
>>> df = pd.DataFrame({'name': ['User 1', 'User 2', 'User 3']})
>>> df
   name
0  User 1
1  User 2
2  User 3
>>> df.to_sql('users', con=engine)
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3')]
```

```python
>>> df1 = pd.DataFrame({'name': ['User 4', 'User 5']})
>>> df1.to_sql('users', con=engine, if_exists='append')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 1'), (1, 'User 2'), (2, 'User 3'),
 (0, 'User 4'), (1, 'User 5')]
```

Overwrite the table with just `df1`.

```python
>>> df1.to_sql('users', con=engine, if_exists='replace',
... index_label='id')
>>> engine.execute("SELECT * FROM users").fetchall()
[(0, 'User 4'), (1, 'User 5')]
```

Specify the dtype (especially useful for integers with missing values). Notice that while pandas is forced to store the data as floating point, the database supports nullable integers. When fetching the data with Python, we get back integer scalars.

```python
>>> df = pd.DataFrame({"A": [1, None, 2]})
>>> df
   A
0  1.0
1  NaN
2  2.0
```
>>> from sqlalchemy.types import Integer
>>> df.to_sql('integers', con=engine, index=False, 
... dtype={"A": Integer()})

>>> engine.execute("SELECT * FROM integers").fetchall()
[(1,), (None,), (2,)]

Note: The function `read_sql()` is a convenience wrapper around `read_sql_table()` and `read_sql_query()` (and for backward compatibility) and will delegate to specific function depending on the provided input (database table name or sql query). Table names do not need to be quoted if they have special characters.

In the following example, we use the SQLite SQL database engine. You can use a temporary SQLite database where data are stored in “memory”.

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to. For more information on `create_engine()` and the URI formatting, see the examples below and the SQLAlchemy documentation.

```python
In [527]: from sqlalchemy import create_engine
# Create your engine.
In [528]: engine = create_engine('sqlite:///memory:')
```

If you want to manage your own connections you can pass one of those instead:

```python
with engine.connect() as conn, conn.begin():
    data = pd.read_sql_table('data', conn)
```

### 24.11.5 Writing DataFrames

Assuming the following data is in a DataFrame `data`, we can insert it into the database using `to_sql()`.

<table>
<thead>
<tr>
<th>id</th>
<th>Date</th>
<th>Col_1</th>
<th>Col_2</th>
<th>Col_3</th>
</tr>
</thead>
<tbody>
<tr>
<td>26</td>
<td>2012-10-18</td>
<td>X</td>
<td>25.7</td>
<td>True</td>
</tr>
<tr>
<td>42</td>
<td>2012-10-19</td>
<td>Y</td>
<td>-12.4</td>
<td>False</td>
</tr>
<tr>
<td>63</td>
<td>2012-10-20</td>
<td>Z</td>
<td>5.73</td>
<td>True</td>
</tr>
</tbody>
</table>

```python
In [529]: data.to_sql('data', engine)
```

With some databases, writing large DataFrames can result in errors due to packet size limitations being exceeded. This can be avoided by setting the `chunksize` parameter when calling `to_sql`. For example, the following writes `data` to the database in batches of 1000 rows at a time:

```python
In [530]: data.to_sql('data_chunked', engine, chunksize=1000)
```

Note: The function `to_sql()` will perform a multivalue insert if the engine dialect supports `multivalues_insert`. This will greatly speed up the insert in some cases.
24.11.5.1 SQL data types

to_sql() will try to map your data to an appropriate SQL data type based on the dtype of the data. When you have columns of dtype object, pandas will try to infer the data type.

You can always override the default type by specifying the desired SQL type of any of the columns by using the dtype argument. This argument needs a dictionary mapping column names to SQLAlchemy types (or strings for the sqlite3 fallback mode). For example, specifying to use the sqlalchemy String type instead of the default Text type for string columns:

```python
In [531]: from sqlalchemy.types import String
In [532]: data.to_sql('data_dtype', engine, dtype={'Col_1': String})
```

Note: Due to the limited support for timedelta's in the different database flavors, columns with type timedelta64 will be written as integer values as nanoseconds to the database and a warning will be raised.

Note: Columns of category dtype will be converted to the dense representation as you would get with np.asarray(categorical) (e.g. for string categories this gives an array of strings). Because of this, reading the database table back in does not generate a categorical.

24.11.6 Reading Tables

read_sql_table() will read a database table given the table name and optionally a subset of columns to read.

Note: In order to use read_sql_table(), you must have the SQLAlchemy optional dependency installed.

```python
In [533]: pd.read_sql_table('data', engine)
Out[533]:
   index  id     Date       Col_1  Col_2  Col_3
0       0  26 2010-10-18      X  27.50   True
1       1  42 2010-10-19    Y  -12.50  False
2       2  63 2010-10-20    Z   5.73   True

In [534]: pd.read_sql_table('data', engine, index_col='id')
Out[534]:
   index     Date       Col_1  Col_2  Col_3
id
26     0 2010-10-18      X  27.50   True
42     1 2010-10-19    Y  -12.50  False
63     2 2010-10-20    Z   5.73   True

In [535]: pd.read_sql_table('data', engine, columns=['Col_1', 'Col_2'])
```

You can also specify the name of the column as the DataFrame index, and specify a subset of columns to be read.
And you can explicitly force columns to be parsed as dates:

```python
In [536]: pd.read_sql_table('data', engine, parse_dates=['Date'])
Out[536]:
    index  id       Date  Col_1  Col_2  Col_3
0   0     26 2010-10-18    X    27.5   True
1   1     42 2010-10-19    Y   -12.5   False
2   2     63 2010-10-20    Z     5.73   True
```

If needed you can explicitly specify a format string, or a dict of arguments to pass to `pandas.to_datetime()`:

```python
pd.read_sql_table('data', engine, parse_dates={'Date': '%Y-%m-%d'})
pd.read_sql_table('data', engine, parse_dates={'Date': {'format': '%Y-%m-%d %H:%M:%S'}})
```

You can check if a table exists using `has_table()`

### 24.11.7 Schema support

Reading from and writing to different schema’s is supported through the schema keyword in the `read_sql_table()` and `to_sql()` functions. Note however that this depends on the database flavor (sqlite does not have schema’s). For example:

```python
df.to_sql('table', engine, schema='other_schema')
pd.read_sql_table('table', engine, schema='other_schema')
```

### 24.11.8 Querying

You can query using raw SQL in the `read_sql_query()` function. In this case you must use the SQL variant appropriate for your database. When using SQLAlchemy, you can also pass SQLAlchemy Expression language constructs, which are database-agnostic.

```python
In [537]: pd.read_sql_query('SELECT * FROM data', engine)
Out[537]:
    index  id       Date  Col_1  Col_2  Col_3
0   0     26 2010-10-18 00:00:00.000000    X    27.50    1
1   1     42 2010-10-19 00:00:00.000000    Y   -12.50    0
2   2     63 2010-10-20 00:00:00.000000    Z     5.73    1
```

Of course, you can specify a more “complex” query.

```python
In [538]: pd.read_sql_query("SELECT id, Col_1, Col_2 FROM data WHERE id = 42;", engine)
Out[538]:
     id  Col_1  Col_2
0   42   Y   -12.5
```

The `read_sql_query()` function supports a `chunksize` argument. Specifying this will return an iterator through chunks of the query result:

```python
In [539]: df = pd.DataFrame(np.random.randn(20, 3), columns=list('abc'))
In [540]: df.to_sql('data_chunks', engine, index=False)
```

24.11. SQL Queries 1219
```python
In [541]: for chunk in pd.read_sql_query("SELECT * FROM data_chunks", engine, _
    ...:     chunksize=5):
    ....:     print(chunk)
    ....:     ...
      a   b   c
0  0.280665 -0.073113  1.160339
1  0.369493  1.904659  1.11057
2  0.659050 -1.627438  0.602319
3  0.420282  0.810952  1.044442
4 -0.400878  0.824006 -0.562305
      a   b   c
0  1.954878 -1.331952 -1.760689
1 -1.650721 -0.890556 -1.119115
2  1.956079 -0.326499 -1.342676
3  1.114383 -0.586524 -1.236853
4  0.875839  0.623362 -0.434957
      a   b   c
0  1.407540  0.129102  1.616950
1  0.502741  1.558806  0.109403
2 -1.219744  2.449369 -0.545774
3 -0.198838 -0.700399 -0.203394
4  0.242669  0.201830  0.661020
      a   b   c
0  1.792158 -0.120465 -1.233121
1 -1.182318 -0.665755 -1.674196
2  0.825030 -0.498214 -0.310985
3 -0.001891 -1.396620 -0.861316
4  0.674712  0.618539 -0.443172
```

You can also run a plain query without creating a DataFrame with `execute()` . This is useful for queries that don’t return values, such as INSERT. This is functionally equivalent to calling `execute` on the SQLAlchemy engine or db connection object. Again, you must use the SQL syntax variant appropriate for your database.

```python
from pandas.io import sql
sql.execute('SELECT * FROM table_name', engine)
sql.execute('INSERT INTO table_name VALUES(?, ?, ?)', engine,
            params=[('id', 1, 12.2, True)])
```

### 24.11.9 Engine connection examples

To connect with SQLAlchemy you use the `create_engine()` function to create an engine object from database URI. You only need to create the engine once per database you are connecting to.

```python
from sqlalchemy import create_engine
engine = create_engine('postgresql://scott:tiger@localhost:5432/mydatabase')
engine = create_engine('mysql+mysqldb://scott:tiger@localhost/foo')
engine = create_engine('oracle://scott:tiger@127.0.0.1:1521/sidname')
engine = create_engine('mssql+pyodbc://mydsn')
# sqlite://<nohostname>/<path>  
# where <path> is relative:
```
For more information see the examples the SQLAlchemy documentation

### 24.11.10 Advanced SQLAlchemy queries

You can use SQLAlchemy constructs to describe your query.

Use `sqlalchemy.text()` to specify query parameters in a backend-neutral way

```python
In [542]: import sqlalchemy as sa

In [543]: pd.read_sql(sa.text('SELECT * FROM data where Col_1=:col1'),
               engine, params={'col1': 'X'})
```

```
Out[543]:
     index  id  Date       Col_1  Col_2  Col_3
0        0   26 2010-10-18  X     27.5   1
```

If you have an SQLAlchemy description of your database you can express where conditions using SQLAlchemy expressions

```python
In [544]: metadata = sa.MetaData()

In [545]: data_table = sa.Table('data', metadata,
                       sa.Column('index', sa.Integer),
                       sa.Column('Date', sa.DateTime),
                       sa.Column('Col_1', sa.String),
                       sa.Column('Col_2', sa.Float),
                       sa.Column('Col_3', sa.Boolean),
                      )

In [546]: pd.read_sql(sa.select([data_table]).where(data_table.c.Col_3 == True),
               engine)
```

```
Out[546]:
     index  Date       Col_1  Col_2  Col_3
0        0 2010-10-18  X     27.50   True
1        2 2010-10-20  Z      5.73   True
```

You can combine SQLAlchemy expressions with parameters passed to `read_sql()` using `sqlalchemy.bindparam()`

```python
In [547]: import datetime as dt

In [548]: expr = sa.select([data_table]).where(data_table.c.Date > sa.bindparam('date'))

In [549]: pd.read_sql(expr, engine, params={'date': dt.datetime(2010, 10, 18)})
```

```
Out[549]:
     index  Date       Col_1  Col_2  Col_3
0        1 2010-10-19  Y    -12.50   False
1        2 2010-10-20  Z      5.73   True
```

24.11. SQL Queries
24.11.11 Sqlite fallback

The use of sqlite is supported without using SQLAlchemy. This mode requires a Python database adapter which respect the Python DB-API.

You can create connections like so:

```python
import sqlite3
con = sqlite3.connect(':memory:)
```

And then issue the following queries:

```python
data.to_sql('data', cnx)
pd.read_sql_query("SELECT * FROM data", con)
```

24.12 Google BigQuery

**Warning:** Starting in 0.20.0, pandas has split off Google BigQuery support into the separate package pandas-gbq. You can pip install pandas-gbq to get it.

The pandas-gbq package provides functionality to read/write from Google BigQuery. pandas integrates with this external package. if pandas-gbq is installed, you can use the pandas methods pd.read_gbq and DataFrame.to_gbq, which will call the respective functions from pandas-gbq. Full documentation can be found here.

24.13 Stata Format

24.13.1 Writing to Stata format

The method `to_stata()` will write a DataFrame into a .dta file. The format version of this file is always 115 (Stata 12).

```python
In [550]: df = pd.DataFrame(randn(10, 2), columns=list('AB'))
In [551]: df.to_stata('stata.dta')
```

*Stata* data files have limited data type support; only strings with 244 or fewer characters, int8, int16, int32, float32 and float64 can be stored in .dta files. Additionally, *Stata* reserves certain values to represent missing data. Exporting a non-missing value that is outside of the permitted range in *Stata* for a particular data type will retype the variable to the next larger size. For example, int8 values are restricted to lie between -127 and 100 in *Stata*, and so variables with values above 100 will trigger a conversion to int16. nan values in floating points data types are stored as the basic missing data type (. in *Stata*).

**Note:** It is not possible to export missing data values for integer data types.

The *Stata* writer gracefully handles other data types including int64, bool, uint8, uint16, uint32 by casting to the smallest supported type that can represent the data. For example, data with a type of uint8 will be cast to
int8 if all values are less than 100 (the upper bound for non-missing int8 data in Stata), or, if values are outside of this range, the variable is cast to int16.

**Warning:** Conversion from int64 to float64 may result in a loss of precision if int64 values are larger than 2**53.

**Warning:** StataWriter and to_stata() only support fixed width strings containing up to 244 characters, a limitation imposed by the version 115 dta file format. Attempting to write Stata dta files with strings longer than 244 characters raises a ValueError.

## 24.13.2 Reading from Stata format

The top-level function `read_stata` will read a dta file and return either a DataFrame or a StataReader that can be used to read the file incrementally.

```python
In [552]: pd.read_stata('stata.dta')
Out[552]:
   index A       B
0       0  1.810535 -1.305727
1       1 -0.344987 -0.230840
2       2 -2.793085  1.937529
3       3  0.366332 -1.044589
4       4  2.051173  0.585662
5       5  0.429526 -0.606998
6       6  0.106223 -1.525680
7       7  0.795026 -0.374438
8       8  0.134048  1.202055
9       9  0.284748  0.262467
```

Specifying a chunksize yields a StataReader instance that can be used to read chunksize lines from the file at a time. The StataReader object can be used as an iterator.

```python
In [553]: reader = pd.read_stata('stata.dta', chunksize=3)

In [554]: for df in reader:
   ....:     print(df.shape)
   ....:
(3, 3)
(3, 3)
(3, 3)
(1, 3)
```

For more fine-grained control, use `iterator=True` and specify `chunksize` with each call to `read()`.

```python
In [555]: reader = pd.read_stata('stata.dta', iterator=True)
In [556]: chunk1 = reader.read(5)
In [557]: chunk2 = reader.read(5)
```

Currently the index is retrieved as a column.

The parameter `convert_categoricals` indicates whether value labels should be read and used to create a
Categorical variable from them. Value labels can also be retrieved by the function `value_labels`, which requires `read()` to be called before use.

The parameter `convert_missing` indicates whether missing value representations in Stata should be preserved. If `False` (the default), missing values are represented as `np.nan`. If `True`, missing values are represented using `StataMissingValue` objects, and columns containing missing values will have object data type.

**Note:** `read_stata()` and `StataReader` support .dta formats 113-115 (Stata 10-12), 117 (Stata 13), and 118 (Stata 14).

**Note:** Setting `preserve_dtypes=False` will upcast to the standard pandas data types: `int64` for all integer types and `float64` for floating point data. By default, the Stata data types are preserved when importing.

### 24.13.2.1 Categorical Data

Categorical data can be exported to Stata data files as value labeled data. The exported data consists of the underlying category codes as integer data values and the categories as value labels. Stata does not have an explicit equivalent to a `Categorical` and information about whether the variable is ordered is lost when exporting.

**Warning:** Stata only supports string value labels, and so `str` is called on the categories when exporting data. Exporting `Categorical` variables with non-string categories produces a warning, and can result a loss of information if the `str` representations of the categories are not unique.

Labeled data can similarly be imported from Stata data files as `Categorical` variables using the keyword argument `convert_categoricals` (True by default). The keyword argument `order_categoricals` (True by default) determines whether imported `Categorical` variables are ordered.

**Note:** When importing categorical data, the values of the variables in the Stata data file are not preserved since `Categorical` variables always use integer data types between $-1$ and $n-1$ where $n$ is the number of categories. If the original values in the Stata data file are required, these can be imported by setting `convert_categoricals=False`, which will import original data (but not the variable labels). The original values can be matched to the imported categorical data since there is a simple mapping between the original Stata data values and the category codes of imported Categorical variables: missing values are assigned code $-1$, and the smallest original value is assigned $0$, the second smallest is assigned $1$ and so on until the largest original value is assigned the code $n-1$.

**Note:** Stata supports partially labeled series. These series have value labels for some but not all data values. Importing a partially labeled series will produce a `Categorical` with string categories for the values that are labeled and numeric categories for values with no label.

### 24.14 SAS Formats

The top-level function `read_sas()` can read (but not write) SAS `xport` (.XPT) and (since v0.18.0) `SAS7BDAT` (.sas7bdat) format files.
SAS files only contain two value types: ASCII text and floating point values (usually 8 bytes but sometimes truncated). For xport files, there is no automatic type conversion to integers, dates, or categoricals. For SAS7BDAT files, the format codes may allow date variables to be automatically converted to dates. By default the whole file is read and returned as a DataFrame.

Specify a chunksize or use iterator=True to obtain reader objects (XportReader or SAS7BDATReader) for incrementally reading the file. The reader objects also have attributes that contain additional information about the file and its variables.

Read a SAS7BDAT file:

```python
def = pd.read_sas('sas_data.sas7bdat')
```

Obtain an iterator and read an XPORT file 100,000 lines at a time:

```python
rdr = pd.read_sas('sas_xport.xpt', chunk=100000)
for chunk in rdr:
    do_something(chunk)
```

The specification for the xport file format is available from the SAS web site.

No official documentation is available for the SAS7BDAT format.

### 24.15 Other file formats

pandas itself only supports IO with a limited set of file formats that map cleanly to its tabular data model. For reading and writing other file formats into and from pandas, we recommend these packages from the broader community.

#### 24.15.1 netCDF

xarray provides data structures inspired by the pandas DataFrame for working with multi-dimensional datasets, with a focus on the netCDF file format and easy conversion to and from pandas.

### 24.16 Performance Considerations

This is an informal comparison of various IO methods, using pandas 0.20.3. Timings are machine dependent and small differences should be ignored.

```
In [1]: sz = 1000000

In [3]: df.info()
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 1000000 entries, 0 to 999999
Data columns (total 2 columns):
A 1000000 non-null float64
B 1000000 non-null int64
dtypes: float64(1), int64(1)
memory usage: 15.3 MB
```

When writing, the top-three functions in terms of speed are `test_pickle_write`, `test_feather_write` and `test_hdf_fixed_write_compress`. 

24.15. Other file formats
When reading, the top three are `test_feather_read`, `test_pickle_read` and `test_hdf_fixed_read`.

Space on disk (in bytes)
And here’s the code:

```python
import os
import pandas as pd
import sqlite3
from numpy.random import randn
from pandas.io import sql

sz = 1000000

def test_sql_write(df):
    if os.path.exists('test.sql'):
        os.remove('test.sql')
    sql_db = sqlite3.connect('test.sql')
    df.to_sql(name='test_table', con=sql_db)
    sql_db.close()

def test_sql_read():
    sql_db = sqlite3.connect('test.sql')
    pd.read_sql_query("select * from test_table", sql_db)
    sql_db.close()

def test_hdf_fixed_write(df):
    df.to_hdf('test_fixed.hdf', 'test', mode='w')

def test_hdf_fixed_read():
    pd.read_hdf('test_fixed.hdf', 'test')

def test_hdf_fixed_write_compress(df):
    df.to_hdf('test_fixed_compress.hdf', 'test', mode='w', complib='blosc')

def test_hdf_fixed_read_compress():
    pd.read_hdf('test_fixed_compress.hdf', 'test')

def test_hdf_table_write(df):
    df.to_hdf('test_table.hdf', 'test', mode='w', format='table')

def test_hdf_table_read():
    pd.read_hdf('test_table.hdf', 'test')

def test_hdf_table_write_compress(df):
    df.to_hdf('test_table_compress.hdf', 'test', mode='w', complib='blosc', format='table')

def test_hdf_table_read_compress():
    pd.read_hdf('test_table_compress.hdf', 'test')
```

(continues on next page)
def test_csv_write(df):
    df.to_csv('test.csv', mode='w')

def test_csv_read():
    pd.read_csv('test.csv', index_col=0)

def test_feather_write(df):
    df.to_feather('test.feather')

def test_feather_read():
    pd.read_feather('test.feather')

def test_pickle_write(df):
    df.to_pickle('test.pkl')

def test_pickle_read():
    pd.read_pickle('test.pkl')

def test_pickle_write_compress(df):
    df.to_pickle('test.pkl.compress', compression='xz')

def test_pickle_read_compress():
    pd.read_pickle('test.pkl.compress', compression='xz')
In this part of the tutorial, we will investigate how to speed up certain functions operating on pandas DataFrames using three different techniques: Cython, Numba and pandas.eval(). We will see a speed improvement of ~200 when we use Cython and Numba on a test function operating row-wise on the DataFrame. Using pandas.eval() we will speed up a sum by an order of ~2.

### 25.1 Cython (Writing C extensions for pandas)

For many use cases writing pandas in pure Python and NumPy is sufficient. In some computationally heavy applications however, it can be possible to achieve sizeable speed-ups by offloading work to cython. This tutorial assumes you have refactored as much as possible in Python, for example by trying to remove for-loops and making use of NumPy vectorization. It’s always worth optimising in Python first.

This tutorial walks through a “typical” process of cythonizing a slow computation. We use an example from the Cython documentation but in the context of pandas. Our final cythonized solution is around 100 times faster than the pure Python solution.

#### 25.1.1 Pure python

We have a DataFrame to which we want to apply a function row-wise.

```python
In [1]: df = pd.DataFrame({'a': np.random.randn(1000),
                      ...
                      'b': np.random.randn(1000),
                      ...
                      'N': np.random.randint(100, 1000, (1000)),
                      ...
                      'x': 'x'})

In [2]: df
Out[2]:
   a           b       N  x
0  0.469112 -0.218470  585 x
1 -0.282863 -0.061645  841 x
2 -1.509059 -0.723780  251 x
3 -1.135632  0.551225  972 x
4  1.212112 -0.497767  181 x
5 -0.173215  0.837519  458 x
6  0.119209  1.103245  159 x
993 0.131892  0.290162  190 x
994 0.342097  0.215341  931 x
```

(continues on next page)
Here's the function in pure Python:

```python
In [3]: def f(x):
   ...:     return x * (x - 1)
   ...:

In [4]: def integrate_f(a, b, N):
   ...:     s = 0
   ...:     dx = (b - a) / N
   ...:     for i in range(N):
   ...:         s += f(a + i * dx)
   ...:     return s * dx
   ...:
```

We achieve our result by using `apply` (row-wise):

```python
In [7]: %timeit df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 174 ms per loop
```

But clearly this isn’t fast enough for us. Let’s take a look and see where the time is spent during this operation (limited to the most time consuming four calls) using the `prun` ipython magic function:

```python
In [5]: %prun -l 4 df.apply(lambda x: integrate_f(x['a'], x['b'], x['N']), axis=1)
671705 function calls (666685 primitive calls) in 0.217 seconds

Ordered by: internal time
List reduced from 213 to 4 due to restriction <4>

ncalls  tottime  percall  cumtime  percall filename:lineno(function)
1000    0.112    0.000    0.164    0.000 <ipython-input-4-c2a74e076cf0>:1(integrate_f)
3000    0.062    0.000    0.084    0.000 <ipython-input-3-c138bdec57d0e3>:1(f)
3000    0.007    0.000    0.033    0.000 base.py:3075(get_value)
3000    0.004    0.000    0.040    0.000 series.py:763(__getitem__)
```

By far the majority of time is spend inside either `integrate_f` or `f`, hence we’ll concentrate our efforts cythonizing these two functions.

Note: In Python 2 replacing the `range` with its generator counterpart (`xrange`) would mean the `range` line would vanish. In Python 3 `range` is already a generator.

### 25.1.2 Plain Cython

First we’re going to need to import the Cython magic function to ipython:
Now, let’s simply copy our functions over to Cython as is (the suffix is here to distinguish between function versions):

```python
In [7]: %cython
def f_plain(x):
   ...: return x * (x - 1)
def integrate_f_plain(a, b, N):
   ...: s = 0
   ...: dx = (b - a) / N
   ...: for i in range(N):
   ...:     s += f_plain(a + i * dx)
   ...: return s * dx
```

Note: If you’re having trouble pasting the above into your ipython, you may need to be using bleeding edge ipython for paste to play well with cell magics.

```python
In [4]: %timeit df.apply(lambda x: integrate_f_plain(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 85.5 ms per loop
```

Already this has shaved a third off, not too bad for a simple copy and paste.

### 25.1.3 Adding type

We get another huge improvement simply by providing type information:

```python
In [8]: %cython
cdef double f_typed(double x) except? -2:
   ...: return x * (x - 1)
cdef double integrate_f_typed(double a, double b, int N):
   ...: cdef int i
   ...: cdef double s, dx
   ...: s = 0
   ...: dx = (b - a) / N
   ...: for i in range(N):
   ...:     s += f_typed(a + i * dx)
   ...: return s * dx
```

```python
In [4]: %timeit df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
10 loops, best of 3: 20.3 ms per loop
```

Now, we’re talking! It’s now over ten times faster than the original python implementation, and we haven’t really modified the code. Let’s have another look at what’s eating up time:

```python
In [9]: %prun -l 4 df.apply(lambda x: integrate_f_typed(x['a'], x['b'], x['N']), axis=1)
119280 function calls (114260 primitive calls) in 0.055 seconds
Ordered by: internal time
List reduced from 210 to 4 due to restriction <4>

(continues on next page)
25.1.4 Using ndarray

It’s calling series... a lot! It’s creating a Series from each row, and get-ting from both the index and the series (three times for each row). Function calls are expensive in Python, so maybe we could minimize these by cythonizing the apply part.

**Note:** We are now passing ndarrays into the Cython function, fortunately Cython plays very nicely with NumPy.

```cython
In [10]: %%cython
    ....: cimport numpy as np
    ....: import numpy as np
    ....: cdef double f_typed(double x) except? -2:
    ....:     return x * (x - 1)
    ....: cpdef double integrate_f_typed(double a, double b, int N):
    ....:     cdef int i
    ....:     cdef double s, dx
    ....:     s = 0
    ....:     dx = (b - a) / N
    ....:     for i in range(N):
    ....:         s += f_typed(a + i * dx)
    ....:     return s * dx
    ....: cpdef np.ndarray[double] apply_integrate_f(np.ndarray col_a, np.ndarray col_b, np.ndarray col_N):
    ....:     assert (col_a.dtype == np.float and col_b.dtype == np.float and col_N.dtype == np.int)
    ....:     cdef Py_ssize_t i, n = len(col_N)
    ....:     assert (len(col_a) == len(col_b) == n)
    ....:     cdef np.ndarray[double] res = np.empty(n)
    ....:     for i in range(len(col_a)):
    ....:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
    ....:     return res

The implementation is simple, it creates an array of zeros and loops over the rows, applying our integrate_f_typed, and putting this in the zeros array.

**Warning:** You can **not pass** a Series directly as a ndarray typed parameter to a Cython function. Instead pass the actual ndarray using the .values attribute of the Series. The reason is that the Cython definition is specific to an ndarray and not the passed Series.

So, do not do this:

```python
apply_integrate_f(df['a'], df['b'], df['N'])
```

But rather, use .values to get the underlying ndarray:

```python
apply_integrate_f(df['a'].values, df['b'].values, df['N'].values)
```
Note: Loops like this would be extremely slow in Python, but in Cython looping over NumPy arrays is fast.

We’ve gotten another big improvement. Let’s check again where the time is spent:

As one might expect, the majority of the time is now spent in apply_integrate_f, so if we wanted to make anymore efficiencies we must continue to concentrate our efforts here.

25.1.5 More advanced techniques

There is still hope for improvement. Here’s an example of using some more advanced Cython techniques:

```
In [12]: %cython
......: cimport cython
......: cimport numpy as np
......: import numpy as np
......: cdef double f_typed(double x) except? -2:
......:     return x * (x - 1)
......: cpdef double integrate_f_typed(double a, double b, int N):
......:     cdef int i
......:     cdef double s, dx
......:     s = 0
......:     dx = (b - a) / N
......:     for i in range(N):
......:         s += f_typed(a + i * dx)
......:     return s * dx
......: @cython.boundscheck(False)
......: @cython.wraparound(False)
......:     cdef int i, n = len(col_N)
......:     assert len(col_a) == len(col_b) == n
......:     cdef np.ndarray[double] res = np.empty(n)
......:     for i in range(n):
......:         res[i] = integrate_f_typed(col_a[i], col_b[i], col_N[i])
......:     return res
......:
```
Even faster, with the caveat that a bug in our Cython code (an off-by-one error, for example) might cause a segfault because memory access isn’t checked. For more about boundscheck and wraparound, see the Cython docs on compiler directives.

## 25.2 Using Numba

A recent alternative to statically compiling Cython code, is to use a dynamic jit-compiler, Numba.

Numba gives you the power to speed up your applications with high performance functions written directly in Python. With a few annotations, array-oriented and math-heavy Python code can be just-in-time compiled to native machine instructions, similar in performance to C, C++ and Fortran, without having to switch languages or Python interpreters.

Numba works by generating optimized machine code using the LLVM compiler infrastructure at import time, runtime, or statically (using the included pycc tool). Numba supports compilation of Python to run on either CPU or GPU hardware, and is designed to integrate with the Python scientific software stack.

---

**Note:** You will need to install Numba. This is easy with conda, by using: conda install numba, see [installing using miniconda](#).

---

**Note:** As of Numba version 0.20, pandas objects cannot be passed directly to Numba-compiled functions. Instead, one must pass the NumPy array underlying the pandas object to the Numba-compiled function as demonstrated below.

### 25.2.1 Jit

We demonstrate how to use Numba to just-in-time compile our code. We simply take the plain Python code from above and annotate with the @jit decorator.

```python
import numba

@numba.jit
def f_plain(x):
    return x * (x - 1)

@numba.jit
def integrate_f_numba(a, b, N):
    s = 0
    dx = (b - a) / N
    for i in range(N):
        s += f_plain(a + i * dx)
    return s * dx

@numba.jit
def apply_integrate_f_numba(col_a, col_b, col_N):
    n = len(col_N)
    result = np.empty(n, dtype='float64')
    assert len(col_a) == len(col_b) == n
    for i in range(n):
        (continues on next page)```
Note that we directly pass NumPy arrays to the Numba function. `compute_numba` is just a wrapper that provides a nicer interface by passing/returning pandas objects.

```python
result[i] = integrate_f_numba(col_a[i], col_b[i], col_N[i])
return result

def compute_numba(df):
    result = apply_integrate_f_numba(df['a'].values, df['b'].values, df['N'].values)
    return pd.Series(result, index=df.index, name='result')
```

In this example, using Numba was faster than Cython.

## 25.2.2 Vectorize

Numba can also be used to write vectorized functions that do not require the user to explicitly loop over the observations of a vector; a vectorized function will be applied to each row automatically. Consider the following toy example of doubling each observation:

```python
import numba

# Custom function without numba
In [5]: %timeit df['col1_doubled'] = df.a.apply(double_every_value_nonumba)
1000 loops, best of 3: 797 us per loop

# Standard implementation (faster than a custom function)
In [6]: %timeit df['col1_doubled'] = df.a*2
1000 loops, best of 3: 233 us per loop

# Custom function with numba
In [7]: %timeit df['col1_doubled'] = double_every_value_withnumba(df.a.values)
1000 loops, best of 3: 145 us per loop
```

## 25.2.3 Caveats

**Note:** Numba will execute on any function, but can only accelerate certain classes of functions.

Numba is best at accelerating functions that apply numerical functions to NumPy arrays. When passed a function that only uses operations it knows how to accelerate, it will execute in \texttt{numpython} mode.

If Numba is passed a function that includes something it doesn’t know how to work with – a category that currently includes sets, lists, dictionaries, or string functions – it will revert to \texttt{object} mode. In \texttt{object} mode, Numba...
will execute but your code will not speed up significantly. If you would prefer that Numba throw an error if it cannot
compile a function in a way that speeds up your code, pass Numba the argument nopython=True (e.g. @numba.
jit(nopython=True)). For more on troubleshooting Numba modes, see the Numba troubleshooting page.

Read more in the Numba docs.

### 25.3 Expression Evaluation via `eval()`

The top-level function `pandas.eval()` implements expression evaluation of `Series` and `DataFrame` objects.

**Note**: To benefit from using `eval()` you need to install `numexpr`. See the recommended dependencies section for
more details.

The point of using `eval()` for expression evaluation rather than plain Python is two-fold: 1) large `DataFrame`
objects are evaluated more efficiently and 2) large arithmetic and boolean expressions are evaluated all at once by the
underlying engine (by default `numexpr` is used for evaluation).

**Note**: You should not use `eval()` for simple expressions or for expressions involving small DataFrames. In fact,
`eval()` is many orders of magnitude slower for smaller expressions/objects than plain ol’ Python. A good rule of
thumb is to only use `eval()` when you have a `DataFrame` with more than 10,000 rows.

`eval()` supports all arithmetic expressions supported by the engine in addition to some extensions available only in
pandas.

**Note**: The larger the frame and the larger the expression the more speedup you will see from using `eval()`.

#### 25.3.1 Supported Syntax

These operations are supported by `pandas.eval()`:

- Arithmetic operations except for the left shift (<<) and right shift (>>) operators, e.g., `df + 2 * pi / s` **4 % 42 - the_golden_ratio**
- Comparison operations, including chained comparisons, e.g., `2 < df < df2`
- Boolean operations, e.g., `df < df2 and df3 < df4 or not df_bool`
- list and tuple literals, e.g., `[1, 2] or (1, 2)`
- Attribute access, e.g., `df.a`
- Subscript expressions, e.g., `df[0]`
- Simple variable evaluation, e.g., `pd.eval('df')` (this is not very useful)
- Math functions: `sin, cos, exp, log, expm1, log1p, sqrt, sinh, cosh, tanh, arcsin, arccos, arctan, arccosh, arcsinh, arctanh, abs` and `arctan2`.

This Python syntax is **not** allowed:

- Expressions
  - Function calls other than math functions.
- is/is not operations
- if expressions
- lambda expressions
- list/set/dict comprehensions
- Literal dict and set expressions
- yield expressions
- Generator expressions
- Boolean expressions consisting of only scalar values

• Statements
  - Neither simple nor compound statements are allowed. This includes things like for, while, and if.

### 25.3.2 eval() Examples

*pandas.eval()* works well with expressions containing large arrays.

First let’s create a few decent-sized arrays to play with:

```python
In [13]: nrows, ncols = 20000, 100
In [14]: df1, df2, df3, df4 = [pd.DataFrame(np.random.randn(nrows, ncols)) for _ in range(4)]
```

Now let’s compare adding them together using plain ol’ Python versus *eval()*:

```python
In [15]: %timeit df1 + df2 + df3 + df4
10.1 ms +- 787 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [16]: %timeit pd.eval('df1 + df2 + df3 + df4')
7.44 ms +- 317 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

Now let’s do the same thing but with comparisons:

```python
In [17]: %timeit (df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)
28.1 ms +- 1.56 ms per loop (mean +- std. dev. of 7 runs, 10 loops each)

In [18]: %timeit pd.eval('(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)')
9.33 ms +- 511 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

eval() also works with unaligned pandas objects:

```python
In [19]: s = pd.Series(np.random.randn(50))
In [20]: %timeit df1 + df2 + df3 + df4 + s
18.8 ms +- 853 us per loop (mean +- std. dev. of 7 runs, 100 loops each)

In [21]: %timeit pd.eval('df1 + df2 + df3 + df4 + s')
8.32 ms +- 385 us per loop (mean +- std. dev. of 7 runs, 100 loops each)
```

**Note:** Operations such as
should be performed in Python. An exception will be raised if you try to perform any boolean/bitwise operations with scalar operands that are not of type bool or np.bool_. Again, you should perform these kinds of operations in plain Python.

## 25.3.3 The DataFrame.eval method

In addition to the top level pandas.eval() function you can also evaluate an expression in the “context” of a DataFrame.

In [22]: df = pd.DataFrame(np.random.randn(5, 2), columns=['a', 'b'])

In [23]: df.eval('a + b')

Out[23]:
   0      1      2      3      4
0 -0.246747  0.867786 -1.626063 -1.134978 -1.027798
1  0.867786  0.867786  0.867786  0.867786  0.867786
2 -1.626063 -1.626063 -1.626063 -1.626063 -1.626063
3 -1.134978 -1.134978 -1.134978 -1.134978 -1.134978
4 -1.027798 -1.027798 -1.027798 -1.027798 -1.027798

Any expression that is a valid pandas.eval() expression is also a valid DataFrame.eval() expression, with the added benefit that you don’t have to prefix the name of the DataFrame to the column(s) you’re interested in evaluating.

In addition, you can perform assignment of columns within an expression. This allows for formulaic evaluation. The assignment target can be a new column name or an existing column name, and it must be a valid Python identifier.

New in version 0.18.0.

The inplace keyword determines whether this assignment will performed on the original DataFrame or return a copy with the new column.

**Warning:** For backwards compatibility, inplace defaults to True if not specified. This will change in a future version of pandas - if your code depends on an inplace assignment you should update to explicitly set inplace=True.

In [24]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [25]: df.eval('c = a + b', inplace=True)

In [26]: df.eval('d = a + b + c', inplace=True)

In [27]: df.eval('a = 1', inplace=True)

In [28]: df

Out[28]:
   a  b  c  d
0  0  5  5 10
1  1  6  7 14

(continues on next page)
When `inplace` is set to `False`, a copy of the DataFrame with the new or modified columns is returned and the original frame is unchanged.

```python
In [29]: df
Out[29]:
   a  b  c  d  e
0  1  5  5 10 -4
1  1  6  7 14 -6
2  1  7  9 18 -8
3  1  8 11 22 -10
4  1  9 13 26 -12
```

New in version 0.18.0.

As a convenience, multiple assignments can be performed by using a multi-line string.

```python
In [32]: df.eval(""
       ....: c = a + b
       ....: d = a + b + c
       ....: a = 1","", inplace=False)
       ....:"
Out[32]:
   a  b  c  d
0  1  5  6 12
1  1  6  7 14
2  1  7  8 16
3  1  8  9 18
4  1  9 10 20
```

The equivalent in standard Python would be

```python
In [33]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))
```
In [34]: df['c'] = df.a + df.b

In [35]: df['d'] = df.a + df.b + df.c

In [36]: df['a'] = 1

In [37]: df

Out[37]:
   a  b  c  d
0  1  5  5  10
1  1  6  7  14
2  1  7  9  18
3  1  8 11  22
4  1  9 13  26

New in version 0.18.0.

The query method gained the inplace keyword which determines whether the query modifies the original frame.

In [38]: df = pd.DataFrame(dict(a=range(5), b=range(5, 10)))

In [39]: df.query('a > 2')

Out[39]:
   a  b
0  3  8
1  4  9

In [40]: df.query('a > 2', inplace=True)

In [41]: df

Out[41]:
   a  b
0  3  8
1  4  9

Warning: Unlike with eval, the default value for inplace for query is False. This is consistent with prior versions of pandas.

### 25.3.4 Local Variables

You must explicitly reference any local variable that you want to use in an expression by placing the @ character in front of the name. For example,

In [42]: df = pd.DataFrame(np.random.randn(5, 2), columns=list('ab'))

In [43]: newcol = np.random.randn(len(df))

In [44]: df.eval('b + @newcol')

Out[44]:
   0  -0.173926
   1   2.493083
   2  -0.881831
   3  -0.691045
If you don’t prefix the local variable with @, pandas will raise an exception telling you the variable is undefined.

When using `DataFrame.eval()` and `DataFrame.query()`, this allows you to have a local variable and a `DataFrame` column with the same name in an expression.

```python
In [46]: a = np.random.randn()
In [47]: df.query('@a < a')
Out[47]:
   a    b
0 0.863987 -0.115998

In [48]: df.loc[a < df.a]  # same as the previous expression
   a    b
0 0.863987 -0.115998
```

With `pandas.eval()` you cannot use the @ prefix at all, because it isn’t defined in that context. pandas will let you know this if you try to use @ in a top-level call to `pandas.eval()`. For example,

```python
In [49]: a, b = 1, 2
In [50]: pd.eval('@a + b')
Traceback (most recent call last):
    exec(code_obj, self.user_global_ns, self.user_ns)
  File "/Users/taugspurger/sandbox/pandas-docs/pandas/core/computation/eval.py", line 283, in eval
    _check_for_locals(expr, level, parser)
  File "/Users/taugspurger/sandbox/pandas-docs/pandas/core/computation/eval.py", line 150, in _check_for_locals
    raise SyntaxError(msg)
SyntaxError: The '@' prefix is not allowed in top-level eval calls, please refer to your variables by name without the '@' prefix
```

In this case, you should simply refer to the variables like you would in standard Python.
In [51]: pd.eval('a + b')
Out[51]: 3

25.3.5 pandas.eval() Parsers

There are two different parsers and two different engines you can use as the backend.

The default 'pandas' parser allows a more intuitive syntax for expressing query-like operations (comparisons, conjunctions and disjunctions). In particular, the precedence of the & and | operators is made equal to the precedence of the corresponding boolean operations and and or.

For example, the above conjunction can be written without parentheses. Alternatively, you can use the 'python' parser to enforce strict Python semantics.

In [52]: expr = '(df1 > 0) & (df2 > 0) & (df3 > 0) & (df4 > 0)'
In [53]: x = pd.eval(expr, parser='python')
In [54]: expr_no_parens = 'df1 > 0 & df2 > 0 & df3 > 0 & df4 > 0'
In [55]: y = pd.eval(expr_no_parens, parser='pandas')
In [56]: np.all(x == y)
Out[56]: True
